---

```plaintext
)abbrev package PMASS PatternMatchAssertions
++ Author: Manuel Bronstein
++ Date Created: 21 Mar 1989
++ Date Last Updated: 23 May 1990
++ Description:
++ Attaching assertions to symbols for pattern matching.

PatternMatchAssertions():Exports == Implementation where
FE == Expression Integer

Exports => with
  assert : (Symbol, String) -> FE
  ++ assert(x, s) makes the assertion s about x.
  constant: Symbol -> FE
  ++ constant(x) tells the pattern matcher that x should
  ++ match only the symbol 'x and no other quantity.
  optional: Symbol -> FE
  ++ optional(x) tells the pattern matcher that x can match
  ++ an identity (0 in a sum, 1 in a product or exponentiation).
  multiple: Symbol -> FE
  ++ multiple(x) tells the pattern matcher that x should
```

---
++ preferably match a multi-term quantity in a sum or product.
++ For matching on lists, multiple(x) tells the pattern matcher
++ that x should match a list instead of an element of a list.

Implementation ==> add
import FunctionSpaceAssertions(Integer, FE)

constant x == constant(x::FE)
multiple x == multiple(x::FE)
optional x == optional(x::FE)
assert(x, s) == assert(x::FE, s)

Permanent examples

The package Permanent provides the function permanent for square matrices. The permanent of a square matrix can be computed in the same way as the determinant by expansion of minors except that for the permanent the sign for each element is 1, rather than being 1 if the row plus column indices is positive and -1 otherwise. This function is much more difficult to compute efficiently than the determinant.

An example of the use of permanent is the calculation of the n-th derangement number, defined to be the number of different possibilities for n couples to dance but never with their own spouse.

Consider an n by n matrix with entries 0 on the diagonal and 1 elsewhere. Think of the rows as one-half of each couple (for example, the males) and the columns the other half. The permanent of such a matrix gives the desired derangement number.

```
kn n ==
  r : MATRIX INT := new(n,n,1)
  for i in 1..n repeat
      r.i.i := 0
  r
```

Here are some derangement numbers, which you see grow quite fast.

```
permanent(kn(5) :: SQMATRIX(5,INT))
```

```
[permanent(kn(n) :: SQMATRIX(n,INT)) for n in 1..13]
```

)abbrev package PERMAN Permanent
++ Authors: Johannes Grabmeier, Oswald Gschnitzer
++ Date Created: 7 August 1989
++ Date Last Updated: 23 August 1990
++ References:
  ++ Henryk Minc: Evaluation of Permanents,
  ++ Nijenhuis and Wilf: Combinatorial Algorithms, Academic
  ++ S.G.Williamson, Combinatorics for Computer Science,
++ Description:
  ++ Permanent implements the functions permanent, the
  ++ permanent for square matrices.

Permanent(n : PositiveInteger, R : Ring with commutative("*")):
public == private where
  I ==> Integer
  L ==> List
  V ==> Vector
  SM ==> SquareMatrix(n,R)
VECTPKG1 ==> VectorPackage1(I)

NNI ==> NonNegativeInteger

PI ==> PositiveInteger

GRAY ==> GrayCode

public ==> with

permanent: SM -> R
++ permanent(x) computes the permanent of a square matrix x.
++ The permanent is equivalent to
++ the \spadfun{determinant} except that coefficients have
++ no change of sign. This function
++ is much more difficult to compute than the
++ determinant. The formula used is by H.J. Ryser,
++ improved by [Nijenhuis and Wilf, Ch. 19].
++ Note that permanent(x) choose one of three algorithms, depending
++ on the underlying ring R and on n, the number of rows (and
++ columns) of x:
++ if 2 has an inverse in R we can use the algorithm of
++ [Nijenhuis and Wilf, ch.19,p.158]; if 2 has no inverse,
++ some modifications are necessary:
++ if n > 6 and R is an integral domain with characteristic
++ different from 2 (the algorithm works if and only 2 is not a
++ zero-divisor of R and characteristic(R) ̸= 2,
++ but how to check that for any given R ?),
++ the local function permanent2 is called;
++ else, the local function permanent3 is called
++ (works for all commutative rings R).

++ symmetricGroup(n) constructs the symmetric group Sn
++ acting on the integers 1,...,n, generators are the
++ n-cycle (1,...,n) and the 2-cycle (1,2).
symmetricGroup: L I -> PERMGRP I
++ symmetricGroup(li) constructs the symmetric group acting on
++ the integers in the list li, generators are the
++ cycle given by li and the 2-cycle (li.1,li.2).
++ Note that duplicates in the list will be removed.
alternatingGroup: PI -> PERMGRP I
++ alternatingGroup(n) constructs the alternating group An
++ acting on the integers 1,...,n, generators are in general the
++ n-2-cycle (3,...,n) and the 3-cycle (1,2,3)
++ if n is odd and the product of the 2-cycle (1,2) with
++ n-2-cycle (3,...,n) and the 3-cycle (1,2,3)
++ if n is even.
alternatingGroup: L I -> PERMGRP I
++ alternatingGroup(li) constructs the alternating group acting
++ on the integers in the list li, generators are in general the
++ n-2-cycle (li.3,...,li.n) and the 3-cycle
++ (li.1,li.2,li.3), if n is odd and
++ product of the 2-cycle (li.1,li.2) with
++ n-2-cycle (li.3,...,li.n) and the 3-cycle
++ (li.1,li.2,li.3), if n is even.
++ Note that duplicates in the list will be removed.
abelianGroup: L PI -> PERMGRP I
++ abelianGroup([n1,...,nk]) constructs the abelian group that
++ is the direct product of cyclic groups with order ni.
cyclicGroup: PI -> PERMGRP I
++ cyclicGroup(n) constructs the cyclic group of order n acting
++ on the integers 1,...,n.
cyclicGroup: L I -> PERMGRP I
++ cyclicGroup([i1,...,ik]) constructs the cyclic group of
++ order k acting on the integers i1,...,ik.
++ Note that duplicates in the list will be removed.
dihedralGroup: PI -> PERMGRP I
++ dihedralGroup(n) constructs the dihedral group of order 2n
++ acting on integers 1,...,N.
dihedralGroup: L I -> PERMGRP I
++ dihedralGroup([i1,...,ik]) constructs the dihedral group of
++ order 2k acting on the integers out of i1,...,ik.
++ Note that duplicates in the list will be removed.
mathieu11: L I -> PERMGRP I
++ mathieu11(li) constructs the mathieu group acting on the 11
++ integers given in the list li.
++ Note that duplicates in the list will be removed.
++ error, if li has less or more than 11 different entries.
mathieu11: () -> PERMGRP I
++ mathieu11 constructs the mathieu group acting on the
++ integers 1,...,11.
mathieu12: L I -> PERMGRP I
++ mathieu12(li) constructs the mathieu group acting on the 12
++ integers given in the list li.
++ Note that duplicates in the list will be removed
++ Error: if li has less or more than 12 different entries.
mathieu12: () -> PERMGRP I
++ mathieu12 constructs the mathieu group acting on the
++ integers 1,...,12.
mathieu22: L I -> PERMGRP I
++ mathieu22(li) constructs the mathieu group acting on the 22
++ integers given in the list li.
++ Note that duplicates in the list will be removed.
++ Error: if li has less or more than 22 different entries.
mathieu22: () -> PERMGRP I
++ mathieu22 constructs the mathieu group acting on the
++ integers 1,...,22.
mathieu23: L I -> PERMGRP I
++ mathieu23(li) constructs the mathieu group acting on the 23
++ integers given in the list li.
++ Note that duplicates in the list will be removed.
++ Error: if li has less or more than 23 different entries.
mathieu23: () -> PERMGRP I
++ mathieu23 constructs the mathieu group acting on the
++ integers 1,...,23.
mathieu24: L I -> PERMGRP I
++ mathieu24(li) constructs the mathieu group acting on the 24
++ integers given in the list li.
++ Note that duplicates in the list will be removed.
++ Error: if li has less or more than 24 different entries.
mathieu24: () -> PERMGRP I
++ mathieu24 constructs the mathieu group acting on the
++ integers 1,...,24.
janko2: L I -> PERMGRP I
++ janko2(li) constructs the janko group acting on the 100
++ integers given in the list li.
++ Note that duplicates in the list will be removed.
++ Error: if li has less or more than 100 different entries

janko2: () -> PERMGRP I
++ janko2 constructs the janko group acting on the
++ integers 1, ..., 100.

rubiksGroup: () -> PERMGRP I
++ rubiksGroup constructs the permutation group representing
++ Rubic’s Cube acting on integers 10*i+j for
++ 1 <= i <= 6, 1 <= j <= 8.
++ The faces of Rubik’s Cube are labelled in the obvious way
++ Front, Right, Up, Down, Left and Back and numbered from 1 to 6
++ in this given ordering, the pieces on each face
++ (except the unmoveable center piece) are clockwise numbered
++ from 1 to 8 starting with the piece in the upper left
++ corner. The moves of the cube are represented as permutations
++ on these pieces, represented as a two digit
++ integer ij where i is the number of the face (1 to 6)
++ and j is the number of the piece on this face.
++ The remaining ambiguities are resolved by looking
++ at the 6 generators, which represent a 90 degree turn of the
++ faces, or from the following pictorial description.
++ Permutation group representing Rubic’s Cube acting on integers
++ 10*i+j for 1 <= i <= 6, 1 <= j <= 8.
++
++ \begin{verbatim}
++ Rubik’s Cube: +-----+ +-- B where: marks Side #: 
++ / U /|/
++ / / | F(ront) <-> 1
++ L --> +-----+ R| R(ight) <-> 2
++ | | + U(p) <-> 3
++ | F | / D(own) <-> 4
++ | | / L(eft) <-> 5
++ +-----+ B(ack) <-> 6
++ |
++ D
++
++ The Cube’s surface:
++ The pieces on each side
++ (except the unmoveable center
++ piece) are clockwise numbered
++ from 1 to 8 starting with the
++ piece in the upper left
++ corner (see figure on the
++ left). The moves of the cube
++ are represented as
++ permutations on these pieces.
++ Each of the pieces is
++ represented as a two digit
++ integer ij where i is the
++ |765| # of the side (1 to 6 for
++ +---+ F to B (see table above)
++ |567| and j is the # of the piece.
++ |4B8|
++ |321|
++ +---+
++ \end{verbatim}
youngGroup: L I -> PERMGRP I
++ youngGroup([n1,...,nk]) constructs the direct product of the
++ symmetric groups Sn1,...,Snk.
youngGroup: Partition -> PERMGRP I
++ youngGroup(lambda) constructs the direct product of the symmetric
++ groups given by the parts of the partition lambda.

====================================================================
PolyGroebner examples
====================================================================
This package is an interface package to the groebner basis package which allows you to compute groebner bases for polynomials in either lexicographic ordering or total degree ordering refined by reverse lex. The input is the ordinary polynomial type which is internally converted to a type with the required ordering. The resulting groebner basis is converted back to ordinary polynomials. The ordering among the variables is controlled by an explicit list of variables which is passed as a second argument. The coefficient domain is allowed to be any gcd domain, but the groebner basis is computed as if the polynomials were over a field.

The simple Euclidean division algorithm,

given $a \neq 0$, $b \neq 0$ where $a$ and $b$ are two polynomials in the variable $x$, then

output $q$, the quotient and $r$, the remainder

begin
   Let
   $q = 0$
   $r = a$
   $d = \text{degree}(b)$
   $c = \text{leadingCoefficient}(b)$

   while $\text{degree}(r) \geq d$ do
      $e = \text{degree}(r) - d$
      $s = \frac{\text{leadingCoefficient}(r)x^e}{c}$
      $q = q + s$
      $r = r - sb$
   endwhile

   return $(q, r)$
end

For example, given

$p_1 := (x+1) \ast (x+6)$
$p_2 := (x+1) \ast (x-6)$
gcd(p1,p2) -> x+1

In Gathen [?] we find a discussion of applying the Euclidean algorithm to elements of a field. In a field every nonzero rational number is a unit. If we want to define a single element such that

$$gcd(f, g) \in \mathbb{Q}[x]$$

we choose a monic polynomial, that is, the element with a leading coefficient of 1. So

$$abs(a/ leadingCoefficient(a))$$

defines a normal form of $a$.

Gathen also notes that for polynomials we should modify the Euclidean algorithm so all remainders are normalized. Without this constraint the remainders will have huge numerators
and denominators.

Hensel’s lifting lemma states that if a polynomial equation has a simple root modulo a prime number \( p \), then this root corresponds to a unique root of the same equation modulo any higher power of \( p \), which can be found by iteratively “lifting” the solution modulo successive powers of \( p \).

See Volume 10.1 for more details.

++ over the integers.

PolynomialNumberTheoryFunctions(): Exports == Implementation where
I ==> Integer
RN ==> Fraction I
SUP ==> SparseUnivariatePolynomial
NNI ==> NonNegativeInteger

Exports ==> with
bernoulli : I -> SUP RN
  ++ bernoulli(n) returns the nth Bernoulli polynomial \spad{B[n](x)}.
  ++ Bernoulli polynomials denoted \spad{B(n,x)} computed by solving the
  ++ differential equation \spad{differentiate(B(n,x),x) = n B(n-1,x)} where
  ++ \spad{B(0,x) = 1} and initial condition comes from \spad{B(n) = B(n,0)}.
chebyshevT: I -> SUP I
  ++ chebyshevT(n) returns the nth Chebyshev polynomial \spad{T[n](x)}.
  ++ Note that Chebyshev polynomials of the first kind,
  ++ denoted \spad{T[n](x)},
  ++ computed from the two term recurrence. The generating function
  ++ \spad{((1-t*x)/(1-2*t*x+t**2)} = sum(\spad{T[n](x)}*t**n, n=0..infinity).
chebyshevU: I -> SUP I
  ++ chebyshevU(n) returns the nth Chebyshev polynomial \spad{U[n](x)}.
++ Note that Chebyshev polynomials of the second kind,
++ denoted \spad{U[n](x)},
++ computed from the two term recurrence. The generating function
\spad{1/(1-2*t*x+t**2) = sum(T[n](x)*t**n, n=0..infinity)}.

\texttt{cyclotomic: I \to SUP I}
++ cyclotomic(n) returns the nth cyclotomic polynomial \spad{phi[n](x)}.
++ Note that \spad{phi[n](x)} is the factor of \spad{x**n - 1} whose roots
++ are the primitive nth roots of unity.

\texttt{euler : I \to SUP RN}
++ euler(n) returns the nth Euler polynomial \spad{E[n](x)}.
++ Note that Euler polynomials denoted \spad{E(n,x)} computed by solving
++ the differential equation
\spad{differentiate(E(n,x),x) = n E(n-1,x)} where
++ \spad{E(0,x) = 1} and initial condition comes
++ from \spad{E(n) = 2**n E(n,1/2)}.

\texttt{fixedDivisor: SUP I \to I}
++ fixedDivisor(a) for \spad{a(x)} in \spad{Z[x]} is the largest integer
++ f such that f divides \spad{a(x=k)} for all integers k.
++ Note that fixed divisor of \spad{a} is
++ \spad{reduce(gcd,[a(x=k) for k in 0..degree(a)])}.

\texttt{hermite : I \to SUP I}
++ hermite(n) returns the nth Hermite polynomial \spad{H[n](x)}.
++ Note that Hermite polynomials, denoted \spad{H[n](x)}, are computed from
++ the two term recurrence. The generating function is:
\spad{exp(2*t*x-t**2) = sum(H[n](x)*t**n/n!, n=0..infinity)}.

\texttt{laguerre : I \to SUP I}
++ laguerre(n) returns the nth Laguerre polynomial \spad{L[n](x)}.
++ Note that Laguerre polynomials, denoted \spad{L[n](x)}, are computed
++ from the two term recurrence. The generating function is:
\spad{exp(x*t/(t-1))/(1-t) = sum(L[n](x)*t**n/n!, n=0..infinity)}.

\texttt{legendre : I \to SUP RN}
++ legendre(n) returns the nth Legendre polynomial \spad{P[n](x)}.
++ Note that Legendre polynomials, denoted \spad{P[n](x)}, are computed
++ from the two term recurrence. The generating function is:
\spad{1/sqrt(1-2*t*x+t**2) = sum(P[n](x)*t**n, n=0..infinity)}.

