New Foreword

On October 1, 2001 Axiom was withdrawn from the market and ended life as a commercial product. On September 3, 2002 Axiom was released under the Modified BSD license, including this document. On August 27, 2003 Axiom was released as free and open source software available for download from the Free Software Foundation’s website, Savannah.

Work on Axiom has had the generous support of the Center for Algorithms and Interactive Scientific Computation (CAISS) at City College of New York. Special thanks go to Dr. Gilbert Baumslag for his support of the long term goal.

The online version of this documentation is roughly 1000 pages. In order to make printed versions we’ve broken it up into three volumes. The first volume is tutorial in nature. The second volume is for programmers. The third volume is reference material. We’ve also added a fourth volume for developers. All of these changes represent an experiment in print-on-demand delivery of documentation. Time will tell whether the experiment succeeded.

Axiom has been in existence for over thirty years. It is estimated to contain about three hundred man-years of research and has, as of September 3, 2003, 143 people listed in the credits. All of these people have contributed directly or indirectly to making Axiom available. Axiom is being passed to the next generation. I’m looking forward to future milestones.

With that in mind I’ve introduced the theme of the “30 year horizon”. We must invent the tools that support the Computational Mathematician working 30 years from now. How will research be done when every bit of mathematical knowledge is online and instantly available? What happens when we scale Axiom by a factor of 100, giving us 1.1 million domains? How will we integrate theory with code? How will we integrate theorems and proofs of the mathematics with space-time complexity proofs and running code? What visualization tools are needed? How do we support the conceptual structures and semantics of mathematics in effective ways? How do we support results from the sciences? How do we teach the next generation to be effective Computational Mathematicians?

The “30 year horizon” is much nearer than it appears.

Tim Daly
CAISS, City College of New York
November 10, 2003 ((iHy))
Chapter 1

Chapter Overview

This book contains the packages in Axiom, in alphabetical order.

Each package has an associated ‘dotpic’ chunk which only lists the packages, categories, and packages that are in the layer immediately below in the build order. For the full list see the algebra Makefile where this information is maintained.

Each package is preceded by a picture. The picture indicates several things. The colors indicate whether the name refers to a category, package, or package. An ellipse means that the name refers to something in the bootstrap set. Thus,

```
Category  Domain  Package  CABMON
```

Exports ==> with

rootSplit: F -> F
  ++ rootSplit(f) transforms every radical of the form
  ++ \spad{(a/b)**(1/n)} appearing in f into \spad{a**(1/n) / b**(1/n)}.
  ++ This transformation is not in general valid for all
  ++ complex numbers \spad{a} and b.
ratDenom : F -> F
  ++ ratDenom(f) rationalizes the denominators appearing in f
  ++ by moving all the algebraic quantities into the numerators.
ratDenom : (F, F) -> F
  ++ ratDenom(f, a) removes \spad{a} from the denominators in f
  ++ if \spad{a} is an algebraic kernel.
ratDenom : (F, List F) -> F
  ++ ratDenom(f, [a1,...,an]) removes the ai’s which are
  ++ algebraic kernels from the denominators in f.
ratDenom : (F, List K) -> F
  ++ ratDenom(f, [a1,...,an]) removes the ai’s which are
  ++ algebraic from the denominators in f.
ratPoly : F -> SparseUnivariatePolynomial F
  ++ ratPoly(f) returns a polynomial p such that p has no
  ++ algebraic coefficients, and \spad{p(f) = 0}.
if R has Join(OrderedSet, GcdDomain, RetractableTo Integer)
and F has FunctionSpace(R) then
  rootPower : F -> F
  ++ rootPower(f) transforms every radical power of the form
  ++ \spad{(a**(1/n))**m} into a simpler form if \spad{m} and
  ++ \spad{n} have a common factor.
rootProduct: F -> F
  ++ rootProduct(f) combines every product of the form
  ++ \spad{(a**(1/n))**m * (a**(1/s))**t} into a single power
  ++ of a root of \spad{a}, and transforms every radical power
  ++ of the form \spad{(a**(1/n))**m} into a simpler form.
rootSimp : F -> F
  ++ rootSimp(f) transforms every radical of the form
  ++ \spad{(a * b**(q*n+r))**(1/n)} appearing in f into
  ++ \spad{a**(1/n) * (a * b**r)**(1/n)}.
  ++ This transformation is not in general valid for all
  ++ complex numbers b.
rootKerSimp: (OP, F, N) -> F
  ++ rootKerSimp(op,f,n) should be local but conditional.

public ==> with

leftRank: A -> NonNegativeInteger
   ++ leftRank(x) determines the number of linearly independent elements
   ++ in \spad{x*b1},...,\spad{x*bn},
   ++ where \spad{b=[b1,...,bn]} is a basis.
rightRank: A -> NonNegativeInteger
   ++ rightRank(x) determines the number of linearly independent elements
   ++ in \spad{b1*x},...,\spad{bn*x},
   ++ where \spad{b=[b1,...,bn]} is a basis.
doubleRank: A -> NonNegativeInteger
   ++ doubleRank(x) determines the number of linearly
   ++ independent elements
   ++ in \spad{b1*x},...,\spad{x*bn},
   ++ where \spad{b=[b1,...,bn]} is a basis.
weakBiRank: A -> NonNegativeInteger
   ++ weakBiRank(x) determines the number of
   ++ linearly independent elements
   ++ in the \spad{bi*x*bj}, \spad{i,j=1,...,n},
   ++ where \spad{b=[b1,...,bn]} is a basis.
biRank: A -> NonNegativeInteger
   ++ biRank(x) determines the number of linearly independent elements
   ++ in \spad{x}, \spad{x*bi}, \spad{bi*x}, \spad{bi*x*bj},
   ++ \spad{i,j=1,...,n},
   ++ where \spad{b=[b1,...,bn]} is a basis.
   ++ Note that if \spad{A} has a unit,
   ++ then doubleRank, weakBiRank, and biRank coincide.
basisOfCommutingElements: () -> List A
   ++ basisOfCommutingElements() returns a basis of the space of
   ++ all x of \spad{A} satisfying \spad{0 = commutator(x,a)} for all
   ++ \spad{a} in \spad{A}.
basisOfLeftAnnihilator: A -> List A
   ++ basisOfLeftAnnihilator(a) returns a basis of the space of
   ++ all x of \spad{A} satisfying \spad{0 = x*a}.
basisOfRightAnnihilator: A -> List A
   ++ basisOfRightAnnihilator(a) returns a basis of the space of
   ++ all x of \spad{A} satisfying \spad{0 = a*x}.
basisOfLeftNucleus: () -> List A
   ++ basisOfRightNucleus() returns a basis of the space of
   ++ all x of \spad{A} satisfying \spad{0 = associator(x,a,b)}
   ++ for all \spad{a,b} in \spad{A}.
basisOfRightNucleus: () -> List A
   ++ basisOfRightNucleus() returns a basis of the space of
   ++ all x of \spad{A} satisfying \spad{0 = associator(a,b,x)}
   ++ for all \spad{a,b} in \spad{A}.
basisOfMiddleNucleus: () -> List A
   ++ basisOfMiddleNucleus() returns a basis of the space of
   ++ all x of \spad{A} satisfying \spad{0 = associator(a,x,b)}
++ for all \spad{a}, b in \spad{A}.

\textbf{basisOfNucleus: () -> List A}
++ basisOfNucleus() returns a basis of the space of
++ all \spad{x} of \spad{A} satisfying
++ \spad{associator(x,a,b) = associator(a,x,b) = associator(a,b,x) = 0}
++ for all \spad{a}, \spad{b} in \spad{A}.

\textbf{basisOfCenter: () -> List A}
++ basisOfCenter() returns a basis of the space of
++ all \spad{x} of \spad{A} satisfying \spad{comutator(x,a) = 0} and
++ \spad{associator(x,a,b) = associator(a,x,b) = associator(a,b,x) = 0}
++ for all \spad{a}, \spad{b} in \spad{A}.

\textbf{basisOfLeftNucloid: () -> List Matrix R}
++ basisOfLeftNucloid() returns a basis of the space of
++ endomorphisms of \spad{A} as right module.
++ Note that left nucloid coincides with left nucleus
++ if \spad{A} has a unit.

\textbf{basisOfRightNucloid: () -> List Matrix R}
++ basisOfRightNucloid() returns a basis of the space of
++ endomorphisms of \spad{A} as left module.
++ Note that right nucloid coincides with right nucleus
++ if \spad{A} has a unit.

\textbf{basisOfCentroid: () -> List Matrix R}
++ basisOfCentroid() returns a basis of the centroid, i.e. the
++ endomorphism ring of \spad{A} considered as \spad{(A,A)}-bimodule.

\textbf{radicalOfLeftTraceForm: () -> List A}
++ radicalOfLeftTraceForm() returns basis for null space of
++ \spad{leftTraceMatrix()}, if the algebra is
++ associative, alternative or a Jordan algebra, then this
++ space equals the radical (maximal nil ideal) of the algebra.

if \spad{R} has EuclideanDomain then
  \textbf{basis : V A -> V A}
  ++ basis(va) selects a basis from the elements of va.

   integrate: (EF,SOCF,F,F,RT) -> Result
++ integrate(exp, a..b, epsrel, routines) is a top level ANNA function
++ to integrate an expression, {\tt exp}, over a given range {\tt a}
++ to {\tt b} to the required absolute and relative accuracy using
++ the routines available in the RoutinesTable provided.
++
++ It iterates over the \axiom{domains} of
++ \axiomType{NumericalIntegrationCategory}
++ to get the name and other
++ relevant information of the the (domain of the) numerical
++ routine likely to be the most appropriate,
++ i.e. have the best \axiom{measure}.
++
++ It then performs the integration of the given expression
++ on that \axiom{domain}.

   integrate: NumericalIntegrationProblem -> Result
++ integrate(IntegrationProblem) is a top level ANNA function
++ to integrate an expression over a given range or ranges
++ to the required absolute and relative accuracy.
++
++ It iterates over the \axiom{domains} of
++ \axiomType{NumericalIntegrationCategory} to get the name and other
++ relevant information of the the (domain of the) numerical
++ routine likely to be the most appropriate,
++ i.e. have the best \axiom{measure}.
++
++ It then performs the integration of the given expression
++ on that \axiom{domain}.

   integrate: (EF,SOCF,F,F) -> Result
++ integrate(exp, a..b, epsabs, epsrel) is a top level ANNA function
++ to integrate an expression, {\tt exp}, over a given range {\tt a}
++ to {\tt b} to the required absolute and relative accuracy.
++
++ It iterates over the \axiom{domains} of
++ \axiomType{NumericalIntegrationCategory} to get the name and other
++ relevant information of the the (domain of the) numerical
++ routine likely to be the most appropriate,
++ i.e. have the best \axiom{measure}.
++
++ It then performs the integration of the given expression
++ on that \axiom{domain}.

\textbf{integrate: (EF,SDCF,F) -> Result}
++ integrate(exp, a..b, epsrel) is a top level ANNA
++ function to integrate an expression, \{tt exp\}, over a given
++ range \{tt a\} to \{tt b\} to the required relative accuracy.
++
++ It iterates over the \axiom{domains} of
++ \axiomType{NumericalIntegrationCategory} to get the name and other
++ relevant information of the the (domain of the) numerical
++ routine likely to be the most appropriate,
++ i.e. have the best \axiom{measure}.
++
++ It then performs the integration of the given expression
++ on that \axiom{domain}.
++
++ If epsrel = 0, a default absolute accuracy is used.

\textbf{integrate: (EF,SDCF) -> Result}
++ integrate(exp, a..b) is a top
++ level ANNA function to integrate an expression, \{tt exp\},
++ over a given range \{tt a\} to \{tt b\}.
++
++ It iterates over the \axiom{domains} of
++ \axiomType{NumericalIntegrationCategory} to get the name and other
++ relevant information of the the (domain of the) numerical
++ routine likely to be the most appropriate,
++ i.e. have the best \axiom{measure}.
++
++ It then performs the integration of the given expression
++ on that \axiom{domain}.
++
++ Default values for the absolute and relative error are used.

\textbf{integrate:(EF,LSOCF) -> Result}
++ integrate(exp, [a..b,c..d,...]) is a top
++ level ANNA function to integrate a multivariate expression, \{tt exp\},
++ over a given set of ranges.
++
++ It iterates over the \axiom{domains} of
++ \axiomType{NumericalIntegrationCategory} to get the name and other
++ relevant information of the the (domain of the) numerical
++ routine likely to be the most appropriate,
++ i.e. have the best \axiom{measure}.
++
++ It then performs the integration of the given expression
++ on that \axiom{domain}.
++
++ Default values for the absolute and relative error are used.
integrate:(EF,LSOCF,F) -> Result
++ integrate(exp, [a..b,c..d,...], epsrel) is a top
++ level ANNA function to integrate a multivariate expression, \{\tt exp\},
++ over a given set of ranges to the required relative
++ accuracy.
++
++ It iterates over the \texttt{domains} of
++ \texttt{NumericalIntegrationCategory} to get the name and other
++ relevant information of the the (domain of the) numerical
++ routine likely to be the most appropriate,
++ i.e. have the best \texttt{measure}.
++
++ It then performs the integration of the given expression
++ on that \texttt{domain}.
++
++ If epsrel = 0, a default absolute accuracy is used.

integrate:(EF,LSOCF,F,F) -> Result
++ integrate(exp, [a..b,c..d,...], epsabs, epsrel) is a top
++ level ANNA function to integrate a multivariate expression, \{\tt exp\},
++ over a given set of ranges to the required absolute and relative
++ accuracy.
++
++ It iterates over the \texttt{domains} of
++ \texttt{NumericalIntegrationCategory} to get the name and other
++ relevant information of the the (domain of the) numerical
++ routine likely to be the most appropriate,
++ i.e. have the best \texttt{measure}.
++
++ It then performs the integration of the given expression
++ on that \texttt{domain}.

integrate:(EF,LSOCF,F,F,RT) -> Result
++ integrate(exp, [a..b,c..d,...], epsabs, epsrel, routines) is a top
++ level ANNA function to integrate a multivariate expression, \{\tt exp\},
++ over a given set of ranges to the required absolute and relative
++ accuracy, using the routines available in the RoutinesTable provided.
++
++ It iterates over the \texttt{domains} of
++ \texttt{NumericalIntegrationCategory} to get the name and other
++ relevant information of the the (domain of the) numerical
++ routine likely to be the most appropriate,
++ i.e. have the best \texttt{measure}.
++
++ It then performs the integration of the given expression
++ on that \texttt{domain}.

measure:NumericalIntegrationProblem -> Measure
++ measure(prob) is a top level ANNA function for identifying the most
++ appropriate numerical routine for solving the numerical integration
++ problem defined by \axiom{prob}.
++ It calls each \axiom{domain} of \axiom{category}
++ \axiomType{NumericalIntegrationCategory} in turn to calculate all measures
++ and returns the best
++ i.e. the name of the most appropriate domain and any other relevant
++ information.

measure:(NumericalIntegrationProblem,RT) -> Measure
++ measure(prob,R) is a top level ANNA function for identifying the most
++ appropriate numerical routine from those in the routines table
++ provided for solving the numerical integration
++ problem defined by \axiom{prob}.
++ It calls each \axiom{domain} listed in \axiom{R} of \axiom{category}
++ \axiomType{NumericalIntegrationCategory} in turn to calculate all measures
++ and returns the best
++ i.e. the name of the most appropriate domain and any other relevant
++ information.

integrate:(EF,SBOCF,ST) -> Union(Result,"failed")
++ integrate(exp, x = a..b, "numerical") is a top level ANNA function to
++ integrate an expression, \{tt exp\}, over a given range, \{tt a\}
++ to \{tt b\}.
++ It iterates over the \axiom{domains} of
++ \axiomType{NumericalIntegrationCategory} to get the name and other
++ relevant information of the (domain of the) numerical
++ routine likely to be the most appropriate,
++ i.e. have the best \axiom{measure}.
++ It then performs the integration of the given expression
++ on that \axiom{domain}.
++ Default values for the absolute and relative error are used.
++ It is an error if the last argument is not \{tt "numerical"\}.

integrate:(EF,SBOCF,S) -> Union(Result,"failed")
++ integrate(exp, x = a..b, numerical) is a top level ANNA function to
++ integrate an expression, \{tt exp\}, over a given range, \{tt a\}
++ to \{tt b\}.
++ It iterates over the \axiom{domains} of
++ \axiomType{NumericalIntegrationCategory} to get the name and other
++ relevant information of the (domain of the) numerical
++ routine likely to be the most appropriate,
++ i.e. have the best \axiom{measure}.
++ It then performs the integration of the given expression
++ on that \axiom{domain}.
++ Default values for the absolute and relative error are used.
++ It is an error if the last argument is not \tt numerical.

measure: NumericalOptimizationProblem -> Measure
++ measure(prob) is a top level ANNA function for identifying the most
++ appropriate numerical routine from those in the routines table
++ provided for solving the numerical optimization problem defined by
++ \axiom{prob} by checking various attributes of the functions and
++ calculating a measure of compatibility of each routine to these
++ attributes.
++
++ It calls each \axiom{domain} of \axiom{category}
++ \axiomType{NumericalOptimizationCategory} in turn to calculate all
++ measures and returns the best i.e. the name of the most
++ appropriate domain and any other relevant information.

measure: (NumericalOptimizationProblem, RT) -> Measure
++ measure(prob, R) is a top level ANNA function for identifying the most
++ appropriate numerical routine from those in the routines table
++ provided for solving the numerical optimization problem defined by
++ \texttt{prob} by checking various attributes of the functions and
++ calculating a measure of compatibility of each routine to these
++ attributes.
++
++ It calls each \texttt{domain} listed in \texttt{Routines} of \texttt{category}
++ \texttt{NumericalOptimizationCategory} in turn to calculate all
++ measures and returns the best i.e. the name of the most
++ appropriate domain and any other relevant information.

optimize:(NumericalOptimizationProblem,RT) -> Result
++ optimize(prob,routines) is a top level ANNA function to
++ minimize a function or a set of functions with any constraints
++ as defined within \texttt{prob}.
++
++ It iterates over the \texttt{domains} listed in \texttt{routines} of
++ \texttt{NumericalOptimizationCategory}
++ to get the name and other relevant information of the best
++ \texttt{measure} and then optimize the function on that \texttt{domain}.

optimize:NumericalOptimizationProblem -> Result
++ optimize(prob) is a top level ANNA function to
++ minimize a function or a set of functions with any constraints
++ as defined within \texttt{prob}.
++
++ It iterates over the \texttt{domains} of
++ \texttt{NumericalOptimizationCategory}
++ to get the name and other relevant information of the best
++ \texttt{measure} and then optimize the function on that \texttt{domain}.

goodnessOfFit:NumericalOptimizationProblem -> Result
++ goodnessOfFit(prob) is a top level ANNA function to
++ check to goodness of fit of a least squares model
++ as defined within \texttt{prob}.
++
++ It iterates over the \texttt{domains} of
++ \texttt{NumericalOptimizationCategory}
++ to get the name and other relevant information of the best
++ \texttt{measure} and then optimize the function on that \texttt{domain}.
++ It then calls the numerical routine \texttt{E04YCF} to get estimates
++ of the variance-covariance matrix of the regression coefficients of
++ the least-squares problem.
++
++ It thus returns both the results of the optimization and the
++ variance-covariance calculation.

optimize:(EF,LF,LOCF,LEF,LOCF) -> Result
++ optimize(f,start,lower,cons,upper) is a top level ANNA function to
++ minimize a function, \texttt{f}, of one or more variables with the
++ given constraints.
++ These constraints may be simple constraints on the variables
++ in which case \texttt{cons} would be an empty list and the bounds on
++ those variables defined in \texttt{lower} and \texttt{upper}, or a
++ mixture of simple, linear and non-linear constraints, where
++ \texttt{cons} contains the linear and non-linear constraints and
++ the bounds on these are added to \texttt{upper} and \texttt{lower}.
++
++ The parameter \texttt{start} is a list of the initial guesses of the
++ values of the variables.
++
++ It iterates over the \texttt{domains} of
++ \texttt{NumericalOptimizationCategory}
++ to get the name and other relevant information of the best
++ \texttt{measure} and then optimize the function on that \texttt{domain}.

\texttt{optimize:}\langle\texttt{EF,LF,LOCF,LOCF}\rangle \to \texttt{Result}
++ \texttt{optimize(f,start,lower,upper)} is a top level ANNA function to
++ minimize a function, \texttt{f}, of one or more variables with
++ simple constraints. The bounds on
++ the variables are defined in \texttt{lower} and \texttt{upper}.
++
++ The parameter \texttt{start} is a list of the initial guesses of the
++ values of the variables.
++
++ It iterates over the \texttt{domains} of
++ \texttt{NumericalOptimizationCategory}
++ to get the name and other relevant information of the best
++ \texttt{measure} and then optimize the function on that \texttt{domain}.

\texttt{optimize:}\langle\texttt{EF,LF}\rangle \to \texttt{Result}
++ \texttt{optimize(f,start)} is a top level ANNA function to
++ minimize a function, \texttt{f}, of one or more variables without
++ constraints.
++
++ The parameter \texttt{start} is a list of the initial guesses of the
++ values of the variables.
++
++ It iterates over the \texttt{domains} of
++ \texttt{NumericalOptimizationCategory}
++ to get the name and other relevant information of the best
++ \texttt{measure} and then optimize the function on that \texttt{domain}.

\texttt{optimize:}\langle\texttt{LEF,LF}\rangle \to \texttt{Result}
++ \texttt{optimize(lf,start)} is a top level ANNA function to
++ minimize a set of functions, \texttt{lf}, of one or more variables
++ without constraints i.e. a least-squares problem.
++
++ The parameter \texttt{start} is a list of the initial guesses of the
++ values of the variables.
++
++ It iterates over the \axiom{domains} of
++ \axiomType{NumericalOptimizationCategory}
++ to get the name and other relevant information of the best
++ \axiom{measure} and then optimize the function on that \axiom{domain}.

goodnessOfFit: (LEF, LF) -> Result
++ goodnessOfFit(lf, start) is a top level ANNA function to
++ check to goodness of fit of a least squares model i.e. the minimization
++ of a set of functions, \axiom{lf}, of one or more variables without
++ constraints.
++
++ The parameter \axiom{start} is a list of the initial guesses of the
++ values of the variables.
++
++ It iterates over the \axiom{domains} of
++ \axiomType{NumericalOptimizationCategory}
++ to get the name and other relevant information of the best
++ \axiom{measure} and then optimize the function on that \axiom{domain}.
++ It then calls the numerical routine \axiomType{E04YCF} to get estimates
++ of the variance-covariance matrix of the regression coefficients of
++ the least-squares problem.
++
++ It thus returns both the results of the optimization and the
++ variance-covariance calculation.

