# MIT 18.06 Exam 3, Fall 2017 <br> Johnson 

## Your name:

Recitation:

| problem | score |
| :---: | ---: |
| 1 | $/ 30$ |
| 2 | $/ 30$ |
| 3 | $/ 40$ |
| total | $/ 100$ |

## Problem 1 (30 points):

(a) Give a matrix $A$ where $\operatorname{det}(A-\lambda I)=0$ has exactly two roots $\lambda=1$ and $\lambda=3$, but the trace of $A$ does not equal 4 .
(b) The eigenvalues of $\left(A+A^{T}\right)^{-1}$ for any real, square matrix $A$ (assuming $A+A^{T}$ is invertible) must be $\qquad$ .
(c) If $A=Q^{T} \Lambda Q$ for a diagonal matrix $\Lambda$ and a real orthogonal matrix $Q$, then the eigenvectors of $A$ are the $\qquad$ of $Q$.
(d) If $A$ is real, and $e^{A t}\binom{2}{4}=e^{(3+4 i) t}\binom{1+i}{2-2 i}+e^{\alpha t}\binom{\beta}{\gamma}$, then the $(t-$ independent) scalars $\alpha, \beta, \gamma$ are $\qquad$ ?
(e) If $A$ is a $4 \times 4$ matrix with $\operatorname{det} A=5$, then $\frac{d}{d t} \operatorname{det}\left(A^{T} A t\right)=$
(blank page for your work if you need it)

## Problem 2 (30 points):

You are given a matrix $A=e^{-B^{T} B}$ for some real $3 \times 3$ matrix $B$. The nullspace $N(B)$ is spanned by $\left(\begin{array}{l}1 \\ 2 \\ 1\end{array}\right)$.
(a) Circle any of the following vectors that cannot possibly be eigenvectors of $A$, and put a rectangle around any vectors that must be eigenvectors of $A$ :

$$
\left(\begin{array}{l}
1 \\
2 \\
1
\end{array}\right),\left(\begin{array}{l}
1 \\
0 \\
0
\end{array}\right),\left(\begin{array}{l}
0 \\
0 \\
0
\end{array}\right),\left(\begin{array}{c}
1 \\
0 \\
-1
\end{array}\right),\left(\begin{array}{c}
1 \\
-1 \\
1
\end{array}\right),\left(\begin{array}{l}
2 \\
4 \\
2
\end{array}\right),\left(\begin{array}{l}
1 \\
1 \\
1
\end{array}\right)
$$

(b) $A^{n} x$ for some $x \neq 0$ may do what for large $n$ (circle all possibilities)? Oscillate / decay / diverge / go to a nonzero constant vector.
(c) For $x=\left(\begin{array}{l}1 \\ 0 \\ 0\end{array}\right)$, give a good approximation for $A^{n} x$ for a very large $n$.
(blank page for your work if you need it)

## Problem 3 (40 points):

The vector $x(t)$ satisfies the ODE

$$
(I+A) \frac{d x}{d t}=\left(A^{2}-I\right) x
$$

for the diagonalizable matrix $A=\left(\begin{array}{ccc}0.9 & 0.0 & 0.3 \\ 0.0 & 0.8 & 0.4 \\ 0.1 & 0.2 & 0.3\end{array}\right)$. If we square this, we get $A^{2}=\left(\begin{array}{ccc}0.84 & 0.06 & 0.36 \\ 0.04 & 0.72 & 0.44 \\ 0.12 & 0.22 & 0.2\end{array}\right)$.
(a) If $A$ has an eigenvalue $\lambda$ and an eigenvector $v$, give a nonzero solution $x(t)$ satisfying the ODE above, in terms of $\lambda, v$, and $t$.
(b) Both $A$ and $A^{2}$ are $\qquad$ matrices. By inspection of $A^{2}$, what can you say (with no arithmetic! don't calculate $\lambda$ !) about the magnitudes $|\lambda|$ of the three eigenvalues of $A^{2}$ ? What does this tell you about the magnitudes $|\lambda|$ of the eigenvalues of $A$ ?
(c) Give the eigenvalue $\lambda$ of $A$ with the biggest magnitude. A corresponding eigenvector is $\left(\begin{array}{l}\alpha \\ 2 \\ 1\end{array}\right)$ for what $\alpha$ ?
(d) For an initial conditions $x(0)=\left(\begin{array}{l}1 \\ 0 \\ 0\end{array}\right)$, circle what would you expect the solutions $x(t)$ to do for large $t$ : Oscillate / decay / diverge / go to a nonzero constant vector? Give a good approximation for $x(t)$ for a large $t$ - if you can't figure it out exactly, at least give a vector that $x(t)$ is nearly parallel to.