Implementation ==> add

++ then the product \texttt{p1*p2*\ldots*pn} vanishes iff the product \texttt{q1*q2*\ldots*qm} vanishes,
++ and the product of degrees of the \texttt{qi} is not greater than
++ the one of the \texttt{pj}, and no polynomial in \texttt{lq} divides another polynomial in \texttt{lq}.
++ In particular, ++ polynomials lying in the base ring \texttt{R} are removed.
++ Moreover, \texttt{lq} is sorted w.r.t \texttt{infRittWu?}.
++ Furthermore, if \texttt{R} is gcd-domain, the polynomials in \texttt{lq} are
++ pairwise without common non trivial factor.

removeRedundantFactors: (P,P) -> LP
++ \texttt{removeRedundantFactors(p,q)} returns the same as
++ \texttt{removeRedundantFactors([p,q])}

removeSquaresIfCan : LP -> LP
++ \texttt{removeSquaresIfCan(lp)} returns
++ \texttt{removeDuplicates [\texttt{squareFreePart(p)} \texttt{\texttt{P} \texttt{for } p \texttt{in lp}]} if \texttt{R} is gcd-domain else returns \texttt{lp}.

unprotectedRemoveRedundantFactors: (P,P) -> LP
++ \texttt{unprotectedRemoveRedundantFactors(p,q)} returns the same as
++ \texttt{removeRedundantFactors(p,q)} but does assume that neither
++ \texttt{p} nor \texttt{q} lie in the base ring \texttt{R} and assumes that
++ \texttt{infRittWu?(p,q)} holds. Moreover, if \texttt{R} is gcd-domain,
++ then \texttt{\texttt{axiom}[p]} and \texttt{\texttt{axiom}[q]} are assumed to be square free.

removeRedundantFactors: (LP,P) -> LP
++ \texttt{removeRedundantFactors(lp,q)} returns the same as
++ \texttt{removeRedundantFactors(cons(q,lp))} assuming
++ that \texttt{\texttt{removeRedundantFactors(lp)}} returns \texttt{lp}
++ up to replacing some polynomial \texttt{axiom[pj]} in \texttt{lpj}
++ by some some polynomial \texttt{axiom[qj]} associated to \texttt{axiom[pj]}

removeRedundantFactors : (LP,LP) -> LP
++ \texttt{removeRedundantFactors(lp,lq)} returns the same as
++ \texttt{removeRedundantFactors(concat(lp,lq))} assuming
++ that \texttt{\texttt{removeRedundantFactors(lp)}} returns \texttt{lp}
++ up to replacing some polynomial \texttt{axiom[pj]} in \texttt{lpj}
++ by some some polynomial \texttt{axiom[qj]} associated to \texttt{axiom[pj]}

removeRedundantFactors : (LP,LP,(LP -> LP)) -> LP
++ \texttt{removeRedundantFactors(lp,lq,remOp)} returns the same as
++ \texttt{concat(remOp(removeRoughlyRedundantFactorsInPols(lp,lq)),lq)}
++ assuming that \texttt{remOp(lq)} returns \texttt{lq} up to similarity.

certainlySubVariety? : (LP,LP) -> B
++ \texttt{certainlySubVariety?(newlp,lp)} returns true iff for every \texttt{axiom[p]}
++ \texttt{in \texttt{axiom[lp]}} the remainder of \texttt{axiom[p]} by \texttt{axiom[newlp]} using the division algorithm
++ of Groebner techniques is zero.

possiblyNewVariety? : (LP, List LP) -> B
++ \texttt{possiblyNewVariety?(newlp,lp)} returns true iff for every \texttt{axiom[lp]}
++ \texttt{in \texttt{axiom[llp]}} \texttt{certainlySubVariety?(newlp,lp)} does not hold.

probablyZeroDim?: LP -> B
++ \texttt{probablyZeroDim?(lp)} returns true iff the number of polynomials
++ in \texttt{axiom[lp]} is not smaller than the number of variables occurring
++ in these polynomials.
selectPolynomials : ((P -> B),LP) -> Record(goodPols:LP,badPols:LP)
++ \(\text{axiom(selectPolynomials(pred?,ps))}\) returns \(\text{gps,bps}\) where
++ \(\text{axiom(gps)}\) is a list of the polynomial \(\text{axiom(p)}\) in \(\text{axiom(ps)}\)
++ such that \(\text{axiom(pred?(p))}\) holds and \(\text{axiom(bps)}\) are the other ones.
selectOrPolynomials : (List (P -> B),LP) -> Record(goodPols:LP,badPols:LP)
++ \(\text{axiom(selectOrPolynomials(lpred?,ps))}\) returns \(\text{gps,bps}\) where
++ \(\text{axiom(gps)}\) is a list of the polynomial \(\text{axiom(p)}\) in \(\text{axiom(ps)}\)
++ such that \(\text{axiom(pred?(p))}\) holds for some \(\text{axiom(pred?)}\) in \(\text{axiom(lpred?)}\)
++ and \(\text{axiom(bps)}\) are the other ones.
selectAndPolynomials : (List (P -> B),LP) -> Record(goodPols:LP,badPols:LP)
++ \(\text{axiom(selectAndPolynomials(lpred?,ps))}\) returns \(\text{gps,bps}\) where
++ \(\text{axiom(gps)}\) is a list of the polynomial \(\text{axiom(p)}\) in \(\text{axiom(ps)}\)
++ such that \(\text{axiom(pred?(p))}\) holds for every \(\text{axiom(pred?)}\) in \(\text{axiom(lpred?)}\)
++ and \(\text{axiom(bps)}\) are the other ones.
quasiMonicPolynomials : LP -> Record(goodPols:LP,badPols:LP)
++ \(\text{axiom(quasiMonicPolynomials(lp))}\) returns \(\text{qmps,nqmps}\) where
++ \(\text{axiom(qmps)}\) is a list of the quasi-monic polynomials in \(\text{axiom(lp)}\)
++ and \(\text{axiom(nqmps)}\) are the other ones.
univariate? : P -> B
++ \(\text{axiom(univariate?(p))}\) returns true iff \(\text{axiom(p)}\) involves one and
++ only one variable.
univariatePolynomials : LP -> Record(goodPols:LP,badPols:LP)
++ \(\text{axiom(univariatePolynomials(lp))}\) returns \(\text{ups,nups}\) where
++ \(\text{axiom(ups)}\) is a list of the univariate polynomials,
++ and \(\text{axiom(nups)}\) are the other ones.
linear? : P -> B
++ \(\text{axiom(linear?(p))}\) returns true iff \(\text{axiom(p)}\) does not lie
++ in the base ring \(\text{axiom(R)}\) and has main degree \(\text{axiom(1)}\).
linearPolynomials : LP -> Record(goodPols:LP,badPols:LP)
++ \(\text{axiom(linearPolynomials(lp))}\) returns \(\text{lps,nlps}\) where
++ \(\text{axiom(lps)}\) is a list of the linear polynomials in \(\text{axiom(lp)}\)
++ and \(\text{axiom(nlps)}\) are the other ones.
bivariate? : P -> B
++ \(\text{axiom(bivariate?(p))}\) returns true iff \(\text{axiom(p)}\) involves two and
++ only two variables.
bivariatePolynomials : LP -> Record(goodPols:LP,badPols:LP)
++ \(\text{axiom(bivariatePolynomials(lp))}\) returns \(\text{bps,nbps}\) where
++ \(\text{axiom(bps)}\) is a list of the bivariate polynomials,
++ and \(\text{axiom(nbps)}\) are the other ones.
removeRoughlyRedundantFactorsInPols : (LP, LP) -> LP
++ \(\text{axiom(removeRoughlyRedundantFactorsInPols(lp,lp1))}\) returns
++ \(\text{axiom(newlp)}\) where \(\text{axiom(newlp)}\) is obtained from \(\text{axiom(lp1)}\)
++ by removing in every polynomial \(\text{axiom(p)}\) of \(\text{axiom(lp)}\)
++ any occurrence of a polynomial \(\text{axiom(f)}\) in \(\text{axiom(lp1)}\).
++ This may involve a lot of exact-quotients computations.
removeRoughlyRedundantFactorsInPols : (LP, LP,B) -> LP
++ \(\text{axiom(removeRoughlyRedundantFactorsInPols(lp,lp1,opt))}\) returns
++ the same as \(\text{axiom(removeRoughlyRedundantFactorsInPols(lp,lp1))}\)
++ if \(\text{axiom(opt)}\) is \(\text{axiom(false)}\) and if the previous operation
++ does not return any non null and constant polynomial, 
++ else return \texttt{\{1\}}.

\texttt{removeRoughlyRedundantFactorsInPol : (P,LP) -> P}
++ \texttt{removeRoughlyRedundantFactorsInPol(p,lf)} returns the same as
++ \texttt{removeRoughlyRedundantFactorsInPols([p],lf,true)}

\texttt{interReduce: LP -> LP}
++ \texttt{interReduce(lp)} returns \texttt{lp} such that \texttt{lp} and \texttt{lq}
++ in \texttt{lp} is reducible by the others in the sense
++ of Groebner bases. Since no assumptions are required
++ the result may depend on the ordering the reductions are
++ performed.

\texttt{roughBasicSet: LP -> Union(Record(bas:T,top:LP),"failed")}
++ \texttt{roughBasicSet(lp)} returns the smallest (with Ritt-Wu
++ ordering) triangular set contained in \texttt{lp}.

\texttt{crushedSet: LP -> LP}
++ \texttt{crushedSet(lp)} returns \texttt{lq} such that \texttt{lp} and
++ \texttt{lq} generate the same ideal and no rough basic
++ sets reduce (in the sense of Groebner bases) the other
++ polynomials in \texttt{lq}.

\texttt{rewriteSetByReducingWithParticularGenerators : (LP,(P->B),((P,P)->B),((P,P)->P)) -> LP}
++ \texttt{rewriteSetByReducingWithParticularGenerators(lp,pred?,redOp?,redOp)}
++ returns \texttt{lq} where \texttt{lq} is computed by the following
++ algorithm. Chose a basic set w.r.t. the reduction-test \texttt{redOp?}
++ among the polynomials satisfying property \texttt{redOp?},
++ if it is empty then leave, else reduce the other polynomials by
++ this basic set w.r.t. the reduction-operation \texttt{redOp}.
++ Repeat while another basic set with smaller rank can be computed.
++ See code. If \texttt{pred?} is \texttt{quasiMonic?} the ideal is unchanged.

\texttt{rewriteIdealWithQuasiMonicGenerators : (LP,((P,P)->B),((P,P)->P)) -> LP}
++ \texttt{rewriteIdealWithQuasiMonicGenerators(lp,redOp?,redOp)} returns
++ \texttt{lq} where \texttt{lq} is computed by reducing \texttt{lp}
++ w.r.t. some basic set of the ideal generated by
++ the quasi-monic polynomials in \texttt{lp}.

\texttt{if R has GcdDomain}
then

\texttt{squareFreeFactors : P -> LP}
++ \texttt{squareFreeFactors(p)} returns the square-free factors of \texttt{p}
++ over \texttt{R}.

\texttt{univariatePolynomialsGcds : LP -> LP}
++ \texttt{univariatePolynomialsGcds(lp)} returns \texttt{lq} where
++ \texttt{lq} is a list of the gcds of every pair in \texttt{lp}
++ of univariate polynomials in the same main variable.

\texttt{univariatePolynomialsGcds : (LP,B) -> LP}
++ \texttt{univariatePolynomialsGcds(lp,opt)} returns the same as
++ \texttt{univariatePolynomialsGcds(lp)} if \texttt{opt} is
++ \texttt{false} and if the previous operation does not return
++ any non null and constant polynomial, else return \axiom{[1]}.
removeRoughlyRedundantFactorsInContents : (LP, LP) -> LP
++ \axiom{removeRoughlyRedundantFactorsInContents(lp,lf)} returns
++ \axiom{newlp} where \axiom{newlp} is obtained from \axiom{lp}
++ by removing in the content of every polynomial of \axiom{lp}
++ any occurrence of a polynomial \axiom{f} in \axiom{lf}. Moreover,
++ squares over \axiom{R} are first removed in the content
++ of every polynomial of \axiom{lp}.
removeRedundantFactorsInContents : (LP, LP) -> LP
++ \axiom{removeRedundantFactorsInContents(lp,lf)} returns \axiom{newlp}
++ where \axiom{newlp} is obtained from \axiom{lp} by removing
++ in the content of every polynomial of \axiom{lp} any non trivial
++ factor of any polynomial \axiom{f} in \axiom{lf}. Moreover,
++ squares over \axiom{R} are first removed in the content
++ of every polynomial of \axiom{lp}.
removeRedundantFactorsInPols : (LP, LP) -> LP
++ \axiom{removeRedundantFactorsInPols(lp,lf)} returns \axiom{newlp}
++ where \axiom{newlp} is obtained from \axiom{lp} by removing
++ in every polynomial \axiom{p} of \axiom{lp} any non trivial
++ factor of any polynomial \axiom{f} in \axiom{lf}. Moreover,
++ squares over \axiom{R} are first removed in every
++ polynomial \axiom{lp}.
if (R has EuclideanDomain) and (R has CharacteristicZero)
then

irreducibleFactors : LP -> LP
++ \axiom{irreducibleFactors(lp)} returns \axiom{lf} such that if
++ \axiom{lp = [p1,...,pn]} and \axiom{lf = [f1,...,fm]} then
++ \axiom{p1*p2*...*pn=0} means \axiom{f1*f2*...*fm=0}, and the \axiom{fi}
++ are irreducible over \axiom{R} and are pairwise distinct.
lazyIrreducibleFactors : LP -> LP
++ \axiom{lazyIrreducibleFactors(lp)} returns \axiom{lf} such that if
++ \axiom{lp = [p1,...,pn]} and \axiom{lf = [f1,...,fm]} then
++ \axiom{p1*p2*...*pn=0} means \axiom{f1*f2*...*fm=0}, and the \axiom{fi}
++ are irreducible over \axiom{R} and are pairwise distinct.
++ The algorithm tries to avoid factorization into irreducible
++ factors as far as possible and makes previously use of gcd
++ techniques over \axiom{R}.
removeIrreducibleRedundantFactors : (LP, LP) -> LP
++ \axiom{removeIrreducibleRedundantFactors(lp,lq)} returns the same
++ as \axiom{irreducibleFactors(concat(lp,lq))} assuming
++ that \axiom{irreducibleFactors(lp)} returns \axiom{lp}
++ up to replacing some polynomial \axiom{pj} in \axiom{lp}
++ by some polynomial \axiom{qj} associated to \axiom{pj}.

PolynomialSquareFree examples
====================================================================

This package computes square-free decomposition of multivariate polynomials over a coefficient ring which is an arbitrary gcd domain. The requirement on the coefficient domain guarantees that the content can be removed so that factors will be primitive as well as square-free. Over an infinite ring of finite characteristic, it may not be possible to guarantee that the factors are square-free.

IJ ==> Record(ij: List Z, deg:N)

Exports == with
denomRicDE: L -> UP
++ denomRicDE(op) returns a polynomial \spad{d} such that any rational
++ solution of the associated Riccati equation of \spad{op y = 0} is
++ of the form \spad{p/d + q'/q + r} for some polynomials p and q
++ and a reduced r. Also, \spad{deg(p) < deg(d)} and \{gcd(d,q) = 1\}.

leadingCoefficientRicDE: L -> List REC
++ leadingCoefficientRicDE(op) returns
++ \spad{[[m1, p1], [m2, p2], ... , [mk, pk]]} such that the polynomial
++ part of any rational solution of the associated Riccati equation of
++ \spad{op y = 0} must have degree mj for some j, and its leading
++ coefficient is then a zero of pj. In addition,\spad{m1>m2> ... >mk}.

constantCoefficientRicDE: (L, UP -> List F) -> List CNT
++ constantCoefficientRicDE(op, ric) returns
++ \spad{[[a1, L1], [a2, L2], ... , [ak, Lk]]} such that any rational
++ solution with no polynomial part of the associated Riccati equation of
++ \spad{op y = 0} must be one of the ai's in which case the equation for
++ \spad{z = y e^{-\int ai}} is \spad{Li z = 0}.
++ \spad{ric} is a Riccati equation solver over \spad{F}, whose input
++ is the associated linear equation.

polyRicDE: (L, UP -> List F) -> List POL
++ polyRicDE(op, zeros) returns
++ \spad{[[p1, L1], [p2, L2], ... , [pk, Lk]]} such that the polynomial
++ part of any rational solution of the associated Riccati equation of
++ \spad{op y=0} must be one of the pi's (up to the constant coefficient),
++ in which case the equation for \spad{z=y e^{-\int p}} is \spad{Li z =0}.
++ \spad{zeros} is a zero finder in \spad{UP}.

singRicDE: (L, (UP, UP2) -> List UP, UP -> Factored UP) -> List FRC
++ singRicDE(op, zeros, efactor) returns
++ \spad{[[f1, L1], [f2, L2], \ldots, [fk, Lk]]} such that the singular
++ part of any rational solution of the associated Riccati equation of
++ \spad{op y=0} must be one of the fi's (up to the constant coefficient),
++ in which case the equation for \spad{z=y e^{-\int p}} is \spad{Li z=0}.
++ \spad{zeros(C(x),H(x,y))} returns all the \spad{P_i(x)}'s such that
++ \spad{H(x,P_i(x)) = 0 \text{ modulo } C(x)}.
++ Argument \spad{efactor} is a factorisation in \spad{UP},
++ not necessarily into irreducibles.

changeVar: (L, UP) -> L
++ changeVar(+/[ai D^i], a) returns the operator \spad{+/[ai (D+a)^i]}.

The package constructor PseudoRemainderSequence provides efficient algorithms by Lionel Ducos (University of Poitiers, France) for computing sub-resultants. This leads to a speed up in many places in Axiom where sub-resultants are computed (polynomial system solving, algebraic factorization, integration).

This package contains some functions from improvements of the subresultants algorithm.

QuasiAlgebraicSet2 examples
====================================================================

QuasiAlgebraicSet2 adds a function radicalSimplify which uses
IdealDecompositionPackage to simplify the representation of a
quasi-algebraic set.
A quasi-algebraic set is the intersection of a Zariski closed set, defined as the common zeros of a given list of polynomials (the defining polynomials for equations), and a principal Zariski open set, defined as the complement of the common zeros of a polynomial f (the defining polynomial for the inequation).

Quasi-algebraic sets are implemented in the domain QuasiAlgebraicSet, where two simplification routines are provided: idealSimplify and simplify.

The function radicalSimplify is added for comparison study only.

Because the domain IdealDecompositionPackage provides facilities for computing with radical ideals, it is necessary to restrict the ground ring to the domain Fraction Integer, and the polynomial ring to be of type DistributedMultivariatePolynomial.

The routine radicalSimplify uses these to compute groebner basis of radical ideals and is inefficient and restricted when compared to the two in QuasiAlgebraicSet.

====================================================================
QuaternionCategoryFunctions2 examples
====================================================================

QuaternionCategoryFunctions2 implements functions between two
quaternion domains. The function map is used by the system
interpreter to coerce between quaternion types.

