## Today: Modeling Channel Behavior

6.02 Spring 2011

Lecture 4, Slide #2

## System Input and Response

A discrete-time signal is described by an infinite sequence of values, denoted by  $x[n]$ ,  $y[n]$ ,  $z[n]$ , and so on. The indices fall in the range  $-\infty$  to  $+\infty$ .

In the diagram above, the sequence of output values  $y[n]$  is called the *response* of system  $S$  to the *input* sequence  $x[n]$ .

6.02 Spring 2011

Lecture 4, Slide #3

## Unit Step and Unit Step Response

A simple but useful discrete-time signal is the *unit step*,  $u[n]$ , defined as

$$u[n] = \begin{cases} 0, & n < 0 \\ 1, & n \geq 0 \end{cases}$$

6.02 Spring 2011

Lecture 4, Slide #4

## Unit Sample

Another simple but useful discrete-time signal is the *unit sample*,  $\delta[n]$ , defined as

$$\delta[n] = u[n] - u[n-1] = \begin{cases} 0, & n \neq 0 \\ 1, & n = 0 \end{cases}$$

6.02 Spring 2011

Lecture 4, Slide #5

## Unit Sample Response

The *unit sample response* of a system  $S$  is the response of the system to the unit sample input. We will always denote the unit sample response as  $h[n]$ .

6.02 Spring 2011

Lecture 4, Slide #6

## Unit-sample Decomposition

A discrete-time signal can be decomposed into a sum of time-shifted, scaled unit samples.

Example: in the figure,  $x[n]$  is the sum of  $x[-2]\delta[n+2] + x[-1]\delta[n+1] + \dots + x[2]\delta[n-2]$ .

In general:

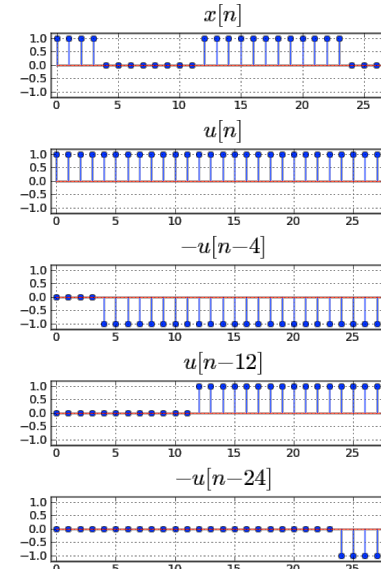

$$x[n] = \sum_{k=-\infty}^{\infty} x[k]\delta[n-k]$$

For any particular index, only one term of this sum is non-zero

6.02 Spring 2011

Lecture 4, Slide #7

## Unit-step Decomposition

Digital signaling waveforms are easily decomposed into time-shifted, scaled unit steps (each transition corresponds to another shifted, scaled unit step).

In this example,  $x[n]$  is the transmission of 1001110 using 4 samples/bit:

$$x[n] = u[n] - u[n-4] + u[n-12] - u[n-24]$$

6.02 Spring 2011

Lecture 4, Slide #8

## Time Invariant Systems

Let  $y[n]$  be the response of  $S$  to input  $x[n]$ .

If for all possible sequences  $x[n]$  and integers  $N$

then system  $S$  is said to be *time invariant*. A time shift in the input sequence to  $S$  results in an identical time shift of the output sequence.

## Linear Systems

Let  $y_1[n]$  be the response of  $S$  to input  $x_1[n]$  and  $y_2[n]$  be the response to  $x_2[n]$ .

If

then system  $S$  is said to be *linear*. If the input is the weighted sum of several signals, the response is the *superposition* (i.e., weighted sum) of the response to those signals.

## Modeling LTI Systems

If system  $S$  is both linear and time-invariant (LTI), then we can use the unit sample response to predict the response to any input waveform  $x[n]$ :

Indeed, the unit sample response  $h[n]$  completely characterizes the LTI system  $S$ , so you often see

## Properties of Convolution

$$x[n] * h[n] \equiv \sum_{k=-\infty}^{\infty} x[k]h[n-k]$$

The summation is called the convolution sum, or more simply, the *convolution* of  $x[n]$  and  $h[n]$ . “ $*$ ” is the convolution operator.

