Overview

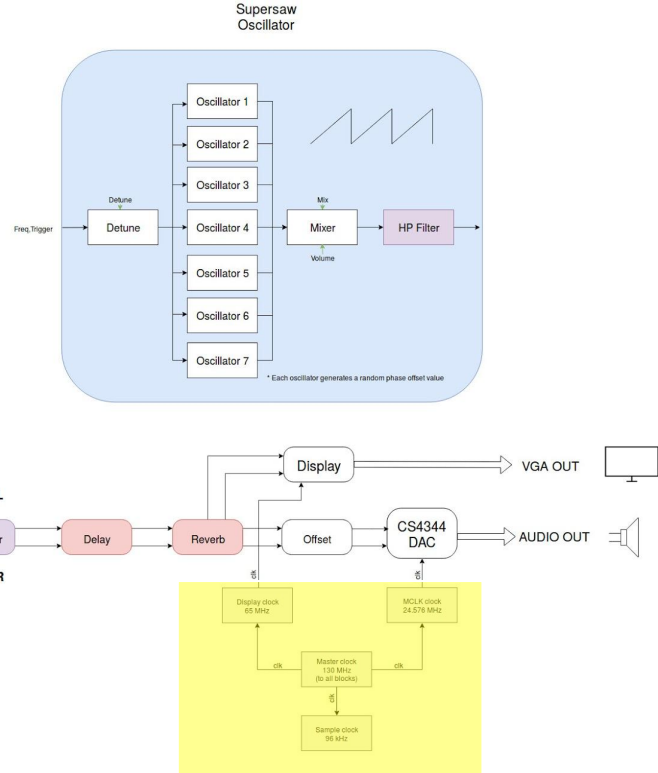

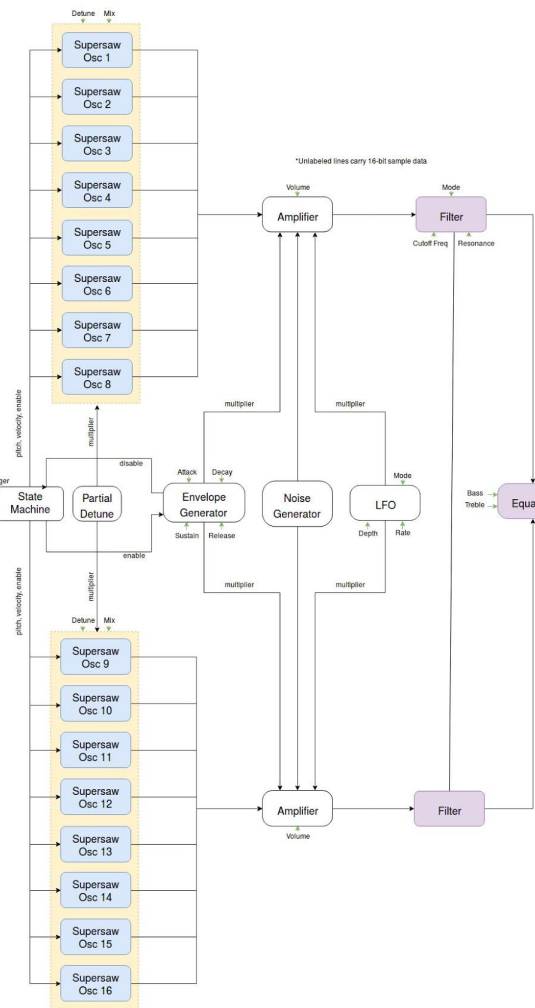

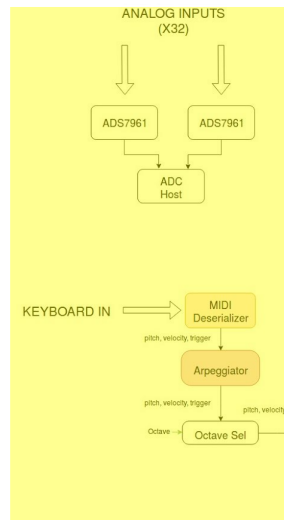

- Supersaw sound: popular in EDM (hardcore, trance)
- Serial data input from USB MIDI keyboard (laptop for handshaking)
- Up to 112 concurrent free-running sawtooth oscillators
- Analog instrument panel + Verilog DSP + Display

