EVENTS

- ~145 my: left-lateral displacement of passive margin truncates facies continuity in Idaho.
- ~250 my: left-lateral displacement of passive margin truncates facies continuity in SW Calif.
- oldest age of oceanic crust in ocean basin, ∵ oceans transient, continents record.
- Antler Orogeny!**: continental margin switches from Passive to Subduction as island arc impinges on N.A., driving W dipping subduction and east-vergent thrusting of deep H2O shales + silts over passive margin sed. Topography created by thrust deposits sed in flexural basin (foredeep), thus switching sed. delivery direction.
- Shallow Marine sedimentation on passive margin**, subsidence rate and sedimentation rate slow as rifted margin cools, becomes more rigid. Still thickening to west. Mostly carbonate seds. Changes in & move shoreline well inland at times, building strat. w/ dif. depo. environs.
- Island Arc Volcanism**: active over extended period. Island Arcs local to N.A. as they share the same fossil assemblage as in continental N.A. seds from the same time. None accreted during period, though one was involved in the Antler Orogeny (above).
- Post-rift non-marine sedimentation** on rapidly subsiding, weak, warm passive margin. Sed. thickness up to 10km!. Hingeline near present Las Vegas. Sedimentation kept pace w/ subsidence, and seds are consistently shallow, nearshore facies.
- First seds on new passive margin are diamictite w/ glacial origin (Snowball E.)
- Belt Group**: THICK seds deposited on weak, thin crust, possibly in early failed rift. (15 km thick!)
- Precambrian (pe) basement** of N.A. records history of continent rifting and assemblage with younger rocks in sutures between older continental blocks. These younger sutures were ancient mtns. but are now eroded away to flat!

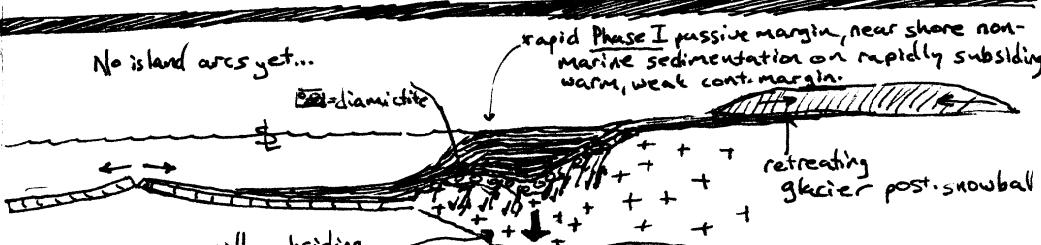

CROSS-SECTIONS

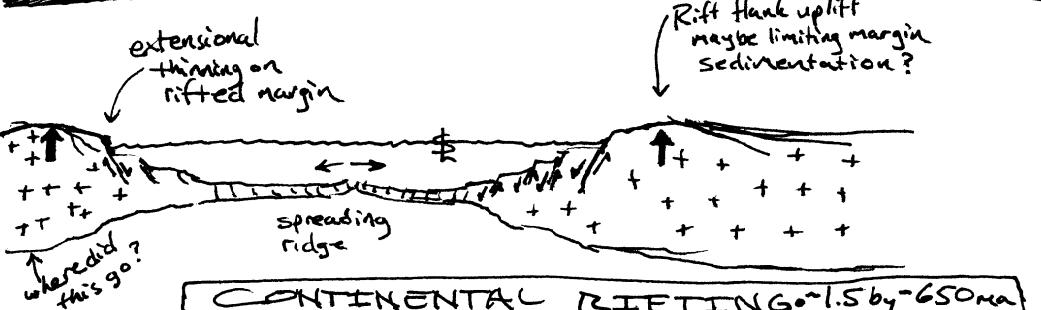

ANTLER OROGENY • ~350 - 340 ma

PHASE II PASSIVE MARGIN • ~ 550 - 350 ma

PHASE I PASSIVE MARGIN • ~ 650 - 550 ma

CONTINENTAL RIFTING • 1.5 by - 650 ma