The package QuaternionCategoryFunctions2 provides a function map
to convert an expression in Quaternion(R) to an expression in
Quaternion(S) using the function f.

q := quatern(2/11,-8,3/4,1)

2 3
-- - 8i + - j + k
11 4

Type: Quaternion Fraction Integer
```
f(a:Fraction Integer):Complex Fraction Integer == a::Complex Fraction Integer

Function declaration f : Fraction Integer -> Complex Fraction Integer has been added to workspace.

Type: Void

map(f,q)

Compiling function f with type Fraction Integer -> Complex Fraction Integer

\[
\begin{align*}
\frac{2}{11} & \quad \frac{3}{4} \\
-8i & + - j + k
\end{align*}
\]

Type: Quaternion Complex Fraction Integer

====================================================================
RadicalEigenPackage examples
====================================================================

Package for the computation of eigenvalues and eigenvectors. This package works for matrices with coefficients which are rational functions over the integers.
The eigenvalues and eigenvectors are expressed in terms of radicals.

See Also:
- )show Radical EigenPackage
- )show Fraction(Polynomial(Integer))
\textbf{PACKAGE REP RADICALEIGENPACKAGE} 3173

\begin{verbatim}
M ==> Matrix(F)
MRE ==> Matrix(RE)
ST ==> SuchThat(SE,P)
NNI ==> NonNegativeInteger

EigenForm ==> Record(eigval:Union(F,ST),eigmult:NNI,eigvec:List(M))
RadicalForm ==> Record(radval:RE,radmult:Integer,radvect:List(MRE))

C == with
  radicalEigenvectors : M -> List(RadicalForm)
  ++ radicalEigenvectors(m) computes
  ++ the eigenvalues and the corresponding eigenvectors of the
  ++ matrix m;
  ++ when possible, values are expressed in terms of radicals.

  radicalEigenvector : (RE,M) -> List(MRE)
  ++ radicalEigenvector(c,m) computes the eigenvector(s) of the
  ++ matrix m corresponding to the eigenvalue c;
  ++ when possible, values are
  ++ expressed in terms of radicals.

  radicalEigenvalues : M -> List RE
  ++ radicalEigenvalues(m) computes the eigenvalues of the matrix m;
  ++ when possible, the eigenvalues are expressed in terms of radicals.

  eigenMatrix : M -> Union(MRE,"failed")
  ++ eigenMatrix(m) returns the matrix b
  ++ such that \(b*m*(inverse b)\) is diagonal,
  ++ or "failed" if no such b exists.

  normalise : MRE -> MRE
  ++ normalise(v) returns the column
  ++ vector v
  ++ divided by its euclidean norm;
  ++ when possible, the vector v is expressed in terms of radicals.

  gramschmidt : List(MRE) -> List(MRE)
  ++ gramschmidt(lv) converts the list of column vectors lv into
  ++ a set of orthogonal column vectors
  ++ of euclidean length 1 using the Gram–Schmidt algorithm.

  orthonormalBasis : M -> List(MRE)
  ++ orthonormalBasis(m) returns the orthogonal matrix b such that
  ++ \(b*m*(inverse b)\) is diagonal.
  ++ Error: if m is not a symmetric matrix.

RationalFactorize examples

Factorization of extended polynomials with rational coefficients. This package implements factorization of extended polynomials whose coefficients are rational numbers. It does this by taking the \text{lcm} of the coefficients of the polynomial and creating a polynomial with integer coefficients. The algorithm in \text{GaloisGroupFactorizer} is then used to factor the integer polynomial. The result is normalized with respect to the original \text{lcm} of the denominators.

RationalFunctionSum examples

Computes sums of rational functions.

There are 4 different forms of the sum operator in this domain. They are variations of the types of the input

```plaintext
sum(i::Polynomial(Integer),variable(i=1..n))

2
6i - 6i + 1
----------
12
```

```plaintext
sum(i::Fraction(Polynomial(Integer)),i::Symbol)

2
6i - 6i + 1
----------
12
```

```plaintext
sum(i,i=1..n)

2
n + n
-----
2
```
We can compute the sum form on part at a time to see what happens. First, we make a SegmentBinding(Polynomial(Integer)):

\[ s := \text{SegmentBinding}(i = 1..n) \]

We pick out the upper and lower bounds of the segment:

\[ \text{hiseg} := \text{high}(s) \]
\[ \text{loseg} := \text{low}(s) \]

We pick out the variable from the segment:

\[ v := \text{variable}(s) \]

We create a polynomial we wish to sum:

\[ p := i::\text{Polynomial(Integer)} \]

And we create the sum for that polynomial:

\[ f := \text{sum}(p, v) \]
The new evaluate it at the upper endpoint:

\[
t_1 := \text{eval}(f, v, (1+\text{hiseg}))
\]

\[
\frac{2}{6n + 6n + 1} \frac{\text{------------}}{12}
\]

And the lower endpoint:

\[
t_2 := \text{eval}(f, v, \text{loseg})
\]

\[
\frac{1}{12}
\]

And we take the difference of the endpoints:

\[
t_1 - t_2
\]

\[
\frac{2}{n + n} \frac{\text{------}}{2}
\]

package RINTERP RationalInterpolation

Introduction

This file contains a crude naïve implementation of rational interpolation, where the coefficients of the rational function are in any given field.

Questions and Outlook

- Maybe this file should be joined with pinterp.spad, where polynomial Lagrange interpolation is implemented. I have a second version that parallels the structure of pinterp.spad closely.
- There are probably better ways to implement rational interpolation. Maybe http://www.cs.ucsb.edu/omer/personal/abstracts/rational.html contains something useful, but I don’t know.
- Comments welcome!

RationalInterpolation (RINTERP)

Exports:
interpolate

— package RINTERP RationalInterpolation —

)abbrev package RINTERP RationalInterpolation
++ Description:
++ This package exports rational interpolation algorithms

RationalInterpolation(xx,F): Exports == Implementation where
xx: Symbol
F: Field
Exports == with
   interpolate: (List F, List F, NonNegativeInteger,
               NonNegativeInteger) -> Fraction Polynomial F

The implementation sets up a system of linear equations and solves it.
— package RINTERP RationalInterpolation —

Implementation == add
   interpolate(xlist, ylist, m, k) ==

First we check whether we have the right number of points and values. Clearly the number
of points and the number of values must be identical. Note that we want to determine the
numerator and denominator polynomials only up to a factor. Thus, we want to determine
In fact, we could also leave $k$ unspecified and determine it as $k = \#\text{list} - m - 1$:

I don’t know whether this would be better.

The next step is to set up the matrix. Suppose that our numerator polynomial is $p(x) = a_0 + a_1 x + \ldots + a_m x^m$ and that our denominator polynomial is $q(x) = b_0 + b_1 x + \ldots + b_m x^m$.

Then we have the following equations, writing $n$ for $m + k + 1$:

\[
\begin{align*}
    p(x_1) - y_1 q(x_1) &= a_0 + a_1 x_1 + \ldots + a_m x_1^m - y_1 (b_0 + b_1 x_1 + \ldots + b_k x_1^k) = 0 \\
    p(x_2) - y_2 q(x_2) &= a_0 + a_1 x_2 + \ldots + a_m x_2^m - y_2 (b_0 + b_1 x_2 + \ldots + b_k x_2^k) = 0 \\
    \vdots \\
    p(x_n) - y_n q(x_n) &= a_0 + a_1 x_n + \ldots + a_m x_n^m - y_n (b_0 + b_1 x_n + \ldots + b_k x_n^k) = 0
\end{align*}
\]

This can be written as

\[
\begin{bmatrix}
    1 & x_1 & \cdots & x_1^m & -y_1 & -y_1 x_1 & \cdots & -y_1 x_1^k \\
    1 & x_2 & \cdots & x_2^m & -y_2 & -y_2 x_2 & \cdots & -y_2 x_2^k \\
    \vdots \\
    1 & x_n & \cdots & x_n^m & -y_n & -y_n x_n & \cdots & -y_n x_2^k
\end{bmatrix}
\begin{bmatrix}
    a_0 \\
    a_1 \\
    \vdots \\
    a_m \\
    b_0 \\
    b_1 \\
    \vdots \\
    b_k
\end{bmatrix} = 0
\]

We generate this matrix columnwise:
Now we can solve the system:
   — package RINTERP RationalInterpolation —
   
   res: List Vector F := nullSpace((transpose matrix collist) _
   ::Matrix F)
   
   Note that it may happen that the system has several solutions. In this case, some of the
   data points may not be interpolated correctly. However, the solution is often still useful,
   thus we do not signal an error.
   
   — package RINTERP RationalInterpolation —
   
   if #res = 1 then output("Warning: unattainable points!" _
   ::OutputForm)$OutputPackage
   
   In this situation, all the solutions will be equivalent, thus we can always simply take the first
   one:
   
   — package RINTERP RationalInterpolation —
   
   reslist: List List Polynomial F := _
   [[(res.1).(i+1)*(xx::Polynomial F)**i for i in 0..m], _
   [(res.1).(i+m+2)*(xx::Polynomial F)**i for i in 0..k]]
   
   Finally, we generate the rational function:
   
   — package RINTERP RationalInterpolation —
   
   reduce(_,reslist.1)/reduce(_,reslist.2)

U ==> SparseUnivariatePolynomial(R)
RUR ==> Record(complexRoots: U, coordinates: LP)

Exports == with

rur: (LP,Boolean) -> List RUR
++ \spad{rur(lp,univ?)} returns a rational univariate representation
++ of \spad{lp}. This assumes that \spad{lp} defines a regular
++ triangular \spad{ts} whose associated variety is zero-dimensional
++ over \spad{R}. \spad{rur(lp,univ?)} returns a list of items
++ \spad{\{u,lc\}} where \spad{u} is an irreducible univariate polynomial
++ and each \spad{c} in \spad{lc} involves two variables: one from \spad{ls},
++ called the coordinate of \spad{c}, and an extra variable which
++ represents any root of \spad{u}. Every root of \spad{u} leads to
++ a tuple of values for the coordinates of \spad{lc}. Moreover,
++ a point \spad{x} belongs to the variety associated with \spad{lp} iff
++ there exists an item \spad{\{u,lc\}} in \spad{rur(lp,univ?)} and
++ a root \spad{r} of \spad{u} such that \spad{x} is given by the
++ tuple of values for the coordinates of \spad{lc} evaluated at \spad{r}.
++ If \spad{univ?} is \spad{true} then each polynomial \spad{c}
++ will have a constant leading coefficient w.r.t. its coordinate.
++ See the example which illustrates the \spad{ZeroDimensionalSolvePackage}
++ package constructor.

rur: (LP) -> List RUR
++ \spad{rur(lp)} returns the same as \spad{rur(lp,true)}

rur: (LP,Boolean,Boolean) -> List RUR
++ \spad{rur(lp,univ?,check?)} returns the same as \spad{rur(lp,true)}.
++ Moreover, if \spad{check?} is \spad{true} then the result is checked.

package POLUTIL RealPolynomialUtilitiesPackage

This file describes the Real Closure 1.0 package which consists of different packages, categories and domains.

The package RealPolynomialUtilitiesPackage which receives a field and a univariate polynomial domain with coefficients in the field. It computes some simple functions such as Strum and Sylvester sequences.

The category RealRootCharacterizationCategory provides abstract functionalities to work with "real roots" of univariate polynomials. These resemble variables with some functionalities needed to compute important operations.

RealClosedField is a category which provides common operations available over real closed fields. These include finding all the roots of univariate polynomial, taking square roots, ...

CAVEATS
Since real algebraic expressions are stored as depending on "real roots" which are managed like variables, there is an ordering on these. This ordering is dynamical in the sense that any new algebraic takes precedence over older ones. In particular every creation function raises a new "real root". This has the effect that when you type something like sqrt(2) + sqrt(2) you have two new variables which happen to be equal. To avoid this name the expression such as in s2 := sqrt(2) : s2 + s2

Also note that computing times depend strongly on the ordering you implicitly provide. Please provide algebraics in the order which most natural to you.

LIMITATIONS
The file reclos.input show some basic use of the package. This packages uses algorithms which are published in [1] and [2] which are based on field arithmetics, in particular for polynomial gcd related algorithms. This can be quite slow for high degree polynomials and subresultants methods usually work best. Beta versions of the package try to use these techniques in a better way and work significantly faster. These are mostly based on unpublished algorithms and cannot be distributed. Please contact the author if you have a particular problem to solve or want to use these versions.

Be aware that approximations behave as post-processing and that all computations are done exactly. They can thus be quite time consuming when depending on several “real roots”.

--- package RECOP RecurrenceOperator ---

)abbrev package RECOP RecurrenceOperator
++ Author: Martin Rubey
++ Description:
++ This package provides an operator for the n-th term of a recurrence and an
++ operator for the coefficient of x^n in a function specified by a functional
RecurrenceOperator(R, F): Exports == Implementation where
  R: Join(OrderedSet, IntegralDomain, ConvertibleTo InputForm)
  F: Join(FunctionSpace R, AbelianMonoid, RetractableTo Integer, 
      RetractableTo Symbol, PartialDifferentialRing Symbol, 
      CombinatorialOpsCategory)
--RecurrenceOperator(F): Exports == Implementation where
-- F: Join(ExpressionSpace, AbelianMonoid, RetractableTo Integer, 
--      RetractableTo Symbol, PartialDifferentialRing Symbol)

Exports == with

  evalRec: (BasicOperator, Symbol, F, F, F, List F) -> F
  \spad{evalRec(u, dummy, n, n0, eq, values)} creates an expression that 
  \spad{+} stands for \spad{u(n0)}, where \spad{u(n)} is given by the equation \spad{eq}. However, for 
  \spad{+} technical reasons the variable \spad{n} has to be replaced by a dummy 
  \spad{+} variable \spad{dummy} in \spad{eq}. The argument \spad{values} specifies the initial values 
  \spad{+} of the recurrence \spad{u(0)}, \spad{u(1)},... 
  \spad{+} For the moment we don't allow recursions that contain \spad{u} inside of 
  \spad{+} another operator.

  evalADE: (BasicOperator, Symbol, F, F, F, List F) -> F
  \spad{evalADE(f, dummy, x, n, eq, values)} creates an expression that 
  \spad{+} stands for the coefficient of \spad{x^n} in the Taylor expansion of \spad{f(x)}, 
  \spad{+} where \spad{f(x)} is given by the functional equation \spad{eq}. However, for 
  \spad{+} technical reasons the variable \spad{x} has to be replaced by a dummy 
  \spad{+} variable \spad{dummy} in \spad{eq}. The argument \spad{values} specifies the first few 
  \spad{+} Taylor coefficients.

  getEq: F -> F
  \spad{getEq f} returns the defining equation, if \spad{f} represents the 
  \spad{+} coefficient of an ADE or a recurrence.

  getOp: F -> BasicOperator
  \spad{getOp f}, if \spad{f} represents the coefficient of a recurrence or 
  \spad{+} ADE, returns the operator representing the solution

-- should be local
  numberOfValuesNeeded: (Integer, BasicOperator, Symbol, F) -> Integer

-- should be local
  if R has Ring then
    getShiftRec: (BasicOperator, Kernel F, Symbol) -> Union(Integer, "failed")

shiftInfoRec: (BasicOperator, Symbol, F) ->
  Record(max: Union(Integer, "failed"), 
  ord: Union(Integer, "failed"), 
  ker: Kernel F)
Defining new operators

We define two new operators, one for recurrences, the other for functional equations. The operators for recurrences represents the $n^{th}$ term of the corresponding sequence, the other the coefficient of $x^n$ in the Taylor series expansion.

---

```plaintext
implementation: RecurrenceOperator

oprecur := operator("rootOfRec":Symbol)$BasicOperator
opADE := operator("rootOfADE":Symbol)$BasicOperator
setProperty(oprecur, "%dummyVar", 2 pretend None)
setProperty(opADE, "%dummyVar", 2 pretend None)
```

Setting these properties implies that the second and third arguments of oprecure are dummy variables and affects `tower$ES`: the second argument will not appear in `tower$ES`, if it does not appear in any argument but the first and second. The third argument will not appear in `tower$ES`, if it does not appear in any other argument. (%defsum is a good example)

The arguments of the two operators are as follows:

1. eq, i.e. the vanishing expression

```plaintext
---

implementation: RecurrenceOperator

eqAsF: List F -> F
eqAsF l == l.1
```

2. dummy, a dummy variable to make substitutions possible

```plaintext
---

implementation: RecurrenceOperator

dummy: List F -> Symbol
dummy l == retract(l.2)@Symbol
dummyAsF: List F -> F
dummyAsF l == 1.2
```
3. the variable for display

<table>
<thead>
<tr>
<th>implementation: RecurrenceOperator</th>
</tr>
</thead>
<tbody>
<tr>
<td>displayVariable: List F → F</td>
</tr>
<tr>
<td>displayVariable l == 1.3</td>
</tr>
</tbody>
</table>

4. operatorName(argument)

<table>
<thead>
<tr>
<th>implementation: RecurrenceOperator</th>
</tr>
</thead>
<tbody>
<tr>
<td>operatorName: List F → BasicOperator</td>
</tr>
<tr>
<td>operatorName l == operator(kernels(1.4).1)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>operatorNameAsF: List F → F</th>
</tr>
</thead>
<tbody>
<tr>
<td>operatorNameAsF l == 1.4</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>operatorArgument: List F → F</th>
</tr>
</thead>
<tbody>
<tr>
<td>operatorArgument l == argument(kernels(1.4).1).1</td>
</tr>
</tbody>
</table>

Concerning rootOfADE, note that although we have arg as argument of the operator, it is intended to indicate the coefficient, not the argument of the power series.

5. values in reversed order.

- rootOfRec: maybe values should be preceded by the index of the first given value. Currently, the last value is interpreted as \( f(0) \).
- rootOfADE: values are the first few coefficients of the power series expansion in order.

<table>
<thead>
<tr>
<th>implementation: RecurrenceOperator</th>
</tr>
</thead>
<tbody>
<tr>
<td>initialValues: List F → List F</td>
</tr>
<tr>
<td>initialValues l == rest(l, 4)</td>
</tr>
</tbody>
</table>
Recurrences

Extracting some information from the recurrence

We need to find out whether we can determine the next term of the sequence, and how many initial values are necessary.

— implementation: RecurrenceOperator —

```lisp
if R has Ring then
getShiftRec(op: BasicOperator, f: Kernel F, n: Symbol)
  : Union(Integer, "failed") ==
a := argument f
if every?(z -> freeOf?(z, n::F), a) then return 0
if #a ~= 1 then error "RECOP: operator should have only one argument"
p := univariate(a.1, retract(n::F)@Kernel(F))
if denominator p ~= 1 then return "failed"
num := numer p
if degree num = 1 and coefficient(num, 1) = 1
  and every?(z -> freeOf?(z, n::F), coefficients num)
then return retractIfCan(coefficient(num, 0))
else return "failed"
```

-- if the recurrence is of the form
-- $p(n, f(n+m-o), f(n+m-o+1), \ldots, f(n+m)) = 0$
-- in which case shiftInfoRec returns [m, o, f(n+m)].