++ goodnessOfFit(lf, start) is a top level function to iterate over
++ the \axiom{domains} of \axiomType{NumericalOptimizationCategory}
++ to get the name and other relevant information of the best
++ \axiom{measure} and then optimize the function on that \axiom{domain}.
++ It then checks the goodness of fit of the least squares model.

  solve:(NumericalODEProblem) -> Result
  ++ solve(odeProblem) is a top level ANNA function to solve numerically a
  ++ system of ordinary differential equations i.e. equations for the
  ++ derivatives y[1]'..y[n]' defined in terms of x,y[1]..y[n], together
  ++ with starting values for x and y[1]..y[n] (called the initial
  ++ conditions), a final value of x, an accuracy requirement and any
  ++ intermediate points at which the result is required.
  ++
  ++ It iterates over the \axiom{domains} of
  ++ \axiomType{OrdinaryDifferentialEquationsSolverCategory}
  ++ to get the name and other
  ++ relevant information of the the (domain of the) numerical
  ++ routine likely to be the most appropriate,
  ++ i.e. have the best \axiom{measure}.
  ++
  ++ The method used to perform the numerical
  ++ process will be one of the routines contained in the NAG numerical
  ++ Library. The function predicts the likely most effective routine
  ++ by checking various attributes of the system of ODE's and calculating
  ++ a measure of compatibility of each routine to these attributes.
  ++
  ++ It then calls the resulting 'best' routine.

  solve:(NumericalODEProblem,RT) -> Result
  ++ solve(odeProblem,R) is a top level ANNA function to solve numerically a
  ++ system of ordinary differential equations i.e. equations for the
  ++ derivatives y[1]'..y[n]' defined in terms of x,y[1]..y[n], together
  ++ with starting values for x and y[1]..y[n] (called the initial
  ++ conditions), a final value of x, an accuracy requirement and any
  ++ intermediate points at which the result is required.
  ++
  ++ It iterates over the \axiom{domains} of
  ++ \axiomType{OrdinaryDifferentialEquationsSolverCategory} contained in
  ++ the table of routines \axiom{R} to get the name and other
  ++ relevant information of the the (domain of the) numerical
  ++ routine likely to be the most appropriate,
  ++ i.e. have the best \axiom{measure}.
  ++
  ++ The method used to perform the numerical
  ++ process will be one of the routines contained in the NAG numerical
++ Library. The function predicts the likely most effective routine 
++ by checking various attributes of the system of ODE’s and calculating 
++ a measure of compatibility of each routine to these attributes. 
++ It then calls the resulting ‘best’ routine.

solve:(VEF,F,F,LF) -> Result
++ solve(f,xStart,xEnd,yInitial) is a top level ANNA function to solve 
++ numerically a system of ordinary differential equations i.e. equations 
++ for the derivatives y[1]’..y[n]’ defined in terms of x,y[1]..y[n], 
++ together with a starting value for x and y[1]..y[n] (called the initial 
++ conditions) and a final value of x. A default value 
++ is used for the accuracy requirement. 
++ It iterates over the \texttt{domains} of 
++ \texttt{OrdinaryDifferentialEquationsSolverCategory} contained in 
++ the table of routines \texttt{R} to get the name and other 
++ relevant information of the the (domain of the) numerical 
++ routine likely to be the most appropriate, 
++ i.e. have the best \texttt{measure}.

++ It then calls the resulting 'best' routine.

\hspace{1cm}
solve: (\texttt{\texttt{VEF}},\texttt{F},\texttt{F},\texttt{LF},\texttt{EF},\texttt{LF},\texttt{F}) \rightarrow \texttt{Result}
++ \texttt{solve(f,xStart,xEnd,yInitial,G,intVals,tol)} is a top level ANNA function
++ to solve numerically a system of ordinary differential 
++ equations, \texttt{\texttt{axiom}(f)}, i.e. equations for the derivatives \texttt{y[i]}'..\texttt{y[n]}' 
++ defined in terms of \texttt{x},\texttt{y[1]..y[n]} from \texttt{\texttt{axiom}(xStart)} to \texttt{\texttt{axiom}(xEnd)}
++ with the initial values for \texttt{y[i]..y[n]} (\texttt{\texttt{axiom}(yInitial)}) to a
++
tolerance $\texttt{tol}$. The values of $y[1]..y[n]$ will be output for
the values of $x$ in $\texttt{intVals}$. The calculation will stop if the
function $G(x,y[1],..,y[n])$ evaluates to zero before $x = xEnd$.

It iterates over the $\texttt{domains}$ of
$\texttt{OrdinaryDifferentialEquationsSolverCategory}$ contained in
the table of routines $\texttt{R}$ to get the name and other
relevant information of the the (domain of the) numerical
routine likely to be the most appropriate,
 i.e. have the best $\texttt{measure}$.

The method used to perform the numerical
process will be one of the routines contained in the NAG numerical
Library. The function predicts the likely most effective routine
by checking various attributes of the system of ODE's and calculating
a measure of compatibility of each routine to these attributes.

It then calls the resulting 'best' routine.

solve : (\texttt{VEF}, \texttt{F}, \texttt{F}, \texttt{LF}, \texttt{EF}, \texttt{LF}, \texttt{F}, \texttt{F}) \to \texttt{Result}

solve($f, xStart, xEnd, yInitial, G, intVals, epsabs, epsrel$) is a top level
\texttt{ANNA} function to solve numerically a system of ordinary differential
equations, $\texttt{f}$, i.e.
equations for the derivatives $y[1]'..y[n]'$ defined in terms
of $x,y[1]..y[n]$ from $\texttt{xStart}$ to $\texttt{xEnd}$ with the initial
values for $y[1]..y[n]$ ($\texttt{yInitial}$) to an absolute error
requirement $\texttt{epsabs}$ and relative error $\texttt{epsrel}$.
The values of $y[1]..y[n]$ will be output for the values of $x$ in
$\texttt{intVals}$. The calculation will stop if the function
$G(x,y[1],..,y[n])$ evaluates to zero before $x = xEnd$.

It iterates over the $\texttt{domains}$ of
$\texttt{OrdinaryDifferentialEquationsSolverCategory}$ contained in
the table of routines $\texttt{R}$ to get the name and other
relevant information of the the (domain of the) numerical
routine likely to be the most appropriate,
i.e. have the best $\texttt{measure}$.

The method used to perform the numerical
process will be one of the routines contained in the NAG numerical
Library. The function predicts the likely most effective routine
by checking various attributes of the system of ODE's and calculating
a measure of compatibility of each routine to these attributes.

It then calls the resulting 'best' routine.

measure : (\texttt{NumericalODEProblem}) \to \texttt{Measure}

measure($\texttt{prob}$) is a top level \texttt{ANNA} function for identifying the most
appropriate numerical routine from those in the routines table
provided for solving the numerical ODE
problem defined by $\texttt{prob}$. 

++
It calls each `\text{domain}` of `\text{category}` in turn to calculate all measures and returns the best i.e. the name of the most appropriate domain and any other relevant information. It predicts the likely most effective NAG numerical Library routine to solve the input set of ODEs by checking various attributes of the system of ODEs and calculating a measure of compatibility of each routine to these attributes.

\text{measure}: (\text{NumericalODEProblem,RT}) \rightarrow \text{Measure}

It predicts the likely most effective NAG numerical Library routine to solve the input set of ODEs by checking various attributes of the system of ODEs and calculating a measure of compatibility of each routine to these attributes. It calls each `\text{domain}` listed in `\text{R}` of `\text{category}` in turn to calculate all measures and returns the best i.e. the name of the most appropriate domain and any other relevant information. It predicts the likely most effective NAG numerical Library routine to solve the input set of ODEs by checking various attributes of the system of ODEs and calculating a measure of compatibility of each routine to these attributes.

   ++ ANNA function to solve numerically a system of partial differential
   ++ equations. This is defined as a list of coefficients \(\text{pde}\),
   ++ a grid \(\text{xmin}, \text{ymin}, \text{xmax}, \text{ymax}\), \(\text{ngx}, \text{ngy}\),
   ++ the boundary values \(\text{bounds}\). A default value for tolerance is used. There is also a parameter
   ++ \(\text{st}\) which should contain the value "elliptic" if the PDE is
   ++ known to be elliptic, or "unknown" if it is uncertain. This causes the
   ++ routine to check whether the PDE is elliptic.
   ++
   ++ The method used to perform the numerical
   ++ process will be one of the routines contained in the NAG numerical
   ++ Library. The function predicts the likely most effective routine
   ++ by checking various attributes of the system of PDE’s and calculating
++ a measure of compatibility of each routine to these attributes.
++ It then calls the resulting 'best' routine.
++ ** At the moment, only Second Order Elliptic Partial Differential
++ Equations are solved **

measure:(NumericalPDEProblem) -> Measure
++ measure(prob) is a top level ANNA function for identifying the most
++ appropriate numerical routine from those in the routines table
++ provided for solving the numerical PDE
++ problem defined by \texttt{axiom(prob)}.
++ It calls each \texttt{\textbackslash axiom\{domain\}} of \texttt{\textbackslash axiom\{category\}}
++ \texttt{\textbackslash axiomType\{\textbackslash axiom\{PartialDifferentialEquationsSolverCategory\}\}} in turn to
++ calculate all measures and returns the best i.e. the name of
++ the most appropriate domain and any other relevant information.
++ It predicts the likely most effective NAG numerical
++ Library routine to solve the input set of PDEs
++ by checking various attributes of the system of PDEs and calculating
++ a measure of compatibility of each routine to these attributes.

measure:(NumericalPDEProblem,RT) -> Measure
++ measure(prob,R) is a top level ANNA function for identifying the most
++ appropriate numerical routine from those in the routines table
++ provided for solving the numerical PDE
++ problem defined by \texttt{axiom(prob)}.
++ It calls each \texttt{\textbackslash axiom\{domain\}} listed in \texttt{\textbackslash axiom\{R\}} of \texttt{\textbackslash axiom\{category\}}
++ \texttt{\textbackslash axiomType\{\textbackslash axiom\{PartialDifferentialEquationsSolverCategory\}\}} in turn to
++ calculate all measures and returns the best i.e. the name of
++ the most appropriate domain and any other relevant information.
++ It predicts the likely most effective NAG numerical
++ Library routine to solve the input set of PDEs
++ by checking various attributes of the system of PDEs and calculating
++ a measure of compatibility of each routine to these attributes.

The image contains a page from a document discussing various packages in a programming language, specifically Axiom. The text includes a list of types such as `ListMultiDictionary`, `Multiset`, `NeitherSparseOrDensePowerSeries`, `OneDimensionalArray`, `Point`, `PrimitiveArray`, `RegularChain`, `RegularTriangularSet`, `Result`, `RoutinesTable`, `Set`, `SparseTable`, `SquareFreeRegularTriangularSet`, `Stream`, `String`, `StringTable`, `Table`, `U16Vector`, `U32Vector`, `U8Vector`, `Vector`, `WuWenTsunTriangularSet`. It also mentions operations like `difference`, `credits()`, and `Type: Set(Symbol)`. The document also includes a list of contributors to Axiom.
The summary command simply types out the contents of the file $AXIOM/lib/summary so no output is captured in the spool file.

====================================================================
ApplicationProgramInterface examples
====================================================================
This package contains useful functions that expose Axiom system internals.

The ApplicationProgramInterface exposes Axiom internal functions which might be useful for understanding, debugging, or creating tools.

The getDomains function takes the name of a category and returns a set of domains which inherit from that category:

\[
\text{getDomains 'Collection}
\]

\{AssociationList, Bits, CharacterClass, ComplexDoubleFloatVector, DataList, DoubleFloatVector, EqTable, FlexibleArray, GeneralPolynomialSet, GeneralSparseTable, GeneralTriangularSet, HashTable, IndexedBits, IndexedFlexibleArray, IndexedList, IndexedOneDimensionalArray, IndexedString, IndexedVector, InnerTable, KeyedAccessFile, Library, List, ListMultiDictionary, Multiset, NeitherSparseOrDensePowerSeries, OneDimensionalArray, Point, PrimitiveArray, RegularChain, RegularTriangularSet, Result, RoutinesTable, Set, SparseTable, SquareFreeRegularTriangularSet, Stream, String, StringTable, Table, U32Vector, Vector, WuWenTsunTriangularSet\}

Type: Set(Symbol)

This can be used to form the set-difference of two categories:

\[
\text{difference(getDomains 'IndexedAggregate, getDomains 'Collection)}
\]

\{DirectProduct, DirectProductMatrixModule, DirectProductModule, HomogeneousDirectProduct, OrderedDirectProduct, SplitHomogeneousDirectProduct\}

Type: Set(Symbol)

The credits function prints a list of the people who have contributed to the development of Axiom. This is equivalent to the )credits command.

The summary function prints a short list of useful console commands.

The getAncestors function takes the name of a domain or category and returns a list of categories from which it inherits.

\[
\text{getAncestors 'IndexedAggregate}
\]

\{Aggregate, BasicType, CoercibleTo, Eltable, EltableAggregate, Evalable, HomogeneousAggregate, InnerEvalable, SetCategory, Type\}

Type: Set(Symbol)

The reportInstantiations function information about what domains are instantiated by an expression. In a clean Axiom you'll see
(1) -> reportInstantiations(true)

# instantiated/# dropped/domain name
------------------------------------
1 0 Void
1 0 String
1 0 SingleInteger
1 0 PrimitiveArray(OutputForm)
1 0 OutputForm
1 0 List(OutputForm)
1 0 Integer
1 0 Character
Totals: 8 instantiated
   0 inside coerceInteractive
   0 inside canCoerceFrom
   0 inside evalMmCond
   0 reinstantiated
   0 dropped
   8 distinct domains instantiated/dropped

Which shows that 8 domains were instantiated.
If a new domain is requested, more will be instantiated.

(2) -> 1

(2) 1

# instantiated/# dropped/domain name
------------------------------------
1 0 PositiveInteger
1 0 NonNegativeInteger
Totals: 2 instantiated
   0 inside coerceInteractive
   0 inside canCoerceFrom
   0 inside evalMmCond
   0 reinstantiated
   0 dropped
   2 distinct domains instantiated/dropped

However, this happens only once. Invoking already instantiated
domains does nothing since they already exist.

(3) -> 1

(3) 1

# instantiated/# dropped/domain name
------------------------------------
Totals: 0 instantiated
   0 inside coerceInteractive
0 inside canCoerceFrom
0 inside evalMmCond
0 reinstantiated
0 dropped
0 distinct domains instantiated/dropped

We call the function with false to turn off this information.

(4) -> reportInstantiations(false)

Type: Void

package AXSERV AxiomServer

— AxiomServer.input —

)set break resume
)sys rm -f AxiomServer.output
)spool AxiomServer.output
)set message test on
This package provides functions to support a web server for the new Axiom Browser functions.

See Also:
- )show AxiomServer

Exports:
- multiServ
- axServer
- getDatabase
The axServer function handles the socket connection on the given port. When it gets a input on the socket it calls the server function on the socket input.

— package AXSERV AxiomServer —

axServer(port:Integer,serverfunc:SExpression->Void):Void ==
  WriteLine$Lisp "$listening on port 8085"
  s := SiSock(port,serverfunc)$ Lisp
  -- To listen for just one connection and then close the socket
  -- uncomment i := 0.
The multiServ function parses the socket input. It expects either a GET or POST request. A GET request fetches a new page, calling “getFile”. A POST request starts with

- “command=” which expects axiom interpreter commands. When this is recognized we call the “getCommand” function.
- “lispcall=” which expects lisp interpreter input. When this is recognized we call the “getLisp” function.

---

--- package AXSERV AxiomServer ---

   page:=page "<p>" msg "</p></body></html>
   -- WriteLine(page)$Lisp
   page

---

getDescription

We need to fish around in the data structure to return the piece of documentation for the domain. We have to call the lisp version of GETDATABASE because the version above returns a string object. The string object is missing quotes and cannot be properly read. So we need to get the lisp object and work with it in native form first.
The doc string also contains spad markup which we need to replace with html.

    — package AXSERV AxiomServer —

getDescription(dom:String):String ==
   d:=CADR(CADAR(GETDATABASE(INTERN(dom)$Lisp,'DOCUMENTATION)$Lisp)$Lisp)$Lisp
   string d

---

ggetSourceFile

During build we construct a hash table that takes the chunk name as the key and returns the filename. We reconstruct the chunk name here and do a lookup for the source file.

    — package AXSERV AxiomServer —

getSourceFile(constructorkind:String,_
    abbreviation:String,_

page = "</tr>
page = "</table>
```

```
```
readTheFile

We have q which is a stream which contains the file. We read the file into a string-stream to get it all into one string. We return the string.

    — package AXSERV AxiomServer —

    readTheFile(q:SExpression):String ==
      r := MAKE_-STRING_-OUTPUT_-STREAM()
      SiCopyStream(q,r)
      filestream:String := GET_-OUTPUT_-STREAM_-STRING(r)
      CLOSE(r)
      CLOSE(q)
      filestream

outputToSocket

We have “s” which is the socket, “filestream” which is the text of the file to output, and “contentType” which is the HTML Content-Type. We construct the HTML header information according to the standard and prepend it to the file. The resulting string is output to the socket.

    — package AXSERV AxiomServer —

    outputToSocket(s:SExpression,filestream:String,contentType:String):Void ==
      filelength:String := string(#filestream)
      file:String := ""
      nl:STRING(NewLine$Lisp)
      file := concat ["Content-Length: ",filelength,nl,nl,file]
      file := concat ["Connection: close",nl,file]
      file := concat ["Content-Type: ",contentType,nl,file]
      file := concat ["HTTP/1.1 200 OK",nl,file]
      file := concat [file,filestream]
      f:=MAKE_-STRING_-INPUT_-STREAM(file)$Lisp
      SiCopyStream(f,s)$Lisp
      CLOSE(f)$Lisp
      CLOSE(s)$Lisp
getCommand

The getCommand function is invoked when the HTTP request is a POST and contains the string "command". Essentially the game here is to rebind the various output streams used by Axiom so we can capture the normal output. This function returns a set of HTML 5 div blocks:

1. stepnum, the value of lastStep()
2. command, the value of the command variable
3. algebra, the value of the algebra variable
4. mathml, the value of the mathml variable
5. type, the value of lastType()

The HTML functions in the hyperdoc browser depend on the order of these variables so do not change this without changing the corresponding functions in the browser HTML.

```lisp
package AXSERV AxiomServer

lastType
To examine the $internalHistoryTable use the following line

)lisp |$internalHistoryTable|

We need to pick out first member of internalHistoryTable and then pick out the element
with % as first element. Here is an example showing just the first element of the list, which
corresponds to the last command.

Note that the last command does not necessarily correspond to the last element of the first
element of $internalHistoryTable as it is in this example.
We also need to check for input error in which case the $internalHistoryTable is not changed and the type retrieved would be that for the last correct input.

---

)abbrev package BALFACT BalancedFactorisation
++ Author: Manuel Bronstein
++ Date Created: 1 March 1991
++ Date Last Updated: 11 October 1991
++ Description:
++ This package provides balanced factorisations of polynomials.

BalancedFactorisation(R, UP): Exports == Implementation where
R : Join(GcdDomain, CharacteristicZero)
UP : UnivariatePolynomialCategory R

Exports ==> with
balancedFactorisation: (UP, UP) -> Factored UP
++ balancedFactorisation(a, b) returns
++ a factorisation \spad{a = p1^e1 ... pm^em} such that each
++ \spad{pi} is balanced with respect to b.
balancedFactorisation: (UP, List UP) -> Factored UP
++ balancedFactorisation(a, [b1,...,bn]) returns
++ a factorisation \spad{a = p1^e1 ... pm^em} such that each
++ pi is balanced with respect to \spad{[b1,...,bn]}.

Implementation ==> add
balSqr : (UP, Integer, List UP) -> Factored UP
balSqfr1: (UP, Integer, UP) -> Factored UP

balancedFactorisation(a:UP, b:UP) == balancedFactorisation(a, [b])

balSqfr1(a, n, b) ==
g := gcd(a, b)
fa := sqfrFactor((a exquo g)::UP, n)
ground? g => fa
fa * balSqfr1(g, n, (b exquo (g ** order(b, g))::UP))

balSqfr(a, n, l) ==
b := first l
empty? rest l => balSqfr1(a, n, b)
*/[balSqfr1(f.factor, n, b) for f in factors balSqfr(a,n,rest l)]

balancedFactorisation(a:UP, l:List UP) ==

This package exports functions to set some commonly used properties of operators, including properties which contain functions.

See Also:
  o )show BasicOperatorFunctions1
++ Description:
++ This package exports functions to set some commonly used properties
++ of operators, including properties which contain functions.

BasicOperatorFunctions1(A:SetCategory): Exports == Implementation where
OP ==> BasicOperator
EVAL ==> "%eval"
CONST ==> "%constant"
DIFF ==> "%diff"
OUT ==> OutputForm
IN ==> InputForm

Exports ==> with
  evaluate : (OP, List A) -> Union(A, "failed")
  ++ evaluate(op, [a1,...,an]) checks if op has an "%eval"
  ++ property f. If it has, then \spad{f(a1,...,an)} is returned, and
  ++ "failed" otherwise.
  evaluate : (OP, List A -> A) -> OP
  ++ evaluate(op, foo) attaches foo as the "%eval" property
  ++ of op. If op has an "%eval" property f, then applying op
  ++ to \spad{(a1,...,an)} returns the result of \spad{f(a1,...,an)}.
  evaluate : (OP, A -> A) -> OP
  ++ evaluate(op, foo) attaches foo as the "%eval" property
  ++ of op. If op has an "%eval" property f, then applying op
  ++ to a returns the result of \spad{f(a)}. Argument op must be unary.
  evaluate : OP -> Union(List A -> A, "failed")
  ++ evaluate(op) returns the value of the "%eval" property of
  ++ op if it has one, and "failed" otherwise.
  derivative : (OP, List (List A -> A)) -> OP
  ++ derivative(op, [foo1,...,foon]) attaches [foo1,...,foon] as
  ++ the "%diff" property of op. If op has an "%diff" property
  ++ \spad{f1,...,fn)} then applying a derivation D
  ++ to \spad{op(a1,...,an)}
  ++ returns \spad{f1(a1,...,an) * D(a1) + ... + fn(a1,...,an) * D(an)}.
  derivative : (OP, A -> A) -> OP
  ++ derivative(op, foo) attaches foo as the "%diff" property
  ++ of op. If op has an "%diff" property f, then applying a
  ++ derivation D to op(a) returns \spad{f(a) * D(a)}.
  ++ Argument op must be unary.
  derivative : OP -> Union(List(List A -> A), "failed")
  ++ derivative(op) returns the value of the "%diff" property of
  ++ op if it has one, and "failed" otherwise.
if A has OrderedSet then
  constantOperator: A -> OP
  ++ constantOperator(a) returns a nullary operator op
  ++ such that \spad{op()} always evaluate to \spad{a}.
  constantOpIfCan : OP -> Union(A, "failed")
  ++ constantOpIfCan(op) returns \spad{a} if op is the constant
  ++ nullary operator always returning \spad{a}, "failed" otherwise.

BezoutMatrix contains functions for computing resultants and discriminants using Bezout matrices.
A linear Bezier curve is a simple interpolation between the starting point and the ending point based on a parameter t.

Given a start point $a=[x_1,y_1]$ and an endpoint $b=[x_2,y_2]$
\[
f(t) = [(1-t)x_1 + tx_2, (1-t)y_1 + ty_2]
\]
\[
n:=\text{linearBezier}([2.0,2.0],[4.0,4.0])
\]
\[
\text{theMap(BEZIER;linearBezier;2LM;110,707)}
\]
\[
[n(t/10.0) \text{ for } t \text{ in } 0..10 \text{ by } 1]
\]
\[
[[2.0,2.0], [2.2,2.2], [2.4,2.4], [2.6,2.6], [2.8,2.8], [3.0,3.0], [3.2,3.2], [3.4,3.4], [3.6,3.6], [3.8,3.8], [4.0,4.0]]
\]

A quadratic Bezier curve is a simple interpolation between the starting point, a middle point, and the ending point based on a parameter t.

Given a start point $a=[x_1,y_1]$, a middle point $b=[x_2,y_2]$, and an endpoint $c=[x_3,y_3]$
\[
f(t) = [(1-t)^2 x_1 + 2t(1-t) x_2 + t^2 x_3, (1-t)^2 y_1 + 2t(1-t) y_2 + t^2 y_3]
\]
\[
n:=\text{quadraticBezier}([2.0,2.0],[4.0,4.0],[6.0,2.0])
\]
\[
\text{theMap(BEZIER;quadraticBezier;3LM;210,291)}
\]
\[
[n(t/10.0) \text{ for } t \text{ in } 0..10 \text{ by } 1]
\]
\[
[[2.0,2.0], [2.4,2.36], [2.8,2.64], [3.2,2.84], [3.6,2.96], [4.0,3.0], [4.4,2.96], [4.8,2.84], [5.2,2.64], [5.6,2.36], [6.0,2.0]]
\]

A cubic Bezier curve is a simple interpolation between the starting point, a left-middle point, a right-middle point, and the ending point based on a parameter t.

