

INTRODUCTION TO EECS II DIGITAL COMMUNICATION SYSTEMS

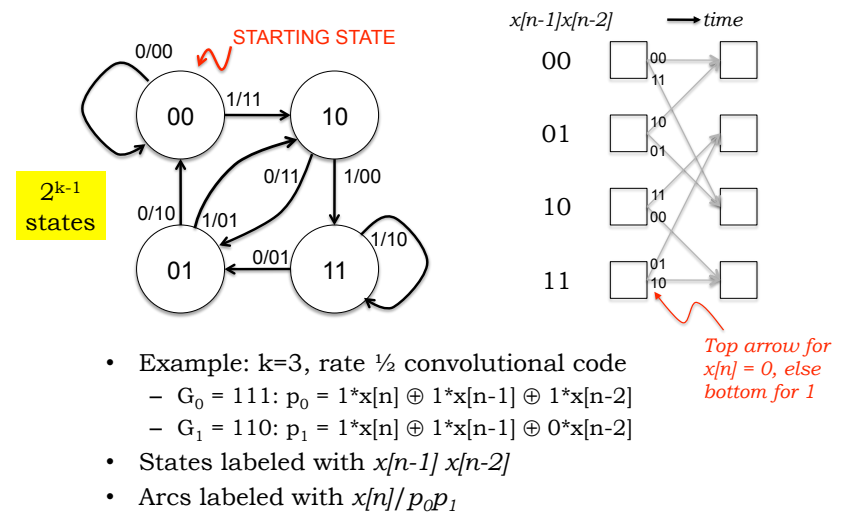

6.02 Spring 2009 Lecture #10

- state machines & trellises
- path and branch metrics
- Viterbi algorithm: add-compare-select
- hard decisions vs. soft decisions

6.02 Spring 2009

Lecture 10, Slide #1

State Machines & Trellises

6.02 Spring 2009

Lecture 10, Slide #2

Example

- Using $k=3$, rate $\frac{1}{2}$ code from earlier slides
- Received: 11101100011000
- Some errors have occurred...
- What's the 4-bit message?
- Look for message whose xmit bits are closest to rcvd bits

Msg	Xmit	Rcvd	d
0000	0000000000000000	11101100011000	7
0001	0000001111110000		8
0010	0000111111000000		8
0011	0000110101110000		4
0100	0011111100000000		6
0101	0011111011110000		5
0110	0011010010000000		7
0111	0011001001100000		6
1000	1111100000000000		4
1001	1111101111110000		5
1010	1111011111000000		7
1011	1111010001100000		2
1100	1100011000000000		5
1101	1100010111110000		4
1110	1100100110000000		6
1111	1100101001100000		3

Most likely: 1011

6.02 Spring 2009

Lecture 10, Slide #3

Finding the Most-likely Path

- Path metric: number of errors on most-likely path to given state (min of all paths leading to state)
- Branch metric: for each arrow, the Hamming distance between received parity and expected parity

6.02 Spring 2009

Lecture 10, Slide #4

Viterbi Algorithm

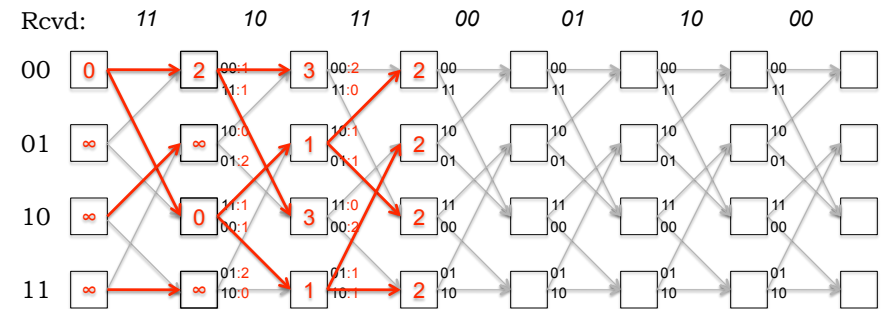

- Compute branch metrics for next set of parity bits
- Compute path metric for next column
 - add branch metric to path metric for old state
 - compare sums for paths arriving at new state
 - select path with smallest value (fewest errors, most likely)

6.02 Spring 2009

Lecture 10, Slide #5

Example (cont'd.)