```lisp
shiftInfoRec(op: BasicOperator, argsym: Symbol, eq: F):
  Record(max: Union(Integer, "failed"),
         ord: Union(Integer, "failed"),
         ker: Kernel F) ==
```

-- ord and ker are valid only if all shifts are Integers
-- ker is the kernel of the maximal shift.
maxShift: Integer
minShift: Integer
nextKernel: Kernel F

-- We consider only those kernels that have op as operator. If there is none,
-- we raise an error. For the moment we don't allow recursions that contain op
-- inside of another operator.
error? := true

for f in kernels eq repeat
if is?(f, op) then
    shift := getShiftRec(op, f, argsym)
if error? then
    error? := false
nextKernel := f
if shift case Integer then
    maxShift := shift
    minShift := shift
else return ["failed", "failed", nextKernel]
else
    if shift case Integer then
        if maxShift < shift then
            maxShift := shift
            nextKernel := f
        if minShift > shift then
            minShift := shift
    else return ["failed", "failed", nextKernel]
if error? then error "evalRec: equation does not contain operator"

Functional Equations

Determining the number of initial values for ADE’s

We use Joris van der Hoeven’s instructions for ADE’s. Given $Q = p(f, f', \ldots, f^{(r)})$ we first need to differentiate $Q$ with respect to $f^{(i)}$ for $i \in \{0, 1, \ldots, r\}$, plug in the given truncated power series solution and determine the valuation.

— NOTYET implementation: RecurrenceOperator —

```
getValuation(op, argsym, eq, maxorder, values): Integer ==
  max: Integer := -1;
  ker: Kernel F
  for i in 0..maxorder repeat

———
A package providing a new algorithm for solving polynomial systems by means of regular chains. Two ways of solving are proposed: in the sense of Zariski closure (like in Kalkbrener's algorithm) or in the sense of the regular zeros (like in Wu, Wang or Lazard methods). This algorithm is valid for any type of regular set. It does not care about the way a polynomial is added in an regular set, or how two quasi-components are compared (by an inclusion-test), or how the invertibility test is made in the tower of simple extensions associated with a regular set.

These operations are realized respectively by the domain TS and the packages QCMPACK(R,E,V,P,TS) and RSETGCD(R,E,V,P,TS).

The same way it does not care about the way univariate polynomial gcd (with coefficients in the tower of simple extensions associated with a regular set) are computed. The only requirement is that these gcd need to have invertible initials (normalized or not).

WARNING. There is no need for a user to call directly any operation of this package since they can be accessed by the domain TS. Thus, the operations of this package are not documented.

package REPSQ RepeatedSquaring

— RepeatedSquaring.input —
This code computes $x^n$ by repeated squaring. It takes advantage of the law of exponents so that if $n = a \times b$ then

$$x^n = x^a \times x^b$$

It also takes advantage of the fact that $n$ has a binary representation so that a one-bit right-shift of a number divides it by 2. Thus we get three cases:

- $n = 1 \rightarrow x^1$
- $n$ odd $\rightarrow$ repeatedsquare($x^x, n/2$)$\times x$
- $n$ even $\rightarrow$ repeatedsquare($x^x, n/2$)

Since each recursive call divides $n$ by 2 the algorithm is $O(\log(n))$.

RepresentationPackage1 examples
====================================================================

RepresentationPackage1 provides functions for representation theory for finite groups and algebras.

The package creates permutation representations and uses tensor products and its symmetric and antisymmetric components to create new representations of larger degree from given ones.

Note that instead of having parameters from Permutation this package
allows list notation of permutations as well: e.g. \([1,4,3,2]\) denotes
permutes 2 and 4 and fixes 1 and 3.

if R has commutative("*") then
  antisymmetricTensors : (M R,PI) -> M R
  ++ antisymmetricTensors(a,n) applies to the square matrix
  ++ a the irreducible, polynomial representation of the
  ++ general linear group GL_m, where m is the number of
  ++ rows of a, which corresponds to the partition
  ++ \((1,1,\ldots,1,0,0,\ldots,0)\) of n.
  ++ Error: if n is greater than m.
  ++ Note that this corresponds to the symmetrization of the
  ++ representation with the sign representation of the symmetric group
  ++ Sn. The carrier spaces of the representation are the antisymmetric
  ++ tensors of the n-fold tensor product.
  if R has commutative("*") then
    antisymmetricTensors : (L M R, PI) -> L M R
    ++ antisymmetricTensors(la,n) applies to each
    ++ m-by-m square matrix in
    ++ the list la the irreducible, polynomial representation
    ++ of the general linear group GL_m
    ++ which corresponds
    ++ to the partition \((1,1,\ldots,1,0,0,\ldots,0)\) of n.
    ++ Error: if n is greater than m.
    ++ Note that this corresponds to the symmetrization of the
    ++ representation with the sign representation of the symmetric group
    ++ Sn. The carrier spaces of the representation are the antisymmetric
    ++ tensors of the n-fold tensor product.
createGenericMatrix : NNI -> M P R
++ createGenericMatrix(m) creates a square matrix of dimension k
++ whose entry at the i-th row and j-th column is the
++ indeterminate x[i,j] (double subscripted).

++ symmetricTensors : (M R, PI) -> M R
++ symmetricTensors(a,n) applies to the m-by-m
++ square matrix a the
++ irreducible, polynomial representation of the general linear
++ group GLm
++ which corresponds to the partition (n,0,...,0) of n.
++ Error: if a is not a square matrix.
++ Note that this corresponds to the symmetrization of the
++ representation with the trivial representation of the symmetric
++ group Sn.
++ The carrier spaces of the representation are the symmetric
++ tensors of the n-fold tensor product.

++ symmetricTensors : (L M R, PI) -> L M R
++ symmetricTensors(la,n) applies to each m-by-m square matrix in the
++ list la the irreducible, polynomial representation
++ of the general linear group GLm
++ which corresponds
++ to the partition (n,0,...,0) of n.
++ Error: if the matrices in la are not square matrices.
++ Note that this corresponds to the symmetrization of the
++ representation with the trivial representation of the symmetric
++ group Sn.
++ The carrier spaces of the representation are the symmetric
++ tensors of the n-fold tensor product.

++ tensorProduct : (M R, M R) -> M R
++ tensorProduct(a,b) calculates the Kronecker product
++ of the matrices a and b.
++ Note that if each matrix corresponds to a group representation
++ (repr. of generators) of one group, then these matrices
++ correspond to the tensor product of the two representations.

++ tensorProduct : (L M R, L M R) -> L M R
++ tensorProduct([a1,...,ak],[b1,...,bk]) calculates the list of
++ Kronecker products of the matrices ai and bi
++ for {1 <= i <= k}.
++ Note that if each list of matrices corresponds to a group
++ representation (repr. of generators) of one group, then these
++ matrices correspond to the tensor product of the two representations.

++ tensorProduct : M R -> M R
++ tensorProduct(a) calculates the Kronecker product
++ of the matrix a with itself.

++ tensorProduct : L M R -> L M R
++ tensorProduct([a1,...,ak]) calculates the list of
++ Kronecker products of each matrix ai with itself
++ for {1 <= i <= k}.
++ Note that if the list of matrices corresponds to a group
++ representation (repr. of generators) of one group, then these
++ matrices correspond to the tensor product of the representation.
++ with itself.

permutationRepresentation : (PERM I, I) -> M I
++ permutationRepresentation(pi,n) returns the matrix
++ (deltai,pi(i)) (Kronecker delta) for a permutation
++ pi of \{1,2,...,n\}.

permutationRepresentation : L I -> M I
++ permutationRepresentation(pi,n) returns the matrix
++ (deltai,pi(i)) (Kronecker delta) if the permutation
++ pi is in list notation and permutes \{1,2,...,n\}.

permutationRepresentation : (L PERM I, I) -> L M I
++ permutationRepresentation([pi1,...,pik],n) returns the list
++ of matrices [(deltai,pi1(i)),...,deltai(pik(i))]
++ (Kronecker delta) for the permutations pi1,...,pik
++ of \{1,2,...,n\}.

permutationRepresentation : L L I -> L M I
++ permutationRepresentation([pi1,...,pik],n) returns the list
++ of matrices [(deltai,pi1(i)),...,deltai(pik(i))]
++ if the permutations pi1,...,pik are in
++ list notation and are permuting \{1,2,...,n\}.

RepresentationPackage2 examples
====================================================================

RepresentationPackage2 provides functions for working with
modular representations of finite groups and algebra.
The routines in this package are created, using ideas of R. Parker,
(the meat-Axe) to get smaller representations from bigger ones,
i.e. finding sub- and factormodules, or to show, that such the
representations are irreducible.

Note that most functions are randomized functions of Las Vegas type
i.e. every answer is correct, but with small probability
the algorithm fails to get an answer.

public == with

completeEchelonBasis : V V R -> M R
++ completeEchelonBasis(lv) completes the basis lv assumed
++ to be in echelon form of a subspace of R**n (n the length
++ of all the vectors in lv with unit vectors to a basis of
++ R**n. It is assumed that the argument is not an empty
++ vector and that it is not the basis of the 0-subspace.
++ Note that the rows of the result correspond to the vectors
++ of the basis.
createRandomElement : (L M R, M R) -> M R
++ createRandomElement(aG,x) creates a random element of the group
++ algebra generated by aG.
randomWord : (L L I, L M) -> M R
--++ You can create your own 'random' matrix with "randomWord(lli, lm)".
--++ Each li in lli determines a product of matrices, the entries in li
--++ determine which matrix from lm is chosen. Finally we sum over all
--++ products. The result "sm" can be used to call split with (e.g.)
--++ second parameter "first nullSpace sm"
if R has EuclideanDomain then -- using rowEchelon
  cyclicSubmodule : (L M R, V R) -> V V R
  ++ cyclicSubmodule(lm,v) generates a basis as follows.
  ++ It is assumed that the size n of the vector equals the number
  ++ of rows and columns of the matrices. Then the matrices generate
  ++ a subalgebra, say \spad{A}, of the algebra of all square matrices of
  ++ dimension n. V R is an \spad{A}-module in the natural way.
++ cyclicSubmodule(lm,v) generates the $R$-Basis of $Av$ as
++ described in section 6 of R. A. Parker's "The Meat-Axe".
++ Note that in contrast to the description in "The Meat-Axe" and to
++ standardBasisOfCyclicSubmodule the result is in echelon form.
++ It is assumed that the size $n$ of the vector equals the number
++ of rows and columns of the matrices. Then the matrices generate
++ a subalgebra, say $\text{spad}(A)$,
++ of the algebra of all square matrices of
++ dimension $n$. $V_R$ is an $\text{spad}(A)$-module in the natural way.
++ standardBasisOfCyclicSubmodule(lm,v) calculates a matrix whose
++ non-zero column vectors are the $R$-Basis of $Av$ achieved
++ in the way as described in section 6
++ of R. A. Parker's "The Meat-Axe".
++ Note that in contrast to cyclicSubmodule, the result is not
++ in echelon form.

if $R$ has Field then -- only because of inverse in SM
++ cyclicSubmodule(lm,v) generates the $R$-Basis of $Av$ as
++ described in section 6 of R. A. Parker's "The Meat-Axe".
++ Note that in contrast to the description in "The Meat-Axe" and to
++ standardBasisOfCyclicSubmodule the result is in echelon form.
++ It is assumed that the size $n$ of the vector equals the number
++ of rows and columns of the matrices. Then the matrices generate
++ a subalgebra, say $\text{spad}(A)$,
++ of the algebra of all square matrices of
++ dimension $n$. $V_R$ is an $\text{spad}(A)$-module in the natural way.
++ standardBasisOfCyclicSubmodule(lm,v) calculates a matrix whose
++ non-zero column vectors are the $R$-Basis of $Av$ achieved
++ in the way as described in section 6
++ of R. A. Parker's "The Meat-Axe".
++ Note that in contrast to cyclicSubmodule, the result is not
++ in echelon form.

areEquivalent? : (L M R, L M R, B, I) -> M R
++ areEquivalent?(aG0,aG1,randomelements,numberOfTries) tests
++ whether the two lists of matrices, all assumed of same
++ square shape, can be simultaneously conjugated by a non-singular
++ matrix. If these matrices represent the same group generators,
++ the representations are equivalent.
++ The algorithm tries
++ numberOfTries times to create elements in the
++ generated algebras in the same fashion. If their ranks differ,
++ they are not equivalent. If an
++ isomorphism is assumed, then
++ the kernel of an element of the first algebra
++ is mapped to the kernel of the corresponding element in the
++ second algebra. Now consider the one-dimensional ones.
++ If they generate the whole space (e.g. irreducibility !)
++ we use standardBasisOfCyclicSubmodule to create the
++ only possible transition matrix. The method checks whether the
++ matrix conjugates all corresponding matrices from aG1.
++ The way to choose the singular matrices is as in meatAxe.
++ If the two representations are equivalent, this routine
++ returns the transformation matrix TM with
++ aG0.ij * TM = TM * aG1.ij for all i. If the representations
++ are not equivalent, a small 0-matrix is returned.
++ Note that the case
++ with different sets of group generators cannot be handled.
++ areEquivalent? : (L M R, L M R) -> M R
++ areEquivalent?(aG0,aG1) calls areEquivalent?(aG0,aG1,true,25).
++ Note that the choice of 25 was rather arbitrary.
areEquivalent? : (L M R, L M R, I) -> M R
++ areEquivalent?(aG0,aG1,numberOfTries) calls
++ areEquivalent?(aG0,aG1,true,25).
++ Note that the choice of 25 was rather arbitrary.
isAbsolutelyIrreducible? : (L M R, I) -> B
++ isAbsolutelyIrreducible?(aG, numberOfTries) uses
++ Norton's irreducibility test to check for absolute
++ irreducibility, assuming if a one-dimensional kernel is found.
++ As no field extension changes create "new" elements
++ in a one-dimensional space, the criterium stays true
++ for every extension. The method looks for one-dimensionals only
++ by creating random elements (no fingerprints) since
++ a run of meatAxe would have proved absolute irreducibility
++ anyway.

isAbsolutelyIrreducible? : L M R -> B
++ isAbsolutelyIrreducible?(aG) calls
++ isAbsolutelyIrreducible?(aG,25).
++ Note that the choice of 25 was rather arbitrary.

split : (L M R, V R) -> L L M R
++ split(aG, vector) returns a subalgebra \spad{A} of all
++ square matrix of dimension n as a list of list of matrices,
++ generated by the list of matrices aG, where n denotes both
++ the size of vector as well as the dimension of each of the
++ square matrices.
++ V R is an A-module in the natural way.
++ split(aG, vector) then checks whether the cyclic submodule
++ generated by vector is a proper submodule of V R.
++ If successful, it returns a two-element list, which contains
++ first the list of the representations of the submodule,
++ then the list of the representations of the factor module.
++ If the vector generates the whole module, a one-element list
++ of the old representation is given.
++ Note that a later version this should call the other split.

split: (L M R, V V R) -> L L M R
++ split(aG, submodule) uses a proper submodule of R**n
++ to create the representations of the submodule and of
++ the factor module.

if (R has Finite) and (R has Field) then

meatAxe : (L M R, B, I, I) -> L L M R
++ meatAxe(aG,randomElements,numberOfTries, maxTests) returns
++ a 2-list of representations as follows.
++ All matrices of argument aG are assumed to be square
++ and of equal size.
++ Then \spad{aG} generates a subalgebra, say \spad{A}, of the algebra
++ of all square matrices of dimension n. V R is an A-module
++ in the usual way.
++ meatAxe(aG,numberOfTries, maxTests) creates at most
++ numberOfTries random elements of the algebra, tests
++ then for singularity. If singular, it tries at most maxTests
++ elements of its kernel to generate a proper submodule.
++ If successful, a 2-list is returned: first, a list
++ containing first the list of the
++ representations of the submodule, then a list of the
++ representations of the factor module.
Otherwise, if we know that all the kernel is already scanned, Norton’s irreducibility test can be used either to prove irreducibility or to find the splitting. If randomElements is false, the first 6 tries use Parker’s fingerprints.

meatAxe : L M R -> L L M R
++ meatAxe(aG) calls meatAxe(aG,false,25,7) returns a 2-list of representations as follows.
++ All matrices of argument \spad{aG} are assumed to be square and of equal size. Then \spad{aG} generates a subalgebra, say \spad{A}, of the algebra of all square matrices of dimension n. \spad{V R} is an \spad{A}-module in the usual way.
++ meatAxe(aG) creates at most 25 random elements of the algebra, tests them for singularity. If singular, it tries at most 7 elements of its kernel to generate a proper submodule. If successful a list which contains first the list of the representations of the submodule, then a list of the representations of the factor module is returned.
++ Otherwise, if we know that all the kernel is already scanned, Norton’s irreducibility test can be used either to prove irreducibility or to find the splitting.
++ Notes: the first 6 tries use Parker’s fingerprints. Also, 7 covers the case of three-dimensional kernels over the field with 2 elements.

meatAxe: (L M R, B) -> L L M R
++ meatAxe(aG, randomElements) calls meatAxe(aG,false,6,7), only using Parker’s fingerprints, if randomElements is false. If it is true, it calls meatAxe(aG,true,25,7), only using random elements.
++ Note that the choice of 25 was rather arbitrary. Also, 7 covers the case of three-dimensional kernels over the field with 2 elements.

meatAxe : (L M R, PI) -> L L M R
++ meatAxe(aG, numberOfTries) calls meatAxe(aG,true,numberOfTries,7).
++ Notes: 7 covers the case of three-dimensional kernels over the field with 2 elements.

scanOneDimSubspaces: (L V R, I) -> V R
++ scanOneDimSubspaces(basis,n) gives a canonical representative of the n-th one-dimensional subspace of the vector space generated by the elements of basis, all from \spad{R**n}. The coefficients of the representative are of shape (0,...,0,1,*,...,*) in \spad{R}. If the size of \spad{R} is \spad{q}, then there are \spad{(q**n-1)/(q-1)} of them.
++ We first reduce n modulo this number, then find the largest i such that +/[q**i for i in 0..i-1] <= n.
++ Subtracting this sum of powers from n results in an
++ i-digit number to basis q. This fills the positions of the
++ stars.