Given a start point $a=[x_1,y_1]$, the left-middle point $b=[x_2,y_2]$, the right-middle point $c=[x_3,y_3]$ and an endpoint $d=[x_4,y_4]$
\[
f(t) = [(1-t)^3 x_1 + 3t(1-t)^2 x_2 + 3t^2 (1-t) x_3 + t^3 x_4, (1-t)^3 y_1 + 3t(1-t)^2 y_2 + 3t^2 (1-t) y_3 + t^3 y_4]
\]
\[
n:=\text{cubicBezier}([2.0,2.0],[2.0,4.0],[6.0,4.0],[6.0,2.0])
\]
\[
\text{theMap(BEZIER;cubicBezier;4LM;310,915)}
\]
\[
[n(t/10.0) \text{ for } t \text{ in } 0..10 \text{ by } 1]
\]
\[
[[2.0,2.0], [2.112,2.54], [2.416,2.96], [2.816,3.26], [3.408,3.44], [4.0,3.5], [4.592,3.44], [5.136,3.26], [5.584,2.96], [5.888,2.54], [6.0,2.0]]
\]

Bezier curves "move" based on moving their control points, which
in the case of the three components of a quadratic Bezier curve are the three points given. To see this motion we can show what happens when you "drag" the middle control point along the line from \([-4,4]\) to \([4,4]\) by increments of 1.

First, we form the line as a list of Floats, 9 in all.

\[
\text{line:}=[\{i::\text{Float}, 4.0\} \text{ for } i \in \{\ldots -4 \ldots 4\} \text{ by } 1]
\]

Next, we form a list of functions, each with a different center control point. Notice that the endpoints remain fixed so we expect that the curve will begin and end at the same point but that the midpoint is pulled around.

\[
\text{functions:}=[\text{quadraticBezier}(\{2.0,2.0\}, m, \{6.0,2.0\}) \text{ for } m \in \text{line}]
\]

Then we form a list of the graphs by calling each function in the above list. Each function call happens 101 times (to include both endpoints). Thus we get a List of Lists of Points of DoubleFloats

\[
\text{graphs:}=[\{\text{point}\left(\left(\left(\text{functions}.i\right)(j/100.0)\right):\text{LIST}(\text{DFLOAT})\right)\}_j\text{ for } j \in \{0 \ldots 100\} \text{ for } i \in \{1 \ldots 9\}]
\]

We draw the first graph to see if it looks reasonable:

\[
\text{d1:=draw(graphs}.1)
\]

Since it does we add the other 8 graphs. The 2D graphs can hold up to 9 simultaneous graphs.

\[
\text{others:=}=[\text{graphs}.i \text{ for } i \in \{2 \ldots 9\}]
\] for \(i \in \{2 \ldots 9\}\) for graph in others repeat putGraph(d1, [graph], i)

and now we display them all on one graph.

\[
\text{vp:=makeViewport2D(d1)}
\]

BoundIntegerRoots (BOUNDZRO)

Exports:
  integerBound

---

package BOUNDZRO BoundIntegerRoots ---
)abbrev package BOUNDZRO BoundIntegerRoots
++ Author: Manuel Bronstein
++ Date Created: 11 March 1991
++ Date Last Updated: 18 November 1991
++ Description:
++ \spadtype{BoundIntegerRoots} provides functions to
++ find lower bounds on the integer roots of a polynomial.

BoundIntegerRoots(F, UP): Exports == Implementation where
  F : Join(Field, RetractableTo Fraction Integer)
  UP : UnivariatePolynomialCategory F
  Z ==> Integer
  Q ==> Fraction Z
  K ==> Kernel F
  UPQ ==> SparseUnivariatePolynomial Q
  ALGOP ==> "%alg"

Exports ==> with
  integerBound: UP -> Z
  ++ integerBound(p) returns a lower bound on the negative integer
  ++ roots of p, and 0 if p has no negative integer roots.

Implementation ==> add
  import RationalFactorize(UPQ)
  import UnivariatePolynomialCategoryFunctions2(F, UP, Q, UPQ)

  qbound : (UP, UPQ) -> Z
  zroot1 : UP -> Z
  qzroot1: UPQ -> Z
  negint : Q -> Z

-- returns 0 if p has no integer root < 0, its negative integer root otherwise
qzroot1 p == negint(- leadingCoefficient(reductum p) / leadingCoefficient p)

-- returns 0 if p has no integer root < 0, its negative integer root otherwise
zroot1 p ==
  z := - leadingCoefficient(reductum p) / leadingCoefficient p
  (r := retractIfCan(z)@Union(Q, "failed"); case Q => negint(r::Q)) 0

-- returns 0 if r is not a negative integer, r otherwise
negint r ==
  (u := retractIfCan(r)@Union(Z, "failed"); case Z) and (u::Z < 0) => u::Z 0

if F has ExpressionSpace then
  bringDown: F -> Q

-- the random substitution used by bringDown is NOT always a ring-homorphism
-- (because of potential algebraic kernels), but is ALWAYS a Z-linear map.
-- this guarantees that bringing down the coefficients of \((x + n) q(x)\) for an
-- integer \(n\) yields a polynomial \(h(x)\) which is divisible by \(x + n\)
-- the only problem is that evaluating with random numbers can cause a
-- division by 0. We should really be able to trap this error later and
-- reevaluate with a new set of random numbers  MB 11/91

\[
\text{bringDown } f ==
\t t := \text{tower } f
\text{ retract eval}(f, t, [\text{random()}$\mathbb{Q}$ :: \(F\) for \(k\) in \(t\)])
\]

\[
\text{integerBound } p ==
\quad \text{one? degree } p \Rightarrow z\text{root1 } p
\quad (\text{degree } p) = 1 \Rightarrow z\text{root1 } p
\quad q1 := \text{map(bringDown, } p)
\quad q2 := \text{map(bringDown, } p)
\quad q\text{bound}(p, \gcd(q1, q2))
\]

\[
\text{else integerBound } p ==
\quad \text{one? degree } p \Rightarrow z\text{root1 } p
\quad (\text{degree } p) = 1 \Rightarrow z\text{root1 } p
\quad q\text{bound}(p, \text{map}((z1:F)\!::\!\mathbb{Q} \mapsto \text{retract}(z1)@\mathbb{Q}, p))
\]

-- we can probably do better here (i.e. without factoring)
\[
q\text{bound}(p, q) ==
\quad \text{bound:} \mathbb{Z} := 0
\quad \text{for rec in factors factor } q \text{ repeat}
\quad \quad \text{if one??(degree(rec.factor)) and ((r := qz\text{root1}(rec.factor)) < bound)
\quad \quad \quad \text{if ((degree(rec.factor)) = 1) and ((r := qz\text{root1}(rec.factor)) < bound)
\quad \quad \quad \quad \text{and zero? p(r::\mathbb{Q}::F) then bound := r)
\quad bound}

— CombinatorialFunction.help —

====================================================================
CombinatorialFunction examples
====================================================================

Provides combinatorial functions over an integral domain.

\( f := \text{operator 'f} \)

(1) \( f \)

\( \text{Type: BasicOperator} \)

\( D(\text{product}(f(i,x),i=1..m),x) \)

\( \begin{array}{c}
\mbox{m} \\
\mbox{m} \\
\end{array} \)
\( \begin{array}{c}
f(i,x) \\
\mbox{---+} \\
\mbox{++-+} \\
\end{array} \)
\( \mbox{,2} \)

(2) \( \begin{array}{c}
\mbox{f(i,x)>} \\
\mbox{---+} \\
i=1 \\
i=1 \\
\end{array} \)

\( \text{Type: Expression Integer} \)

The binomial\( (n, r) \) returns the number of subsets of \( r \) objects taken among \( n \) objects, i.e. \( n!/(r! \cdot (n-r)! \)

The binomial coefficients are the coefficients of the series expansion of a power of a binomial, that is

\( \begin{array}{c}
n \\
---+ \\
\mbox{n} \\
\mbox{/ n \ \ k} \\

> \mbox{x} = (1 + x) \\
---+ \\
\mbox{\ k /} \\
\mbox{k= 0} \\
\end{array} \)
This leads to the famous pascal triangle. First we expose the OutputForm domain, which is normally hidden, so we can use it to format the lines.

)set expose add constructor OutputForm

Next we define a function that will output the list of binomial coefficients right justified with proper spacing:

\[
pascalRow(n) == \text{[right(binomial(n,i),4) for i in 0..n]}
\]

and now we format the whole line so that it looks centered:

\[
displayRow(n) == \text{output center blankSeparate pascalRow(n)}
\]

and we compute the triangle

\[
\text{for i in 0..7 repeat displayRow i}
\]

giving the pretty result:

```
Compiling function pascalRow with type NonNegativeInteger -> List OutputForm
Compiling function displayRow with type NonNegativeInteger -> Void

1
  1
  1 2 1
  1 3 3 1
  1 4 6 4 1
  1 5 10 10 5 1
  1 6 15 20 15 6 1
  1 7 21 35 35 21 7 1
```

binomial

We currently simplify binomial coefficients only for non-negative integral second argument, using the formula
\[
\binom{n}{k} = \frac{1}{k!} \prod_{i=0}^{k-1} (n - i),
\]
except if the second argument is symbolic: in this case \(\binom{n}{n}\) is simplified to one.

Note that there are at least two different ways to define binomial coefficients for negative integral second argument. One way, particular suitable for combinatorics, is to set the binomial coefficient equal to zero for negative second argument. This is, partially, also the approach taken in combinat.spad, where we find

\[
\text{binomial}(n, m) ==
\begin{align*}
& n < 0 \text{ or } m < 0 \text{ or } m > n \Rightarrow 0 \\
& m = 0 \Rightarrow 1
\end{align*}
\]

Of course, here \(n\) and \(m\) are integers. This definition agrees with the recurrence
\[
\binom{n}{k} + \binom{n}{k+1} = \binom{n+1}{k+1}.
\]

Alternatively, one can use the formula
\[
\binom{n}{k} = \frac{\Gamma(n+1)}{\Gamma(k+1)\Gamma(n-k+1)}.
\]
and leave the case where \(k \in \mathbb{Z}, n \in \mathbb{Z}\) and \(k \leq n < 0\) undefined, since the limit does not exist in this case:

Since we then have that \(n - k + 1 \geq 1\), \(\Gamma(n - k + 1)\) is finite. So it is sufficient to consider \(\frac{\Gamma(n + 1)}{\Gamma(k + 1)}\). On the one hand, we have

\[
\lim_{n_0 \to n} \lim_{k_0 \to k} \frac{\Gamma(n_0 + 1)}{\Gamma(k_0 + 1)} = 0,
\]

since for any non-integral \(n_0\), \(\Gamma(n_0 + 1)\) is finite. On the other hand,

\[
\lim_{k_0 \to k} \lim_{n_0 \to n} \frac{\Gamma(n_0 + 1)}{\Gamma(k_0 + 1)}
\]

does not exist, since for non-integral \(k_0\), \(\Gamma(k_0 + 1)\) is finite while \(\Gamma(n_0 + 1)\) is unbounded.

However, since for \(k \in \mathbb{Z}, n \in \mathbb{Z}\) and \(0 < k < n\) both definitions agree, one could also combine them. This is what, for example, Mathematica does. It seems that MuPAD sets \(\text{binomial}(n,n)=1\) for all arguments \(n\), and returns \(\text{binomial}(-2, n)\) unevaluated. Provisos may help here.

dvsum and dvdsum

The dvsum and dvdsum operations implement differentiation of sums with and without bounds. Note that the function

\[
n \mapsto \sum_{k=1}^{n} f(k,n)
\]

is well defined only for integral values of \(n\) greater than or equal to zero. There is not even consensus how to define this function for \(n < 0\). Thus, it is not differentiable. Therefore, we need to check whether we erroneously are differentiating with respect to the upper bound or the lower bound, where the same reasoning holds.

Differentiating a sum with respect to its indexing variable correctly gives zero. This is due to the introduction of dummy variables in the internal representation of a sum: the operator \%defsum\ takes 5 arguments, namely

1. the summands, where each occurrence of the indexing variable is replaced by
2. the dummy variable,
3. the indexing variable,
4. the lower bound, and
5. the upper bound.
The dvprod and dvdprod operations implement differentiation of products with and without bounds. Note again, that we cannot even properly define products with bounds that are not integral.

To differentiate the product, we use Leibniz rule:

\[
\frac{d}{dx} \prod_{i=a}^{b} f(i, x) = \sum_{i=a}^{b} \frac{d}{dx} f(i, x) \prod_{i=a}^{b} f(i, x)
\]

There is one situation where this definition might produce wrong results, namely when the product is zero, but axiom failed to recognize it: in this case,

\[
\frac{d}{dx} f(i, x) / f(i, x)
\]

is undefined for some \(i\). However, I was not able to come up with an example. The alternative definition

\[
\frac{d}{dx} \prod_{i=a}^{b} f(i, x) = \sum_{i=a}^{b} \left( \frac{d}{dx} f(i, x) \right) \prod_{j=a, j \neq i}^{b} f(j, x)
\]

has the slight (display) problem that we would have to come up with a new index variable, which looks very ugly. Furthermore, it seems to me that more simplifications will occur with the first definition.

\[f := \text{operator 'f}
\]
\[D(\text{product}(f(i, x), i=1..m), x)\]

The dvpow2 operation implements the differentiation of the power operator \(\%\text{power}\) with respect to its second argument, i.e., the exponent. It uses the formula

\[
\frac{d}{dx} g(y)^x = \frac{d}{dx} e^{x \log g(y)} = \log g(y) g(y)^x.
\]

If \(g(y)\) equals zero, this formula is not valid, since the logarithm is not defined there. Although strictly speaking \(0^x\) is not differentiable at zero, we return zero for convenience.

— package CDEN CommonDenominator —

)abbrev package CDEN CommonDenominator
++ Author: Manuel Bronstein
++ Date Created: 2 May 1988
++ Date Last Updated: 22 Nov 1989
++ Description:
++ CommonDenominator provides functions to compute the
++ common denominator of a finite linear aggregate of elements of
++ the quotient field of an integral domain.

CommonDenominator(R, Q, A):Exports == Implementation where
  R: IntegralDomain
  Q: QuotientFieldCategory R
  A: FiniteLinearAggregate Q

Exports ==> with
  commonDenominator: A -> R
    ++ commonDenominator([q1,...,qn]) returns a common denominator
    ++ d for q1,...,qn.
  clearDenominator : A -> A
    ++ clearDenominator([q1,...,qn]) returns \spad{[p1,...,pn]} such that
    ++ \spad{qi = pi/d} where d is a common denominator for the qi’s.
  splitDenominator : A -> Record(num: A, den: R)
    ++ splitDenominator([q1,...,qn]) returns
    ++ \spad{[[p1,...,pn], d]} such that
    ++ \spad{qi = pi/d} and d is a common denominator for the qi’s.

Implementation ==> add
  clearDenominator l ==
    d := commonDenominator l
    map(x+->numer(d*x)::Q, l)
splitDenominator l ==
    d := commonDenominator l
    [map(x+->numer(d*x)::Q, l), d]

if R has GcdDomain then
    qlcm: (Q, Q) -> Q
    qlcm(a, b) == lcm(numer a, numer b)::Q
    commonDenominator l == numer reduce(qlcm, map(x+->denom(x)::Q, l), 1)
else
    commonDenominator l == numer reduce("*", map(x+->denom(x)::Q, l), 1)

package CRFP ComplexRootFindingPackage

"CPMATCH"
"COMPCAT"
"CPMATCH" -> "COMPCAT"
ComplexRootFindingPackage provides functions to find all roots of a polynomial \( p \) over the complex number by using Plesken's idea to calculate in the polynomial ring modulo \( f \) and employing the Chinese Remainder Theorem.

In this first version, the precision (see digits) is not increased when this is necessary to avoid rounding errors. Hence it is the user's responsibility to increase the precision if necessary.

Note also, if this package is called with e.g. Fraction Integer, the precise calculations could require a lot of time.

Also note that evaluating the zeros is not necessarily a good check whether the result is correct: already evaluation can cause rounding errors.

OF ==> OutputForm
ICF ==> IntegerCombinatoricFunctions(I)

public ==> with
complexZeros : UP -> L C
++ complexZeros(p) tries to determine all complex zeros
++ of the polynomial p with accuracy given by the package
++ constant globalEps which you may change by setErrorBound.
complexZeros : (UP, R) -> L C
++ complexZeros(p, eps) tries to determine all complex zeros
++ of the polynomial p with accuracy given by eps.
divisorCascade : (UP,UP, Boolean) -> L FAE
++ divisorCascade(p,tp) assumes that degree of polynomial tp
++ is smaller than degree of polynomial p, both monic.
++ A sequence of divisions are calculated
++ using the remainder, made monic, as divisor
++ for the the next division. The result contains also the error of the
++ factorizations, i.e. the norm of the remainder polynomial.
++ If info is true, then information messages are issued.
divisorCascade : (UP,UP) -> L FAE
++ divisorCascade(p,tp) assumes that degree of polynomial tp
++ is smaller than degree of polynomial p, both monic.
++ A sequence of divisions is calculated
++ using the remainder, made monic, as divisor
++ for the the next division. The result contains also the error of the
++ factorizations, i.e. the norm of the remainder polynomial.
factor: (UP,R,Boolean) -> FR UP
++ factor(p, eps, info) tries to factor p into linear factors
++ with error atmost eps. An overall error bound
++ eps0 is determined and iterated tree-like calls
++ to pleskenSplit are used to get the factorization.
++ If info is true, then information messages are given.
factor: (UP,R) -> FR UP
++ factor(p, eps) tries to factor p into linear factors
++ with error atmost eps. An overall error bound
++ eps0 is determined and iterated tree-like calls
++ to pleskenSplit are used to get the factorization.
factor: UP -> FR UP
++ factor(p) tries to factor p into linear factors
++ with error atmost globalEps, the internal error bound,
++ which can be set by setErrorBound. An overall error bound
++ eps0 is determined and iterated tree-like calls
++ to pleskenSplit are used to get the factorization.
graeffe : UP -> UP
++ graeffe p determines q such that \spad{q(-z**2) = p(z)*p(-z)}.
++ Note that the roots of q are the squares of the roots of p.
norm : UP -> R
++ norm(p) determines sum of absolute values of coefficients
++ Note that this function depends on abs.
pleskenSplit: (UP, R, Boolean) -> FR UP
++ pleskenSplit(poly,eps,info) determines a start polynomial start
++ by using "startPolynomial then it increases the exponent
++ n of start ** n mod poly to get an approximate factor of
++ poly, in general of degree "degree poly -1". Then a divisor
++ cascade is calculated and the best splitting is chosen, as soon
++ as the error is small enough.
---++ In a later version we plan
---++ to use the whole information to get a split into more than 2
---++ factors.
++ If info is true, then information messages are issued.
pleskenSplit: (UP, R) -> FR UP
++ pleskenSplit(poly, eps) determines a start polynomial start
++ by using "startPolynomial then it increases the exponent
++ n of start ** n mod poly to get an approximate factor of
++ poly, in general of degree "degree poly -1". Then a divisor
++ cascade is calculated and the best splitting is chosen, as soon
++ as the error is small enough.
---++ In a later version we plan
---++ to use the whole information to get a split into more than 2
---++ factors.
reciprocalPolynomial: UP -> UP
++ reciprocalPolynomial(p) calculates a polynomial which has exactly
++ the inverses of the non-zero roots of p as roots, and the same
++ number of 0-roots.
rootRadius: (UP,R) -> R
++ rootRadius(p,errQuot) calculates the root radius of p with a
++ maximal error quotient of errQuot.
rootRadius: UP -> R
++ rootRadius(p) calculates the root radius of p with a
++ maximal error quotient of 1+globalEps, where
++ globalEps is the internal error bound, which can be
++ set by setErrorBound.
schwerpunkt: UP -> C
++ schwerpunkt(p) determines the 'Schwerpunkt' of the roots of the
++ polynomial p of degree n, i.e. the center of gravity, which is
++ coefficient of \spad{x**(n-1)} divided by
++ n times coefficient of \spad{x**n}.
setErrorBound : R -> R
++ setErrorBound(eps) changes the internal error bound,
-- by default being 10 ** (-20) to eps, if R is
++ by default being 10 ** (-3) to eps, if R is
++ a member in the category \spadtype{QuotientFieldCategory Integer}.
++ The internal globalDigits is set to
++ \em ceiling(1/r)**2*10 being 10**7 by default.
startPolynomial: UP -> Record(start: UP, factors: FR UP)
++ startPolynomial(p) uses the ideas of Schoenhage's
++ variant of Graeffe's method to construct circles which separate
++ roots to get a good start polynomial, i.e. one whose
++ image under the Chinese Remainder Isomorphism has both entries
++ of norm smaller and greater or equal to 1. In case the
++ roots are found during internal calculations.
++ The corresponding factors
++ are in factors which are otherwise 1.

++ coordinates: the function produced will map the point \(r, \theta\)
++ to \((r * \cos(\theta)), (r * \sin(\theta))\).
cylindrical: Pt -> Pt
++ cylindrical(pt) transforms pt from polar coordinates to Cartesian
++ coordinates: the function produced will map the point
++ \((r, \theta, z)\)
++ to \((r * \cos(\theta)), (r * \sin(\theta)), z\).
spherical: Pt -> Pt
++ spherical(pt) transforms pt from spherical coordinates to Cartesian
++ coordinates: the function produced will map the point
++ \((r, \theta, \phi)\)
++ to \((r * \sin(\phi) * \cos(\theta)), (r * \sin(\phi) * \sin(\theta)), r * \cos(\phi)\).
parabolic: Pt -> Pt
++ parabolic(pt) transforms pt from parabolic coordinates to Cartesian
++ coordinates: the function produced will map the point \((u, v)\)
++ to \((1/2 * (u^2 - v^2)), (u * v)\).
parabolicCylindrical: Pt -> Pt
++ parabolicCylindrical(pt) transforms pt from parabolic cylindrical
++ coordinates to Cartesian coordinates: the function produced will
++ map the point \((u, v, z)\) to \((1/2 * (u^2 - v^2)), (u * v), z\).
paraboloidal: Pt -> Pt
++ paraboloidal(pt) transforms pt from paraboloidal coordinates to
++ Cartesian coordinates: the function produced will map the point
++ \((u, v, \phi)\) to \((u * \sinh(\phi)), (u * \sin(\phi)), (1/2 * (u^2 - v^2))\).
elliptic: R -> (Pt -> Pt)
++ elliptic(a) transforms from elliptic coordinates to Cartesian
++ coordinates: \(a\) is a function which will map the
++ point \((u, v)\) to \((a * \cosh(u) * \cos(v)), (a * \sinh(u) * \sin(v))\).
ellipticCylindrical: R -> (Pt -> Pt)
++ ellipticCylindrical(a) transforms from elliptic cylindrical coordinates
++ to Cartesian coordinates: \(a\) is a function
++ which will map the point \((u, v, z)\) to \((a * \cosh(u) * \cos(v)), (a * \sinh(u) * \sin(v)), (z)\).
prolateSpheroidal: R -> (Pt -> Pt)
++ prolateSpheroidal(a) transforms from prolate spheroidal coordinates to
++ Cartesian coordinates: \(a\) is a function
++ which will map the point \((u, v, \phi)\) to \((a * \cosh(u) * \cos(v)), (a * \sinh(u) * \sin(v)), (1/2 * (u^2 - v^2))\).
++ Cartesian coordinates: \spad{prolateSpheroidal(a)} is a function
++ which will map the point \spad{(xi,eta,phi)} to
++ \spad{x = a*sinh(xi)*sin(eta)*cos(phi)}, \spad{y = a*sinh(xi)*sin(eta)*sin(phi)},
++ \spad{z = a*cosh(xi)*cos(eta)}.

oblateSpheroidal: R -> (Pt -> Pt)
++ oblateSpheroidal(a) transforms from oblate spheroidal coordinates to
++ Cartesian coordinates: \spad{oblateSpheroidal(a)} is a function which
++ will map the point \spad{(xi,eta,phi)} to \spad{x = a*sinh(xi)*sin(eta)*cos(phi)},
++ \spad{y = a*sinh(xi)*sin(eta)*sin(phi)}, \spad{z = a*cosh(xi)*cos(eta)}.

bipolar: R -> (Pt -> Pt)
++ bipolar(a) transforms from bipolar coordinates to Cartesian coordinates:
++ \spad{bipolar(a)} is a function which will map the point \spad{(u,v)} to
++ \spad{x = a*sinh(v)/(cosh(v)-cos(u))}, \spad{y = a*sin(u)/(cosh(v)-cos(u))}.

bipolarCylindrical: R -> (Pt -> Pt)
++ bipolarCylindrical(a) transforms from bipolar cylindrical coordinates
++ to Cartesian coordinates: \spad{bipolarCylindrical(a)} is a function which
++ will map the point \spad{(u,v,z)} to \spad{x = a*sinh(v)/(cosh(v)-cos(u))},
++ \spad{y = a*sin(u)/(cosh(v)-cos(u))}, \spad{z}.

toroidal: R -> (Pt -> Pt)
++ toroidal(a) transforms from toroidal coordinates to Cartesian
++ coordinates: \spad{toroidal(a)} is a function which will map the point
++ \spad{(u,v,phi)} to \spad{x = a*sinh(v)*cos(phi)/(cosh(v)-cos(u))},
++ \spad{y = a*sinh(v)*sin(phi)/(cosh(v)-cos(u))}, \spad{z = a*sin(u)/(cosh(v)-cos(u))}.

conical: (R,R) -> (Pt -> Pt)
++ conical(a,b) transforms from conical coordinates to Cartesian coordinates:
++ \spad{conical(a,b)} is a function which will map the point \spad{(lambda,mu,nu)} to
++ \spad{x = lambda*mu*nu/(a*b)},
++ \spad{y = lambda/a*sqrt((mu**2-a**2)*(nu**2-a**2)/(a**2-b**2))},
++ \spad{z = lambda/b*sqrt((mu**2-b**2)*(nu**2-b**2)/(b**2-a**2))}.

package CRAPACK CRApackage

--- CRApackage.input ---

\)set break resume
\)sys rm -f CRApackage.output
\)spool CRApackage.output
\)set message test on
CRApkg is a package that provides functions for working with modular arithmetic. It exports several functions, including:

- modTree
- chineseRemainder
- multiEuclideanTree

Here is an example of how to use CRApkg:

```lisp
)read crapkg
```

### Example

```
> CRApkg
> CRApkg
> set message auto off
> clear all

--S 1 of 1
> show CRApkg
--E 1

> spool
> lisp (bye)
```

---

--- CRApkg.help ---

--- CRApkg examples ---

This package has no documentation

See Also:
- `)show CRApkg`
---

**CRApkg (CRAPACK)**

Exports:

- modTree
- chineseRemainder
- multiEuclideanTree

--- package CRAPACK CRApkg ---

`)abbrev package CRAPACK CRApkg`
++ Description:
++ This package has no documentation

CRAPackage(R:EuclideanDomain): Exports == Implementation where
Exports == with
modTree: (R,List R) -> List R
  ++ modTree(r,l) undocumented{}
chineseRemainder: (List R, List R) -> R
  ++ chineseRemainder(lv,lm) returns a value \axiom{v} such that, if
  ++ \axiom{x} is \axiom{lv.i} modulo \axiom{lm.i} for all \axiom{i}, then
  ++ \axiom{x} is \axiom{v} modulo \axiom{lm(1)*lm(2)*...*lm(n)}.
chineseRemainder: (List List R, List R) -> List R
  ++ chineseRemainder(llv,lm) returns a list of values, each of which
  ++ corresponds to the Chinese remainder of the associated element of
  ++ \axiom{llv} and \axiom{lm}. This is more efficient than applying
  ++ chineseRemainder several times.
multiEuclideanTree: (List R, R) -> List R
  ++ multiEuclideanTree(l,r) undocumented{}

====================================================================

Polya-Redfield enumeration by cycle indices.