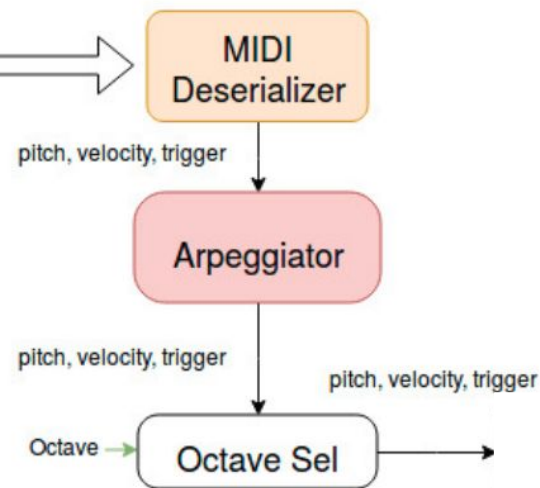

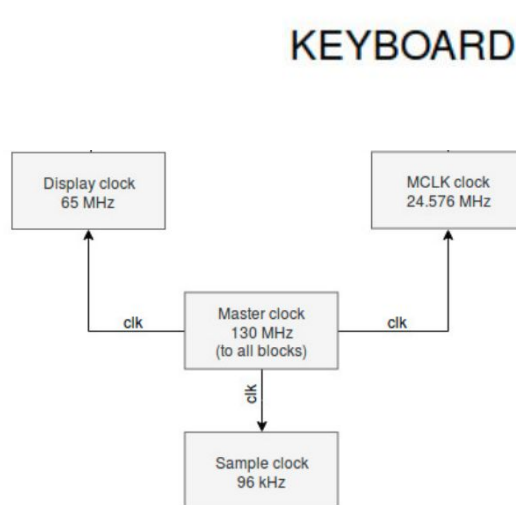

