Radio 6.111 Final Project Report

Dexter Chan

December 14, 2005

1 Abstract

Over the course of the last six weeks, the author attempted to implement a digital radio in Verilog with an RF front end. While the author did not manage to succeed at this task, many things were learned. In the future, the author will not attempt to integrate digital and analog domains.
2 Overview

Over the course of the previous six weeks, the author attempted to design and build a digital radio with an analog RF receiving end. The project was ultimately unsuccessful; however, a great deal was learned in the process of building this device. Upon reflections, the author spotted many ways to improve the process.

The desired goal was a system which could take as input a signal from an antenna and output the received signal as sound. Later, functionality for a VGA output to graph a signal was added. The system was to be tuned to the radio station WRKO, broadcasting at 680 kilohertz. This station was one of the strongest in the Boston area, with a transmitter power of 50 kilowatts. No user input was required; the signal would be output to the VGA display and AC’97 audio codec. This digital system was implemented via the 6.111 Lab Kit, containing a Xilinx Virtex 2 FPGA and a series of buttons and switches.

3 Description of Modules

The actual system consisted of several interconnected Verilog modules, as well as additional hardware hooked up to the system. These parts were the antenna, responsible for gathering a radio signal; the analog-to-digital converter, obtained from Analog Devices; the digital down converter, which demodulates the signal; and the VGA display, as hooked up in Figure 1. A description of each of these modules follows.

The antenna was built using a schematic provided by Ike Chuang, originally from techlib.com. The antenna was built using Radio Shack parts, with passive components from the Course 6 labs. The antenna had a gain of about 10, amplifying a 300-mv signal at the antenna base to about 3 V peak-to-peak at the output, assuming full battery.

The output from the antenna was filtered using an active filter; this was constructed out of a 741 op-amp, with two 22-nanofarad capacitors, a 90-ohm resistor and a 27-ohm resistor. While this filter removed the 60-hertz interference from the power cables, it did not manage to transmit a radio signal at 680 kilohertz.

Figure 1: The block diagram, describing all parts of the system.
The analog to digital converter used was the Analog Devices 9240 evaluation board, part number 9240EB. The ADC had 14 bits of resolution and an adjustable reference voltage, which was set appropriately low. The ADC was capable of sampling at a maximum rate of 10 megahertz, which was sufficient; the minimum sampling rate to recover the entire AM band was 3.4 megahertz. The original 9 megahertz clock proved to be too high a sampling rate, as samples were being dropped at the digital down converter; the author was testing clocking the ADC at 1.5 megahertz (extracting samples every 18 cycles); however, tests were inconclusive.

The digital downconverter was a built-in Xilinx module, which was implemented using the Xilinx CoreGen tool. As it included a lowpass filter, the use of this module could have simplified the demodulation process greatly. However, the author found out that he was specifying the outputs incorrectly, which was a factor in causing the signal to display incorrectly. This will be described in further detail below.

The VGA module was integrated on suggestion of Jae Lee; the goal was to display an arbitrary signal on the screen. This was largely taken from Ike Chuang’s VGA display module, with some modifications to integrate it into the radio system.

4 Testing and Debugging

The author learned firsthand that redesign of a system is expensive and often painful in terms of time and components. Over the course of this project, the author redesigned the system and revised many of his initial assumptions, many of which proved to be wrong.

The first redesign involved rethinking the signal theory in demodulating the signal. Originally, the plan was to use Fourier transforms to bring the signal into the frequency domain, then use hardware multipliers to filter and demodulate. However, after discussion, it was determined that doing this was much more complex than necessary, and it would suffice to multiply the incoming signal by a sine wave and pass the resulting signal through a lowpass filter to demodulate; the resultant wave would be passed to the audio codec.

The second redesign involved adding a VGA module on recommendation, to visualize the output. This would help debug the signal as it traveled through the system. This VGA module would be connected to the inputs of various other modules and graph the output.