— package RESLATC ResolveLatticeCompletion —

)abbrev package RESLATC ResolveLatticeCompletion
++ Author: Stephen M. Watt
++ Date Created: 1986
++ Date Last Updated: May 30, 1991
++ Description:
++ This package provides coercions for the special types \spadtype{Exit}
++ and \spadtype{Void}.

ResolveLatticeCompletion(S: Type): with
  coercex: S -> Void
  ++ coerce(s) throws all information about s away.
  ++ This coercion allows values of any type to appear
  ++ in contexts where they will not be used.
  ++ For example, it allows the resolution of different types in
  ++ the \spad{then} and \spad{else} branches when an \spad{if}
  ++ is in a context where the resulting value is not used.
  coercex: Exit -> S
  ++ coerce(e) is never really evaluated. This coercion is
  ++ used for formal type correctness when a function will not
  ++ return directly to its caller.

== add
  coercex(s: S): Void == void()
  coercex(e: Exit): S ==
      error "Bug: Should not be able to obtain value of type Exit"

RootsFindingPackage examples
====================================================================

This pacakage finds all the roots of a polynomial. If the constant field is not large enough then it returns the list of found zeros and the degree of the extension need to find the other roots missing. If the return degree is 1 then all the roots have been found. If 0 is return for the extension degree then there are an infinite number of zeros, that is you ask for the zeroes of 0. In the case of infinite field a list of all found zeros is kept and for each other call of a function that finds zeroes, a check is made on that list; this is to keep a kind of "canonical" representation of the elements.

====================================================================
SquareFreeRegularSetDecompositionPackage examples
====================================================================

A package providing a new algorithm for solving polynomial systems
by means of regular chains. Two ways of solving are provided:
in the sense of Zariski closure (like in Kalkbrener's algorithm)
or in the sense of the regular zeros (like in Wu, Wang or Lazard-
Moreno methods). This algorithm is valid for any type
of regular set. It does not care about the way a polynomial is
added in an regular set, or how two quasi-components are compared
(by an inclusion-test), or how the invertibility test is made in the tower of simple extensions associated with a regular set.

These operations are realized respectively by the domain TS and the packages QCMPPK(R,E,V,P,TS) and RSETGCD(R,E,V,P,TS).

The same way it does not care about the way univariate polynomial gcds (with coefficients in the tower of simple extensions associated with a regular set) are computed. The only requirement is that these gcds need to have invertible initials (normalized or not).

WARNING. There is no need for a user to call directly any operation of this package since they can be accessed by the domain \texttt{\textbackslash axiomType\{TS\}}. Thus, the operations of this package are not documented.

--- package MATSTOR StorageEfficientMatrixOperations ---

)abbrev package MATSTOR StorageEfficientMatrixOperations
++ Author: Clifton J. Williamson
++ Date Created: 18 July 1990
++ Date Last Updated: 18 July 1990
++ Description:
++ This package provides standard arithmetic operations on matrices.
++ The functions in this package store the results of computations
++ in existing matrices, rather than creating new matrices. This
++ package works only for matrices of type Matrix and uses the
++ internal representation of this type.

StorageEfficientMatrixOperations(R): Exports == Implementation where
R : Ring
M ==> Matrix R
NNI ==> NonNegativeInteger
ARR ==> PrimitiveArray R
REP ==> PrimitiveArray PrimitiveArray R

Exports ==> with
  copy_! : (M,M) -> M
  ++ \spad{copy!(c,a)} copies the matrix \spad{a} into the matrix \spad{c}.
  ++ Error: if \spad{a} and \spad{c} do not have the same
  ++ dimensions.
  plus_! : (M,M,M) -> M
  ++ \spad{plus!(c,a,b)} computes the matrix sum \spad{a + b} and stores the
  ++ result in the matrix \spad{c}.
  ++ Error: if \spad{a}, \spad{b}, and \spad{c} do not have the same dimensions.
  minus_! : (M,M) -> M
  ++ \spad{minus!(c,a)} computes \spad{-a} and stores the result in the
++ matrix c.
++ Error: if a and c do not have the same dimensions.

minus_! : (M,M,M) -> M
++ \spad{\text{\textbackslash minus!(c,a,b)}} computes the matrix difference \spad{c - b}
++ and stores the result in the matrix c.
++ Error: if \spad{\text{\textbackslash}{\ spad{a}}, b, and c do not have the same dimensions.}

leftScalarTimes_! : (M,R,M) -> M
++ \spad{\text{\textbackslash leftScalarTimes!(c,r,a)}} computes the scalar product
++ \spad{r \times a} and stores the result in the matrix c.
++ Error: if \spad{\text{\textbackslash}{\ spad{a}} and c do not have the same dimensions.}

rightScalarTimes_! : (M,M,R) -> M
++ \spad{\text{\textbackslash rightScalarTimes!(c,a,r)}} computes the scalar product
++ \spad{a \times r} and stores the result in the matrix c.
++ Error: if \spad{\text{\textbackslash}{\ spad{a}} and c do not have the same dimensions.}

times_! : (M,M,M) -> M
++ \spad{\text{\textbackslash times!(c,a,b)}} computes the matrix product \spad{a \times b}
++ and stores the result in the matrix c.
++ Error: if \spad{\text{\textbackslash}{\ spad{a}}, b, and c do not have
++ compatible dimensions.}

power_! : (M,M,M,M,NNI) -> M
++ \spad{\text{\textbackslash power!(a,b,c,m,n)}} computes m ** n and stores the result in
++ \spad{\text{\textbackslash}{\ spad{a}}}. The matrices b and c are used to store intermediate results.
++ Error: if \spad{\text{\textbackslash}{\ spad{a}}, b, c, and m are not square
++ and of the same dimensions.}

"**" : (M,NNI) -> M
++ \spad{x ** n} computes the n-th power
++ of a square matrix. The power n is assumed greater than 1.

StreamTaylorSeriesOperations examples

StreamTaylorSeriesOperations implements Taylor series arithmetic,
where a Taylor series is represented by a stream of its coefficients.

Problems raising a UTS to a negative integer power.

The code in powern(rn,x) which raises an unnecessary error
where no distinction between rational and integer powers are made.

The fix is easy. Since the problem does not exist in SUPS we can
just take the definition there.

   ++ a + b returns the power series sum of \spad{a} and \spad{b}:
   ++ \spad{[a0,a1,...] + [b0,b1,...] = [a0 + b0,a1 + b1,...]}
"-": (ST A,ST A) -> ST A
   ++ a - b returns the power series difference of \spad{a} and \spad{b}:
   ++ \spad{[a0,a1,...] - [b0,b1,...] = [a0 - b0,a1 - b1,...]}
"-": ST A -> ST A
   ++ - a returns the power series negative of \spad{a}:
   ++ \spad{[a0,a1,...] = [- a0,- a1,...]}
"*": (ST A,ST A) -> ST A
   ++ a * b returns the power series (Cauchy) product of \spad{a} and \spad{b}:
   ++ \spad{[a0,a1,...] * [b0,b1,...] = [c0,c1,...]} where
   ++ \spad{ck = sum(i + j = k,ai * bk)}.
"*": (A,ST A) -> ST A
   ++ r * a returns the power series scalar multiplication of \spad{r} by \spad{a}:
   ++ \spad{r * [a0,a1,...] = [r * a0,r * a1,...]}
"*": (ST A,A) -> ST A
   ++ a * r returns the power series scalar multiplication of \spad{a} by \spad{r}:
   ++ \spad{[a0,a1,...] * r = [a0 * r,a1 * r,...]}
"exquo": (ST A,ST A) -> Union(ST A,"failed")
   ++ exquo(a,b) returns the power series quotient of \spad{a} by \spad{b},
   ++ if the quotient exists, and "failed" otherwise
"/": (ST A,ST A) -> ST A
   ++ a / b returns the power series quotient of \spad{a} by \spad{b}.
   ++ An error message is returned if \spad{b} is not invertible.
   ++ This function is used in fixed point computations.
recip : ST A -> UN
   ++ recip(a) returns the power series reciprocal of \spad{a}, or
   ++ "failed" if not possible.
monom : (A,I) -> ST A
   ++ monom(deg,coef) is a monomial of degree deg with coefficient
   ++ coef.
integers : I -> ST I
   ++ integers(n) returns \spad{[n,n+1,n+2,...]}
oddintegers : I -> ST I
   ++ oddintegers(n) returns \spad{[n,n+2,n+4,...]}
int : A -> ST A
   ++ int(r) returns \spad{[r,r+1,r+2,...]}, where \spad{r} is a ring element.
mapmult : (ST A,ST A) -> ST A
   ++ mapmult([a0,a1,...],[b0,b1,...]) returns \spad{[a0*b0,a1*b1,...]}
deriv : ST A -> ST A
   ++ deriv(a) returns the derivative of the power series with
   ++ respect to the power series variable. Thus
   ++ \spad{deriv([a0,a1,a2,...])} returns \spad{[a1,2 a2,3 a3,...]}
gderiv : (I -> A,ST A) -> ST A
   ++ gderiv(f,[a0,a1,a2,...]) returns \spad{[f(0)*a0,f(1)*a1,f(2)*a2,...]}. 
coerce : A -> ST A
++ coerce(r) converts a ring element r to a stream with one element.

eval : (ST A,A) -> ST A
++ eval(a,r) returns a stream of partial sums of the power series
++ \spad{a} evaluated at the power series variable equal to r.

compose : (ST A,ST A) -> ST A
++ compose(a,b) composes the power series \spad{a} with
++ the power series b.

lagrange : ST A -> ST A
++ lagrange(g) produces the power series for f where f is
++ implicitly defined as \spad{f(z) = z*g(f(z))}.

revert : ST A -> ST A
++ revert(a) computes the inverse of a power series \spad{a}
++ with respect to composition.
++ the series should have constant coefficient 0 and first
++ order coefficient 1.

addiag : ST ST A -> ST A
++ addiag(x) performs diagonal addition of a stream of streams. if x =
++ \spad{[\ldots,[a<0,0>,a<0,1>,\ldots],[a<1,0>,a<1,1>,\ldots],[a<2,0>,a<2,1>,\ldots]\ldots]}.
++ and \spad{addiag(x) = \[b<0,b<1>,\ldots\], then b<k> = \sum(i+j=k,a<i,j>)}.

lambert : ST A -> ST A
++ lambert(st) computes \spad{f(x) + f(x**2) + f(x**3) + \ldots}
++ if st is a stream representing \spad{f(x)}.
++ This function is used for computing infinite products.
++ If \spad{f(x)} is a power series with constant coefficient 1 then
++ \spad{prod(f(x**n),n = 1..infinity) = exp(lambert(log(f(x))))}.

oddlambert : ST A -> ST A
++ oddlambert(st) computes \spad{f(x) + f(x**3) + f(x**5) + \ldots}
++ if st is a stream representing \spad{f(x)}.
++ This function is used for computing infinite products.
++ If f(x) is a power series with constant coefficient 1 then
++ \spad{prod(f(x**(2*n-1)),n=1..infinity) = exp(oddlambert(log(f(x))))}.

evenlambert : ST A -> ST A
++ evenlambert(st) computes \spad{f(x**2) + f(x**4) + f(x**6) + \ldots}
++ if st is a stream representing \spad{f(x)}.
++ This function is used for computing infinite products.
++ If \spad{f(x)} is a power series with constant coefficient 1, then
++ \spad{prod(f(x**(2*n)),n=1..infinity) = exp(evenlambert(log(f(x))))}.

generalLambert : (ST A,I,I) -> ST A
++ generalLambert(f(x),a,d) returns
++ \spad{f(x**a) + f(x**(a + d)) + f(x**(a + 2 d)) + \ldots}.
++ \spad{f(x)} should have zero constant
++ coefficient and \spad{a} and \spad{d} should be positive.

multisect : (I,I,ST A) -> ST A
++ multisect(a,b,st)
++ selects the coefficients of \spad{x**((a+b)*n+a)},
++ and changes them to \spad{x**n}.

invmultisect : (I,I,ST A) -> ST A
++ invmultisect(a,b,st) substitutes \spad{x**((a+b)*n)} for \spad{x**n}
++ and multiplies by \spad{x**b}.
if A has Algebra RN then
  integrate : (A,ST A) -> ST A
  ++ integrate(r,a) returns the integral of the power series \spad{a}
  ++ with respect to the power series variable integration where
  ++ r denotes the constant of integration. Thus
  ++ \spad{\text{integrate}(a,[a0,a1,a2,\ldots]) = [a,a0,a1/2,a2/3,\ldots]}.
lazyIntegrate : (A,() -> ST A) -> ST A
  ++ lazyIntegrate(r,f) is a local function
  ++ used for fixed point computations.
nlde : ST ST A -> ST A
  ++ nlde(u) solves a
  ++ first order non-linear differential equation described by u of the
  ++ form \spad{[[b<0,0>,b<0,1>,\ldots],[b<1,0>,b<1,1>,\ldots],\ldots]}.
  ++ the differential equation has the form
  ++ \spad{y'=\text{sum}(i=0 \text{ to infinity},j=0 \text{ to infinity},b<i,j>*(x**i)*(y**j))}.
powern : (RN,ST A) -> ST A
  ++ powern(r,f) raises power series f to the power r.
if A has Field then
  mapdiv : (ST A,ST A) -> ST A
  ++ mapdiv([a0,a1,\ldots],[b0,b1,\ldots]) returns
  ++ \spad{[a0/b0,a1/b1,\ldots]}.
lazyGintegrate : (I -> A,A,() -> ST A) -> ST A
  ++ lazyGintegrate(f,r,g) is used for fixed point computations.
power : (A,ST A) -> ST A
  ++ power(a,f) returns the power series f raised to the power \spad{a}.

====================================================================
SystemSolvePackage examples
====================================================================

Symbolic solver for systems of rational functions with coefficients in an integral domain R.

The systems are solved in the field of rational functions over R. Solutions are exact of the form variable = value when the value is a member of the coefficient domain R. Otherwise the solutions are implicitly expressed as roots of univariate polynomial equations over R.

Care is taken to guarantee that the denominators of the input equations do not vanish on the solution sets.

The arguments to solve can either be given as equations or as rational functions interpreted as equal to zero. The user can specify an explicit list of symbols to be solved for, treating all other symbols appearing as parameters or omit the list of symbols in which case the system tries to solve with respect to all symbols appearing in the input.

Cat == with
solve: (L F, L SE) -> L L EQ F
  ++ solve(lp,lv) finds the solutions of the list lp of
  ++ rational functions with respect to the list of symbols lv.
solve: (L EQ F, L SE) -> L L EQ F
  ++ solve(le,lv) finds the solutions of the
  ++ list le of equations of rational functions
  ++ with respect to the list of symbols lv.
solve: L F -> L L EQ F
  ++ solve(lp) finds the solutions of the list lp of rational
  ++ functions with respect to all symbols appearing in lp.
solve: L EQ F -> L L EQ F
  ++ solve(le) finds the solutions of the list le of equations of
  ++ rational functions with respect to all symbols appearing in le.
solve: (F, SE) -> L EQ F
  ++ solve(p,v) solves the equation p=0, where p is a rational function
  ++ with respect to the variable v.
solve: (EQ F,SE) -> L EQ F
  ++ solve(eq,v) finds the solutions of the equation
  ++ eq with respect to the variable v.
solve: F -> L EQ F
  ++ solve(p) finds the solution of a rational function p = 0
  ++ with respect to the unique variable appearing in p.
solve: EQ F -> L EQ F
  ++ solve(eq) finds the solutions of the equation eq
  ++ with respect to the unique variable appearing in eq.

triangularSystems: (L F, L SE) -> L L P R
  ++ triangularSystems(lf,lv) solves the system of equations
  ++ defined by lf with respect to the list of symbols lv;
  ++ the system of equations is obtaining
++ by equating to zero the list of rational functions lf.
++ The output is a list of solutions where
++ each solution is expressed as a "reduced" triangular system of
++ polynomials.

public ==> with

-- IS THERE A WORKING DOMAIN Tableau ??
-- coerce : M I -> Tableau(I)
--   ++ coerce(ytab) coerces the Young-Tableau ytab to an element of
--   ++ the domain Tableau(I).

coleman : (L I, L I, L I) -> M I
   ++ coleman(alpha,beta,pi):
   ++ there is a bijection from the set of matrices having nonnegative
   ++ entries and row sums alpha, column sums beta
   ++ to the set of Salpha - Sbeta double cosets of the
   ++ symmetric group Sn. (Salpha is the Young subgroup
   ++ corresponding to the improper partition alpha).
   ++ For a representing element pi of such a double coset,
   ++ coleman(alpha,beta,pi) generates the Coleman-matrix
   ++ corresponding to alpha, beta, pi.
   ++ Note that The permutation pi of \{1,2,...,n\} has to be given
   ++ in list form.
   ++ Note that the inverse of this map is inverseColeman
   ++ (if pi is the lexicographical smallest permutation
   ++ in the coset). For details see James/Kerber.
inverseColeman : (L I, L I, M I) -> L I
   ++ inverseColeman(alpha,beta,C):
   ++ there is a bijection from the set of matrices having nonnegative
   ++ entries and row sums alpha, column sums beta
   ++ to the set of Salpha - Sbeta double cosets of the
   ++ symmetric group Sn. (Salpha is the Young subgroup
   ++ corresponding to the improper partition alpha).
   ++ For such a matrix C, inverseColeman(alpha,beta,C)
++ calculates the lexicographical smallest \( \pi \) in the
++ corresponding double coset.
++ Note that the resulting permutation \( \pi \) of \( \{1,2,\ldots,n\} \)
++ is given in list form.
++ Notes: the inverse of this map is coleman.
++ For details, see James/Kerber.