This section is based upon the paper J. H. Redfield, ‘‘The Theory of
Group-Reduced Distributions’’, American J. Math.,49 (1927) 433-455,
and is an application of group theory to enumeration problems. It is
a development of the work by P. A. MacMahon on the application of
symmetric functions and Hammond operators to combinatorial theory.

The theory is based upon the power sum symmetric functions s(i) which
are the sum of the i-th powers of the variables. The cycle index of a
permutation is an expression that specifies the sizes of the cycles of
a permutation, and may be represented as a partition. A partition of
a non-negative integer n is a collection of positive integers called
its parts whose sum is n. For example, the partition (3^2 2 1^2) will
be used to represent s^2_3 s_2 s^2_1 and will indicate that the
permutation has two cycles of length 3, one of length 2 and two of
length 1. The cycle index of a permutation group is the sum of the
cycle indices of its permutations divided by the number of
permutations. The cycle indices of certain groups are provided.

The operation complete returns the cycle index of the symmetric group
of order n for argument n. Alternatively, it is the n-th complete
homogeneous symmetric function expressed in terms of power sum
symmetric functions.

complete 1
(1)

Type: SymmetricPolynomial Fraction Integer

complete 2
The operation `elementary` computes the n-th elementary symmetric function for argument n.

\[ \text{elementary 7} \]
\[ \begin{array}{cccccccccccc}
1 & 1 & 2 & \\
- (2) + - (1) & \\
2 & 2 & \\
\end{array} \]

Type: SymmetricPolynomial Fraction Integer

The operation `alternating` returns the cycle index of the alternating group having an even number of even parts in each cycle partition.

\[ \text{alternating 7} \]
\[ \begin{array}{cccccccccccc}
2 & 1 & 2 & 1 & 1 & 2 & 1 & 2 & 1 & 4 & 1 & 2 & 3 \\
- (7) + - (5 1) + - (4 2 1) + - (3 1) + - (2 1) + - (2 1) & \\
7 & 5 & 4 & 9 & 12 & 36 & 24 & \\
\end{array} \]

Type: SymmetricPolynomial Fraction Integer
The operation cyclic returns the cycle index of the cyclic group.

\[
\begin{align*}
1 & \quad 7 \\
\text{cyclic 7} & \\
6 & \quad 1 \quad 7 \\
- (7) & \quad + \quad - (1) \\
7 & \quad 7 \\
\end{align*}
\]

Type: SymmetricPolynomial Fraction Integer

The operation dihedral is the cycle index of the dihedral group.

\[
\begin{align*}
1 & \quad 3 \quad 1 \quad 7 \\
dihedral 7 & \\
3 & \quad 1 \quad 3 \quad 1 \quad 7 \\
- (7) & \quad + \quad - (2 \ 1) \quad + \quad - (1) \\
7 & \quad 2 \quad 14 \\
\end{align*}
\]

Type: SymmetricPolynomial Fraction Integer

The operation graphs for argument n returns the cycle index of the group of permutations on the edges of the complete graph with n nodes induced by applying the symmetric group to the nodes.

\[
\begin{align*}
1 & \quad 2 \quad 1 \quad 2 \quad 1 \quad 3 \quad 1 \quad 4 \quad 2 \quad 1 \quad 3 \quad 4 \quad 1 \quad 10 \\
graphs 5 & \\
6 & \quad 5 \quad 4 \quad 6 \quad 8 \quad 12 \quad 120 \\
- (6 \ 3 \ 1) & \quad + \quad - (5) \quad + \quad - (4 \ 2) \quad + \quad - (3 \ 1) \quad + \quad - (2 \ 1) \quad + \quad - (2 \ 1) \quad + \quad - (1) \\
\end{align*}
\]

Type: SymmetricPolynomial Fraction Integer

The cycle index of a direct product of two groups is the product of the cycle indices of the groups. Redfield provided two operations on two cycle indices which will be called "cup" and "cap" here. The cup of two cycle indices is a kind of scalar product that combines monomials for permutations with the same cycles. The cap operation provides the sum of the coefficients of the result of the cup operation which will be an integer that enumerates what Redfield called group-reduced distributions.

We can, for example, represent complete 2 * complete 2 as the set of objects a a b b and complete 2 * complete 1 * complete 1 as c c d e.

This integer is the number of different sets of four pairs.

\[
\begin{align*}
\text{cap(complete 2**2, complete 2*complete 1**2)} & \\
4 & \\
\text{Type: Fraction Integer} \\
\end{align*}
\]

For example,
This integer is the number of different sets of four pairs no two pairs being equal.

\[
\text{cap}(\text{elementary } 2^{*2}, \text{ complete } 2*\text{complete } 1^{*2})
\]
\[
2
\]
Type: Fraction Integer

For example,

\[
\begin{align*}
a & a \ b \ b \\
c & d \ e \ c \\
\end{align*}
\]

In this case the configurations enumerated are easily constructed, however the theory merely enumerates them providing little help in actually constructing them.

Here are the number of 6-pairs, first from a a b b c, second from d d e e f g.

\[
\text{cap}(\text{complete } 3*\text{complete } 2*\text{complete } 1, \text{complete } 2^{*2}*\text{complete } 1^{*2})
\]
\[
24
\]
Type: Fraction Integer

Here it is again, but with no equal pairs.

\[
\text{cap}(\text{elementary } 3*\text{elementary } 2*\text{elementary } 1, \text{complete } 2^{*2}*\text{complete } 1^{*2})
\]
\[
8
\]
Type: Fraction Integer

\[
\text{cap}(\text{complete } 3*\text{complete } 2*\text{complete } 1, \text{elementary } 2^{*2}*\text{elementary } 1^{*2})
\]
\[
8
\]
Type: Fraction Integer

The number of 6-triples, first from a a b b c, second from d d e e f g, third from h h i i j j.

\[
\text{eval}(\text{cup}(\text{complete } 3*\text{complete } 2*\text{complete } 1, \text{cup}(\text{complete } 2^{*2}*\text{complete } 1^{*2}, \text{complete } 2^{*3})))
\]
\[
1500
\]
Type: Fraction Integer

The cycle index of vertices of a square is dihedral 4.

\[
square:=\text{dihedral} \ 4
\]
\[
1 \ 3 \ 2 \ 1 \ 2 \ 1 \ 4
\]
\[
- (4) + - (2 ) + - (2 1 ) + - (1 )
\]
\[
4 \ 8 \ 4 \ 8
\]
Type: Symmetric Polynomial Fraction Integer
The number of different squares with 2 red vertices and 2 blue vertices.
\[
\text{cap(complete } 2**2, \text{square)}
\]
\[2\]
Type: Fraction Integer

The number of necklaces with 3 red beads, 2 blue beads and 2 green beads.
\[
\text{cap(complete } 3*\text{complete } 2**2, \text{dihedral } 7)
\]
\[18\]
Type: Fraction Integer

The number of graphs with 5 nodes and 7 edges.
\[
\text{cap(graphs } 5, \text{complete } 7*\text{complete } 3)
\]
\[4\]
Type: Fraction Integer

The cycle index of rotations of vertices of a cube.
\[
s(x) \equiv \text{powerSum}(x)
\]
Type: Void
\[
cube:=((1/24)*(s 1**8+9*s 2**4+8*s 3**2*s 1**2+6*s 4**2)
1 2 1 2 2 3 4 1 8
- (4 ) + - (3 1 ) + - (2 ) + -- (1 )
4 3 8 24
Type: SymmetricPolynomial Fraction Integer
\]

The number of cubes with 4 red vertices and 4 blue vertices.
\[
\text{cap(complete } 4**2, \text{cube)}
\]
\[7\]
Type: Fraction Integer

The number of labeled graphs with degree sequence 2 2 2 1 1 with no loops or multiple edges.
\[
\text{cap(complete } 2**3*\text{complete } 1**2, \text{wreath(elementary } 4, \text{elementary } 2))
\]
\[7\]
Type: Fraction Integer

Again, but with loops allowed but not multiple edges.
\[
\text{cap(complete } 2**3*\text{complete } 1**2, \text{wreath(elementary } 4, \text{complete } 2))
\]
\[17\]
Type: Fraction Integer

Again, but with multiple edges allowed, but not loops
Again, but with both multiple edges and loops allowed
\[\text{cap}(\text{complete } 2^*3 \text{complete } 1^*2, \text{wreath}(\text{complete } 4, \text{elementary } 2))\]
\[23\]
\[\text{Type: Fraction Integer}\]

Having constructed a cycle index for a configuration we are at liberty to evaluate the \(s_i\) components any way we please. For example we can produce enumerating generating functions. This is done by providing a function \(f\) on an integer \(i\) to the value required of \(s_i\), and then evaluating \(\text{eval}(f, \text{cycleindex})\).

\[
x: \text{ULS}(\text{FRAC INT, 'x, 0}) := 'x
\]

\[\text{x}\]
\[\text{Type: UnivariateLaurentSeries(Fraction Integer,x,0)}\]

\[
\text{ZeroOrOne: INT -> ULS(\text{FRAC INT, 'x, 0})}
\]

\[\text{Type: Void}\]

\[
\text{Integers: INT -> ULS(\text{FRAC INT, 'x, 0})}
\]

\[\text{Type: Void}\]

For the integers 0 and 1, or two colors.

\[
\text{ZeroOrOne n == 1+x**n}
\]

\[\text{Type: Void}\]

\[
\text{ZeroOrOne 5}
\]

\[5\]

\[1 + x\]

\[\text{Type: UnivariateLaurentSeries(Fraction Integer,x,0)}\]

For the integers 0, 1, 2, ... we have this.

\[
\text{Integers n == 1/(1-x**n)}
\]

\[\text{Type: Void}\]

\[
\text{Integers 5}
\]

\[5\]

\[10\]

\[11\]

\[1 + x + x + O(x)\]

\[\text{Type: UnivariateLaurentSeries(Fraction Integer,x,0)}\]

The coefficient of \(x^n\) is the number of graphs with 5 nodes and \(n\) edges.

Note that there is an \text{eval} function that takes two arguments. It has the
signature:

\[(\text{Integer} \rightarrow \text{D1}), \text{SymmetricPolynomial Fraction Integer} \rightarrow \text{D1}\]

from EvaluateCycleIndicators D1 if D1 has ALGEBRA FRAC INT

This function is not normally exposed (it will not normally be considered in the list of eval functions) as it is only useful for this particular domain. To use it we ask that it be considered thus:

>expose EVALCYC

and now we can use it:

\[
eval(\text{ZeroOrOne}, \text{graphs 5})
\]

\[
1 + x + 2x + 4x + 6x + 6x + 4x + 2x + x + x + O(x^8)
\]

Type: UnivariateLaurentSeries(Fraction Integer, x, 0)

The coefficient of \(x^n\) is the number of necklaces with \(n\) red beads and \(n-8\) green beads.

\[
eval(\text{ZeroOrOne}, \text{dihedral 8})
\]

\[
1 + x + 4x + 5x + 8x + 5x + 4x + x + x
\]

Type: UnivariateLaurentSeries(Fraction Integer, x, 0)

The coefficient of \(x^n\) is the number of partitions of \(n\) into 4 or fewer parts.

\[
eval(\text{Integers}, \text{complete 4})
\]

\[
1 + x + 2x + 3x + 5x + 6x + 9x + 11x + 15x + 18x + 23x + O(x^{11})
\]

Type: UnivariateLaurentSeries(Fraction Integer, x, 0)

The coefficient of \(x^n\) is the number of partitions of \(n\) into 4 boxes containing ordered distinct parts.

\[
eval(\text{Integers}, \text{elementary 4})
\]

\[
x + x + 2x + 3x + 5x + 6x + 9x + 11x + 15x + 18x + 23x + 17
\]

Type: UnivariateLaurentSeries(Fraction Integer, x, 0)

The coefficient of \(x^n\) is the number of different cubes with \(n\) red vertices and \(8-n\) green ones.

\[
eval(\text{ZeroOrOne}, \text{cube})
\]

\[
1 + x + 3x + 3x + 7x + 3x + 3x + x + x
\]
The coefficient of $x^n$ is the number of different cubes with integers on the vertices whose sum is $n$.

\begin{verbatim}
  eval(Integers,cube)
  2 3 4 5 6 7 8 9 10
  1 + x + 4x + 7x + 21x + 37x + 85x + 151x + 292x + 490x + 848x
  +
  11
  O(x^11)
\end{verbatim}

The coefficient of $x^n$ is the number of graphs with 5 nodes and with integers on the edges whose sum is $n$. In other words, the enumeration is of multigraphs with 5 nodes and $n$ edges.

\begin{verbatim}
  eval(Integers,graphs 5)
  2 3 4 5 6 7 8 9 10
  1 + x + 3x + 7x + 17x + 35x + 76x + 149x + 291x + 539x + 974x
  +
  11
  O(x^11)
\end{verbatim}

Graphs with 15 nodes enumerated with respect to number of edges.

\begin{verbatim}
  eval(ZeroOrOne,graphs 15)
  2 3 4 5 6 7 8 9 10
  1 + x + 2x + 5x + 11x + 26x + 68x + 177x + 496x + 1471x + 4583x
  +
  11
  O(x^11)
\end{verbatim}

Necklaces with 7 green beads, 8 white beads, 5 yellow beads and 10 red beads.

\begin{verbatim}
  cap(dihedral 30,complete 7*complete 8*complete 5*complete 10)
  4995897238320
\end{verbatim}

The operation SFunction is the S-function or Schur function of a partition written as a descending list of integers expressed in terms of power sum symmetric functions.

In this case the argument partition represents a tableau shape. For example $3,2,2,1$ represents a tableau with three boxes in the first row, two boxes in the second and third rows, and one box in the fourth row. SFunction $[3,2,2,1]$ counts the number of different tableaux of
shape 3, 2, 2, 1 filled with objects with an ascending order in the columns and a non-descending order in the rows.

\[ sf3221 := \text{SFUnction}[3,2,2,1] \]

\[
\begin{array}{cccccccc}
1 & 1 & 2 & 1 & 2 & 1 & 1 & 4 & 1 & 2 \\
\text{-- (6 2) -- (6 1) -- (4) + -- (4 3 1) + -- (4 1) -- (3 2)} \\
12 & 12 & 16 & 12 & 24 & 36 \\
+ \\
1 & 2 & 2 & 1 & 2 & 1 & 3 & 1 & 5 & 1 & 4 & 1 & 3 & 2 \\
\text{-- (3 1) -- (3 2 1) -- (3 2 1) -- (3 1) -- (2) + -- (2 1)} \\
36 & 24 & 16 & 12 & 24 & 36 & 72 & 192 & 48 \\
+ \\
1 & 2 & 4 & 1 & 6 & 1 & 8 \\
\text{-- (2 1) -- (2 1) + (1)} \\
96 & 144 & 576
\end{array}
\]

Type: SymmetricPolynomial Fraction Integer

This is the number filled with a a b b c c d d.

\[ \text{cap(sf3221, complete 2**4)} \]

3

Type: Fraction Integer

The configurations enumerated above are:

a a b a a c a a d
b c b b b b
c d c d c c
d d d

This is the number of tableaux filled with 1..8.

\[ \text{cap(sf3221, powerSum 1**8)} \]

70

Type: Fraction Integer

The coefficient of \( x^n \) is the number of column strict reverse plane partitions of \( n \) of shape 3 2 2 1.

\[ \text{eval(Integers, sf3221)} \]

\[
\begin{array}{cccccccccccccccc}
9 & 10 & 11 & 12 & 13 & 14 & 15 & 16 & 17 \\
x & + & 3x & + & 7x & + & 14x & + & 27x & + & 47x & + & 79x & + & 126x & + & 196x \\
+ \\
18 & 19 & 20 \\
294x & + & 432x & + & 0(x) \\
\end{array}
\]

Type: UnivariateLaurentSeries(Fraction Integer,x,0)

  blowUp: InfClsPoint -> List InfClsPoint

  divisorAtDesingTree: (PolyRing, DesTree) -> DIVISOR
  ++ divisorAtDesingTree(f, tr) computes the local
  ++ divisor of f at a desingularisation tree tr of
  ++ a singular point.

  adjunctionDivisor: DesTree -> DIVISOR
  ++ adjunctionDivisor(tr) compute the local
  ++ adjunction divisor of a desingularisation tree tr of
  ++ a singular point.

  blowUpWithExcpDiv: DesTree -> Void -- DesTree

  desingTreeAtPoint: (ProjPt, PolyRing) -> DesTree
  ++ desingTreeAtPoint(pt, pol) computes
  ++ the desingularisation tree at the point pt
  ++ on the curve defined by pol.
  ++ This function recursively compute the tree.

  desingTree: PolyRing -> List DesTree
  ++ desingTree(pol) returns all the desingularisation
  ++ trees of all singular points on the curve
  ++ defined by pol.

  fullParamInit: DesTree -> Void
  ++ fullParamInit(tr) initialize the local
  ++ parametrization at all places (leaves of tr),
  ++ computes the local exceptional divisor
  ++ at each infinitely close points in the tree.
  ++ This function is equivalent to the following called:
  ++ initParLocLeaves(tr)
  ++ initializeParamOfPlaces(tr)
  ++ blowUpWithExcpDiv(tr)

  initParLocLeaves: DesTree -> Void
  ++ initParLocLeaves(tr) initialize the local
  ++ parametrization at simple points corresponding to
  ++ the leaves of tr.

  initializeParamOfPlaces: DesTree -> Void
  ++ initParLocLeaves(tr) initialize the local
++ parametrization at places corresponding to
  ++ the leaves of tr.

initializeParamOfPlaces: (DesTree, List PolyRing) -> Void
  ++ initParLocLeaves(tr,listOfFnc) initialize
  ++ the local parametrization at places corresponding to
  ++ the leaves of tr according to the given
  ++ list of functions in listOfFnc.

genus: PolyRing -> NNI
  ++ genus(pol) computes the genus of the curve defined by pol.

genusNeg: PolyRing -> INT
  ++ genusNeg(pol) computes the "genus" of a curve
  ++ that may be not absolutely irreducible.
  ++ A "negative" genus means that
  ++ the curve is reducible !.

genusTree: (NNI, List(DesTree)) -> NNI
  ++ genusTree(n,listOfTrees) computes the genus of a curve,
  ++ where n is the degree of a polynomial pol
  ++ defining the curve and listOfTrees is all
  ++ the desingularisation trees at all singular points
  ++ on the curve defined by pol.

inBetweenExcpDiv: DesTree -> DIVISOR

genusTreeNeg: (NNI, List(DesTree)) -> INT
  ++ genusTreeNeg(n,listOfTrees) computes the "genus"
  ++ of a curve that may be not absolutely irreducible,
  ++ where n is the degree of a polynomial pol
  ++ defining the curve and listOfTrees is all the
  ++ desingularisation trees at all singular points
  ++ on the curve defined by pol.
  ++ A "negative" genus means that
  ++ the curve is reducible !.

Any solution of a homogeneous linear Diophantine equation can be represented as a sum of minimal solutions, which form a "basis" (a minimal solution cannot be represented as a nontrivial sum of solutions) in the case of an inhomogeneous linear Diophantine equation, each solution is the sum of a inhomogeneous solution and any number of homogeneous solutions therefore, it suffices to compute two sets:

1. all minimal inhomogeneous solutions
2. all minimal homogeneous solutions

the algorithm implemented is a completion procedure, which enumerates all solutions in a recursive depth-first-search it can be seen as finding monotone paths in a graph for more details see Reference

DistinctDegreeFactorize (DDFACT)

Package for the factorization of a univariate polynomial with coefficients in a finite field. The algorithm used is the "distinct degree" algorithm of Cantor-Zassenhaus, modified to use trace instead of the norm and a table for computing Frobenius as suggested by Naudin and Quitte.

++ Date Last Updated: 22 November 1993
++ Description:
++ Package for the factorization of a univariate polynomial with
++ coefficients in a finite field. The algorithm used is the
++ "distinct degree" algorithm of Cantor-Zassenhaus, modified
++ to use trace instead of the norm and a table for computing
++ Frobenius as suggested by Naudin and Quitte.

DistinctDegreeFactorize(F,FP): C == T
where
F : FiniteFieldCategory
FP : UnivariatePolynomialCategory(F)
fUnion ==> Union("nil", "sqfr", "irred", "prime")
FFE ==> Record(flg:fUnion, fctr:FP, xpnt:Integer)
NNI == NonNegativeInteger
Z == Integer
fact == Record(deg : NNI, prod : FP)
ParFact == Record(irr:FP, pow:Z)
FinalFact == Record(cont:F, factors:List(ParFact))

C == with
factor : FP -> Factored FP
++ factor(p) produces the complete factorization of the polynomial p.
factorSquareFree : FP -> Factored FP
++ factorSquareFree(p) produces the complete factorization of the
++ square free polynomial p.
distdfact : (FP,Boolean) -> FinalFact
++ distdfact(p, sqfrflag) produces the complete factorization
++ of the polynomial p returning an internal data structure.
++ If argument sqfrflag is true, the polynomial is assumed square free.
separateDegrees : FP -> List fact
++ separateDegrees(p) splits the square free polynomial p into
++ factors each of which is a product of irreducibles of the
++ same degree.
separateFactors : List fact -> List FP
++ separateFactors(lfact) takes the list produced by separateDegrees
++ and produces the complete list of factors.
exptMod : (FP,NNI,FP) -> FP
++ exptMod(u,k,v) raises the polynomial u to the kth power
++ modulo the polynomial v.
\end{verbatim}
trace2PowMod : (FP,NNI,FP) -> FP  
++ trace2PowMod(u,k,v) produces the sum of u**(2**i) for i running  
++ from 1 to k all computed modulo the polynomial v.

tracePowMod : (FP,NNI,FP) -> FP  
++ tracePowMod(u,k,v) produces the sum of \spad{u**(q**i)}  
++ for i running and q= size F

irreducible? : FP -> Boolean  
++ irreducible?(p) tests whether the polynomial p is irreducible.