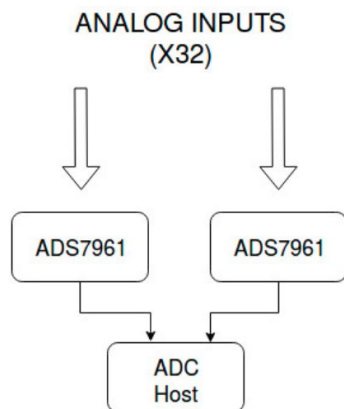

Analog control panel

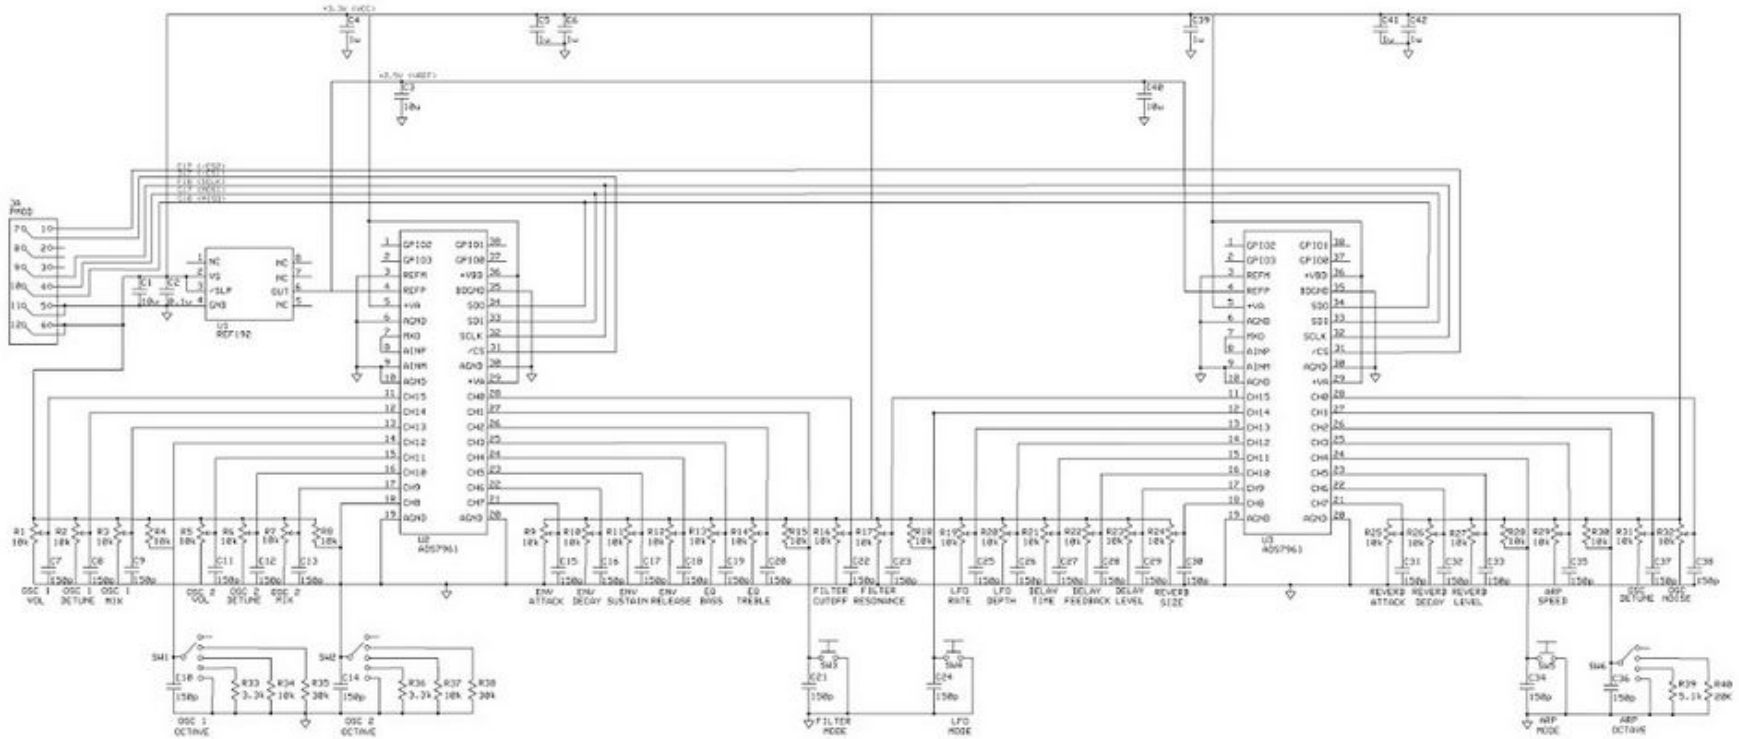