Unfortunately, rethinking the project meant that much of the previous work done was invalidated due to incorrect initial assumptions. The author assumed that fast fourier transforms in hardware were fast; instead, compared to the rest of the system, they were much slower than multipliers. While doing many of the calculations in frequency space would have simplified the problem, it would introduce other design considerations–decreasing the sample rate of the ADC to compensate for the delay time and registering the outputs would be some of the issues raised. Thus, the decision was made to do all calculations in the time domain.

Interfacing the analog to digital converter to the lab kit was, surprisingly, the most straightforward part of the system. The fact that the Analog Devices ADC took a standard IDE cable spacing was immensely helpful; it was not difficult to refer to the Analog Devices schematic and determine the pinout diagram for the IDE cable. After some initial difficulty with the IDE plugs, the cable slotted smoothly into the board. The protocol written to feed a clock signal into the ADC worked on the first try; as the input clock was set to a multiple of 27 megahertz, the inputs would arrive after an integer number of clock cycles. Connecting the ADC input to the signal analyzer confirmed that the signal received was the test sine wave.

More testing was made possible with a more complex signal generator; modulated signals could be fed into the system and the output could be visualized on the VGA display. These signals were correct.

The next most straightforward part of the system to test were the outputs. While there was difficulty integrating both video and sound, there were preexisting test beds for both; furthermore, the author had
done previous work in both sound and video in labs 3 and 4 respectively. Thus, after some creativity, it was not too difficult to build a system capable of displaying arbitrary video and sound.

The Xilinx modules were poorly documented, which made them difficult to integrate into the rest of the system. It was necessary to consult outside references in order to understand the sometimes erratic behavior of each individual module. The author conducted rudimentary tests on these modules, but after confirming they behaved according to their specifications they were mostly left alone.

The antenna was by far the most difficult and frustrating module to debug. While testing outside of the lab produced a reasonable signal; testing with a signal generator produced a small (1.5 to 2 V) but measurable waveform at the appropriate frequency. By setting the reference voltage of the analog to digital converter at 1 volt, and boosting the gain of the signal using an op-amp, it would be possible to feed that signal into the labkit.

However, in lab, the presence of several dozen power cables, with 120 volts AC at 15 amperes, made the antenna essentially unusable. Despite attempts to detect a signal by extending the length of the antenna wire (at last count, to about six feet) was still insufficient. Filtering did not solve the problem; building a bandpass filter and passing the signal through removed the 60 Hz signal; however, the author was told recently that an op-amp filter would not pass frequencies in the kilohertz range well and that a tuned LC circuit was really the only way to solve the problem effectively.

Testing the lowpass filter was done mostly in Matlab, as it was difficult to link a signal generator and output the signal. Coefficients for a sine wave were generated in Matlab; an FFT of that wave was taken and multiplied by the FFT of the filter. The inverse FFT was then taken; while the gain varied, due to rounding issues, the returned signal was correct.

In summary, the VGA modules, sound and ADC worked as described; as their output was visible, it was easy to see problems with these systems. The Xilinx modules were not functional, nor were some of the hardware components.

5 Conclusion

The author was told that “real companies try building software radios and fail”. While disheartening, this was both true and appropriate. The project as initially devised was simply too complex; even the simplified system was not too complex to complete. While the author did learn a great deal about design, a purely digital project would have been much easier to implement. Much time was spent debugging the hardware and hooking all the pieces of the hardware together; in a purely digital project, this time could have been spent doing actual design.

While many individual parts of the system functioned, linking them together became increasingly difficult as the complexity increased. Attempting to build a VGA module was a mistake, as it took time away from developing the core functionality of the system. The author spent too much time attempting to get this to work and not enough time on the audio portion of the system.

The author regrets embarking on this project alone. Making incorrect assumptions about the system slowed down the project greatly; having someone else versed in the theory would have made the work easier to check for sanity. The author has also learned that he does not have the appropriate engineering common sense to immediately see elegant solutions; being able to produce a good solution will require time and multiple revisions. Starting with correct assumptions helps this problem.

The author also regrets embarking on an ambitious project to link digital and analog parts. A simpler digital project would have been easier to complete, without the mess and fuss of hardware interference. The author, however, did learn how to solder properly, which will in the future be useful.