The special functions in this section are developed as special cases but can all be expressed in terms of generalized hypergeometric functions $pF_q$ or its generalization, the Meijer G function. The long term plan is to reimplement these functions using the generalized version.

This package provides special functions for double precision real and complex floating point.

The formula used will agree with the Table of the Fresnel Integral by Pearcey (1959) to 6 decimal places up to an argument of about 35.0. After that the summation gets slowly worse, agreeing to only 2 digits at about 45.0.

Exports ==> with
Gamma: R -> R
++ Gamma(x) is the Euler gamma function, \spad{Gamma(x)}, defined by
++ \spad{Gamma(x) = integrate(t^(x-1)*exp(-t), t=0..%infinity)}.  
Gamma: C -> C
++ Gamma(x) is the Euler gamma function, \spad{Gamma(x)}, defined by
++ \spad{Gamma(x) = integrate(t^(x-1)*exp(-t), t=0..%infinity)}.  
E1: R -> OPR
++ E1(x) is the Exponential Integral function
++ The current implementation is a piecewise approximation
++ involving one poly from -4..4 and a second poly for x > 4

En: (PI,R) -> OPR
++ En(n,x) is the nth Exponential Integral Function

Ei: (OPR) -> OPR
++ Ei is the Exponential Integral function
++ This is computed using a 6 part piecewise approximation.
++ DoubleFloat can only preserve about 16 digits but the
++ Chebyshev approximation used can give 30 digits.

Ei1: (OPR) -> OPR
++ Ei1 is the first approximation of Ei where the result is
++ x*%e^-x*Ei(x) from -infinity to -10 (preserves digits)

Ei2: (OPR) -> OPR
++ Ei2 is the first approximation of Ei where the result is
++ x*%e^-x*Ei(x) from -10 to -4 (preserves digits)

Ei3: (OPR) -> OPR
++ Ei3 is the first approximation of Ei where the result is
++ (Ei(x)-log |x| - gamma)/x from -4 to 4 (preserves digits)

Ei4: (OPR) -> OPR
++ Ei4 is the first approximation of Ei where the result is
++ x*%e^-x*Ei(x) from 4 to 12 (preserves digits)

Ei5: (OPR) -> OPR
++ Ei5 is the first approximation of Ei where the result is
++ x*%e^-x*Ei(x) from 12 to 32 (preserves digits)

Ei6: (OPR) -> OPR
++ Ei6 is the first approximation of Ei where the result is
++ x*%e^-x*Ei(x) from 32 to infinity (preserves digits)

Beta: (R, R) -> R
++ Beta(x, y) is the Euler beta function, \spad{\text{\text{\text{\text{B(x,y)}}}}}, defined by
++ \spad{\text{\text{\text{\text{integrate(t^{(x-1)}(1-t)^{(y-1)}, t=0..1)}}}}}. 
++ This is related to \spad{\text{\text{\text{\text{Gamma(x)}}}}} by
++ \spad{\text{\text{\text{\text{integrate(t^{(x-1)}(1-t)^{(y-1)}, t=0..1)}}}}}. 

Beta: (C, C) -> C
++ Beta(x, y) is the Euler beta function, \spad{\text{\text{\text{\text{B(x,y)}}}}}, defined by
++ \spad{\text{\text{\text{\text{integrate(t^{(x-1)}(1-t)^{(y-1)}, t=0..1)}}}}}. 
++ This is related to \spad{\text{\text{\text{\text{Gamma(x)}}}}} by
++ \spad{\text{\text{\text{\text{integrate(t^{(x-1)}(1-t)^{(y-1)}, t=0..1)}}}}}. 

logGamma: R -> R
++ logGamma(x) is the natural log of \spad{\text{\text{\text{\text{Gamma(x)}}}}}.
logGamma: C -> C
++ logGamma(x) is the natural log of \spad{Gamma(x)}.
++ This can often be computed even if \spad{Gamma(x)} cannot.

digamma: R -> R
++ digamma(x) is the function, \spad{psi(x)}, defined by
++ \spad{psi(x) = Gamma'(x)/Gamma(x)}.

digamma: C -> C
++ digamma(x) is the function, \spad{psi(x)}, defined by
++ \spad{psi(x) = Gamma'(x)/Gamma(x)}.

polygamma: (NNI, R) -> R
++ polygamma(n, x) is the n-th derivative of \spad{digamma(x)}.

besselJ: (R, R) -> R
++ besselJ(v, x) is the Bessel function of the first kind,
++ \spad{J(v, x)}.
++ This function satisfies the differential equation:
++ \spad{x^2 w''(x) + x w'(x) + (x^2-v^2)w(x) = 0}.

besselJ: (C, C) -> C
++ besselJ(v, x) is the Bessel function of the first kind,
++ \spad{J(v, x)}.
++ This function satisfies the differential equation:
++ \spad{x^2 w''(x) + x w'(x) + (x^2-v^2)w(x) = 0}.

besselY: (R, R) -> R
++ besselY(v, x) is the Bessel function of the second kind,
++ \spad{Y(v, x)}.
++ This function satisfies the differential equation:
++ \spad{x^2 w''(x) + x w'(x) + (x^2-v^2)w(x) = 0}.
++ Note that the default implementation uses the relation
++ \spad{Y(v, x) = (J(v, x) cos(v*%pi) - J(-v, x))/sin(v*%pi)}
++ so is not valid for integer values of v.

besselY: (C, C) -> C
++ besselY(v, x) is the Bessel function of the second kind,
++ \spad{Y(v, x)}.
++ This function satisfies the differential equation:
++ \spad{x^2 w''(x) + x w'(x) + (x^2-v^2)w(x) = 0}.
++ Note that the default implementation uses the relation
++ \spad{Y(v, x) = (J(v, x) cos(v*%pi) - J(-v, x))/sin(v*%pi)}
++ so is not valid for integer values of v.

besselI: (R, R) -> R
++ besselI(v, x) is the modified Bessel function of the first kind,
++ \spad{I(v, x)}.
++ This function satisfies the differential equation:
++ \spad{x^2 w''(x) + x w'(x) - (x^2+v^2)w(x) = 0}.
besselI: (C,C) -> C
++ besselI(v,x) is the modified Bessel function of the first kind,
++ \ \spad{I(v,x)}.
++ This function satisfies the differential equation:
++ \ \spad{x^2 w''(x) + x w'(x) - (x^2+v^2)w(x) = 0}.

besselK: (R, R) -> R
++ besselK(v,x) is the modified Bessel function of the second kind,
++ \ \spad{K(v,x)}.
++ This function satisfies the differential equation:
++ \ \spad{x^2 w''(x) + x w'(x) - (x^2+v^2)w(x) = 0}.
++ Note that the default implementation uses the relation
++ \ \spad{K(v,x) = \pi/2*(I(-v,x) - I(v,x))/\sin(v*\pi)}.
++ so is not valid for integer values of v.

besselK: (C, C) -> C
++ besselK(v,x) is the modified Bessel function of the second kind,
++ \ \spad{K(v,x)}.
++ This function satisfies the differential equation:
++ \ \spad{x^2 w''(x) + x w'(x) - (x^2+v^2)w(x) = 0}.
++ Note that the default implementation uses the relation
++ \ \spad{K(v,x) = \pi/2*(I(-v,x) - I(v,x))/\sin(v*\pi)}
++ so is not valid for integer values of v.

airyAi: C -> C
++ airyAi(x) is the Airy function \spad{Ai(x)}.
++ This function satisfies the differential equation:
++ \ \spad{Ai''(x) - x \cdot Ai(x) = 0}.

airyAi: R -> R
++ airyAi(x) is the Airy function \spad{Ai(x)}.
++ This function satisfies the differential equation:
++ \ \spad{Ai''(x) - x \cdot Ai(x) = 0}.

airyBi: R -> R
++ airyBi(x) is the Airy function \spad{Bi(x)}.
++ This function satisfies the differential equation:
++ \ \spad{Bi''(x) - x \cdot Bi(x) = 0}.

airyBi: C -> C
++ airyBi(x) is the Airy function \spad{Bi(x)}.
++ This function satisfies the differential equation:
++ \ \spad{Bi''(x) - x \cdot Bi(x) = 0}.

hypergeometric0F1: (R, R) -> R
++ hypergeometric0F1(c,z) is the hypergeometric function
++ \ \spad{0F1(c;z)}.

hypergeometric0F1: (C, C) -> C
++ hypergeometric0F1(c,z) is the hypergeometric function
++ \ \spad{0F1(c;z)}.

def: F -> F
++ def(f) denotes the Fresnel integral S
The Exponential Integral

The E1 function

(Quoted from Segletes[7]):

A number of useful integrals exist for which no exact solutions have been found. In other cases, an exact solution, if found, may be impractical to utilize over the complete domain of the function because of precision limitations associated with what usually ends up as a series solution to the challenging integral. For many of these integrals, tabulated values may be published in various mathematical handbooks and articles. In some handbooks, fits (usually piecewise) also are offered. In some cases, an application may be forced to resort to numerical integration in order to acquire the integrated function. In this context, compact (i.e. not piecewise) analytical fits to some of these problematic integrals, accurate to within a small fraction of the numerically integrated value, serve as a useful tool to applications requiring the results of the integration, especially when the integration is required numerous times throughout the course of the application. Furthermore, the ability and methodology to develop intelligent fits, in contract to the more traditional “brute force” fits, provide the means to minimize parameters and maximize accuracy when tackling some of these difficult functions. The exponential integral will be used as an opportunity to both demonstrate a methodology for intelligent fitting as well as for providing an accurate, compact, analytical fit to the exponential integral.

The exponential integral is a useful class of functions that arise in a variety of applications [...]. The real branch of the family of exponential integrals may be defined as

\[ E_n(x) = x^{n-1} \int_x^\infty \frac{e^{-t}}{t^n} \, dt \] (5.1)

where \( n \), a positive integer, denotes the specific member of the exponential integral family.
The argument of the exponential integral, rather than expressing a lower limit of integration as in (1), may be thought of as describing the exponential decay constant, as given in this equivalent (and perhaps more popular) definition of the integral:

\[ E_n(x) = \int_1^\infty \frac{e^{-xt}}{t^n} \, dt \]  

(5.2)

Integration by parts permits any member of the exponential integral family to be converted to an adjacent member of the family, by way of

\[ \int_x^\infty \frac{e^{-t}}{t^{n+1}} \, dt = \frac{1}{n} \left( \frac{e^{-x}}{x^n} - \int_x^\infty \frac{e^{-t}}{t^n} \, dt \right) \]  

(5.3)

expressable in terms of \( E_n \) as

\[ E_{n+1}(x) = \frac{1}{n} \left[ e^{-x} - xE_n(x) \right] \quad (n = 1, 2, 3) \]  

(5.4)

Through recursive employment of this equation, all members of the exponential integral family may be analytically related. However, this technique only allows for the transformation of one integral into another. There remains the problem of evaluating \( E_1(x) \). There is an exact solution to the integral of \( (e^{-t}/t) \), appearing in a number of mathematical references [?, ?] which is obtainable by expanding the exponential into a power series and integrating term by term. That exact solution, which is convergent, may be used to specify \( E_1(x) \) as

\[ E_1(x) = -\gamma - \ln(x) + \frac{x}{1!} - \frac{x^2}{2!} + \frac{x^3}{3!} - \ldots \]  

(5.5)

Euler’s constant, \( \gamma \), equal to 0.57721..., arises when the power series expansion for \( (e^{-t}/t) \) is integrated and evaluated at its upper limit, as \( x \to \infty \). [?]

Employing eqn (5), however, to evaluate \( E_1(x) \) is problematic for finite \( x \) significantly larger than unity. One may well ask of the need to evaluate the exponential integral for large \( x \), since the function to be integrated drops off so rapidly that the integral is surely a very flat function. Such reasoning is true when comparing the integrand at large \( x \) to that at small \( x \). However, the definition of eqn (1) has as its upper limit not a small value of \( x \), but rather that of \( \infty \). Therefore, the actual values for \( E_n(x) \) are extremely small numbers for large values of \( x \). This is not sufficient merely to select enough terms of eqn (5) to evaluate the integral to within a value of, for example \( \pm 0.0001 \) because the actual integral value for large \( x \) would be smaller than this arbitrary tolerance. To draw an analogy, it would be like saying that it is good enough to approximate \( e^{-x} \) as 0.0 for \( x > 10 \), since its actual value is within 0.0001 of zero. For some applications, such an approximation may be warranted. In general, though, such an approximation is mathematically unacceptable. Worse yet, as seen from eqns (1) and (2), the need to evaluate the exponential integral for large arguments can arise in real-world problems from either a large integration limit or a large value of an exponential decay constant. Thus, the need to evaluate exponential integrals for large values of the argument is established. It is here that the practical problems with the evaluation of eqn (5) become manifest.
First, the number of terms, \( N \), required to achieve convergence rises rapidly with increasing \( x \), making the summation an inefficient tool, even when expressed as a recursion relation (for three digits of accuracy, \( N \) is observed to vary roughly as \( 9 + 1.6x \), for \( 1 < x < 7 \)). More important, however, is the fact that, for calculations of finite precision, the accuracy of the complete summation will be governed by the individual term of greatest magnitude. The source of the problem is that as \( x \) is increased, the total summation decreases in magnitude more rapidly than a decaying exponential, while at the same time, the largest individual term in the series is observed to grow rapidly with increasing \( x \) (\( \sim 10^1 \) for \( x = 7 \), \( \sim 10^2 \) for \( x = 10 \), \( \sim 10^3 \) for \( x = 13 \), etc.). The magnitude of this largest individual term consumes the available precision and, as a result, leaves little or none left for the ever-diminishing net sum that constitutes the desired integral.

Literally, the use of eqn (5), even with (32-bit) double precision, does not permit the exponential integral to be evaluated to three places for \( x > 14 \) in any case, and with the situation worsening for lesser precision. For these reasons, the use of eqn (5) to evaluate the exponential integral numerically for large \( x \) is wholly unsuitable.

\[
E_1(x) = e^{-x} \cdot \frac{1}{x + \frac{1}{x + \frac{2}{x + \ldots}}} \tag{5.6}
\]

But as \( x \) becomes smaller, the number of terms required for convergence rises quickly. Similar arguments apply for the use of an asymptotic expansion for \( E_1 \), which also converges for large \( x \). As such, the more typical approach employed by handbooks is that of a fit. While some steps are taken to make the fits intelligent (e.g., transformation of variables), the fits are all piecewise over the domain of the integral.

Cody and Thatcher [?] performed what is perhaps the definitive work, with the use of Chebyshev[? , ?] approximations to the exponential integral \( E_1 \). Like others, they fit the integral over a piecewise series of subdomains (three in their case) and provide the fitting parameters necessary to evaluate the function to various required precisions, down to relative errors of \( 10^{-20} \). One of the problems with piecewise fitting over two or more subdomains is that functional value and derivatives of the spliced fits will not, in general, match at the domain transition point, unless special accommodations are made. This sort of discontinuity in functional value and/or slope, curvature, etc., may cause difficulties for some numerical algorithms operating upon the fitted function. Numerical splicing/smoothing algorithms aimed at eliminating discontinuities in the value and/or derivatives of a piecewise fit are not, in general, computationally insignificant. Problems associated with piecewise splicing of fits may also be obviated by obtaining an accurate enough fit, such that the error is on the order of magnitude of the limiting machine precision. This alternative, however, requires the use of additional fitting parameters to acquire the improved precision. Thus, regardless of approach, the desire to eliminate discontinuities in the function and its derivatives, between piecewise splices, requires extra computational effort. One final benefit to be had by avoiding the use of piecewise fits is the concomitant avoidance of conditional (i.e., IF...THEN) programming.
statements in the coding of the routine. The use of conditional statements can preclude maximum computing efficiency on certain parallel computing architectures.

Segletes constructs an analytic, non-piecewise fit to the Exponential Integral but the precision is on the order of 4 decimal places and is not sufficient to compare against the Abramowitz and Stegun Handbook.

Instead we have chosen to use a two piece fitting function based on the Chebyshev polynomial for computing $E_1$. This agrees with the handbook values to almost the last published digit. See the e1.input pamphlet for regression testing against the handbook tables.

**E1**: $\mathbb{R} \rightarrow \mathbb{O} \mathbb{P} \mathbb{R}$

The special function E1 below was originally derived from a function written by T. Haavie as the `expint.c` function in the Numlibc library by Lars Erik Lund. Haavie approximates the E1 function by two Chebyshev polynomials. For the range $-4 < x < 4$ the Chebyshev coefficients are:

$$\begin{align*}
7.8737715392882774, & -8.0314874286705335, & 3.8797325768522250, \\
-1.6042971072992259, & 0.5630905453891458, & -0.1704423017433357, \\
0.045209939015415, & -0.0106538986439085, & 0.0022562638123478, \\
-0.004335700473221, & 0.0000762166811878, & -0.0000123417443064, \\
0.000018519745698, & -0.0000002588698662, & 0.000000338604319, \\
-0.000000041611418, & 0.000000004821606, & -0.00000000528465, \\
0.00000000054945, & -0.00000000005433, & 0.0000000000512, \\
-0.00000000000046, & 0.00000000000004
\end{align*}$$

and for the range $x > 4$ the Chebyshev coefficients are:

$$\begin{align*}
0.2155283776715125, & 0.1028106215227030, & -0.0045526707131788, \\
0.000357163122851, & -0.000379341616932, & 0.00004914394914, \\
-0.0000073565024922, & 0.0000001230603606, & -0.0000000225236907, \\
0.00000004412375, & -0.000000009328509, & 0.000000002069297, \\
-0.0000000000481502, & 0.000000000116891, & -0.000000000029474, \\
0.000000000007691, & -0.000000000002070, & 0.00000000000583, \\
-0.0000000000000163, & 0.0000000000000047, & -0.0000000000000014, \\
0.0000000000000004, & -0.0000000000000001
\end{align*}$$

I've rewritten the polynomial to use precomputed coefficients that take into account the scaling used by Haavie. I've also rewritten the polynomial using Horner's method so the large powers of $x$ are only computed once.

The result can be either a double float or, if the argument is zero, infinity. Thus we need to extend the result to be a one-point completion to include infinity.

The $E_n$ function is computed using the recurrence relation:

$$E_{n+1}(z) = \frac{1}{n} \left( e^{-z} - zE_n(z) \right) \quad (n = 1, 2, 3, \ldots)$$

The base case of the recursion depends on $E_1$ above.

The formula is 5.1.14 in Abramowitz and Stegun, 1965, p229[?].

The Ei Function

This function is based on Kin L. Lee’s work[?]. See also [?].

Abstract

The exponential integral $Ei(x)$ is evaluated via Chebyshev series expansion of its associated functions to achieve high relative accuracy throughout the entire real line. The Chebyshev coefficients for these functions are given to 30 significant digits. Clenshaw’s[?] method is modified to furnish an efficient procedure for the accurate solution of linear systems having near-triangular coefficient matrices.

Introduction

The evaluation of the exponential integral

$$Ei(x) = \int_{-\infty}^{x} \frac{e^u}{u} \, du = -E_1(-x), x \neq 0$$

is usually based on the value of its associated functions, for example, $xe^{-x}Ei(x)$. High accuracy tabulations of integral (1) by means of Taylor series techniques are given by Harris
[?] and Miller and Hurst [?]. The evaluation of \( Ei(x) \) for \(-4 \leq x \leq \infty\) by means of Chebyshev series is provided by Clenshaw [?] to have the absolute accuracy of 20 decimal places. The evaluation of the same integral (1) by rational approximation of its associated functions is furnished by Cody and Thacher [?, ?] for \(-\infty < x < \infty\), and has the relative accuracy of 17 significant figures.

The approximation of Cody and Thacher from the point of view of efficient function evaluation are preferable to those of Clenshaw. However, the accuracy of the latter’s procedure, unlike those of the former, is not limited by the accuracy or the availability of a master function, which is a means of explicitly evaluating the function in question.

In this paper \( Ei(x) \) (or equivalently \(-E_1(-x)\)) for the entire real line is evaluated via Chebyshev series expansion of its associated functions that are accurate to 30 significant figures by a modification of Clenshaw’s procedure. To verify the accuracy of the several Chebyshev series, values of the associated functions were checked against those computed by Taylor series and those of Murnaghan and Wrench [?] (see Remarks on Convergence and Accuracy).

Although for most purposes fewer than 30 figures of accuracy are required, such high accuracy is desirable for the following reasons. In order to further reduce the number of arithmetical operations in the evaluation of a function, the Chebyshev series in question can either be converted into a rational function or rearranged into an ordinary polynomial. Since several figures may be lost in either of these procedures, it is necessary to provide the Chebyshev series with a sufficient number of figures to achieve the desired accuracy. Furthermore, general function approximation routines, such as those used for minimax rational function approximations, require the explicit evaluation of the function to be approximated. To take account of the errors committed by these routines, the function values must have an accuracy higher than the approximation to be determined. Consequently, high-precision results are useful as a master function for finding approximations for (or involving) \( Ei(x) \) (e.g. [?, ?]) where prescribed accuracy is less than 30 figures.

**Discussion**

It is proposed here to provide for the evaluation of \( Ei(x) \) by obtaining Chebyshev coefficients for the associated functions given by table 1.

**Table 1:** Associated Functions of \( Ei(x) \) and their ranges of Chebyshev Series Expansions

<table>
<thead>
<tr>
<th>Associated function</th>
<th>Range of expansion</th>
</tr>
</thead>
<tbody>
<tr>
<td>( Ei_1 ) ( xe^{-x}Ei(x) )</td>
<td>(-\infty &lt; x \leq -10)</td>
</tr>
<tr>
<td>( Ei_2 ) ( xe^{-x}Ei(x) )</td>

<tr>
<td>( Ei_5 ) ( xe^{-x}Ei(x) )</td>
<td>(12 \leq x \leq 32)</td>
</tr>
<tr>
<td>( Ei_6 ) ( xe^{-x}Ei(x) )</td>
<td>(32 \leq x &lt; \infty)</td>
</tr>
</tbody>
</table>

(\( \gamma = 0.5772156649... \) is Euler’s constant.)
Note that the functions \( Ei(x) = x - \log|\log x|/x \) and \( x e^{-x} Ei(x) \) have the limiting values of unity at the origin and at infinity, respectively, and that the range of the associated function values is close to unity (see table 4). This makes for the evaluation of the associated functions over the indicated ranges in table 1 (and thus \( Ei(x) \) over the entire real line) with high relative accuracy by means of the Chebyshev series. The reason for this will become apparent later.

Some remarks about the choice of the intervals of expansion for the several Chebyshev series are in order here. The partition of the real line indicated by table 1 is chosen to allow for the approximation of the associated functions with a maximum error of \( 0.5 \times 10^{-30} \) by polynomials of degree \( < 50 \). The real line has also been partitioned with the objective of providing the interval about zero with the lowest degree of polynomial approximation of the six intervals. This should compensate for the computation of \( \log|x| \) required in the evaluation of \( Ei(x) \) over that interval. The ranges \(-\infty < x \leq -4 \) and \( 4 \leq x < \infty \) are partitioned into 2 and 3 intervals, respectively, to provide approximations to \( x e^{-x} Ei(x) \) by polynomials of about the same degree.

Expansions in Chebyshev Series

Let \( \phi(t) \) be a differentiable function defined on \([-1,1]\). To facilitate discussion, denote its Chebyshev series and that of its derivative by

\[
\phi(t) = \sum_{k=0}^{\infty} a_k^{(0)} T_k(t) \quad \phi'(t) = \sum_{k=0}^{\infty} a_k^{(1)} T_k(t)
\]
where \( T_k(t) \) are Chebyshev polynomials defined by
\[
T_k(t) = \cos(k \arccos t), \quad -1 \leq t \leq 1
\]
(A prime over a summation sign indicates that the first term is to be halved.)

