

# Routing Algorithms: Dealing With Failures

6.02 Fall 2013 Lecture 21

INTRODUCTION TO BECS II  
**DIGITAL  
COMMUNICATION  
SYSTEMS**

# Today's Plan

- ▶ Network Dynamics and Failures
- ▶ Analysis of Dijkstra Algorithm (Static/Ideal)
- ▶ Consequences of Incomplete LSA Flooding
- ▶ Dealing With Loopy Forwarding
- ▶ Analysis of Distance-Vector Algorithms (Static/Ideal)
- ▶ Count-To-Infinity
- ▶ Split-Horizon and Path-Vector Routing

# Network Dynamics And Failures

Link Failure:

Link Recovery:

Probabilistic Nature of Packet Delivery:

$$P(\text{delivery}) = p$$

# Dijkstra's Shortest Path Algorithm: Complexity

Parameters:

- ▶ **N**: number of nodes
- ▶ **L**: number of links

Complexity:

- ▶ **finding  $u$**  (minimal cost node):  
N times:  **$O(\log N)$**  each time, total  **$O(N \log N)$**
- ▶ **updating costs**:  
 **$O(L)$** , since each link appears twice

# Correctness of Shortest Path Routing (Ideal)

## Shortest Path Routing:

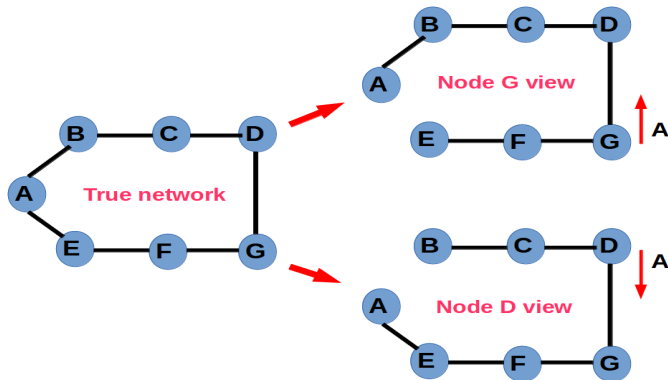

forward to the neighbor with minimal total cost to destination

Distance to destination decreases monotonically at **every** step.

# Consequences of Incomplete LSA Flooding

Node G does not get the LSA from A and E  
Node D does not get the LSA from A and B

# Dealing With Forwarding Loops

Eventually, in the LSA framework, we expect all nodes to have complete info about the network.

In the meanwhile, **hop limit** eliminates infinite loops:

- ▶ **Passing every node, a package reduces its hop limit by 1**
- ▶ **A package with hop limit of zero is dropped**

# Distance-Vector Algorithms

$$D^+(A, X) = \min_{B \text{ is neighbor}(A)} \{C(A, B) + D(B, X)\}$$

$$R(A, X) = \arg \min_{B \text{ is neighbor}(A)} \{C(A, B) + D(B, X)\}$$

# Counting To Infinity

C: 2,L1

C: 1,L2

C: 2,L1

C: inf,None (3,L1 is even worse)

C: inf,None

C: 3,L1

C: 4,L1

C: inf,None

C: inf,None

C: 5,L1

...

...

A ghost of C is lurking in the links...

# The "Split-Horizon" Fix

Do not advertise (advertize  $\infty$ ) down the forward route

# The "Split-Horizon" Fix Does Not Always Work

When Advertisements Are Not In Sync

D: 2,L3

D: 2,L2

D: 1,L4

D: 2,L3

D: 2,L2

D: inf,None

D: 3,L1

D: 3,L1

D: inf,None

D: inf,None

D: inf,None

D: 4,L2

...

...

...

# The "Path-Vector" Fix

- ▶ Report not just the first forward, but the whole path
- ▶ Do not advertise (advertize  $\infty$ ) down the path

D: 2,L3,L4    D: 2,L2,L4    D: 1,L4

D: 2,L3,L4    D: 2,L2,L4    D: inf,None

D: inf,None    D: 3,L1,L3,L4    D: inf,None

D: inf,None    D: inf,None    D: inf,None

...

...

...

# Summary

- ▶ The network layer implements the glue that achieves connectivity
- ▶ Does addressing, forwarding, and routing
- ▶ Forwarding entails a routing table lookup; the table is built using routing protocol
- ▶ DV protocol: distributes route computation; each node advertises its best routes to neighbors
- ▶ Path-vector: include path, not just cost, in advertisement to avoid count-to-infinity