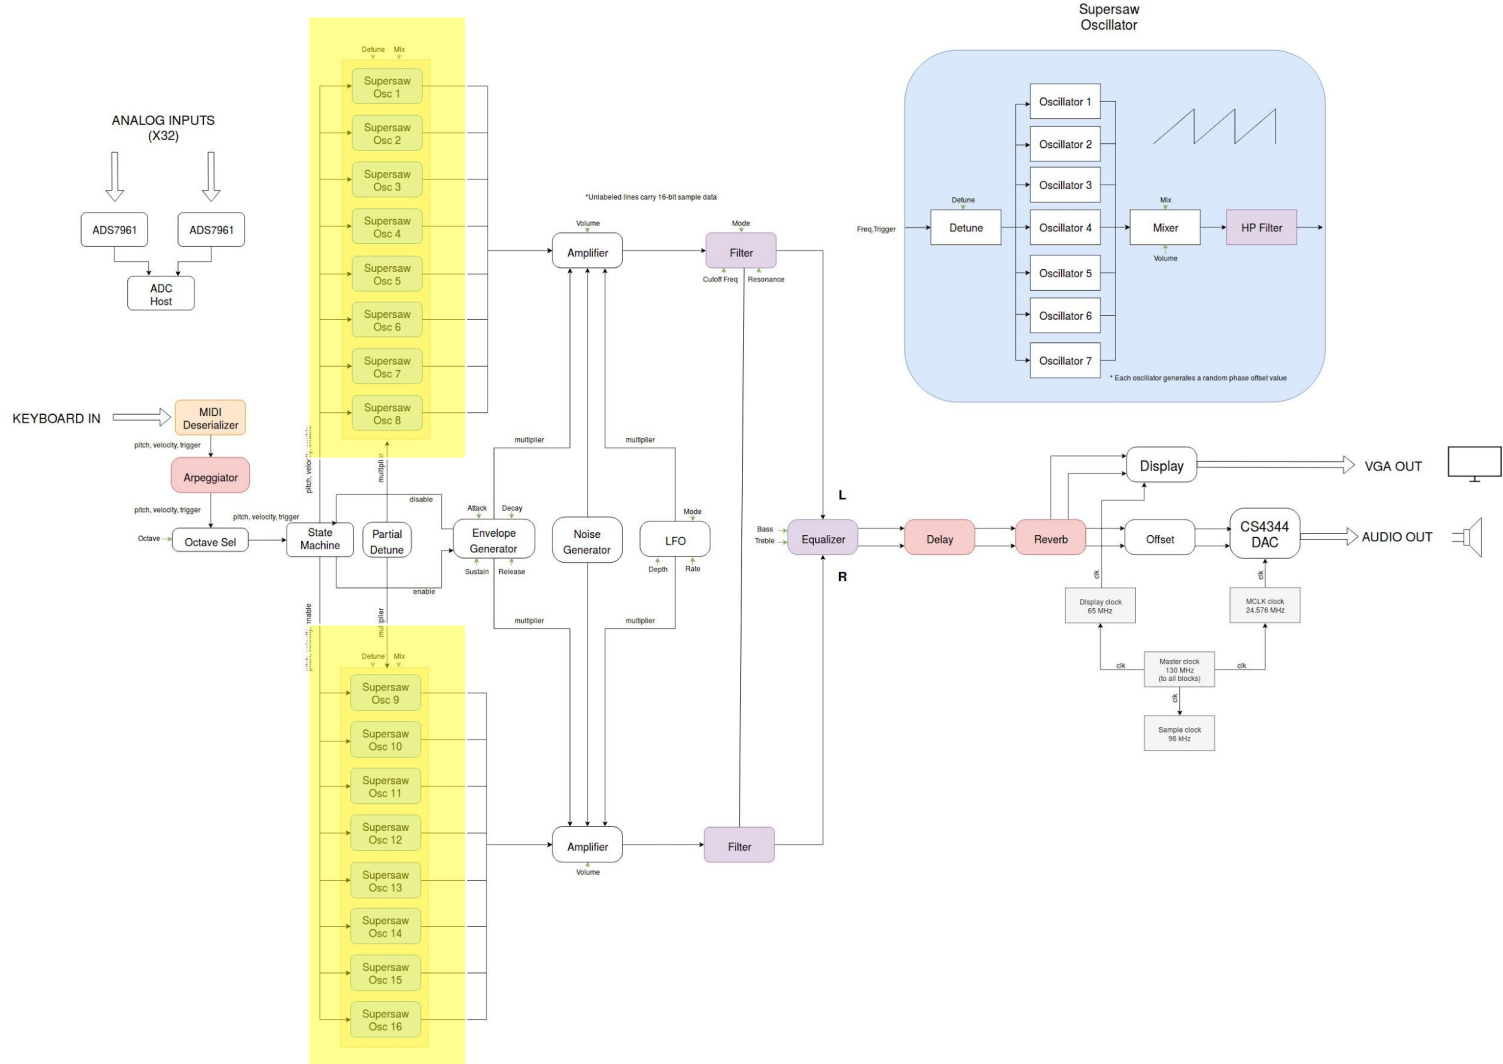

Input Modules

ADC (2x ADS7961)