If \( \phi(t) \) and \( \phi'(t) \) are continuous, the Chebyshev coefficients \( A_k^{(0)} \) and \( A_k^{(1)} \) can be obtained analytically (if possible) or by numerical quadrature. However, since each function in table 1 satisfies a linear differential equation with polynomial coefficients, the Chebyshev coefficients can be more readily evaluated by the method of Clenshaw [?].

There are several variations of Clenshaw’s procedure (see, e.g. [?]), but for high-precision computation, where multiple precision arithmetic is employed, we find his original procedure easiest to implement. However, straightforward application of it may result in a loss of accuracy if the trial solutions selected are not sufficiently independent. How the difficulty is overcome will be pointed out subsequently.

The function \( xe^{-x}\text{Ei}(x) \) on the Finite Interval

We consider first the Chebyshev series expansion of
\[
f(x) = xe^{-x}\text{Ei}(x), \quad (a \leq x \leq b)
\]
where \( x \neq 0 \). One can easily verify that after the change of variables
\[
x = [(b - a)T + a + b]/2, \quad (-1 \leq t \leq 1)
\]
the function
\[
\phi(t) = f \left[ \frac{(b - a)t + a + b}{2} \right] = f(x)
\]
satisfies the differential equation
\[
2(pt + q)\phi'(t) + p(pt + q - 2)\phi(t) = p(pt + q)
\]
with
\[
\phi(-1) = ae^{-a}\text{Ei}(a)
\]
where \( p = b - a \) and \( q = b + a \). Replacing \( \phi(t) \) and \( \phi'(t) \) in equations 7 by their Chebyshev series, we obtain
\[
\sum_{k=0}^{\infty} (-1)^k A_k^{(0)} = \phi(-1)
\]
\[
2 \sum_{k=0}^{\infty} A_k^{(1)}(pt + q)T_k(t) + p \sum_{k=0}^{\infty} A_k^{(0)}(pt + q - 2)T_k(t) = p(pt + q)
\]
\[
\text{The value of } \text{Ei}(a) \text{ may be evaluated by means of the Taylor series. In this report } \text{Ei}(a) \text{ is computed by first finding the Chebyshev series approximation to } [\text{Ei}(x) - \log|x| - \gamma]/x \text{ to get } \text{Ei}(a). \text{ The quantities } e^a \text{ and } \log|a| \text{ for integral values of } a \text{ may be found in existing tables.}
It can be demonstrated that if \( B_k \) are the Chebyshev coefficients of a function \( \Psi(t) \), then \( C_k \), the Chebyshev coefficients of \( t^r \Psi(t) \) for positive integers \( r \), are given by

\[
C_k = 2^{-r} \sum_{i=0}^{r} \binom{r}{i} B_{|k-r+2i|} \quad (5.17)
\]

Consequently, the left member of equation 15 can be rearranged into a single series involving \( T_k(t) \). The comparison of the coefficients of \( T_k(t) \) that yields the infinite system of equations

\[
\sum_{k=0}^{\infty} (-1)^k A_k^{(0)} = \phi(-1)
\]

\[
2pA_{k-1}^{(1)} + 4qA_k^{(1)} + 2pA_{k+1}^{(1)} + p^2A_{k-1}^{(0)} + 2p(q-2)A_k^{(0)} + p^2A_{k+1}^{(0)} = \begin{cases} 
4pq & k = 0 \\
2p^2 & k = 1 \\
0 & k = 2, 3, \ldots
\end{cases} \quad (5.18)
\]

The relation \( 2kA_k^{(0)} = A_{k-1}^{(1)} - A_{k+1}^{(1)} \) \( (5.19) \) can be used to reduce equation 18 to a system of equations involving only \( A_k^{(0)} \). Thus, replacing \( k \) of equations 18 by \( k + 2 \) and subtracting the resulting equation from equations 18, we have, by means of equation 19, the system of equations

\[
\sum_{k=0}^{\infty} (-1)^k A_k^{(0)} = \phi(-1)
\]

\[
2p(q-2)A_0 + (8q + p^2)A_1 + 2p(6-q)A_2 - p^2A_3 = 4pq
\]

\[
p^2A_{k-1} + 2p(2k + q - 2)A_k + 8q(k+1)A_{k+1} + 2p(2k - q + 6)A_{k+2} - p^2A_{k+3} = \begin{cases} 
2p^2 & k = 1 \\
0 & k = 2, 3, \ldots
\end{cases} \quad (5.20)
\]

The superscript of \( A_k^{(0)} \) is dropped for simplicity. In order to solve the infinite system 20, Clenshaw \( [?] \) essentially considered the required solution as the limiting solution of the sequence of truncated systems consisting of the first \( M + 1 \) equations of the same system, that is, the solution of the system

\[
\sum_{k=0}^{M} (-1)^k A_k = \phi(-1)
\]

\[
2p(q-2)A_0 + (8q + p^2)A_1 + 2p(q - 6)A_2 - p^2A_3 = 4pq \quad (5.21)
\]
\[ \begin{align*}
    p^2 A_{k-1} + 2p(2k + q - 2)A_k + 8q(k + 1)A_{k+1} + 2p(2k - q + 6)A_{k+2} - p^2 A_{k+3} \\
    = \begin{cases} 
        2p^2, & k = 1 \\
        0, & k = 2, 3, \ldots, M - 3
    \end{cases} \\
    p^2 A_{M-3} + 2p(2M + q - 6)A_{M-2} + 8q(M - 1)A_{M-1} + 2p(2M + 4 - q)A_M = 0 \\
    p^2 A_{M-2} + 2p(2M + q - 4)A_{M-1} + 8qMA_M = 0
\end{align*} \] (5.23)

where \( A_k \) is assumed to vanish for \( K \geq M + 1 \). To solve system (21,22,23) consider first the subsystem 23 consisting of \( M - 2 \) equations in \( M \) unknowns. Here use is made of the fact that the subsystem 23 is satisfied by

\[ A_k = c_1 \alpha_k + c_2 \beta_k + \gamma_k \quad (k = 0, 1, 2, \ldots) \] (5.24)

for arbitrary constants \( c_1 \) and \( c_2 \), where \( \gamma_k \) is a particular solution of 23 and where \( \alpha_k \) and \( \beta_k \) are two independent solutions of the homogeneous equations (23 with \( 2p^2 \) deleted) of the same subsystem. Hence, if \( \alpha_k \), \( \beta_k \), and \( \gamma_k \) are available, the solution of system (21,22,23) reduces to the determinant of \( c_1 \) and \( c_2 \) from equations 21 and 22.

To solve equations (21,22,23), we note that

\[ \gamma_0 = 2, \quad \gamma_k = 0, \quad \text{for } k = 1(1)M \] (5.25)

is obviously a particular solution of equation 23. The two independent solutions \( \gamma_k \) and \( \beta_k \) of the homogeneous equations of the same subsystem can be generated in turn by backward recurrence if we set

\[ \begin{align*}
    &\alpha_{M-1} = 0, \quad \alpha_M = 1 \\
    &\beta_{M-1} = 1, \quad \beta_M = 0
\end{align*} \] (5.26)

or choose any \( \alpha_M - 1, \alpha_M, \) and \( \beta_M - 1, \beta_M \) for which \( \alpha_{M-1} \beta_M - \alpha_M \beta_{M-1} \neq 0 \). The arbitrary constants \( c_1 \) and \( c_2 \) are determined, and consequently the solution of equations (21,22,23) if equation 24 is substituted into equation 21 and 22 and the resulting equations

\[ c_1 R(\alpha) + c_2 R(\beta) = \phi(-1) - 1 \] (5.27)

\[ c_1 S(\alpha) + c_2 S(\beta) = 8p \] (5.28)

are solved as two equations in two unknowns. The terms \( R(\alpha) \) and \( S(\alpha) \) are equal, respectively, to the left members of equations 21 and 22 corresponding to solution \( \alpha_k \). (The identical designation holds for \( R(\beta) \) and \( S(\beta) \).)

The quantities \( \alpha_k \) and \( \beta_k \) are known as trial solutions in reference [?]. Clenshaw has pointed out that if \( \alpha_k \) and \( \beta_k \) are not sufficiently independent, loss of significance will occur in the formation of the linear combination 24, with consequent loss of accuracy. Clenshaw suggested the Gauss-Seidel iteration procedure to improve the accuracy of the solution. However, this requires the application of an additional computing procedure and may prove to be extremely slow. A simpler procedure which does not alter the basic computing scheme given above is
proposed here. The loss of accuracy can effectively be regained if we first generate a third trial solution \( \delta_k \) (\( k=0,1, \ldots, M \)), where \( \delta_{M-1} \) and \( \delta_M \) are equal to \( c_1 \alpha_{M-1} + c_2 \beta_{M-1} \) and \( c_1 \alpha_M + c_2 \beta_M \), respectively, and where \( \delta_k \) (\( k=M-2, M-3, \ldots, 0 \)) is determined using backward recurrence as before by means of equation 23. Then either \( \alpha_k \) or \( \beta_k \) is replaced by \( \delta_k \) and a new set of \( c_1 \) and \( c_2 \) is determined by equations 27 and 28. Such a procedure can be repeated until the required accuracy is reached. However, only one application of it was necessary in the computation of the coefficients of this report.

As an example, consider the case for \( 4 \leq x \leq 12 \) with \( M = 15 \). The right member of equation 27 and of equation 28 assume, respectively, the values of 0.43820800 and 64. The trial solutions \( \alpha_k \) and \( \beta_k \) generated with \( \alpha_{14} = 8, \alpha_{15} = 9 \) and \( \beta_{14} = 7, \beta_{15} = 8 \) are certainly independent, since \( \alpha_{14} \beta_{15} - \alpha_{15} \beta_{14} = 1 \neq 0 \). A check of table 2 shows that equations 27 and 28 have, respectively, the residuals of \(-0.137 \times 10^{-4} \) and \(-0.976 \times 10^{-3} \). The same table also shows that \( c_1 \alpha_k \) is opposite in sign but nearly equal in magnitude to \( c_2 \beta_k \). Cancellations in the formation of the linear combination 24 causes a loss of significance of 2 to 6 figures in the computed \( A_k \). In the second iteration, where a new set of \( \beta_k \) is generated replacing \( \beta_{14} \) and \( \beta_{15} \), respectively, by \( c_1 \alpha_{14} + c_2 \beta_{14} \) and \( c_1 \alpha_{15} + c_2 \beta_{15} \) of the first iteration, the new \( c_1 \alpha_k \) and \( c_2 \beta_k \) differed from 2 to 5 orders of magnitude. Consequently, no cancellation of significant figures in the computation of \( A_k \) occurred. Notice that equations 27 and 28 are now satisfied exactly. Further note that the new \( c_1 \) and \( c_2 \) are near zero and unity, respectively, for the reason that if equations 21, 22, and 23 are satisfied by equation 24 exactly in the first iteration, the new \( c_1 \) and \( c_2 \) should have the precise values zero and 1, respectively. The results of the third iteration show that the \( A_k \) of the second iteration are already accurate to eight decimal places, since the \( A_k \) in the two iterations differ in less that \( 0.5 \times 10^{-8} \). Notice that for the third iteration, equations 27 and 28 are also satisfied exactly and that \( c_1 = 1 \) and \( c_2 = 0 \) (relative to 8 places of accuracy).

**Table 2**: Computation of Chebyshev Coefficients for \( xe^{-x} Ei(x) \)

| First iteration: | \( \alpha_{14} = 8 \), \( \alpha_{15} = 9 \); \( \beta_{14} = 7 \), \( \beta_{15} = 8 \) |

It is worth noting that the coefficient matrix of system (21, 22, 23) yields an upper triangular matrix of order \( M - 1 \) after the deletion of the first two rows and the last two columns. Consequently, the procedure of this section is applicable to any linear system having this property. As a matter of fact, the same procedure can be generalized to solve linear systems having coefficient matrices of order \( N \), the deletion of whose first \( r \) \((r < N)\) rows and last \( r \) columns yields upper triangular matrices of order \( N - r \).

The Function \((1/x)[Ei(x) - \log|x| - \gamma]\)

Let
\[ f(x) = (1/x)[Ei(x) - \log|x| - \gamma], \; g(x) = e^x, \; |x| \leq b \] \hspace{1cm} (5.29)

These functions, with the change of variable \( x = bt \), simultaneously satisfy the differential equations
\[ bt^2 \phi'(t) + bt \phi(t) - \psi(t) = -1 \] \hspace{1cm} (5.30)
\[ \psi'(t) - b \psi(t) = 0, \; -1 \leq t \leq 1 \] \hspace{1cm} (5.31)
Conversely,\(^2\) any solution of equations 30 and 31 is equal to the functions given by equations 29 for the change of variable \(x = bt\). Therefore, boundary conditions need not be imposed for the solution of the differential equations.

A procedure similar to that of the previous section gives the coupled infinite recurrence relations

\[
\begin{align*}
&bA_1 + bA_3 - B_0 + B_2 = -2 \\
&kbA_{k-1} + 2(k + 1)bA_{k+1} + (k + 2)bA_{k+3} - 2B_k + 2B_{k+2} = 0 \\
&bB_{k-1} - 2kB_k - bB_{k+1} = 0, \quad k = 1, 2, \ldots
\end{align*}
\]

(5.32)

(5.33)

where \(A_k\) and \(B_k\) are the Chebyshev coefficients of \(\phi(t)\) and \(\psi(t)\), respectively.

Consider first the subsystem 33. If \(A_k = \alpha_k\) and \(B_k = \beta_k\) are a simultaneous solution of the system, which is homogeneous, then

\[
\begin{align*}
&A_k = c\alpha_k \\
&B_k = c\beta_k
\end{align*}
\]

(5.34)

are also a solution for an arbitrary constant \(c\). Thus based on considerations analogous to the solution of equations 21, 22, and 23, one can initiate an approximate solution of equations 32 and 33 by setting

\[
\begin{align*}
&\alpha_M = 0, \quad \alpha_k = 0 \quad \text{for } k \geq M + 1 \\
&\beta_M = 1, \quad \beta_k = 0 \quad \text{for } k \geq M + 1
\end{align*}
\]

(5.35)

and then determining \(\alpha_k\) and \(\beta_k\) \((k = M - 1, M - 2, \ldots, 0)\) by backward recurrence by means of equation 33. The arbitrary constant \(c\) is determined by substituting 34 into 32.

The Function \(xe^{-x}Ei(x)\) on the Infinite Interval

Let

\[
f(x) = xe^{-x}Ei(x), \quad -\infty < x \leq b < 0, \quad \text{or} 0 < b \leq x < \infty
\]

(5.36)

By making the change of variables,

\[
x = \frac{2b}{t+1}
\]

(5.37)

we can easily demonstrate that

\[
f(x) = f\left[\frac{2b}{t+1}\right] = \phi(t)
\]

(5.38)

\(^2\)The general solution of the differential equations has the form

\[
\phi(t) = (c_1/t) + [Ei(bt) - \log|bt| - \gamma]/bt
\]

\[
\psi(t) = c_2e^{bt}
\]

where the first and second terms of \(\phi(t)\) are, respectively, the complementary solution and a particular integral of equation 30. The requirement that \(\phi(t)\) is bounded makes the constant \(c_1 = 0\). The fact that \(\psi(0) = 1\) is implicit in equation 30.
satisfies the differential equation
\[(t + 1)^2 \phi'(t) + (t + 1 - 2b)\phi(t) = -2b\] (5.39)

with
\[\phi(1) = be^{-b}Ei(b)\] (5.40)

An infinite system of equations involving the Chebyshev coefficients \(A_k\) of \(\phi(t)\) is deducible from equations 39 and 40 by the same procedure as applied to equations 13 and 14 to obtain the infinite system 20; it is given as follows.

\[\sum_{k=0}^{\infty} A_k = \phi(1) = be^{-b}Ei(b)\] (5.41)

\[(1 - 2b)A_0 + 3A_1 + (3 + 2b)A_2 + A_3 = -4b\] (5.42)

\[kA_{k-1} + 2[(2k + 1) - 2b]A_k + 6(k + 1)A_{k+1} + 2(2k + 3 + 2b)A_{k+2} + (k + 2)A_{k+3} = 0, \quad k = 1, 2, \ldots\] (5.43)

As in the case of equations 21, 22 and 23, the solution of 41, 42 and 43 can be assumed to be
\[A_k = c_1\alpha_k + c_2\beta_k\] (5.44)

with \(A_k\) vanishing for a \(k \geq M\). Thus, we can set, say

\[\begin{align*}
\alpha_{M-1} &= 0, & \alpha_M &= 1 \\
\beta_{M-1} &= 1, & \beta_M &= 0
\end{align*}\] (5.45)

and determine the trial solutions \(\alpha_k\) and \(\beta_k\) (\(k=M-1,M-2,\ldots,0\)) by means of equation 43 by backward recurrence. The required solution of equations 41, 42, and 43 is then determined by substituting equation 44 in equations 41 and 42 and solving the resulting equations for \(c_1\) and \(c_2\).

Loss of accuracy in the computation of \(A_k\) can also occur here, as in the solution of equations 21, 22 and 23, if the trial solutions are not sufficiently independent. The process used to improve the accuracy of \(A_k\) of the system 21, 22 and 23 can also be applied here.

For efficiency in computation, it is worth noting that for \(b < 0\) (\(-\infty < x \leq b < 0\)) the boundary condition 40 is not required for the solution of equation 39 and 40. This follows from the fact that any solution of the differential equation 39 is equal to \(xe^{-x}Ei(x)\) \((x = 2b/(t + 1))\). Hence the \(A_k\) of \(xe^{-x}Ei(x)\) for \(-\infty < x \leq b < 0\) can be obtained without the use of equation 39 and can be assumed to have the form
\[A_k = c\alpha_k, \quad (k = 0, 1, \ldots, M)\] (5.46)

The \(M+1\) values of \(\alpha_k\) can be generated by setting \(\alpha_M = 1\) and computing \(\alpha_k\) (\(k=0,1,\ldots,M-1\)) by means of equation 43 by backward recurrence. The substitution of equation 46 into 42 then enables one to determine \(c\) from the resulting equation.

---

3The general solution of the differential equation 39. Since equation 39 has no bounded complementary solution for \(-\infty < x \leq b < 0\), every solution of it is equal to the particular integral \(xe^{-x}Ei(x)\). On the other hand, a solution of equation 39 for \(0 < x \leq b < \infty\) would, in general, involve the complementary function. Hence, boundary condition 40 is required to guarantee that the solution of equation 39 is equal to \(xe^{-x}Ei(x)\).
Remarks on Convergence and Accuracy

The Chebyshev coefficients of table 3 were computed on the IBM 7094 with 50-digit normalized floating-point arithmetic. In order to assure that the sequence of approximate solutions (see Discussion) converged to the limiting solution of the differential equation in question, a trial $M$ was incremented by 4 until the approximate Chebyshev coefficients showed no change greater than or equal to $0.5 \times 10^{-35}$. Hence the maximum error is bounded by

$$0.5(M + 1) \times 10^{-35} + \sum_{M+1}^{\infty} |A_k|$$

where the first term is the maximum error of the $M+1$ approximate Chebyshev coefficients, and the sum is the maximum error of the truncated Chebyshev series of $M+1$ terms. If the Chebyshev series is rapidly convergent, the maximum error of the approximate Chebyshev series should be of the order of $10^{-30}$. The coefficients of table 3 have been rounded to 30 digits, and higher terms for $k > N$ giving the maximum residual

$$\sum_{k=N+1}^{M} |A_k| < 0.5 \times 10^{-30}$$

have been dropped. This should allow for evaluation of the relevant function that is accurate to 30 decimal places. Since the range of values of each function is bounded between $2/5$ and 5, the evaluated function should be good to 30 significant digits. Taylor series evaluation also checks with that of the function values of table 4 (computed with 30-digit floating-point arithmetic using the coefficients of table 3) for at least $28-1/2$ significant digits. Evaluation of $\text{Ei}(x)$ using the coefficients of table 3 also checked with Murnaghan and Wrench [?] for $28-1/2$ significant figures.

Table 3: Chebyshev Coefficients (a)

$$xe^{-x} \text{Ei}(x) = \sum_{k=0}^{40} tA_k T_k(t), \quad t = (-20/x) - 1, \quad (-\infty < x \leq -10)$$

The Fresnel Integral[?, ?]

The Fresnel function is

\[ C(x) - iS(x) = \int_0^x \exp(-i\pi t^2/2) \, dt \]

We compare Axiom’s results to Pearcey’s tables which show the fresnel results to 6 decimal places. Computation of these values requires floats as the range quickly exceeds DoubleFloat. In each decade of the range we increase the number of terms by a factor of 10. So we compute with 10 terms in the range 0.0-10.0, 100 terms in 10.0-20.0, etc.

fresnelC

The fresnelC is the real portion of the Fresnel integral, \( C(u) \), is defined as:

\[ C(\sqrt{2x/\pi}) = \frac{1}{2} \int_0^x J_{-\frac{1}{2}}(t) \, dt = \frac{1}{\sqrt{(2\pi)}} \int_0^x \cos(t) \, dt \]

where \( J_{-\frac{1}{2}}(t) \) is the Bessel function of the first kind of order \( -\frac{1}{2} \).

This is related to the better known definition of \( C(u) \), namely:

\[ C(u) = \int_0^u \cos \frac{\pi t^2}{2} \, dt \]

where \( x = \pi u^2/2 \), or \( u = (2x/\pi)^{1/2} \)

fresnelC is an analytic function of \( z \) with \( z=0 \) as a two-sheeted branch point. Along the positive real axis the real definition gives:

\[ C(0) = 0 \]

\[ \lim_{x \to +\infty} C(x) = \frac{1}{2} \]

The asymptotic behavior of the function in the corner \( |\text{arc } z| \leq \pi - \epsilon \), (\( \epsilon > 0 \)), for \( |z| \gg 1 \) is given by

\[ C(z) \approx \frac{1}{2} + \frac{\sin z}{\sqrt{2\pi z}} \left( 1 - \frac{1 \cdot 3}{(2z)^2} + \frac{1 \cdot 3 \cdot 5 \cdot 7}{(2z)^4} - \cdots \right) - \frac{\cos z}{\sqrt{2\pi z}} \left( \frac{1}{(2z)} - \frac{1 \cdot 3 \cdot 5}{(2z)^3} + \cdots \right) \]

(Note: Pearcey has a sign error for the second term ([?],p7)

The first approximation is

\[ C(z) \approx \frac{1}{2} + \frac{\sin z}{\sqrt{2\pi z}} \]

Axiom uses the power series at the zero point:

\[ C(z) = \sqrt{\frac{2z}{\pi}} \sum_{k=0}^{n} \frac{(-1)^k z^{2k}}{(4k+1)(2k)!} \]
fresnelC(z:F):F ==
z < 0 => error "fresnelC not defined for negative argument"
z = 0 => 0
n:PI:= 100
sqrt((2.0/pi()$F)*z)*_
reduce(_+,[(-1)**k*z**(2*k)/(factorial(2*k)*(4*k+1))_
for k in 0..n])$LF

fresnelS

The fresnelS is the complex portion of the Fresnel integral, S(u), is defined as:

\[
S(\sqrt{2x/\pi}) = \frac{1}{2} \int_0^x J_{\frac{1}{2}}(t) \, dt = \frac{1}{\sqrt{(2\pi)}} \int_0^x \frac{\sin(t)}{\sqrt{t}} \, dt
\]

where \(J_{\frac{1}{2}}(t)\) is the Bessel function of the first kind of order \(\frac{1}{2}\).