- After receiving 3 pairs of parity bits we can see that all ending states are equally likely
- Power of convolutional code: use future information to constrain choices about most likely events in the past

6.02 Spring 2009

Lecture 10, Slide #6

Survivor Paths

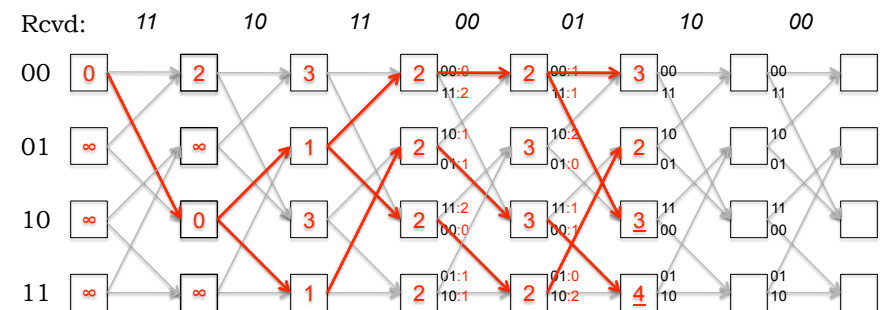

- Notice that some paths don't continue past a certain state
 - Will not participate in finding most-likely path: eliminate
 - Remaining paths are called *survivor paths*
 - When there's only one path: we've got a message bit!

6.02 Spring 2009

Lecture 10, Slide #7

Example (cont'd.)

- When there are “ties” (sum of metrics are the same)
 - Make an arbitrary choice about incoming path
 - If state is not on most-likely path: choice doesn't matter
 - If state is on most-likely path: choice may matter and error correction has failed (*mark state with underline to tell*)

6.02 Spring 2009

Lecture 10, Slide #8

Example (cont'd.)

- When we reach end of received parity bits
 - Each state's path metric indicates how many errors have happened on most-likely path to state
 - Most-likely final state has smallest path metric
 - Ties means end of message uncertain (but survivor paths may merge to a unique path earlier in message)

6.02 Spring 2009

Lecture 10, Slide #9

Traceback

- Use most-likely path to determine message bits
 - Trace back through path: message in reverse order
 - Message bit determined by high-order bit of each state (remember that came from message bit when encoding)
 - Message in example: 1011000 (w/ 2 transmission errors)

6.02 Spring 2009

Lecture 10, Slide #10

Hard Decisions

- As we receive each bit it's immediately digitized to "0" or "1" by comparing it against a threshold voltage
 - We lose the information about how "good" the bit is: a "1" at .9999V is treated the same as a "1" at .5001V
- The branch metric used in the Viterbi decoder is the Hamming distance between the digitized received voltages and the expected parity bits
 - This is called *hard-decision Viterbi decoding*
- Throwing away information is (almost) never a good idea when making decisions
 - Can we come up with a better branch metric that uses more information about the received voltages?

6.02 Spring 2009

Lecture 10, Slide #11

Soft Decisions

- Let's limit the received voltage range to [0.0, 1.0]
 - $V_{\text{eff}} = \max(0.0, \min(1.0, V_{\text{received}}))$
 - Voltages outside this range are "good" 0's or 1's
- Define our "soft" branch metric as the Euclidian distance between received V_{eff} and expected voltages

- Soft-decision decoder chooses path that minimizes sum of Euclidian distances between received and expected voltages
 - Different branch metric but otherwise the same recipe

6.02 Spring 2009

Lecture 10, Slide #12

Channel Coding Summary

- Add redundant info to allow error detection/correction
 - CRC to detect error-transmission (our safety net for catching undiscovered or uncorrectable errors)
 - Block codes: multiple parity bits, RC codes: oversampled polynomials
 - Convolutional codes: continuous streams of parity bits
- Error correction
 - Block codes: use parity errors to triangulate which bits are in error
 - RS codes: use subsets of bits to vote for message, majority rules!
 - Convolutional codes: use Viterbi algorithm to find most-likely message