\text{listYoungTableaus} : (L \ I) \rightarrow L \ M \ I
++ \text{listYoungTableaus}(\lambda) \text{ where } \lambda \text{ is a proper partition}
++ generates the list of all standard tableaus of shape \( \lambda \)
++ by means of lattice permutations. The numbers of the lattice
++ permutation are interpreted as column labels. Hence the
++ contents of these lattice permutations are the conjugate of
++ \( \lambda \).
++ Notes: the functions \text{nextLatticePermutation} and
++ \text{makeYoungTableau} are used.
++ The entries are from 0,\ldots,n-1.

\text{makeYoungTableau} : (L \ I, L \ I) \rightarrow M \ I
++ \text{makeYoungTableau}(\lambda, g) \text{ computes for a given lattice}
++ permutation \( g \) and for an improper partition \( \lambda \)
++ the corresponding standard tableau of shape \( \lambda \).
++ Notes: see \text{listYoungTableaus}.
++ The entries are from 0,\ldots,n-1.

\text{nextColeman} : (L \ I, L \ I, M \ I) \rightarrow M \ I
++ \text{nextColeman}(\alpha, \beta, C) \text{ generates the next Coleman matrix}
++ of column sums \( \alpha \) and row sums \( \beta \) according
++ to the lexicographical order from bottom-to-top.
++ The first Coleman matrix is achieved by \( C = \text{new}(1,1,0) \).
++ Also, \( \text{new}(1,1,0) \) indicates that \( C \) is the last Coleman matrix.

\text{nextLatticePermutation} : (L \ I, L \ I, B) \rightarrow L \ I
++ \text{nextLatticePermutation}(\lambda, l, \text{constructNotFirst}) \text{ generates}
++ the lattice permutation according to the proper partition
++ \( \lambda \) succeeding the lattice permutation \( l \) in
++ lexicographical order as long as \text{constructNotFirst} is true.
++ If \text{constructNotFirst} is false, the first lattice permutation
++ is returned.
++ The result \text{nil} indicates that \( l \) has no successor.

\text{nextPartition} : (V \ I, V \ I, I) \rightarrow V \ I
++ \text{nextPartition}(\gamma, \text{part}, \text{number}) \text{ generates the partition of}
++ \text{number which follows part according to the right-to-left}
++ lexicographical order. The partition has the property that
++ its components do not exceed the corresponding components of
++ \( \gamma \). The first partition is achieved by \text{part}=[].
++ Also, \( [] \) indicates that part is the last partition.

\text{nextPartition} : (L \ I, V \ I, I) \rightarrow V \ I
++ \text{nextPartition}(\gamma, \text{part}, \text{number}) \text{ generates the partition of}
++ \text{number which follows part according to the right-to-left}
++ lexicographical order. The partition has the property that
++ its components do not exceed the corresponding components of
++ \( \gamma \). The first partition is achieved by \text{part}=[].
++ Also, \( [] \) indicates that part is the last partition.
numberOfImproperPartitions: (I,I) -> I
  ++ numberOfImproperPartitions(n,m) computes the number of partitions
  ++ of the nonnegative integer n in m nonnegative parts with regarding
  ++ the order (improper partitions).
  ++ Example: numberOfImproperPartitions (3,3) is 10,
  ++ since [0,0,3], [0,1,2], [0,2,1], [0,3,0], [1,0,2], [1,1,1],
  ++ [1,2,0], [2,0,1], [2,1,0], [3,0,0] are the possibilities.
  ++ Note that this operation has a recursive implementation.

subSet : (I,I,I) -> L I
  ++ subSet(n,m,k) calculates the k-th m-subset of the set
  ++ 0,1,...,(n-1) in the lexicographic order considered as
  ++ a decreasing map from 0,...,(m-1) into 0,...,(n-1).
  ++ See S.G. Williamson: Theorem 1.60.
  ++ Error: if not (0 <= m <= n and 0 <= k <= (n choose m)).

unrankImproperPartitions0 : (I,I,I) -> L I
  ++ unrankImproperPartitions0(n,m,k) computes the k-th improper
  ++ partition of nonnegative n in m nonnegative parts in reverse
  ++ lexicographical order.
  ++ Example: [0,0,3] < [0,1,2] < [0,2,1] < [0,3,0] <
  ++ [1,0,2] < [1,1,1] < [1,2,0] < [2,0,1] < [2,1,0] < [3,0,0].
  ++ Error: if k is negative or too big.
  ++ Note that counting of subtrees is done by
  ++ numberOfImproperPartitions

unrankImproperPartitions1: (I,I,I) -> L I
  ++ unrankImproperPartitions1(n,m,k) computes the k-th improper
  ++ partition of nonnegative n in at most m nonnegative parts
  ++ ordered as follows: first, in reverse
  ++ lexicographically according to their non-zero parts, then
  ++ according to their positions (i.e. lexicographical order
  ++ using subSet: [3,0,0] < [0,3,0] < [0,0,3] < [2,1,0] <
  ++ [2,0,1] < [0,2,1] < [1,2,0] < [1,0,2] < [0,1,2] < [1,1,1].
  ++ Note that counting of subtrees is done by
  ++ numberOfImproperPartitionsInternal.

====================================================================
TaylorSolve examples
====================================================================

UTSSOL is a facility to compute the first few coefficients of a Taylor
series given only implicitly by a function f that vanishes when applied to
the Taylor series.

It uses the method of undetermined coefficients.

Could I either
take a function UTSCAT F $\rightarrow$ UTSCAT F and still be able to compute
with undetermined coefficients, or
take a function F $\rightarrow$ F, and do likewise?

Let’s see.

Try to compute the equation without resorting to power series. I.e., \%
c: SUP SUP F, and f: SUP SUP F $\rightarrow$ SUP SUP F. Won’t this make the
computation of coefficients terribly slow?

I could also try to replace transcendental kernels with variables\dots

Unfortunately, SUP F does not have TRANFUN -- well, it can’t, of
course. However, I’d like to be able to compute \%
\sin(1+\text{monomial}(1,1)$UFPS SUP EXPR INT).

++ This package has no description

TaylorSolve(F, UTSF, UTSSUPF): Exports == Implementation where
  F: Field
  SUP ==> SparseUnivariatePolynomialExpressions
  UTSF: UnivariateTaylorSeriesCategory F
  UTSSUPF: UnivariateTaylorSeriesCategory SUP F
  NNI ==> NonNegativeInteger

Exports == with
  seriesSolve: (UTSSUPF -> UTSSUPF, List F) -> UTSF

Implementation == add

\getchunk{implementation: UTSSOL TaylorSolve}

--- implementation: UTSSOL TaylorSolve ---

seriesSolve(f, l) ==
c1 :=
  map((x:F):SUP F +-> x::(SUP F), l)
  $ListFunctions2(F, SUP F)::(Stream SUP F)
coeffs: Stream SUP F := concat(c1, generate(monomial(1$F,1$NNI)))

---
coeffs is the stream of the already computed coefficients of the solution, plus one which is so far undetermined. We store in st.2 the complete stream and in st.1 the stream starting with the first coefficient that has possibly not yet been computed.

The mathematics is not quite worked out. If coeffs is initialized as a stream with all coefficients set to the \emph{same} transcendental value, and not enough initial values are given, then the missing ones are implicitly assumed to be all identical. It may well happen that a solution is produced, although it is not uniquely determined.

— implementation: UTSSOL TaylorSolve —

\begin{verbatim}
  st: List Stream SUP F := [coeffs, coeffs]
\end{verbatim}

Consider an arbitrary equation $f(x, y(x)) = 0$. When setting $x = 0$, we obtain $f(0, y(0)) = 0$. It is not necessarily the case that this determines $y(0)$ uniquely, so we need one initial value that satisfies this equation.

seriesSolve should check that the given initial values satisfy $f(0, y(0), y'(0), ...) = 0$.

Now consider the derivatives of $f$, where we write $y$ instead of $y(x)$ for better readability:

$$\frac{d}{dx} f(x, y) = f_1(x, y) + f_2(x, y)y'$$

and

$$\frac{d^2}{dx^2} f(x, y) = f_{1,1}(x, y) + f_{1,2}(x, y)y' + f_{2,1}(x, y)y' + f_{2,2}(x, y)(y')^2 + f_2(x, y)y''.$$  

In general, $\frac{d^2}{dx^2} f(x, y)$ depends only linearly on $y''$.

This points to another possibility: Since we know that we only need to solve linear equations, we could compute two values and then use interpolation. This might be a bit slower, but more importantly: can we still check that we have enough initial values? Furthermore, we then really need that $f$ is analytic, i.e., operators are not necessarily allowed anymore. However, it seems that composition is allowed.

— implementation: UTSSOL TaylorSolve —
If the next element was already calculated, we can simply return it:

--- implementation: UTSSOL TaylorSolve ---

then

res := ground coeff
st.1 := rest nr

else

Otherwise, we have to find the first non-satisfied relation and solve it. It should be linear, or a single non-constant monomial. That is, the solution should be unique.

--- implementation: UTSSOL TaylorSolve ---

ns := st.2
eqs: Stream SUP F := coefficients f series ns
while zero? first eqs repeat eqs := rest eqs
eq: SUP F := first eqs
if degree eq > 1 then
    if monomial? eq then res := 0
else
    output(hconcat("The equation is: ", eq::OutputForm))$OutputPackage
    error "seriesSolve: equation for coefficient not linear"
else res := (-coefficient(eq, 0$NNI)$(SUP F)
    /coefficient(eq, 1$NNI)$(SUP F))

nr.1 := res::SUP F
--
concat!(st.2, monomial(1$F,1$NNI))
st.1 := rest nr

Implementation ==> add

I have had to work my way around the following bug in the compiler: When a local variable
is given a mapping as a value, e.g.

\[
\text{foo : SF} \to \text{SF} := \text{makeFloatFunction}(f,t),
\]

the compiler cannot distinguish that local variable from a local function defined elsewhere
in the package. Thus, when 'foo' is passed to a function, e.g.

\[
\text{bird} := \text{fcn}(\text{foo}),
\]

foo will often be compiled as DRAW;foo rather than foo. This, of course, causes a run-time
error.

To avoid this problem, local variables are not given mappings as values, but rather (single-
ton) lists of mappings. The first element of the list can always be extracted and everything
goes through as before. There is no major loss in efficiency, as the computation of points
will always dominate the computation time.

— package TRMANIP TranscendentalManipulations —

)abbrev  package TRMANIP TranscendentalManipulations
++ Author: Bob Sutor, Manuel Bronstein
++ Date Created: Way back
++ Date Last Updated: 22 January 1996, added simplifyLog MCD.
++ Description:
++ TranscendentalManipulations provides functions to simplify and
++ expand expressions involving transcendental operators.

TranscendentalManipulations(R, F): Exports == Implementation where
R : Join(OrderedSet, GcdDomain)
F : Join(FunctionSpace R, TranscendentalFunctionCategory)

Z   ==>   Integer
K   ==>   Kernel F
P   ==>   SparseMultivariatePolynomial(R, K)
UP  ==>   SparseUnivariatePolynomial P
POWER ==> "%power"::Symbol
POW  ==>   Record(val: F, exponent: Z)
PRODUCT ==> Record(coef : Z, var : K)
FPR  ==>   Fraction Polynomial R

Exports ==> with
  expand  : F -> F
    ++ expand(f) performs the following expansions on f:
    ++ \item 1. logs of products are expanded into sums of logs,
    ++ \item 2. trigonometric and hyperbolic trigonometric functions
    ++ of sums are expanded into sums of products of trigonometric
    ++ and hyperbolic trigonometric functions.
    ++ \item 3. formal powers of the form \spad{(a/b)**c} are expanded into
    ++ \spad{a**c * b**(-c)}.
    ++ \end(items)

  simplify  : F -> F
    ++ simplify(f) performs the following simplifications on f:
    ++ \item 1. rewrites trigs and hyperbolic trigs in terms
    ++ of \spad{sin}, \spad{cos}, \spad{sinh}, \spad{cosh}.
    ++ \item 2. rewrites \spad{sin**2} and \spad{sinh**2} in terms
++ of \spad{cos} and \spad{cosh},
++ \item 3. rewrites \spad{exp(a)*exp(b)} as \spad{exp(a+b)}.
++ \item 4. rewrites \spad{(a**(1/n))**m * (a**(1/s))**t} as a single
++ power of a single radical of \spad{a}.
++ \end{items}

htrigs : F -> F
++ htrigs(f) converts all the exponentials in f into
++ hyperbolic sines and cosines.
simplifyExp: F -> F
++ simplifyExp(f) converts every product \spad{exp(a)*exp(b)}
++ appearing in f into \spad{exp(a+b)}.
simplifyLog : F -> F
++ simplifyLog(f) converts every \spad{log(a) - log(b)} appearing in f
++ into \spad{log(a/b)}, every \spad{log(a) + log(b)} into \spad{log(a*b)}
++ and every \spad{n*log(a)} into \spad{log(a^n)}.
expandPower: F -> F
++ expandPower(f) converts every power \spad{(a/b)**c} appearing
++ in f into \spad{a**c * b**(-c)}.
expandLog : F -> F
++ expandLog(f) converts every \spad{log(a/b)} appearing in f into
++ \spad{log(a) - log(b)}, and every \spad{log(a*b)} into
++ \spad{log(a) + log(b)}.

++ cos2sec : F -> F
++ cos2sec(f) converts every \spad{cos(u)} appearing in f into
++ \spad{1/sec(u)}.

++ cosh2sech : F -> F
++ cosh2sech(f) converts every \spad{cosh(u)} appearing in f into
++ \spad{1/sech(u)}.

cot2trig : F -> F
++ cot2trig(f) converts every \spad{cot(u)} appearing in f into
++ \spad{cos(u)/sin(u)}.

++ coth2trigh : F -> F
++ coth2trigh(f) converts every \spad{coth(u)} appearing in f into
++ \spad{cosh(u)/sinh(u)}.

csc2sin : F -> F
++ csc2sin(f) converts every \spad{csc(u)} appearing in f into
++ \spad{1/sin(u)}.

++ csch2sinh : F -> F
++ csch2sinh(f) converts every \spad{csch(u)} appearing in f into
++ \spad{1/sinh(u)}.

sec2cos : F -> F
++ sec2cos(f) converts every \spad{sec(u)} appearing in f into
++ \spad{1/cos(u)}.

++ sech2cosh : F -> F
++ sech2cosh(f) converts every \spad{sech(u)} appearing in f into
++ \spad{1/cosh(u)}.

++ sin2csc : F -> F
++ sin2csc(f) converts every \spad{sin(u)} appearing in f into
++ \spad{1/csc(u)}.

++ sinh2csch : F -> F
++ sinh2csch(f) converts every \spad{sinh(u)} appearing in f into
++ \spad{1/csch(u)}.

\textbf{tan2trig} : F -> F
++ tan2trig(f) converts every \spad{tan(u)} appearing in f into
++ \spad{sin(u)/cos(u)}.
\textbf{tanh2trigh} : F -> F
++ tanh2trigh(f) converts every \spad{tanh(u)} appearing in f into
++ \spad{sinh(u)/cosh(u)}.

\textbf{tan2cot} : F -> F
++ tan2cot(f) converts every \spad{tan(u)} appearing in f into
++ \spad{1/cot(u)}.

\textbf{tanh2coth} : F -> F
++ tanh2coth(f) converts every \spad{tanh(u)} appearing in f into
++ \spad{1/coth(u)}.

\textbf{cot2tan} : F -> F
++ cot2tan(f) converts every \spad{cot(u)} appearing in f into
++ \spad{1/tan(u)}.

\textbf{coth2tanh} : F -> F
++ coth2tanh(f) converts every \spad{coth(u)} appearing in f into
++ \spad{1/tanh(u)}.

\textbf{removeCosSq} : F -> F
++ removeCosSq(f) converts every \spad{cos(u)**2} appearing in f into
++ \spad{1 - sin(x)**2}, and also reduces higher
++ powers of \spad{cos(u)} with that formula.

\textbf{removeSinSq} : F -> F
++ removeSinSq(f) converts every \spad{sin(u)**2} appearing in f into
++ \spad{1 - cos(x)**2}, and also reduces higher powers of
++ \spad{sin(u)} with that formula.

\textbf{removeCoshSq} : F -> F
++ removeCoshSq(f) converts every \spad{cosh(u)**2} appearing in f into
++ \spad{1 - sinh(x)**2}, and also reduces higher powers of
++ \spad{cosh(u)} with that formula.

\textbf{removeSinhSq} : F -> F
++ removeSinhSq(f) converts every \spad{sinh(u)**2} appearing in f into
++ \spad{1 - cosh(x)**2}, and also reduces higher powers
++ of \spad{sinh(u)} with that formula.

if R has PatternMatchable(R) and R has ConvertibleTo(Pattern(R))
and F has ConvertibleTo(Pattern(R)) and F has PatternMatchable R then

\textbf{expandTrigProducts} : F -> F
++ expandTrigProducts(e) replaces \axiom{sin(x)*sin(y)} by
++ \spad{(cos(x-y)-cos(x+y))/2}, \axiom{cos(x)*cos(y)} by
++ \spad{(cos(x-y)+cos(x+y))/2}, and \axiom{sin(x)*cos(y)} by
++ \spad{(sin(x-y)+sin(x+y))/2}. Note that this operation uses
++ the pattern matcher and so is relatively expensive. To avoid
++ getting into an infinite loop the transformations are applied
++ at most ten times.

The htrigs function

The htrigs function can be used to replace and reduce hyperbolic trigonometric identities. The identity for $\sinh(x)$ is $(e^x - e^{-x})/2$.

If we difference these we should get zero

$$ f := \sinh(x) - (e^x - e^{-x})/2 $$

instead, by default, we get

$$ x -x 
2\sinh(x) - \frac{e^{-x}}{e} + \frac{e^x}{e} 
\frac{-------------}{2} $$

The function htrigs(f) gives 0.

This works as follows:

```math
m := mainKernel f => \sinh(x)
Type: Union(Kernel(Expression(Integer)), ...)
```

which is coerced to the first part of the union:
k:=m::Kernel(Expression(Integer))

and the operator is extracted:

\[
\text{op:=} \text{operator}(k) \Rightarrow \sinh
\]

Type: BasicOperator

The argument function extracts the variable used as arguments:

argument k =>> [x]  
Type Kernel(Expression(Integer))

At this point we have picked apart the main Kernel into its operator and its arguments. We now process the list of arguments.