This is related to the better known definition of \(S(u)\), namely:

\[
S(u) = \int_0^u \sin \frac{\pi t^2}{2} \, dt
\]

where \(x = \pi u^2/2\), or \(u = (2x/\pi)^{1/2}\)

fresnelS is an analytic function of \(z\) with \(z=0\) as a two-sheeted branch point. Along the positive real axis the real definition gives:

\[
S(0) = 0
\]

\[
\lim_{x \to +\infty} S(x) = \frac{1}{2}
\]

The asymptotic behavior of the function in the corner \(|\text{arc } z| \leq \pi - \epsilon, (\epsilon > 0)\), for \(|z| \gg 1\) is given by

\[
S(z) \approx \frac{1}{2} - \frac{\cos z}{\sqrt{2\pi z}} \left( 1 - \frac{1 \cdot 3}{(2z)^2} + \frac{1 \cdot 3 \cdot 5 \cdot 7}{(2z)^4} - \cdots \right) - \frac{\sin z}{\sqrt{2\pi z}} \left( \frac{1}{(2z)} - \frac{1 \cdot 3 \cdot 5}{(2z)^3} + \cdots \right)
\]

The first approximation is

\[
S(z) \approx \frac{1}{2} - \frac{\cos z}{\sqrt{2\pi z}}
\]
Axiom uses the power series at the zero point:

\[ S(z) = \sqrt{\frac{2z}{\pi}} \sum_{k=0}^{n} \frac{(-1)^k \pi^{2k+1}}{(4k+3)(2k+1)!} \]

d01AgentsPackage examples

d01AgentsPackage is a package of numerical agents to be used to investigate attributes of an input function so as to decide the measure of an appropriate numerical integration routine.

It contains functions `rangeIsFinite` to test the input range and `functionIsContinuousAtEndPoints` to check for continuity at the end points of the range.

E ==> with
  combineFeatureCompatibility: (F,F) -> F
  ++ combineFeatureCompatibility(C1,C2) is for interacting attributes
  combineFeatureCompatibility: (F,LF) -> F
  ++ combineFeatureCompatibility(C1,L) is for interacting attributes
  sparsityIF: MEDF -> F
  ++ sparsityIF(m) calculates the sparsity of a jacobian matrix
  jacobian: (VEDF,LS) -> MEDF
  ++ jacobian(v,w) is a local function to make a jacobian matrix
  eval: (MEDF,LS,VEDF) -> MEDF
  ++ eval(mat,symbols,values) evaluates a multivariable matrix at given values
  ++ for each of a list of variables
  stiffnessAndStabilityFactor: MEDF -> RSS
  ++ stiffnessAndStabilityFactor(me) calculates the stability and
  ++ stiffness factor of a system of first-order differential equations
  ++ (by evaluating the maximum difference in the real parts of the
  ++ negative eigenvalues of the jacobian of the system for which O(10)
  ++ equates to mildly stiff whereas stiffness ratios of O(10^6) are not
  ++ uncommon) and whether the system is likely to show any oscillations
  ++ (identified by the closeness to the imaginary axis of the complex
  ++ eigenvalues of the jacobian).
  stiffnessAndStabilityOfODEIF:ODEA -> RSS
  ++ stiffnessAndStabilityOfODEIF(ode) calculates the intensity values
  ++ of stiffness of a system of first-order differential equations
  ++ (by evaluating the maximum difference in the real parts of the
  ++ negative eigenvalues of the jacobian of the system for which O(10)
  ++ equates to mildly stiff whereas stiffness ratios of O(10^6) are not
  ++ uncommon) and whether the system is likely to show any oscillations
  ++ (identified by the closeness to the imaginary axis of the complex
  ++ eigenvalues of the jacobian).
  ++
  ++ It returns two values in the range [0,1].
  systemSizeIF:ODEA -> F
  ++ systemSizeIF(ode) returns the intensity value of the size of
  ++ the system of ODEs. 20 equations corresponds to the neutral
  ++ value. It returns a value in the range [0,1].
  expenseOFEvaluationIF:ODEA -> F
  ++ expenseOFEvaluationIF(o) returns the intensity value of the
  ++ cost of evaluating the input ODE. This is in terms of the number
  ++ of ‘‘operational units’’ . It returns a value in the range
  ++ [0,1].
  ++ 400 ‘‘operation units’’ -> 0.75
  ++ 200 ‘‘operation units’’ -> 0.5
  ++ 83 ‘‘operation units’’ -> 0.25
  ++ exponentiation = 4 units , function calls = 10 units.
  accuracyIF:ODEA -> F
  ++ accuracyIF(o) returns the intensity value of the accuracy
++ requirements of the input ODE. A request of accuracy of $10^{-6}$
++ corresponds to the neutral intensity. It returns a value
++ in the range $[0,1]$.

intermediateResultsIF: ODEA -> F
++ intermediateResultsIF(ode) returns a value corresponding to the
++ required number of intermediate results required and, therefore,
++ an indication of how much this would affect the step-length of the
++ calculation. It returns a value in the range $[0,1]$.

++ Description:
++ This is a package for the exact computation of eigenvalues and eigenvectors.
++ This package can be made to work for matrices with coefficients which are
++ rational functions over a ring where we can factor polynomials.
++ Rational eigenvalues are always explicitly computed while the
++ non-rational ones are expressed in terms of their minimal
++ polynomial.
-- Functions for the numeric computation of eigenvalues and eigenvectors
-- are in numeigen.spad.

EigenPackage(R) : C == T
where
R : GcdDomain
P ==> Polynomial R
F ==> Fraction P
SE ==> Symbol()
SUP ==> SparseUnivariatePolynomial(P)
SUF ==> SparseUnivariatePolynomial(F)
M ==> Matrix(F)
NNI ==> NonNegativeInteger
ST ==> SuchThat(SE,P)

Eigenvalue ==> Union(F,ST)
EigenForm ==> Record(eigval:Eigenvalue,eigmult:NNI,eigvec : List M)
GenEigen ==> Record(eigval:Eigenvalue,geneigvec:List M)

C == with
  characteristicPolynomial : (M,Symbol) -> P
  ++ characteristicPolynomial(m,var) returns the
  ++ characteristicPolynomial of the matrix m using
  ++ the symbol var as the main variable.

  characteristicPolynomial : M -> P
  ++ characteristicPolynomial(m) returns the
  ++ characteristicPolynomial of the matrix m using
  ++ a new generated symbol symbol as the main variable.

  eigenvalues : M -> List Eigenvalue
  ++ eigenvalues(m) returns the
  ++ eigenvalues of the matrix m which are expressible
  ++ as rational functions over the rational numbers.

  eigenvector : (Eigenvalue,M) -> List M
  ++ eigenvector(eigval,m) returns the
  ++ eigenvectors belonging to the eigenvalue eigval
  ++ for the matrix m.

  generalizedEigenvector : (Eigenvalue,M,NNI,NNI) -> List M
  ++ generalizedEigenvector(alpha,m,k,g) returns the generalized eigenvectors
  ++ of the matrix relative to the eigenvalue alpha.
  ++ The integers k and g are respectively the algebraic and the
  ++ geometric multiplicity of the eigenvalue alpha.
  ++ alpha can be either rational or not.
  ++ in the second case alpha is the minimal polynomial of the
  ++ eigenvalue.

  generalizedEigenvector : (EigenForm,M) -> List M
  ++ generalizedEigenvector(eigen,m) returns the generalized eigenvectors
  ++ of the matrix relative to the eigenvalue eigen, as
  ++ returned by the function eigenvectors.

  generalizedEigenvectors : M -> List GenEigen
+ generalizedEigenvectors(m)  
+ returns the generalized eigenvectors  
+ of the matrix m.

eigenvectors : M -> List(EigenForm)  
+ eigenvectors(m) returns the eigenvalues and eigenvectors  
+ for the matrix m.  
+ The rational eigenvalues and the correspondent eigenvectors  
+ are explicitly computed, while the non rational ones  
+ are given via their minimal polynomial and the corresponding  
+ eigenvectors are expressed in terms of a "generic" root of  
+ such a polynomial.

Parameterized constructors traced:

\[ D(\cos(3x + 6y), x) \]

\[ (1) - 3\sin(6y + 3x) \]

Type: Expression(Integer)
Note that both Mathematica and Maxima return this result as $3\sec(3x + 6y)^2$ but Maple returns the same result as Axiom. They are equivalent results.

Note that Mathematica and Maxima return $-3\csc(3x + 6y)^2$ and Maple returns the same form as Axiom. They are equivalent.
simplify \((-3\cot(6y+3x)^2+3) -(-3\csc(3x+6y)^2)\)

\[\text{(7) 0}\]

Type: Expression(Integer)

\(\text{D(sec}(3x+6y),x)\)

\[\text{(8) 3sec}(6y + 3x)\tan(6y + 3x)\]

Type: Expression(Integer)

\(\text{D(csc}(3x+6y),x)\)

\[\text{(9) - 3cot}(6y + 3x)\csc(6y + 3x)\]

Type: Expression(Integer)

\(\text{D(asin}(3x+6y),x)\)

\[\text{(10) \frac{1}{2 - 36y - 36x y - 9x + 1}}\]

Type: Expression(Integer)

\(\text{D(acos}(3x+6y),x)\)

\[\text{(11) \frac{1}{2 - 36y - 36x y - 9x + 1}}\]

Type: Expression(Integer)
\[ D(\tan(3x+6y),x) \]

\[ 3 \]

\[ \frac{2}{2} \]

\[ 36y + 36x y + 9x + 1 \]

Type: Expression(Integer)

\[ D(\cot(3x+6y),x) \]

\[ 3 \]

\[ \frac{2}{2} \]

\[ 36y + 36x y + 9x + 1 \]

Type: Expression(Integer)

Mathematica, Maple, and Maxima give:

\[ \frac{3}{(3x+6y)^2} \sqrt{1 - \frac{1}{(3x+6y)^2}} \]

which proceeds directly from the formula for the derivative of \( \text{arcsec}(x) \):

\[ \frac{d}{dx} \text{arcsec}(x) = \frac{1}{x\sqrt{x^2 - 1}} \]

---

\[ D(\text{asec}(3x+6y),x) \]

\[ 1 \]

\[ \frac{1}{2} \]

\[ (2y + x)\sqrt{36y + 36x y + 9x - 1} \]

Type: Expression(Integer)
If we use the same formula for this example:

\[
\frac{1}{(3x + 6y)\sqrt{(3x + 6y)^2 - 1}} \, d(3x + 6y)/dx
\]

--- ElementaryFunction.input ---

-- S 17 of 32

\[
\frac{3}{((3x + 6y)\sqrt{(3x + 6y)^2 - 1})}
\]

-- R

-- R

-- R (15) \[ \frac{1}{(2y + x)\sqrt{36y + 36x y + 9x - 1}} \]

-- R Type: Expression(Integer)

---

Mathematica, Maple, and Maxima give

\[
-\frac{3}{(3x + 6y)^2\sqrt{1 - \frac{1}{(3x + 6y)^2}}}
\]

which is just the negative of the above result and we can see that the same analysis applies to explain the results.

--- ElementaryFunction.input ---

-- S 18 of 32

\[
D(\text{acsc}(3x + 6y), x)
\]

-- R

-- R

-- R (16) \[ \frac{1}{(2y + x)\sqrt{36y + 36x y + 9x - 1}} \]

-- R Type: Expression(Integer)

---

-- S 19 of 32

\[
D(\text{sinh}(3x + 6y), x)
\]

-- R

-- R (17) \[ 3\text{cosh}(6y + 3x) \]
Mathematica and Maxima return

\[3\text{sech}(3x + 6y)^2\]

Maple returns Axiom’s answer. Both are equivalent.

—— ElementaryFunction.input ——

Mathematica and Maxima return

\[-3\text{csch}(3x + 6y)^2\]

Maple returns Axiom’s answer. Both are equivalent.

—— ElementaryFunction.input ——
Mathematica and Maple show

\[
\frac{3}{\sqrt{-1 + 3x + 6y} \sqrt{1 + 3x + 6y}}
\]

Maxima gives Axiom’s answer. Both are equivalent, just factored forms.
--- ElementaryFunction.input ---

**ElementaryFunctionLODESolver (LODEEF)**

Exports:
solve

— package LODEEF ElementaryFunctionLODESolver —

)abbrev package LODEEF ElementaryFunctionLODESolver
++ Author: Manuel Bronstein
++ Date Created: 3 February 1994
++ Date Last Updated: 9 March 1994
++ Description:
++ \spad{ElementaryFunctionLODESolver} provides the top-level
++ functions for finding closed form solutions of linear ordinary
++ differential equations and initial value problems.

ElementaryFunctionLODESolver(R, F, L): Exports == Implementation where
R: Join(OrderedSet, EuclideanDomain, RetractableTo Integer,
    LinearlyExplicitRingOver Integer, CharacteristicZero)
F: Join(AlgebraicallyClosedFunctionSpace R, TranscendentalFunctionCategory, PrimitiveFunctionCategory)
L: LinearOrdinaryDifferentialOperatorCategory F
SY ==> Symbol
N ==> NonNegativeInteger
K ==> Kernel F
V ==> Vector F
M ==> Matrix F
UP ==> SparseUnivariatePolynomial F
RF ==> Fraction UP
UPUP==> SparseUnivariatePolynomial RF
P ==> SparseMultivariatePolynomial(R, K)
P2 ==> SparseMultivariatePolynomial(P, K)
LQ ==> LinearOrdinaryDifferentialOperator1 RF
REC ==> Record(particular: F, basis: List F)
U ==> Union(REC, "failed")
ALGOP ==> "%alg"

Exports ==> with
solve: (L, F, SY) -> U
++ solve(op, g, x) returns either a solution of the ordinary differential
++ equation \( \text{op y = g} \) or "failed" if no non-trivial solution can be
++ found; When found, the solution is returned in the form
++ \( \text{spad[h, [b1,...,bm]]} \) where \( \text{spad(h)} \) is a particular solution and
++ and \( \text{spad[bi,...,bm]} \) are linearly independent solutions of the
++ associated homogenous equation \( \text{spad[op y = 0]} \).
++ A full basis for the solutions of the homogenous equation
++ is not always returned, only the solutions which were found;
++ \( \text{spad(x)} \) is the dependent variable.
solve: (L, F, SY, F, List F) -> Union(F, "failed")
++ solve(op, g, x, a, \{y0,...,ym\}) returns either the solution
++ of the initial value problem \( \text{op y = g, y(a) = y0, y'(a) = y1,...} \)
++ or "failed" if the solution cannot be found;
++ \( \text{spad(x)} \) is the dependent variable.

Exports => with
solve: (M, V, SY) -> Union(VEC, "failed")
  ++ solve(m, v, x) returns \spad{[v_p, [v_1,...,v_m]]} such that
  ++ the solutions of the system \spad{D y = m y + v} are
  ++ \spad{v_p + c_1 v_1 + ... + c_m v_m} where the \spad{c_i's} are
  ++ constants, and the \spad{v_i's} form a basis for the solutions of
  ++ \spad{D y = m y}.
  ++ \spad{x} is the dependent variable.
solve: (M, SY) -> Union(List V, "failed")
  ++ solve(m, x) returns a basis for the solutions of \spad{D y = m y}.
  ++ \spad{x} is the dependent variable.
solve: (List EQ, List OP, SY) -> Union(VEC, "failed")
  ++ solve([eq_1,...,eq_n], [y_1,...,y_n], x) returns either "failed"
  ++ or, if the equations form a first order linear system, a solution
  ++ of the form \spad{[h_p, [b_1,...,b_n]]} where \spad{h_p} is a
  ++ particular solution and \spad{[b_1,...b_m]} are linearly independent
  ++ solutions of the associated homogeneous system.
  ++ error if the equations do not form a first order linear system
solve: (List F, List OP, SY) -> Union(VEC, "failed")
  ++ solve([eq_1,...,eq_n], [y_1,...,y_n], x) returns either "failed"
  ++ or, if the equations form a first order linear system, a solution
  ++ of the form \spad{[h_p, [b_1,...,b_n]]} where \spad{h_p} is a
  ++ particular solution and \spad{[b_1,...b_m]} are linearly independent
  ++ solutions of the associated homogeneous system.
  ++ error if the equations do not form a first order linear system
solve: (EQ, OP, SY) -> U
  ++ solve(eq, y, x) returns either a solution of the ordinary differential
  ++ equation \spad{eq} or "failed" if no non-trivial solution can be found;
  ++ If the equation is linear ordinary, a solution is of the form
  ++ \spad{h, [b_1,...,b_m]} where \spad{h} is a particular solution
  ++ and \spad{[b_1,...b_m]} are linearly independent solutions of the
  ++ associated homogeneous equation \spad{f(x,y) = 0};
  ++ A full basis for the solutions of the homogeneous equation
  ++ is not always returned, only the solutions which were found;
  ++ If the equation is of the form \spad{dy/dx = f(x,y)}, a solution is of
  ++ the form \spad{h(x,y)} where \spad{h(x,y) = c} is a first integral
  ++ of the equation for any constant \spad{c};
  ++ error if the equation is not one of those 2 forms;
solve: (F, OP, SY) -> U
  ++ solve(eq, y, x) returns either a solution of the ordinary differential
  ++ equation \spad{eq} or "failed" if no non-trivial solution can be found;
  ++ If the equation is linear ordinary, a solution is of the form
  ++ \spad{h, [b_1,...,b_m]} where \spad{h} is a particular solution and
  ++ and \spad{[b_1,...b_m]} are linearly independent solutions of the
  ++ associated homogeneous equation \spad{f(x,y) = 0};
  ++ A full basis for the solutions of the homogeneous equation
++ is not always returned, only the solutions which were found;
++ If the equation is of the form \(\frac{dy}{dx} = f(x,y)\), a solution is of
++ the form \(h(x,y)\) where \(h(x,y) = c\) is a first integral
++ of the equation for any constant \(c\);
solve: (EQ, OP, EQ, List F) -> UU
++ solve(eq, y, x = a, [y0,...,ym]) returns either the solution
++ of the initial value problem \(eq, y(a) = y0, y'(a) = y1,...\)
++ or "failed" if the solution cannot be found;
++ error if the equation is not one linear ordinary or of the form
++ \(\frac{dy}{dx} = f(x,y)\);
solve: (F, OP, EQ, List F) -> UU
++ solve(eq, y, x = a, [y0,...,ym]) returns either the solution
++ of the initial value problem \(eq, y(a) = y0, y'(a) = y1,...\)
++ or "failed" if the solution cannot be found;
++ error if the equation is not one linear ordinary or of the form
++ \(\frac{dy}{dx} = f(x,y)\);

ElementaryFunctionStructurePackage examples
====================================================================

ElementaryFunctionStructurePackage provides functions to test the algebraic independence of various elementary functions, using the Risch structure theorem (real and complex versions). It also provides transformations on elementary functions which are not considered simplifications.

Exports ==> with
normalize: F -> F
  ++ normalize(f) rewrites \spad{f} using the least possible number of
  ++ real algebraically independent kernels.
normalize: (F, SY) -> F
  ++ normalize(f, x) rewrites \spad{f} using the least possible number of
  ++ real algebraically independent kernels involving \spad{x}.
rischNormalize: (F, SY) -> REC
  ++ rischNormalize(f, x) returns \spad{[g, [k1,...,kn], [h1,...,hn]]}
  ++ such that \spad{g = normalize(f, x)} and each \spad{ki} was
  ++ rewritten as \spad{hi} during the normalization.
realElementary: F -> F
  ++ realElementary(f) rewrites \spad{f} in terms of the 4 fundamental real
  ++ transcendental elementary functions: \spad{log, exp, tan, atan}.
realElementary: (F, SY) -> F
  ++ realElementary(f,x) rewrites the kernels of \spad{f} involving
  ++ \spad{x} in terms of the 4 fundamental real
  ++ transcendental elementary functions: \spad{log, exp, tan, atan}.
validExponential: (List K, F, SY) -> Union(F, "failed")
  ++ validExponential([k1,...,kn],f,x) returns \spad{g} if \spad{exp(f)=g}
  ++ and \spad{g} involves only \spad{k1...kn}, and "failed" otherwise.
rootNormalize: (F, K) -> F
  ++ rootNormalize(f, k) returns \spad{f} rewriting either \spad{k} which
  ++ must be an nth-root in terms of radicals already in \spad{f}, or some
  ++ radicals in \spad{f} in terms of \spad{k}.
tanQ: (Q, F) -> F
  ++ tanQ(q,a) is a local function with a conditional implementation.

algint(f, t, y,
Bug #100 is an infinite loop that eventually kills Axiom from the input

\texttt{integrate((z}^{a+1})^b,z)\]

Line 2 of this function used to read:

\texttt{symbolIfCan(k := kmax(1 := union(1, varselect(kernels g, x))))}

The loop occurs when the call to union causes

\begin{verbatim}
  a log(z) %e
\end{verbatim}

to get added to the list every time. This gives the argument to kmax

\begin{verbatim}
  a log(z) arg1= [z,%e ]
\end{verbatim}

and the result being

\begin{verbatim}
  a log(z) %e
\end{verbatim}

We keep coming back to process this term, which ends up putting the same term back on the list and we loop. Waldek's solution is to remove the union call.

The original patch fixed the infinite regression mentioned above but caused Axiom to return a closed form of the integral:

\texttt{integrate(asech(x)/x,x)}

which should not have a closed form. This is referenced in the FriCAS SVN revision 279.

Essentially this new patch uses only logarithms of rational functions when integrating rational functions. It is unclear whether this is the correct fix.
lfextendedint(f, x, g) ==
  empty?(l := varselect(kernels f, x)) => [x::F * f, 0]
  symbolIfCan(k := kmax(l))

package ERROR ErrorFunctions

--- ErrorFunctions.input ---
ErrorFunctions implements error functions callable from the system interpreter. Typically, these functions would be called in user functions. The simple forms of the functions take one argument which is either a string (an error message) or a list of strings which all together make up a message. The list can contain formatting codes (see below). The more sophisticated versions takes two arguments where the first argument is the name of the function from which the error was invoked and the second argument is either a string or a list of strings, as above. When you use the one argument version in an interpreter function, the system will automatically insert the name of the function as the new first argument. Thus in the user interpreter function

\[
\text{f x == if x < 0 then error "negative argument" else x}
\]

the call to error will actually be of the form

\[
\text{error("f","negative argument")}
\]

because the interpreter will have created a new first argument.

Formatting codes: error messages may contain the following formatting codes (they should either start or end a string or else have blanks around them):

- %l: start a new line
- %b: start printing in a bold font (where available)
%d  stop printing in a bold font (where available)
%ceon  start centering message lines
%ceoff  stop centering message lines
%rjon  start displaying lines "ragged left"
%rjoff  stop displaying lines "ragged left"
%i  indent following lines 3 additional spaces
%u  unindent following lines 3 additional spaces
%xN  insert N blanks (eg, %x10 inserts 10 blanks)

Examples:
1. error "Whoops, you made a %l %ceon %b big %d %ceoff %l mistake!"
2. error ["Whoops, you made a",%l %ceon %b","big",
   "%d %ceoff %l","mistake!"]

reduced Critpair - Polynom :

There are 3 Groebner Basis Polynomials.
EuclideanGroebnerBasisPackage computes groebner bases for polynomial ideals over euclidean domains. The basic computation provides a distinguished set of generators for these ideals. This basis allows an easy test for membership: the operation euclideanNormalForm returns zero on ideal members. The string "info" and "redcrit" can be given as additional args to provide incremental information during the computation.

If "info" is given, a computational summary is given for each s-polynomial. If "redcrit" is given, the reduced critical pairs are printed.

The term ordering is determined by the polynomial type used.
Suggested types include
* DistributedMultivariatePolynomial
* HomogeneousDistributedMultivariatePolynomial
* GeneralDistributedMultivariatePolynomial

Example to call euclideanGroebner:

```plaintext
a1:DMP([y,x],INT):= (9*x**2 + 5*x - 3)+ y*(3*x**2 + 2*x + 1)
a2:DMP([y,x],INT):= (6*x**3 - 2*x**2 - 3*x +3) + y*(2*x**3 - x - 1)
a3:DMP([y,x],INT):= (3*x**3 + 2*x**2) + y*(x**3 + x**2)
an:=[a1,a2,a3]
euclideanGroebner(an)
```

This will return the weak euclidean Groebner basis set. All reductions are total reductions.