Convolution is commutative:

$$x[n] * h[n] = h[n] * x[n]$$

Convolution is associative:

$$x[n] * (h_1[n] * h_2[n]) = (x[n] * h_1[n]) * h_2[n]$$

Convolution is distributive:

$$x[n] * (h_1[n] + h_2[n]) = x[n] * h_1[n] + x[n] * h_2[n]$$

## Parallel Interconnection of LTI Systems

$$y[n] = y_1[n] + y_2[n] = x[n] * h_1[n] + x[n] * h_2[n] = x[n] * (h_1[n] + h_2[n])$$

6.02 Spring 2011

Lecture 4, Slide #13

## Series Interconnection of LTI Systems

$$y[n] = w[n] * h_2[n] = (x[n] * h_1[n]) * h_2[n] = x[n] * (h_1[n] * h_2[n])$$

6.02 Spring 2011

## Channels as LTI Systems

Many transmission channels can be effectively modeled as LTI systems. When modeling transmissions, there are few simplifications we can make:

- We'll call the time transmissions start  $t=0$ ; the signal before the start is 0. So  $x[m] = 0$  for  $m < 0$ .
- Real-world channels are *causal*: the output at any time depends on values of the input at only the present and past times. So  $h[m] = 0$  for  $m < 0$ .

These two observations allow us to rework the convolution sum when it's used to describe transmission channels:

$$y[n] = \sum_{k=-\infty}^{\infty} x[k]h[n-k] = \sum_{k=0}^{\infty} x[k]h[n-k] = \sum_{k=0}^n x[k]h[n-k] = \sum_{j=0}^n x[n-j]h[j]$$

start at  $t=0$ 
causal
 $j=n-k$

Lecture 4, Slide #15

## Relationship between $h[n]$ and $s[n]$

We're often given one of  $h[n]$  or  $s[n]$  and would like to know the other. On slide #5 we saw

$$\delta[n] = u[n] - u[n-1]$$

Which for LTI systems implies

$$h[n] = s[n] - s[n-1]$$

In other words, the unit sample response is the first difference of the unit step response. Also

$$s[n] = \sum_{k=-\infty}^n h[k]$$

6.02 Spring 2011

## Computing $y[28]$ using $s_4[n]$

We can use  $s_4[n]$  to compute  $y[28]$  as follows:

$$x[n] = u[n] - u[n-4] + u[n-12] - u[n-24] + u[n-28] + \dots$$

So

$$y[n] = s_4[n] - s_4[n-4] + s_4[n-12] - s_4[n-24] + s_4[n-28] + \dots$$

For  $n=28$

$$\begin{aligned} y[28] &= s_4[28] - s_4[28-4] + s_4[28-12] - s_4[28-24] + s_4[28-28] + \dots \\ &= s_4[28] - s_4[24] + s_4[16] - s_4[4] + s_4[0] + \dots \\ &= 1.0 - 1.0 + 1.0 - 0.8125 + 0.0625 \\ &= 0.25 \end{aligned}$$

So the noise margin is  $0.5 - 0.25 = 0.25V$ .

n	$s_4[n]$
<0	0.0
0	0.0625
1	0.1875
2	0.375
3	0.625
4	0.8125
5	0.9375
$\geq 6$	1.0

6.02 Spring 2011

Lecture 4, Slide #23

## Computing $y[28]$ using $h_4[n]$

We can use  $h_4[n]$  to compute  $y[28]$  as follows: first expand convolution sum keeping non-zero  $h_4[n]$  terms (see bottom right, slide #15):

$$y[n] = x[n]h_4[0] + x[n-1]h_4[1] + x[n-2]h_4[2] + x[n-3]h_4[3] + x[n-4]h_4[4] + x[n-5]h_4[5] + x[n-6]h_4[6]$$

For  $n=28$ :

$$\begin{aligned} y[28] &= x[28]h_4[0] + x[27]h_4[1] + x[26]h_4[2] + x[25]h_4[3] + x[24]h_4[4] + x[23]h_4[5] + x[22]h_4[6] \\ &= 0.0625 + 0 + 0 + 0 + 0 + 0.125 + 0.0625 \\ &= 0.25 \end{aligned}$$

This agrees with the previous calculation. ✓

n	$h_4[n]$
<0	0.0
0	0.0625
1	0.125
2	0.1875
3	0.25
4	0.1875
5	0.125
6	0.0625
$\geq 7$	0.0
