## L9: Intro Network Systems

Dina Katabi 6.033 Spring 2007

http://web.mit.edu/6.033
Some slides are from lectures by Nick Mckeown, Ion Stoica, Frans
Kaashoek, Hari Balakrishnan, Sam Madden, and Robert Morris

Ilii

## What have you seen so far?

| Systems | Complexity <br> Modularity <br> Dtechnology/dt | Hierarchy <br> Therac-25 |
| :--- | :--- | :--- |
| Naming systems | Gluing systems | File system <br> name space |
| Client/service <br> design | Enforced <br> modularity | X windows |
| Operating <br> systems | Client/service <br> with in a <br> computer | Eraser and Unix |
| Performance | Coping with <br> bottlenecks | MapReduce |

## Client/service using network

- Sharing irrespective of geography
- Strong modularity through geographic separation

## Network is a system too!

- Network consists of many networks, many links, many switches
- Internet is a case study of successful network system

## Today's topic: challenges

- Economical:
- Universality
- Topology, Sharing, Utilization
- Organizational
- Routing, Addressing, Packets, Delay
- Best-effort contract
- Physical
- Errors, speed of light, wide-range of parameters

## MIT Campus Network

Topology Overview ${ }^{\text {T}}$

## Circuit Switching

- It's the method used by the telephone network
- A call has three phases:
Establish circuit from end-to-end ("dialing"),
Communicate,
Close circuit ("tear down").
- If circuit not available: "busy signal"

## Isochronous Multiplexing/Demultiplexing

## One way for sharing a link is TDM:

- A time interval is divided into $n$ frames
- Each frame carries the data of a particular conversation
- E.g., frame 0 belongs to the red conversation

## Circuit Switching

- Assume link capacity is C bits/sec
- Each communication requires R bits/sec
- \#frames = C/R
- Maximum number of concurrent communications is $C / R$
- What happens if we have more than $C / R$ communications?
- What happens if the a communication sends less/more than R bits/sec?
$\rightarrow$ Design is unsuitable for bursty communications

## Packet Switching

- Used in the Internet
- Data is sent in Packets (header contains control info, e.g., source and destination addresses)

- Per-packet routing
- At each node the entire packet is received, buffered, and then forwarded)
- No capacity is allocated

## Asynchronous Multiplexing/ Demultiplexing

- Multiplex using a queue
- Switch need memory/buffer
- Demultiplex using information in packet header
- Header has destination
- Switch has a forwarding table that contains information about which link to use to reach a destination

## Aggregate Internet Traffic Smooths

5-min average traffic rate at an MIT-CSAIL router

Max In: $12.2 \mathrm{Mb} / \mathrm{s} \quad$ Avg. In: $2.5 \mathrm{Mb} / \mathrm{s}$
Max Out: $12.8 \mathrm{Mb} / \mathrm{s} \quad$ Avg. Out: $3.4 \mathrm{Mb} / \mathrm{s}$

## Best Effort

No Guarantees:

- Variable Delay (jitter)
- Variable rate
- Packet loss
- Duplicates
- Reordering

## Networks are heterogeneous

$d(t e c h n o l o g y) / d t$ for networks

## Normalized Growth since 1980

Thanks to Nick Mckeown @ Stanford for some of these data points

## Plan for studying network systems

| Sharing and <br> challenges | $7 . \mathrm{A}$ | Ethernet |
| :--- | :--- | :--- |
| Layering | $7 . \mathrm{B}+\mathrm{C}$ | End-to-end |
| Routing | $7 . \mathrm{D}$ | Internet <br> routing |
| End-to-end <br> reliability | $7 . \mathrm{E}$ | Network file <br> system |
| Congestion <br> control | $7 . F$ | NATs |
