

1. The device shown below is used to measure the state of a liquid-vapor mixture flowing through an insulated pipe (main flow). The procedure is to bleed off a small amount of the mixture to be measured, throttle it through a valve, and make measurements at station 2 as shown below. Changes in kinetic energy can be neglected and the entire setup is well insulated. The working fluid is water.

$$P_1 = 7 \text{ bar}$$

$$T_1 = 165^\circ\text{C}$$

Measurements:  $P_2 = 0.1 \text{ bar}$

$$T_2 = 75^\circ\text{C}$$

- Discuss possible changes in state variables across the valve (which state variables change, which don't, and why). Corroborate your findings from 1<sup>st</sup> principles.
- Draw an  $h-s$  diagram for the flow bled off through the valve (state change from station 1 to station 2) and indicate relevant isobars and isotherms.
- Calculate the quality of the main flow liquid-vapor mixture at station 1.

2. A jet engine takes in air from the atmosphere which is at temperature  $T_0$  and pressure  $p_0$  and exhausts air at a static temperature of  $T_6$  at the nozzle exit. The engine is on the ground at static conditions and the maximum temperature in the cycle is  $T_{tmax}$ . Assume an ideal cycle and that air and the combustion gas are perfect gases with the same specific heat  $c_p$  and  $\gamma$ . Express your answers in terms of the given quantities.

- Sketch the thermodynamic cycle in an  $h$ - $s$  diagram and indicate work and heat transfer in each segment of the cycle (label static and stagnation states where appropriate).
- What is the specific entropy change during heat rejection to the atmosphere?
- What is the specific entropy change during heat addition to the engine?
- What is the compressor exit stagnation temperature?
- What is the thermal efficiency  $\eta_{thermal}$  of the engine?
- What is the jet exhaust velocity of the engine  $c_6$ ?