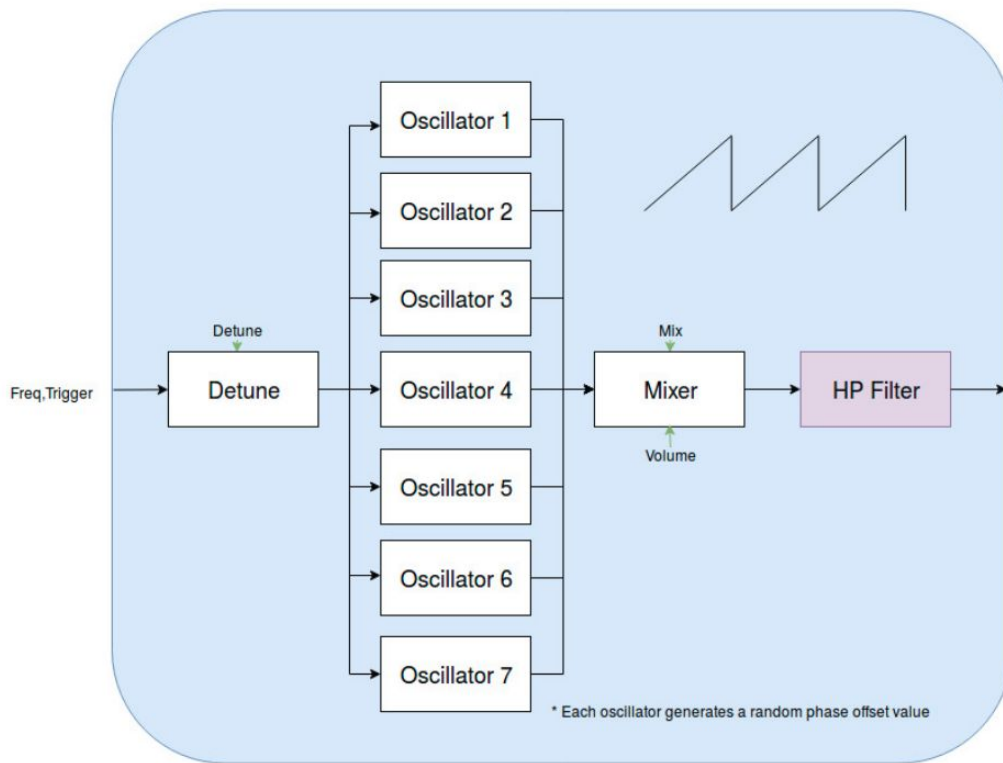

The Supersaw Algorithm

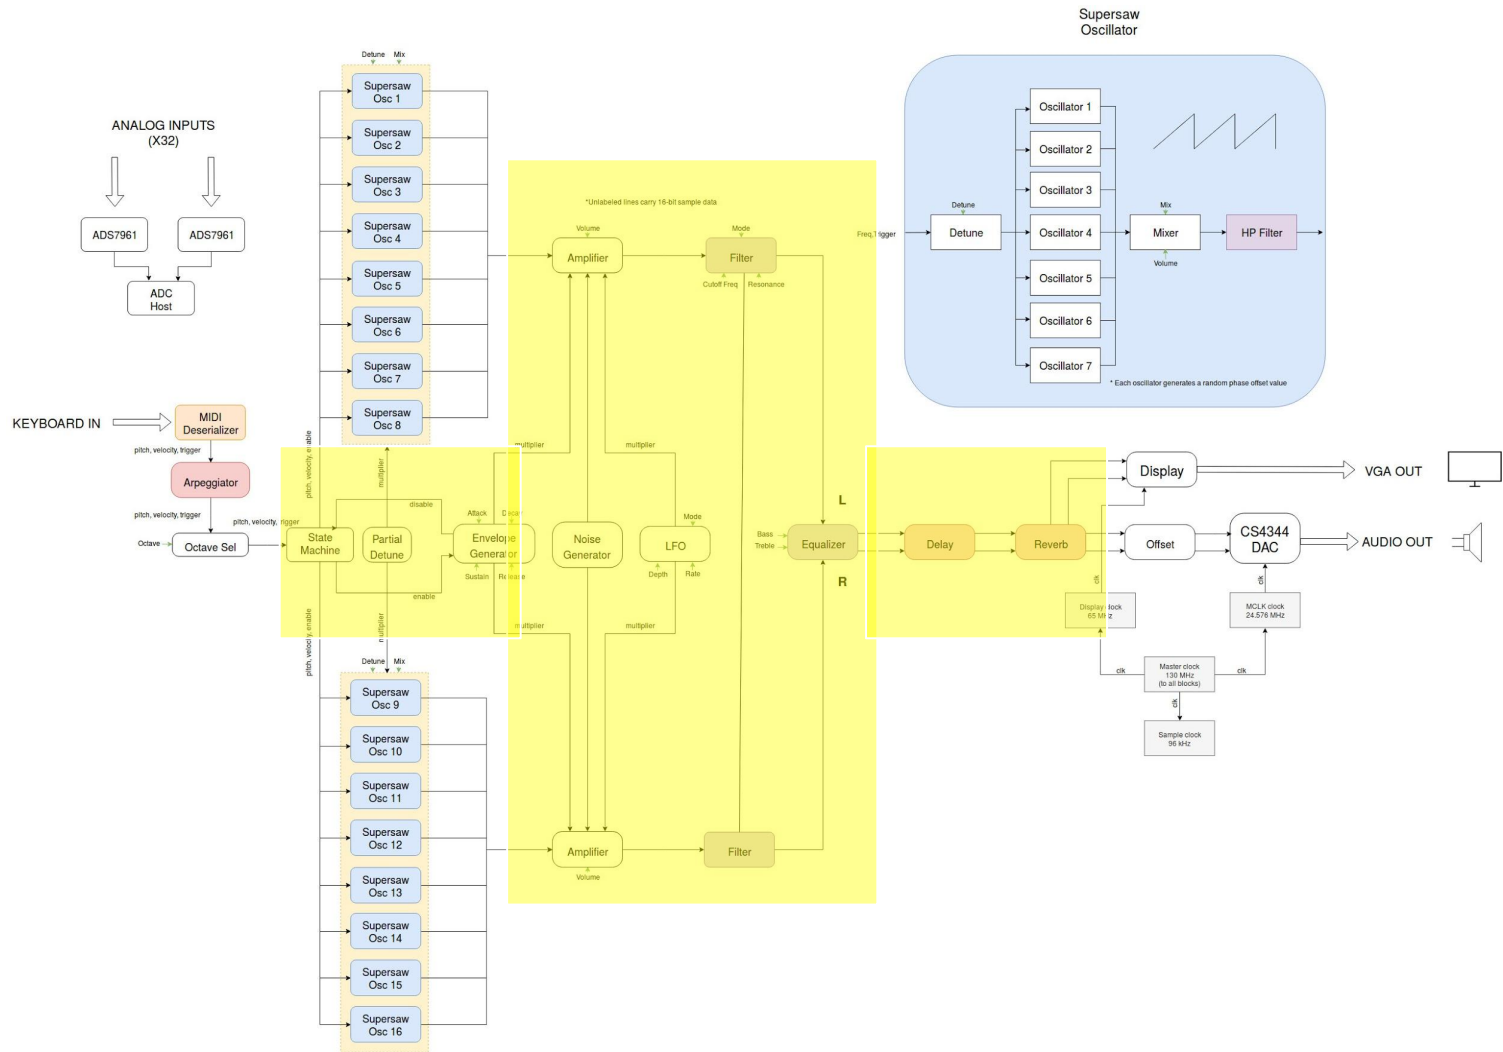

To represent a single note, seven sawtooth waves with random phase offset are superimposed and sent through a high-pass filter whose cutoff frequency tracks the fundamental frequency. The frequency of the center saw corresponds to the fundamental, while the other six saws are detuned according to a variable ratiometric spread. The spread control was found to follow an 11th order polynomial. Control of the mix ratio between center and side oscillators is also non-linear.¹

Commitment

The commitment goal includes everything needed to hear the basic Supersaw waveform in stereo and monitor it with the display. The following modules apply to this level: **ADS7961 ADC**, **ADC Host**, **Deserializer**, **State Machine**, **Oscillator**, **Supersaw** (to be further subdivided), **Amplifier**, **Offset**, **CS4344 DAC**, and **Display**.