The function htrigs is called on every element of the argument list, which in this case, returns a list:

\[
\text{arg:=[htrigs x for x in argument k]$List(Expression(Integer))
=> [x]
}\]

Type: List(Expression(Integer))

We form a polynomial by replacing the kernel in the numerator with ?

\[
\text{num := univariate(numer f, k)}
\]

\[
x - x
2? - %e + %e
\]

Type: SparseUnivariatePolynomial(SparseMultivariatePolynomial(Integer, Kernel(Expression(Integer))))

and a polynomial of the denominator, replacing the kernel

\[
\text{den := univariate(denom f, k)}
\]

\[
2
\]

Type: SparseUnivariatePolynomial(SparseMultivariatePolynomial(Integer, Kernel(Expression(Integer))))

In this case the op is not the exponential so we are doing straight trig substitution. We reconstruct the function call using the op and arg values, that is:

\[
\text{g1 := op arg =>> sinh(x)}
\]

Type: Expression(Integer)

So sup2htrigs, which is a local function, is used to simplify the parts of the fraction. In this case,
Thus, the result is 0
The identity for \( \cosh(x) \) is \( (\exp(x) + \exp(-x))/2 \)
If we difference these we should get zero

\[
f := \cosh(x) - (\exp^x + \exp^{-x})/2
\]

instead, by default, we get

\[
\frac{x - x}{2} - \frac{\exp^x + \exp^{-x} + 2\cosh(x)}{2}
\]

and the function call \( htrigs(f) \) gives 0
This works as follows:

\[
m := \text{mainKernel } f \Rightarrow \exp^x
\]

which is coerced to the first part of the union:

\[
k := m : \text{Kernel(Expression(Integer))} \Rightarrow \exp^x
\]

and the operator is extracted:

\[
\text{op} := \text{operator}(k) \Rightarrow \exp
\]

The argument function extracts the variable used as arguments:

\[
\text{argument } k \Rightarrow [x]
\]

At this point we have picked apart the main Kernel into its operator and its arguments. We now process the list of arguments.
The \( htrigs \) function is called on every element of the argument list, which in this case, returns a list:
arg:=[htrigs x for x in argument k]$List(Expression(Integer))
  => [x]
  Type: List(Expression(Integer))

We form polynomial by replacing the kernel in the numerator with ?

num := univariate(numer f, k)

- x
- ? - %e + 2cosh(x)

Type: SparseUnivariatePolynomial(
  SparseMultivariatePolynomial(
    Integer, Kernel(Expression(Integer))))

and a polynomial of the denominator, replacing the kernel

den := univariate(denom f, k)

2

Type: SparseUnivariatePolynomial(
  SparseMultivariatePolynomial(
    Integer, Kernel(Expression(Integer))))

In this case, the expression

is?(op, "exp"::Symbol) => true

so we form

a := first arg => x

Type: Expression(Integer)

since we know that

x
cosh(x)+sinh(x) => %e

we can form this use this expression in substitutions

g1 := cosh(a)+sinh(a) => sinh(x)+cosh(x)

Type: Expression(Integer)

since we know that

- x
cosh(x)-sinh(x) => - %e

we can form this use this expression in substitutions
\begin{verbatim}
g2 := cosh(a)-sinh(a) => -sinh(x)+cosh(x)
    Type: Expression(Integer)

b := (degree num)::Integer quo 2 => 0
    Type: NonNegativeInteger

The supexp function is using the g1 and g2 identities to replace exp(x)

\texttt{supexp(num,g1,g2,b) => sinh(x)-cosh(x)-sinh(x)+2cosh(x)-cosh(x)}
    Type: Expression(Integer)

\texttt{supexp(den,g1,g2,b) => 2}
    Type: Expression(Integer)

which is effectively

\texttt{t1/t2 => (sinh(x)-cosh(x)-sinh(x)+2cosh(x)-cosh(x))/2}
    Type: Expression(Integer)

the last form of which can be rearranged as:

\texttt{(sinh(x)-sinh(x) + 2cosh(x)-cosh(x)-cosh(x))/2 => 0}

so the result is 0

TransSolvePackage examples

This package tries to find solutions of equations of type Expression(R).
This means expressions involving transcendental, exponential, logarithmic
and nthRoot functions.

After trying to transform different kernels to one kernel by applying
several rules, it calls zerosOf for the SparseUnivariatePolynomial in
the remaining kernel.

For example the expression
\[ \sin(x) \cdot \cos(x) - 2 \]
will be transformed to
\[ -2 \tan(x/2)^4 - 2 \tan(x/2)^3 - 4 \tan(x/2)^2 + 2 \tan(x/2) - 2 \]
by using the function normalize and then to
\[ -2 \tan(x)^2 + \tan(x) - 2 \]
with help of subsTan. This function tries to express the given function
in terms of \( \tan(x/2) \) to express in terms of \( \tan(x) \).

Other examples are the expressions
\[ \sqrt{x+1} + \sqrt{x+7} + 1 \]
\[ \sqrt{\sin(x)} + 1 \]
\[ \text{solve}(1/2*v^2*cos(theta+phi)*cos(theta+phi)+g*l*cos(phi)=g*l,phi) \]

++ Author: W. Wiwianka, Martin Rubey
++ Date Created: Summer 1991
++ Date Last Changed: 9/91
++ Description:
++ This package tries to find solutions of equations of type Expression(R).
++ This means expressions involving transcendental, exponential, logarithmic
++ and nthRoot functions.
++ After trying to transform different kernels to one kernel by applying
++ several rules, it calls zerosOf for the SparseUnivariatePolynomial in
++ the remaining kernel.
++ For example the expression \spad{\sin(x)\cos(x)-2} will be transformed to
++ \spad{-2 \tan(x/2)^4 -2 \tan(x/2)^3 -4 \tan(x/2)^2 +2 \tan(x/2) -2}
++ by using the function normalize and then to
++ \spad{-2 \tan(x)^2 + \tan(x) -2}
++ with help of subsTan. This function tries to express the given function
++ in terms of \spad{\tan(x/2)} to express in terms of \spad{\tan(x)}.
++ Other examples are the expressions \spad{sqrt(x+1)+sqrt(x+7)+1} or
++ \spad{sqrt(sin(x))+1}.

This package finds the function func3 where func1 and func2 are given and func1 = func3(func2). If there is no solution then function func1 will be returned.
An example would be

\[ \text{func1} := 8\times^3 + 32\times^2 - 14\times \] ::EXPR INT

and

\[ \text{func2} := 2\times \] ::EXPR INT

convert them via univariate to \( \text{FRAC SUP EXPR INT} \) and then the solution is

\[ \text{func3} := \times^3 + \times^2 - \times \]

of type \( \text{FRAC SUP EXPR INT} \)

TriangularMatrixOperations examples
====================================================================

This package provides functions that compute "fraction-free" inverses of upper and lower triangular matrices over a integral domain. By "fraction-free inverses" we mean the following: given a matrix B with entries in R and an element d of R such that d * inv(B) also has entries in R, we return d * inv(B). Thus, it is not necessary to pass to the quotient field in any of our computations.

package TUBETOOL TubePlotTools
Tools for constructing tubes around 3-dimensional parametric curves.

See Also:
o )show TubePlotTools
++ point(x1,x2,x3,c) creates and returns a point from the three
++ specified coordinates \spad{x1}, \spad{x2}, \spad{x3}, and also
++ a fourth coordinate, c, which is generally used to specify the
++ color of the point.

"*" : (SF,Pt) -> Pt
++ s * p returns a point whose coordinates are the scalar multiple
++ of the point p by the scalar s, preserving the color, or fourth
++ coordinate, of p.

"+" : (Pt,Pt) -> Pt
++ p + q computes and returns a point whose coordinates are the sums
++ of the coordinates of the two points \spad{p} and \spad{q}, using
++ the color, or fourth coordinate, of the first point \spad{p}
++ as the color also of the point \spad{q}.

"-" : (Pt,Pt) -> Pt
++ p - q computes and returns a point whose coordinates are the
++ differences of the coordinates of two points \spad{p} and \spad{q},
++ using the color, or fourth coordinate, of the first point \spad{p}
++ as the color also of the point \spad{q}.

dot : (Pt,Pt) -> SF
++ dot(p,q) computes the dot product of the two points \spad{p}
++ and \spad{q} using only the first three coordinates, and returns
++ the resulting \spadtype{DoubleFloat}.

cross : (Pt,Pt) -> Pt
++ cross(p,q) computes the cross product of the two points \spad{p}
++ and \spad{q} using only the first three coordinates, and keeping
++ the color of the first point p. The result is returned as a point.

unitVector: Pt -> Pt
++ unitVector(p) creates the unit vector of the point p and returns
++ the result as a point. Note that \spad{unitVector(p) = p/|p|}.

cosSinInfo: I -> L L SF
++ cosSinInfo(n) returns the list of lists of values for n, in the form
++ \spad{[[cos(n-1) a,sin(n-1) a],...,[cos 2 a,sin 2 a],[cos a,sin a]]}
++ where \spad{a = 2 \pi/n}. Note that n should be greater than 2.

loopPoints: (Pt,Pt,Pt,SF,L L SF) -> L Pt
++ loopPoints(p,n,b,r,lls) creates and returns a list of points
++ which form the loop with radius r, around the center point
++ indicated by the point p, with the principal normal vector of
++ the space curve at point p given by the point(vector) n, and the
++ binormal vector given by the point(vector) b, and a list of lists,
++ lls, which is the \spadfun{cosSinInfo} of the number of points
++ defining the loop.

package UPSQFREE UnivariatePolynomialSquareFree

---

UnivariatePolynomialSquareFree examples

This package provides for square-free decomposition of univariate polynomials over arbitrary rings, i.e. a partial factorization such that each factor is a product of irreducibles with multiplicity one and the factors are pairwise relatively prime. If the ring has characteristic zero, the result is guaranteed to satisfy this condition. If the ring is an infinite ring of finite characteristic, then it may not be possible to decide when polynomials contain factors which are $p$th powers. In this case, the flag associated with that polynomial is set to "nil" (meaning that that polynomials are not guaranteed to be square-free).

====================================================================
VectorFunctions2 examples
====================================================================

This package provides operations which all take as arguments vectors of elements of some type A and functions from A to another of type B. The operations all iterate over their vector argument and either return a value of type B or a vector over B.
VectorFunctions2 (VECTOR2)

Exports:
map  reduce  scan

— package VECTOR2 VectorFunctions2 —

)abbrev package VECTOR2 VectorFunctions2
++ Description:
++ This package provides operations which all take as arguments
++ vectors of elements of some type \spad{A} and functions from \spad{A} to
++ another of type B. The operations all iterate over their vector argument
++ and either return a value of type B or a vector over B.

VectorFunctions2(A, B):Exports == Implementation where
A, B: Type
VA ==> Vector A
VB ==> Vector B
O2 ==> FiniteLinearAggregateFunctions2(A, VA, B, VB)
UB ==> Union(B,"failed")

Exports ==> with
scan : ((A, B) -> B, VA, B) -> VB
++ scan(func,vec,ident) creates a new vector whose elements are
++ the result of applying reduce to the binary function func,
++ increasing initial subsequences of the vector vec,
reduce : ((A, B) -> B, VA, B) -> B
  ++ reduce(func,vec,ident) combines the elements in vec using the
  ++ binary function func. Argument ident is returned if vec is empty.
map : (A -> B, VA) -> VB
  ++ map(f, v) applies the function f to every element of the vector v
  ++ producing a new vector containing the values.
map : (A -> UB, VA) -> Union(VB,"failed")
  ++ map(f, v) applies the function f to every element of the vector v
  ++ producing a new vector containing the values or \spad{"failed"}.

Implementation ==> add

  E ==> Expression
  PI ==> PositiveInteger
  NNI ==> NonNegativeInteger
  SF ==> DoubleFloat
  B ==> Boolean

writeAvailable => (["PIXMAP","BITMAP","POSTSCRIPT","IMAGE"]::L S)
-- need not worry about case of letters

Exports => with

  pointColorDefault : () -> PAL
  ++ pointColorDefault() returns the default color of points in a 2D
  ++ viewport.

  pointColorDefault : PAL -> PAL
  ++ pointColorDefault(p) sets the default color of points in a 2D viewport
  ++ to the palette p.

  lineColorDefault : () -> PAL
  ++ lineColorDefault() returns the default color of lines connecting
  ++ points in a 2D viewport.

  lineColorDefault : PAL -> PAL
  ++ lineColorDefault(p) sets the default color of lines connecting points
  ++ in a 2D viewport to the palette p.

  axesColorDefault : () -> PAL
  ++ axesColorDefault() returns the default color of the axes in a
  ++ 2D viewport.

  axesColorDefault : PAL -> PAL
  ++ axesColorDefault(p) sets the default color of the axes in a 2D
++ viewport to the palette p.

unitsColorDefault : () -> PAL
++ unitsColorDefault() returns the default color of the unit ticks in
++ a 2D viewport.

unitsColorDefault : PAL -> PAL
++ unitsColorDefault(p) sets the default color of the unit ticks in
++ a 2D viewport to the palette p.

pointSizeDefault : () -> PI
++ pointSizeDefault() returns the default size of the points in
++ a 2D viewport.

pointSizeDefault : PI -> PI
++ pointSizeDefault(i) sets the default size of the points in a 2D
++ viewport to i.

viewPosDefault : () -> L NNI
++ viewPosDefault() returns the default x and y position of a
++ viewport window unless overriden explicitly, newly created
++ viewports will have this x and y coordinate.

viewPosDefault : L NNI -> L NNI
++ viewPosDefault([x,y]) sets the default x and y position of a
++ viewport window unless overriden explicitly, newly created
++ viewports will have the x and y coordinates x, y.

viewSizeDefault : () -> L PI
++ viewSizeDefault() returns the default viewport width and height.

viewSizeDefault : L PI -> L PI
++ viewSizeDefault([w,h]) sets the default viewport width to w and height
++ to h.

viewDefaults : () -> Void
++ viewDefaults() resets all the default graphics settings.

viewWriteDefault : () -> L S
++ viewWriteDefault() returns the list of things to write in a viewport
++ data file; a viewalone file is always generated.

viewWriteDefault : L S -> L S
++ viewWriteDefault(l) sets the default list of things to write in a
++ viewport data file to the strings in l; a viewalone file is always
++ generated.

viewWriteAvailable : () -> L S
++ viewWriteAvailable() returns a list of available methods for writing,
++ such as BITMAP, POSTSCRIPT, etc.
var1StepsDefault : () -> PI
++ var1StepsDefault() is the current setting for the number of steps to
++ take when creating a 3D mesh in the direction of the first defined
++ free variable (a free variable is considered defined when its
++ range is specified (e.g. x=0..10)).

var2StepsDefault : () -> PI
++ var2StepsDefault() is the current setting for the number of steps to
++ take when creating a 3D mesh in the direction of the first defined
++ free variable (a free variable is considered defined when its
++ range is specified (e.g. x=0..10)).

var1StepsDefault : PI -> PI
++ var1StepsDefault(i) sets the number of steps to take when creating a
++ 3D mesh in the direction of the first defined free variable to i
++ (a free variable is considered defined when its range is specified
++ (e.g. x=0..10)).

var2StepsDefault : PI -> PI
++ var2StepsDefault(i) sets the number of steps to take when creating a
++ 3D mesh in the direction of the first defined free variable to i
++ (a free variable is considered defined when its range is specified
++ (e.g. x=0..10)).

tubePointsDefault : PI -> PI
++ tubePointsDefault(i) sets the number of points to use when creating
++ the circle to be used in creating a 3D tube plot to i.

tubePointsDefault : () -> PI
++ tubePointsDefault() returns the number of points to be used when
++ creating the circle to be used in creating a 3D tube plot.

tubeRadiusDefault : Float -> SF -- current tube.spad asks for SF
++ tubeRadiusDefault(r) sets the default radius for a 3D tube plot to r.

tubeRadiusDefault : () -> SF
++ tubeRadiusDefault() returns the radius used for a 3D tube plot.

====================================================================
WeierstrassPreparation examples
====================================================================

This package implements the Weierstrass preparation theorem for multivariate power series.

weierstrass(v,p) where v is a variable, and p is a TaylorSeries(R) in
which the terms of lowest degree $s$ must include $c \cdot v^s$ where $c$ is a constant, $s > 0$, is a list of TaylorSeries coefficients $A[i]$ of the equivalent polynomial

such that $p = A \cdot B$, $B$ being a TaylorSeries of minimum degree 0

)abbrev package WFFINTBS WildFunctionFieldIntegralBasis
++ Authors: Victor Miller, Clifton Williamson
++ Date Created: 24 July 1991
++ Date Last Updated: 20 September 1994
++ Description:
++ In this package K is a finite field, R is a ring of univariate
++ polynomials over K, and F is a framed algebra over R. The package
++ provides a function to compute the integral closure of R in the quotient
++ field of F as well as a function to compute a "local integral basis"
++ at a specific prime.

WildFunctionFieldIntegralBasis(K,R,UP,F): Exports == Implementation where
  K : FiniteFieldCategory
  R : UnivariatePolynomialCategory K
  UP : UnivariatePolynomialCategory R
  F : FramedAlgebra(R,UP)

I   ==> Integer
Mat ==> Matrix R
NNI ==> NonNegativeInteger
SAE ==> SimpleAlgebraicExtension
RResult ==> Record(basis: Mat, basisDen: R, basisInv:Mat)
IRResult ==> Record(basis: Mat, basisDen: R, basisInv:Mat,discr: R)
MATSTOR ==> StorageEfficientMatrixOperations

Exports == with
  integralBasis : () -> RResult
    ++ \spar{integralBasis()} returns a record
    ++ \spar{\spar{basis,\spar{basisDen,basisInv}}} containing information regarding
    ++ the integral closure of R in the quotient field of F, where
    ++ F is a framed algebra with R-module basis \spar{w1,w2,...,wn}.
    ++ If \spar{\spar{basis}} is the matrix \spar{\spar{\spar{a_{ij}, i = 1..n, j = 1..n}}}, then
    ++ the \spar{i}th element of the integral basis is
    ++ \spar{\spar{vi = (1/\spar{basisDen}) * \spar{\sum_{j = 1..n} a_{ij} * w_j}}, i.e. the
    ++ \spar{i}th row of \spar{\spar{basis}} contains the coordinates of the
    ++ \spar{i}th basis vector. Similarly, the \spar{i}th row of the
    ++ matrix \spar{\spar{basisInv}} contains the coordinates of \spar{\spar{wi}} with
    ++ respect to the basis \spar{\spar{v1,...,vn}}: if \spar{\spar{basisInv}} is the

--- ZeroDimensionalSolvePackage.help ---

====================================================================
ZeroDimensionalSolvePackage examples
====================================================================

A package for computing symbolically the complex and real roots of zero-dimensional algebraic systems over the integer or rational numbers. Complex roots are given by means of univariate representations of irreducible regular chains. Real roots are given by means of tuples of coordinates lying in the RealClosure of the coefficient ring.

This constructor takes three arguments. The first one R is the coefficient ring. The second one ls is the list of variables involved in the systems to solve. The third one must be concat(ls,s) where s is an additional symbol used for the univariate representations.

WARNING. The third argument is not checked.

All operations are based on triangular decompositions. The default is to compute these decompositions directly from the input system by using the RegularChain domain constructor.

The lexTriangular algorithm can also be used for computing these decompositions (see LexTriangularPackage package constructor).

For that purpose, the operations univariateSolve, realSolve and positiveSolve admit an optional argument.

The ZeroDimensionalSolvePackage package constructor provides operations for computing symbolically the complex or real roots of zero-dimensional algebraic systems.

The package provides no multiplicity information (i.e. some returned
roots may be double or higher) but only distinct roots are returned.

Complex roots are given by means of univariate representations of irreducible regular chains. These representations are computed by the \texttt{univariateSolve} operation (by calling the \texttt{InternalRationalUnivariateRepresentationPackage} package constructor which does the job).

Real roots are given by means of tuples of coordinates lying in the \texttt{RealClosure} of the coefficient ring. They are computed by the \texttt{realSolve} and \texttt{positiveSolve} operations. The former computes all the solutions of the input system with real coordinates whereas the later concentrate on the solutions with (strictly) positive coordinates. In both cases, the computations are performed by the \texttt{RealClosure} constructor.

Both computations of complex roots and real roots rely on triangular decompositions. These decompositions can be computed in two different ways. First, by applying the \texttt{zeroSetSplit} operation from the \texttt{REGSET} domain constructor. In that case, no Groebner bases are computed. This strategy is used by default. Secondly, by applying the \texttt{zeroSetSplit} from \texttt{LEXTRIPK}. To use this later strategy with the operations \texttt{univariateSolve}, \texttt{realSolve} and \texttt{positiveSolve} one just needs to use an extra boolean argument.

Note that the way of understanding triangular decompositions is detailed in the example of the \texttt{RegularTriangularSet} constructor.

The \texttt{ZeroDimensionalSolvePackage} constructor takes three arguments. The first one \(R\) is the coefficient ring; it must belong to the categories \texttt{OrderedRing}, \texttt{EuclideanDomain}, \texttt{CharacteristicZero} and \texttt{RealConstant}. This means essentially that \(R\) is \texttt{Integer} or \texttt{Fraction(Integer)}. The second argument \(ls\) is the list of variables involved in the systems to solve. The third one MUST BE \texttt{concat(ls,s)} where \(s\) is an additional symbol used for the univariate representations. The abbreviation for \texttt{ZeroDimensionalSolvePackage} is \texttt{ZDSOLVE}.

We illustrate now how to use the constructor \texttt{ZDSOLVE} by two examples: the Arnborg and Lazard system and the L-3 system (Aubry and Moreno Maza). Note that the use of this package is also demonstrated in the example of the \texttt{LexTriangularPackage} constructor.

Define the coefficient ring.

\begin{verbatim}
R := Integer
Integer
Type: Domain
\end{verbatim}

Define the lists of variables:

\begin{verbatim}
ls : List Symbol := [x,y,z,t]
\end{verbatim}
and:

\[
\text{ls2 : List Symbol := [x,y,z,t,new()$Symbol]}
\]

\[
[x,y,z,t,%A]
\]

Type: List Symbol

Call the package:

\[
\text{pack := ZDSOLVE(R,ls,ls2)}
\]

ZeroDimensionalSolvePackage(Integer,[x,y,z,t],[x,y,z,t,%A])

Type: Domain

Define a polynomial system (Arnborg-Lazard)

\[
p1 := x**2*y*y*z + x*y**2*z + x*y*z**2 + x*y*z + x + y*z + x**2 + y + z + x y z + (x y + (x + x + 1)y + x)z + x y
\]

Type: Polynomial Integer

\[
p2 := x**2*y**2*z + x**2*y**2*z**2 + x**2*y**2*z + x*y*z + y*z + x + z
\]

Type: Polynomial Integer

\[
p3 := x**2*y**2*z**2 + x**2*y**2*z + x*y**2*z + x*y*z + x*z + z + 1
\]

Type: Polynomial Integer

\[
lp := [p1, p2, p3]
\]

\[
[x y z + (x y + (x + x + 1)y + x)z + x y,
\]

Type: List Polynomial Integer

Note that these polynomials do not involve the variable \( t \); we will use it in the second example.

First compute a decomposition into regular chains (i.e. regular triangular sets).

\[
\text{triangSolve(lp)$pack}
\]

[ ]
We can see easily from this decomposition (consisting of a single regular chain) that the input system has 20 complex roots.

Then we compute a univariate representation of this regular chain.

```plaintext
type: List RegularChain(Integer,[x,y,z,t])
```

We can see easily from this decomposition (consisting of a single regular chain) that the input system has 20 complex roots.

Then we compute a univariate representation of this regular chain.
We see that the zeros of our regular chain are split into three components. This is due to the use of univariate polynomial factorization.

Each of these components consist of two parts. The first one is an irreducible univariate polynomial \( p(?) \) which defines a simple algebraic extension of the field of fractions of \( R \). The second one consists of multivariate polynomials \( \text{pol1}(x,?A), \text{pol2}(y,?A) \) and \( \text{pol3}(z,?A) \). Each of these polynomials involve two variables: one is an indeterminate \( x, y \) or \( z \) of the input system \( lp \) and the other is \( ?A \) which represents any root of \( p(?) \). Recall that this \( ?A \) is the last element of the third parameter of \( \text{ZDSOLVE} \). Thus any complex root \( ? \) of \( p(?) \) leads to a solution of the input system \( lp \) by replacing \( ?A \) by this \( ? \) in \( \text{pol1}(x,?A), \text{pol2}(y,?A) \) and \( \text{pol3}(z,?A) \). Note that the polynomials \( \text{pol1}(x,?A), \text{pol2}(y,?A) \) and \( \text{pol3}(z,?A) \) have degree one w.r.t. \( x, y \) or \( z \) respectively. This is always the case for all
univariate representations. Hence the operation univariateSolve replaces a system of multivariate polynomials by a list of univariate polynomials, what justifies its name. Another example of univariate representations illustrates the LexTriangularPackage package constructor.

We now compute the solutions with real coordinates:

```plaintext

\]
The number of real solutions for the input system is:

```
# lr
```
Each of these real solutions is given by a list of elements in RealClosure(R). In these 8 lists, the first element is a value of z, the second of y and the last of x. This is logical since by setting the list of variables of the package to [x,y,z,t] we mean that the elimination ordering on the variables is t < z < y < x. Note that each system treated by the ZDSOLVE package constructor needs only to be zero-dimensional w.r.t. the variables involved in the system itself and not necessarily w.r.t. all the variables used to define the package.

We can approximate these real numbers as follows. This computation takes between 30 sec. and 5 min, depending on your machine.

```plaintext
[ [approximate(r,1/1000000) for r in point] for point in lr]

We can also concentrate on the solutions with real (strictly) positive coordinates:

```plaintext
Type: List List RealClosure Fraction Integer
```

We can also concentrate on the solutions with real (strictly) positive coordinates:

```plaintext
lpr := positiveSolve(lp)$pack
[]
```

Type: List List RealClosure Fraction Integer
Thus we have checked that the input system has no solution with strictly positive coordinates.

Let us define another polynomial system (L-3).

\[
\begin{align*}
\text{lts} & := \text{triangSolve}(\text{lfs})$pack \\

f0 & := x^3 + y + z + t - 1 \\
    & \text{Type: Polynomial Integer} \\
\end{align*}
\]

\[
\begin{align*}
f1 & := x + y^3 + z + t - 1 \\
    & \text{Type: Polynomial Integer} \\
\end{align*}
\]

\[
\begin{align*}
f2 & := x + y + z^3 + t - 1 \\
    & \text{Type: Polynomial Integer} \\
\end{align*}
\]

\[
\begin{align*}
f3 & := x + y + z + t^3 - 1 \\
    & \text{Type: Polynomial Integer} \\
\end{align*}
\]

\[
\begin{align*}
lfs & := \left[ f0, f1, f2, f3 \right] \\
    & \text{Type: List Polynomial Integer} \\
\end{align*}
\]

First compute a decomposition into regular chains (i.e. regular triangular sets).

\[
\begin{align*}
lts & := \text{triangSolve}(lfs)$pack \\

\end{align*}
\]
\[\begin{align*}

The number of real solutions for the input system is:

```
#lr2
27
```

Another example of computation of real solutions illustrates the
LexTriangularPackage package constructor.

We concentrate now on the solutions with real (strictly) positive
coordinates:

\[
\begin{align*}
&lpr2 := \text{positiveSolve}(l) \text{pack} \\
&\left[\begin{array}{ccccccc}
1 & 3 & 1 & 1 & 3 & 1 & 1 \\
\%B40, & - & - & %B40 & + & - & - & %B40 & + & - & - & %B40 & + & - \\
3 & 3 & 3 & 3 & 3 & 3 & 3
\end{array}\right] \\
&\text{Type: List List RealClosure Fraction Integer}
\end{align*}
\]

Finally, we approximate the coordinates of this point with 20 exact digits:

\[
\text{[approximate}(r, 1/10**21)::\text{Float for } r \text{ in lpr2.1]}
\]
\[
\{0.32218535462608559291, 0.32218535462608559291, 0.32218535462608559291, 0.32218535462608559291\}
\]
\text{Type: List Float}

)abbrev package ZDSOLVE ZeroDimensionalSolvePackage
++ Author: Marc Moreno Maza
++ Date Created: 23/01/1999
++ Date Last Updated: 08/02/1999
++ Description:
++ A package for computing symbolically the complex and real roots of
++ zero-dimensional algebraic systems over the integer or rational
++ numbers. Complex roots are given by means of univariate representations
++ of irreducible regular chains. Real roots are given by means of tuples
++ of coordinates lying in the \spadtype{RealClosure} of the coefficient ring.
++ This constructor takes three arguments. The first one \spad{R} is the
++ coefficient ring. The second one \spad{ls} is the list of variables
++ involved in the systems to solve. The third one must be \spad{concat(ls,s)}
++ where \spad{s} is an additional symbol used for the univariate
++ representations.
++ WARNING. The third argument is not checked.
++ All operations are based on triangular decompositions.
++ The default is to compute these decompositions directly from the input
++ system by using the \spadtype{RegularChain} domain constructor.
++ The lexTriangular algorithm can also be used for computing these
++ decompositions (see \spadtype{LexTriangularPackage} package constructor).
++ For that purpose, the operations univariateSolve, realSolve and
++ positiveSolve admit an optional argument.

Exports == with
triangSolve: (LP,B,B) -> List RegularChain(R,ls)
++ \spad{triangSolve(lp,info?,lextri?)} decomposes the variety
++ associated with \axiom{lp} into regular chains.
++ Thus a point belongs to this variety iff it is a regular
++ zero of a regular set in the output.
++ Note that \axiom{lp} needs to generate a zero-dimensional ideal.
++ If \axiom{lp} is not zero-dimensional then the result is only
++ a decomposition of its zero-set in the sense of the closure
++ (w.r.t. Zarisky topology).
++ Moreover, if \axiom{info?} is \axiom{true} then some information is
++ displayed during the computations.
++ See zeroSetSplit from RegularTriangularSetCategory(lp,true,info?).
++ If \axiom{lextri?} is \axiom{true} then the lexTriangular algorithm
++ is called
++ from the \spadtype{LexTriangularPackage} constructor
++ (see zeroSetSplit from LexTriangularPackage(lp,false)).
++ Otherwise, the triangular decomposition is computed directly from
++ the input
++ system by using the zeroSetSplit from RegularChain.
triangSolve: (LP,B) -> List RegularChain(R,ls)
++ \spad{triangSolve(lp)} returns the same as
++ \spad{triangSolve(lp,false)}
triangSolve: LP -> List RegularChain(R,ls)
++ \spad{triangSolve(lp)} returns the same as
++ \spad{triangSolve(lp,false,false)}
univariateSolve: RegularChain(R,ls) -> _
++ \spad{univariateSolve(ts)} returns a univariate representation
++ of \spad{ts}.
++ See rur from RationalUnivariateRepresentationPackage(lp,true).
univariateSolve: (LP,B,B,B) -> List RUR
++ \spad{univariateSolve(lp,info?,check?,lextri?)} returns a univariate
++ representation of the variety associated with \spad{lp}.
++ Moreover, if \axiom{info?} is \axiom{true} then some information is
++ displayed during the decomposition into regular chains.
++ If \axiom{check?} is \axiom{true} then the result is checked.
++ See rur from RationalUnivariateRepresentationPackage(lp,true).
++ If \axiom{lextri?} is \axiom{true} then the lexTriangular
++ algorithm is called
++ from the \spadtype{LexTriangularPackage} constructor
++ (see zeroSetSplit from LexTriangularPackage(lp,false)).
++ Otherwise, the triangular decomposition is computed directly
++ from the input
++ system by using the zeroSetSplit from RegularChain.
univariateSolve: (LP,B,B) -> List RUR
++ \spad{univariateSolve(lp,info?,check?)} returns the same as
++ \spad{univariateSolve(lp,info?,check?,false)}.
univariateSolve: (LP,B) -> List RUR
univariateSolve: LP -> List RUR
++ \spad{univariateSolve(lp,info?)} returns the same as
++ \spad{univariateSolve(lp,info?,false,false)}.

realSolve: RegularChain(R,ls) -> List REALSOL
++ \spad{realSolve(ts)} returns the set of the points in the regular
++ zero set of \spad{ts} whose coordinates are all real.
++ The ordering of the indeterminates is reversed w.r.t. \spad{ls}.

realSolve: (LP,B,B,B) -> List REALSOL
++ \spad{realSolve(ts,info?,check?,lextri?)} returns the set of the
++ points in the variety associated with \spad{lp} whose coordinates
++ are all real.
++ Moreover, if \spad{info?} is \spad{true} then some information is
++ displayed during decomposition into regular chains.
++ If \spad{check?} is \spad{true} then the result is checked.
++ If \spad{lextri?} is \spad{true} then the lexTriangular algorithm
++ is called
++ from the \spadtype{LexTriangularPackage} constructor
++ (see zeroSetSplit from LexTriangularPackage(lp,false)).
++ Otherwise, the triangular decomposition is computed directly from
++ the input
++ system by using the zeroSetSplit from \spadtype{RegularChain}.
++ WARNING. For each set of coordinates given by
++ \spad{realSolve(ts,info?,check?,lextri?)}
++ the ordering of the indeterminates is reversed w.r.t. \spad{ls}.

realSolve: (LP,B) -> List REALSOL
++ \spad{realSolve(ts,info?,check?)} returns the same as
++ \spad{realSolve(ts,info?,check?,false)}.

realSolve: LP -> List REALSOL
++ \spad{realSolve(lp)} returns the same as
++ \spad{realSolve(ts,false,false,false)}. 

positiveSolve: RegularChain(R,ls) -> List REALSOL
++ \spad{positiveSolve(ts)} returns the points of the regular
++ set of \spad{ts} with (real) strictly positive coordinates.

positiveSolve: (LP,B,B) -> List REALSOL
++ \spad{positiveSolve(lp,info?,lextri?)} returns the set of the points
++ in the variety associated with \spad{lp} whose coordinates are
++ (real) strictly positive.
++ Moreover, if \spad{info?} is \spad{true} then some information is
++ displayed during decomposition into regular chains.
++ If \spad{lextri?} is \spad{true} then the lexTriangular
++ algorithm is called
++ from the \spadtype{LexTriangularPackage} constructor
++ (see zeroSetSplit from LexTriangularPackage(lp,false)).
++ Otherwise, the triangular decomposition is computed directly
++ from the input
++ system by using the zeroSetSplit from \spadtype{RegularChain}.
++ \textbf{WARNING}. For each set of coordinates given by
++ \spad{positiveSolve(lp,info?,lextri?)}
++ the ordering of the indeterminates is reversed \textit{w.r.t.} \spad{ls}.
positiveSolve: (LP,B) \to List REALSOL
++ \spad{positiveSolve(lp)} returns the same as
++ \spad{positiveSolve(lp,info?,false)}.
positiveSolve: LP \to List REALSOL
++ \spad{positiveSolve(lp)} returns the same as
++ \spad{positiveSolve(lp,false,false)}.
squareFree: (TS) \to List ST
++ \spad{squareFree(ts)} returns the square-free factorization
++ of \spad{ts}. Moreover, each factor is a Lazard triangular set
++ and the decomposition
++ is a Kalkbrener split of \spad{ts}, which is enough here for
++ the matter of solving zero-dimensional algebraic systems.
++ \textbf{WARNING}. \spad{ts} is not checked to be zero-dimensional.
convert: Q \to Q2
++ \spad{convert(q)} converts \spad{q}.
convert: P \to PRC
++ \spad{convert(p)} converts \spad{p}.
convert: Q2 \to PRC
++ \spad{convert(q)} converts \spad{q}.
convert: U \to URC
++ \spad{convert(u)} converts \spad{u}.
convert: ST \to List Q2
++ \spad{convert(st)} returns the members of \spad{st}.