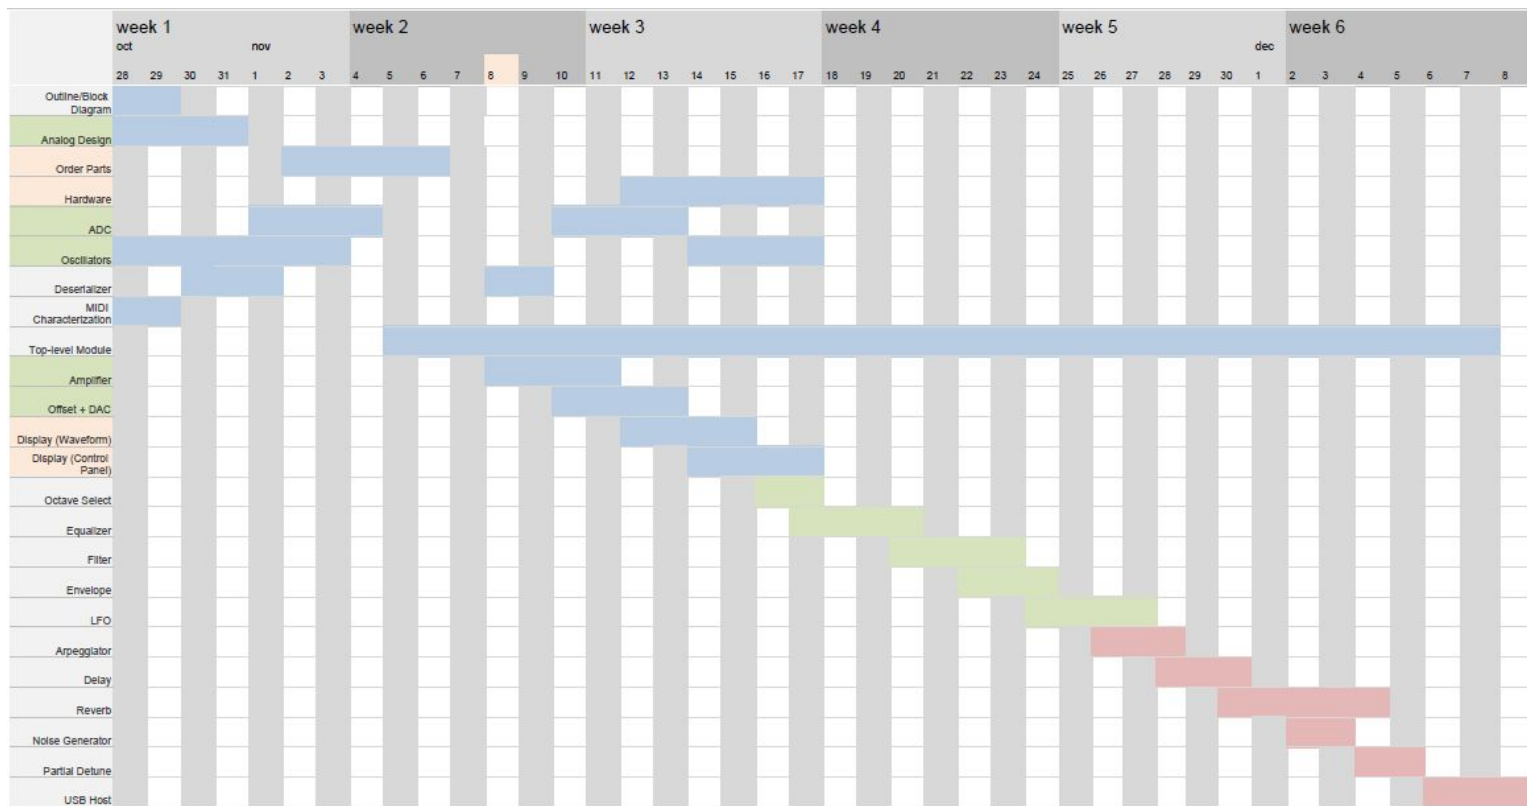

Goal

The primary goal includes the commitment modules plus the **Octave Select**, **Equalizer**, **Filter**, **Envelope**, and **LFO** modules. This represents what we believe to be the most useful addons to the core of the project.

Stretch

The stretch goal includes all of the above plus the **Arpeggiator**, **Delay**, **Reverb**, **Noise Generator**, **Partial Detune**, and **USB Host** modules. These are features that have the potential to create the richest, most pleasing musical palette but which have an uncertain requirement on time investment.