You can get more information by providing a second argument. To get the reduced critical pairs do:

```plaintext
euclideanGroebner(an,"redcrit")
```
You can get other information by calling:

```
euclideanGroebner(an,"info")
```

which returns:

- `ci` => Leading monomial for critpair calculation
- `tci` => Number of terms of polynomial i
- `cj` => Leading monomial for critpair calculation
- `tcj` => Number of terms of polynomial j
- `c` => Leading monomial of critpair polynomial
- `tc` => Number of terms of critpair polynomial
- `rc` => Leading monomial of redcritpair polynomial
- `trc` => Number of terms of redcritpair polynomial
- `tH` => Number of polynomials in reduction list H
- `tD` => Number of critpairs still to do

The three argument form returns all of the information:

```
euclideanGroebner(an,"info","redcrit")
```

The term ordering is determined by the polynomial type used. Suggested types include

- `DistributedMultivariatePolynomial`
- `HomogeneousDistributedMultivariatePolynomial`
- `GeneralDistributedMultivariatePolynomial`

++ Authors: Gebauer, Moeller
++ Date Created: 12-1-86
++ Date Last Updated: 2-28-91
++ Description:
++ \spadtype{EuclideanGroebnerBasisPackage} computes groebner
++ bases for polynomial ideals over euclidean domains.
++ The basic computation provides
++ a distinguished set of generators for these ideals.
++ This basis allows an easy test for membership: the operation
++ \spadfun{euclideanNormalForm} returns zero on ideal members. The string
++ "info" and "redcrit" can be given as additional args to provide
++ incremental information during the computation. If "info" is given,
++ a computational summary is given for each s-polynomial. If "redcrit"
++ is given, the reduced critical pairs are printed. The term ordering
++ is determined by the polynomial type used. Suggested types include
++ \spadtype{DistributedMultivariatePolynomial},
++ \spadtype{HomogeneousDistributedMultivariatePolynomial},
++ \spadtype{GeneralDistributedMultivariatePolynomial}.

EuclideanGroebnerBasisPackage(Dom, Expon, VarSet, Dpol): T == C where

Dom: EuclideanDomain
Expon: OrderedAbelianMonoidSup
VarSet: OrderedSet
Dpol: PolynomialCategory(Dom, Expon, VarSet)

T== with

   euclideanNormalForm: (Dpol, List(Dpol) ) -> Dpol
euclideanNormalForm(poly, gb) reduces the polynomial poly modulo the
precomputed groebner basis gb giving a canonical representative
of the residue class.

euclideanGroebner: List(Dpol) -> List(Dpol)
++ euclideanGroebner(lp) computes a groebner basis for a polynomial
++ ideal over a euclidean domain generated by the list of polys lp.
++
++ a1:DMP([y,x],INT):= (9*x**2 + 5*x - 3)+ y*(3*x**2 + 2*x + 1)
++ a2:DMP([y,x],INT):= (6*x**3 - 2*x**2 - 3*x +3) + y*(2*x**3 - x - 1)
++ a3:DMP([y,x],INT):= (3*x**3 + 2*x**2) + y*(x**3 + x**2)
++ an:=[a1,a2,a3]
++ X euclideanGroebner(an)

euclideanGroebner: (List(Dpol), String) -> List(Dpol)
++ euclideanGroebner(lp, infoflag) computes a groebner basis
++ for a polynomial ideal over a euclidean domain
++ generated by the list of polynomials lp.
++ During computation, additional information is printed out
++ if infoflag is given as
++ either "info" (for summary information) or
++ "redcrit" (for reduced critical pairs)
++
++ a1:DMP([y,x],INT):= (9*x**2 + 5*x - 3)+ y*(3*x**2 + 2*x + 1)
++ a2:DMP([y,x],INT):= (6*x**3 - 2*x**2 - 3*x +3) + y*(2*x**3 - x - 1)
++ a3:DMP([y,x],INT):= (3*x**3 + 2*x**2) + y*(x**3 + x**2)
++ an:=[a1,a2,a3]
++ X euclideanGroebner(an,"redcrit")
++ X euclideanGroebner(an,"info")

euclideanGroebner: (List(Dpol), String, String) -> List(Dpol)
++ euclideanGroebner(lp, "info", "redcrit") computes a groebner basis
++ for a polynomial ideal generated by the list of polynomials lp.
++ If the second argument is "info",
++ a summary is given of the critical pairs.
++ If the third argument is "redcrit", critical pairs are printed.
++
++ a1:DMP([y,x],INT):= (9*x**2 + 5*x - 3)+ y*(3*x**2 + 2*x + 1)
++ a2:DMP([y,x],INT):= (6*x**3 - 2*x**2 - 3*x +3) + y*(2*x**3 - x - 1)
++ a3:DMP([y,x],INT):= (3*x**3 + 2*x**2) + y*(x**3 + x**2)

SOCDF==> Segment OrderedCompletion DoubleFloat
NIA  ==> Record(var:Symbol,fn:EDF,range:SOCDF,abserr:DF,relerr:DF)
UP   ==> UnivariatePolynomial
BO   ==> BasicOperator
RS   ==> Record(zeros: SDF,ones: SDF,singularities: SDF)

E ==>

getlo : SOCDF -> DF
++ getlo(u) gets the \axiomType{DoubleFloat} equivalent of
++ the first endpoint of the range \axiom{u}

gethi : SOCDF -> DF
++ gethi(u) gets the \axiomType{DoubleFloat} equivalent of
++ the second endpoint of the range \axiom{u}

functionIsFracPolynomial?: NIA -> Boolean
++ functionIsFracPolynomial?(args) tests whether the function
++ can be retracted to \axiomType{Fraction(Polynomial(DoubleFloat))}

problemPoints:(EDF,Symbol,SOCDF) -> List DF
++ problemPoints(f,var,range) returns a list of possible problem points
++ by looking at the zeros of the denominator of the function \spad{f}
++ if it can be retracted to \axiomType{Polynomial(DoubleFloat)}.

zerosOf:(EDF,List Symbol,SOCDF) -> SDF
++ zerosOf(e,vars,range) returns a list of points
++ (\axiomType{Doublefloat}) at which a NAG fortran version of \spad{e}
++ will most likely produce an error.

singularitiesOf: (EDF,List Symbol,SOCDF) -> SDF
++ singularitiesOf(e,vars,range) returns a list of points
++ (\axiomType{Doublefloat}) at which a NAG fortran
++ version of \spad{e} will most likely produce
++ an error. This includes those points which evaluate to 0/0.

singularitiesOf: (Vector EDF,List Symbol,SOCDF) -> SDF
++ singularitiesOf(v,vars,range) returns a list of points
++ at which a NAG fortran ++ version of \spad{v} will most likely produce ++ an error. This includes those points which evaluate to 0/0.

polynomialZeros:(PFI,Symbol,SOCDF) -> LDF ++ polynomialZeros(fn,\var,range) calculates the real zeros of the ++ polynomial which are contained in the given interval. It returns ++ a list of points \axiomType{Doublefloat} for which the univariate ++ polynomial \spad{fn} is zero.

def2st:DF -> String ++ df2st(n) coerces a \axiomType{DoubleFloat} to \axiomType{String}

ldf2lst:LDF -> List String ++ ldf2lst(ln) coerces a List of \axiomType{DoubleFloat} to ++ \axiomType{List}(\axiomType{String})

 sdf2lst:SDF -> List String ++ sdf2lst(ln) coerces a Stream of \axiomType{DoubleFloat} to ++ \axiomType{List}(\axiomType{String})

E ==> with

f2df:F -> DF
++ f2df(f) is a function to convert a \axiomType{Float} to a
++ \axiomType{DoubleFloat}

ef2edf:EF -> EDF
++ ef2edf(f) is a function to convert an \axiomType{Expression Float}
++ to an \axiomType{Expression DoubleFloat}

ocf2ocdf: OCF -> OCDF
++ ocf2ocdf(a) is a function to convert an \axiomType{OrderedCompletion
++ Float} to an \axiomType{OrderedCompletion DoubleFloat}

socf2socdf: SOCF -> SOCDF
++ socf2socdf(a) is a function to convert a \axiomType{Segment OrderedCompletion Float}
++ to a \axiomType{Segment OrderedCompletion DoubleFloat}

convert: List SOCF -> List SOCDF
++ convert(l) is a function to convert a \axiomType{Segment OrderedCompletion Float}
++ to a \axiomType{Segment OrderedCompletion DoubleFloat}

df2fi :DF -> FI
++ df2fi(n) is a function to convert a \axiomType{DoubleFloat} to a
++ \axiomType{Fraction Integer}

edf2fi :EDF -> FI
++ edf2fi(n) maps \axiomType{Expression DoubleFloat} to
++ \axiomType{Fraction Integer}
++ It is an error if \spad{n} is not coercible to \axiomType{Fraction Integer}

edf2df :EDF -> DF
++ edf2df(n) maps \axiomType{Expression DoubleFloat} to
++ \axiomType{DoubleFloat}
++ It is an error if \spad{n} is not coercible to \axiomType{DoubleFloat}

isQuotient: EDF -> Union(EDF,"failed")
++ isQuotient(expr) returns the quotient part of the input
++ expression or \spad{"failed"} if the expression is not of that form.

expenseOfEvaluation: VEDF -> F
++ expenseOfEvaluation(o) gives an approximation of the cost of
++ evaluating a list of expressions in terms of the number of basic
++ operations.
++ < 0.3 inexpensive ; 0.5 neutral ; > 0.7 very expensive
++ 400 'operation units' -> 0.75
++ 200 'operation units' -> 0.5
++ 83 'operation units' -> 0.25
++ ** = 4 units , function calls = 10 units.

numberOfOperations: VEDF -> ON
++ numberOfOperations(ode) counts additions, multiplications,
++ exponentiations and function calls in the input set of expressions.

df2efi: EDF -> EFI
++ df2efi(e) coerces \axiomType{Expression DoubleFloat} into
++ \axiomType{Expression Fraction Integer}

dfRange: SOCDF -> SOCDF
++ dfRange(r) converts a range including
++ \inputbitmap{\htbmdir{}/plusminus.bitmap} \infty
++ to \axiomType{DoubleFloat} equivalents.
dflist:List(Record(left:FI,right:FI)) -> LDF
++ dflist(l) returns a list of \axiomType{DoubleFloat} equivalents of list l
df2mf:DF -> MF
++ df2mf(n) coerces a \axiomType{DoubleFloat} to \axiomType{MachineFloat}
1df2vmf:LDF -> VMF
++ 1df2vmf(l) coerces a \axiomType{List DoubleFloat} to
++ \axiomType{List MachineFloat}
edf2ef:EDF -> EF
++ edf2ef(e) maps \axiomType{Expression DoubleFloat} to
++ \axiomType{Expression Float}
vedf2vef:VEDF -> VEF
++ vedf2vef(v) maps \axiomType{Vector Expression DoubleFloat} to
++ \axiomType{Vector Expression Float}
in?:DF,SOCDF -> Boolean
++ in?(p,range) tests whether point p is internal to the
++ range range
df2st:DF -> ST
++ df2st(n) coerces a \axiomType{DoubleFloat} to \axiomType{String}
f2st:F -> ST
++ f2st(n) coerces a \axiomType{Float} to \axiomType{String}
1df2lst:LDF -> LST
++ 1df2lst(ln) coerces a \axiomType{List DoubleFloat} to \axiomType{List String}
sdf2lst:SDF -> LST
++ sdf2lst(ln) coerces a \axiomType{Stream DoubleFloat} to \axiomType{String}
getlo : SOCDF -> DF
++ getlo(u) gets the \axiomType{DoubleFloat} equivalent of
++ the first endpoint of the range \spad{u}
gethi : SOCDF -> DF
++ gethi(u) gets the \axiomType{DoubleFloat} equivalent of
++ the second endpoint of the range \spad{u}
concat:(Result,Result) -> Result
++ concat(a,b) adds two aggregates of type \axiomType{Result}.
concat:(List Result) -> Result
++ concat(l) concatenates a list of aggregates of type \axiomType{Result}
outputMeasure:F -> ST
++ outputMeasure(n) rounds \spad{n} to 3 decimal places and outputs
++ it as a string
measure2Result:Measure -> Result
++ measure2Result(m) converts a measure record into a \axiomType{Result}
measure2Result:Measure2 -> Result
++ measure2Result(m) converts a measure record into a \axiomType{Result}
att2Result:ATT -> Result
++ att2Result(m) converts a attributes record into a \axiomType{Result}
iflist2Result:IFV -> Result
++ iflist2Result(m) converts a attributes record into a \axiomType{Result}
pdf2ef:PDF -> EF
++ pdf2ef(p) coerces a \axiomType{Polynomial DoubleFloat} to
++ \axiomType{Expression Float}
pdf2df:PDF -> DF
++ pdf2df(p) coerces a \axiomType{Polynomial DoubleFloat} to
++ \axiomType{DoubleFloat}. It is an error if \axiom{p} is not
++ retractable to DoubleFloat.
df2ef:DF -> EF
++ df2ef(a) coerces a \axiomType{DoubleFloat} to \axiomType{Expression Float}
fi2df:FI -> DF
++ fi2df(f) coerces a \axiomType{Fraction Integer} to \axiomType{DoubleFloat}
mat:(LDF,NNI) -> MDF
++ mat(a,n) constructs a one-dimensional matrix of a.

— EXPR2.dotabb ——
package EXPRSOL ExpressionSolve

Bugs

seriesSolve(sin f x / cos x, f, x, [1])$EXPRSOL(INT, EXPR INT, UFPS EXPR INT, UFPS SUPEXPR EXPR INT)

returns

(((0 . 1) 0 . 1) NonNullStream #<compiled-function |STREAM;generate;M$;62!0|> . UNPRINTABLE)

but

U ==> UFPS SUPEXPR EXPR INT
seriesSolve(s +-> sin s *((cos monomial(1,1)$U)**-1)$U, f, x, [0])$EXPRSOL(INT, EXPR INT, UFPS SUPEXPR EXPR INT)

works. This is probably due to missing “/” in UFPS.

I'd really like to be able to specify a function that works for all domains in a category. For example, x +-> y(x)^2 + sin x + x should work for EXPR INT as well as for UTS INT, both being domains having TranscendentalFunctionCategory.

\getchunk{implementation: EXPRSOL ExpressionSolve}

The general method is to transform the given expression into a form which can then be compiled. There is currently no other way in Axiom to transform an expression into a function.

We need to replace the differentiation operator by the corresponding function in the power series category, and make composition explicit. Furthermore, we need to replace the variable by the corresponding variable in the power series. It turns out that the compiler doesn’t find the right definition of monomial(1,1). Thus we introduce it as a second argument. In fact, maybe that’s even cleaner. Also, we need to tell the compiler that kernels that are independent of the main variable should be coerced to elements of the coefficient ring, since it will complain otherwise.

I cannot find an example for this behaviour right now. However, if I do use the coerce, the following fails:

\texttt{seriesSolve(h \times -1-\times h \times h(q \times x), h, x, [1])}

Exports ==> with
taylor: SY -> Any
++ \spad{taylor(x)} returns x viewed as a Taylor series.
taylor: FE -> Any
++ \spad{taylor(f)} returns a Taylor expansion of the expression f.
++ Note that f should have only one variable; the series will be
++ expanded in powers of that variable.
taylor: (FE,NNI) -> Any
++ \spad{taylor(f,n)} returns a Taylor expansion of the expression f.
++ Note that f should have only one variable; the series will be
++ expanded in powers of that variable and terms will be computed
++ up to order at least n.
taylor: (FE,EQ FE) -> Any
++ \spad{taylor(f,x = a)} expands the expression f as a Taylor series
++ in powers of \spad{(x - a)}.
taylor: (FE,EQ FE,NNI) -> Any
++ \spad{taylor(f,x = a)} expands the expression f as a Taylor series
++ in powers of \spad{(x - a)}; terms will be computed up to order
++ at least n.

laurent: SY -> Any
++ \spad{laurent(x)} returns x viewed as a Laurent series.
laurent: FE -> Any
++ \spad{laurent(f)} returns a Laurent expansion of the expression f.
++ Note that f should have only one variable; the series will be
++ expanded in powers of that variable.
laurent: (FE,I) -> Any
++ \spad{laurent(f,n)} returns a Laurent expansion of the expression f.
++ Note that f should have only one variable; the series will be
++ expanded in powers of that variable and terms will be computed
++ up to order at least n.
laurent: (FE,EQ FE) -> Any
++ \spad{laurent(f,x = a)} expands the expression f as a Laurent series
++ in powers of \spad{(x - a)}.
laurent: (FE,EQ FE,I) -> Any
++ \spad{laurent(f,x = a,n)} expands the expression f as a Laurent
++ series in powers of \spad{(x - a)}; terms will be computed up to order
++ at least n.
puiseux: SY -> Any
++ \spad{puiseux(x)} returns x viewed as a Puiseux series.
puiseux: FE -> Any
++ \spad{puiseux(f)} returns a Puiseux expansion of the expression f.
++ Note that f should have only one variable; the series will be
++ expanded in powers of that variable.
puiseux: (FE,RN) -> Any
++ \spad{puiseux(f,n)} returns a Puiseux expansion of the expression f.
++ Note that f should have only one variable; the series will be
++ expanded in powers of that variable and terms will be computed
++ up to order at least n.
puiseux: (FE,EQ FE) -> Any
++ \spad{puiseux(f,x = a)} expands the expression f as a Puiseux series
++ in powers of \spad{(x - a)}.

puiseux: \(\text{FE, EQ, FE, RN} \rightarrow \text{Any}\)
++ \spad{puiseux(f, x = a, n)} expands the expression \(f\) as a Puiseux
++ series in powers of \spad{(x - a)}; terms will be computed up to order
++ at least \(n\).

series: \(\text{SY} \rightarrow \text{Any}\)
++ \spad{series(x)} returns \(x\) viewed as a series.

series: \(\text{FE} \rightarrow \text{Any}\)
++ \spad{series(f)} returns a series expansion of the expression \(f\).
++ Note that \(f\) should have only one variable; the series will be
++ expanded in powers of that variable.

series: \(\text{FE, RN} \rightarrow \text{Any}\)
++ \spad{series(f, n)} returns a series expansion of the expression \(f\).
++ Note that \(f\) should have only one variable; the series will be
++ expanded in powers of that variable and terms will be computed
++ up to order at least \(n\).

series: \(\text{FE, EQ, FE} \rightarrow \text{Any}\)

— package EXPRTUBE ExpressionTubePlot —

abbrev package EXPRTUBE ExpressionTubePlot
++ Author: Clifton J. Williamson
++ Date Created: Bastille Day 1989
++ Date Last Updated: 5 June 1990
++ Description:
++ Package for constructing tubes around 3-dimensional parametric curves.

ExpressionTubePlot(): Exports == Implementation where
B ==> Boolean
I ==> Integer
FE ==> Expression Integer
SY ==> Symbol
SF ==> DoubleFloat
L ==> List
S ==> String
SEG ==> Segment
F2F ==> MakeFloatCompiledFunction(FE)
Pt ==> Point SF
PLOT3 ==> Plot3D
TUBE ==> TubePlot Plot3D

Exports == with
constantToUnaryFunction: SF -> (SF -> SF)
++ constantToUnaryFunction(s) is a local function which takes the
++ value of s, which may be a function of a constant, and returns
++ a function which always returns the value \texttt{DoubleFloat} s.
tubePlot: (FE,FE,FE,SF -> SF,SEG SF,SF -> SF,I) -> TUBE
++ tubePlot(f,g,h,colorFcn,a..b,r,n) puts a tube of radius r(t) with
++ n points on each circle about the curve \texttt{DoubleFloat} f(t),
++ \texttt{DoubleFloat} g(t), \texttt{DoubleFloat} h(t) for t in \texttt{DoubleFloat} [a,b].
++ The tube is considered to be open.
tubePlot: (FE,FE,FE,SF -> SF,SEG SF,SF -> SF,I,S) -> TUBE
  ++ tubePlot(f,g,h,colorFcn,a..b,r,n,s) puts a tube of radius \( r(t) \)
  ++ with \( n \) points on each circle about the curve \( x = f(t) \),
  ++ \( y = g(t) \), \( z = h(t) \) for \( t \ in [a,b] \).
  ++ If \( s = "closed" \), the tube is ++ considered to be closed; if \( s = "open" \), the tube is considered ++ to be open.

++ The tube is considered to be open.
tubePlot: (FE,FE,FE,SF -> SF,SEG SF,SF,I,S) -> TUBE
  ++ tubePlot(f,g,h,colorFcn,a..b,r,n) puts a tube of radius \( r \) with ++ \( n \) points on each circle about the curve \( x = f(t) \),
  ++ \( y = g(t) \), \( z = h(t) \) for \( t \ in [a,b] \).
  ++ The tube is considered to be open.

tubePlot: (FE,FE,FE,SF -> SF,SEG SF,SF,I,S) -> TUBE
  ++ tubePlot(f,g,h,colorFcn,a..b,r,n,s) puts a tube of radius \( r \) with ++ \( n \) points on each circle about the curve \( x = f(t) \),
  ++ \( y = g(t) \), \( z = h(t) \) for \( t \ in [a,b] \).
  ++ If \( s = "closed" \), the tube is ++ considered to be closed; if \( s = "open" \), the tube is considered ++ to be open.

LDF ==> List DoubleFloat
INT ==> Integer
NNI ==> NonNegativeInteger
LS ==> List Symbol
EF2 ==> ExpressionFunctions2
NOA ==> Record(fn:EDF, init:LDF, lb:LOCDF, cf:LEDF, ub:LOCDF)
LSA ==> Record(lfn:LEDF, init:LDF)
E ==> with
  finiteBound:(LOCDF,DF) -> LDF
  ++ finiteBound(l,b) replaces all instances of an infinite entry in
  ++ \axiom{l} by a finite entry \axiom{b} or \axiom{-b}.
  sortConstraints:NOA -> NOA
  ++ sortConstraints(args) uses a simple bubblesort on the list of
  ++ constraints using the degree of the expression on which to sort.
  ++ Of course, it must match the bounds to the constraints.
  sumOfSquares:EDF -> Union(EDF, "failed")
  ++ sumOfSquares(f) returns either an expression for which the square is
  ++ the original function of "failed".
  splitLinear:EDF -> EDF
  ++ splitLinear(f) splits the linear part from an expression which it
  ++ returns.
  simpleBounds?:LEDFF -> Boolean
  ++ simpleBounds?(l) returns true if the list of expressions l are
  ++ simple.
  linear?:LEDFF -> Boolean
  ++ linear?(l) returns true if all the bounds l are either linear or
  ++ simple.
  linear?:EDF -> Boolean
++ linear?(e) tests if \(\text{axiom}(e)\) is a linear function.
linearMatrix:(LEDF, NNI) -> MDF
++ linearMatrix(l,n) returns a matrix of coefficients of the linear
++ functions in \(\text{axiom}(l)\). If l is empty, the matrix has at least one
++ row.
linearPart:LEDF -> LEDF
++ linearPart(l) returns the list of linear functions of \(\text{axiom}(l)\).
nonLinearPart:LEDF -> LEDF
++ nonLinearPart(l) returns the list of non-linear functions of l.
quadratic?:EDF -> Boolean
++ quadratic?(e) tests if \(\text{axiom}(e)\) is a quadratic function.
variables:LSA -> LS
++ variables(args) returns the list of variables in \(\text{axiom}(\text{args.lfn})\)
varList:(EDF,NNI) -> LS
++ varList(e,n) returns a list of \(\text{axiom}(n)\) indexed variables with name
++ as in \(\text{axiom}(e)\).
changeNameToObjf:(Symbol,Result) -> Result
++ changeNameToObjf(s,r) changes the name of item \(\text{axiom}(s)\) in \(\text{axiom}(r)\)
++ to objf.
expenseOfEvaluation:LSA -> F
++ expenseOfEvaluation(o) returns the intensity value of the
++ cost of evaluating the input set of functions. This is in terms
++ of the number of ‘operational units’. It returns a value
++ in the range \([0,1]\).
optAttributes:Union(noa:NOA,lsa:LSA) -> List String
++ optAttributes(o) is a function for supplying a list of attributes
++ of an optimization problem.

double(x) == x + x
--R
--R Type: Void
f := factor(720)

map(double,f)

makePoly(b) == x + b

g := map(makePoly,f)

nthFlag(g,1)
FactoredFunctions2 contains functions that involve factored objects whose underlying domains may not be the same. For example, map might be used to coerce an object of type Factored(Integer) to Factored(Complex(Integer)).

The FactoredFunctions2 package implements one operation, map, for applying an operation to every base in a factored object and to the unit.

\[
double(x) = x + x
\]

Type: Void

\[
f := \text{factor}(720)
\]

\[
\begin{align*}
4 & 2 \\
2 & 3 & 5
\end{align*}
\]

Type: Factored Integer

Actually, the map operation used in this example comes from Factored itself, since double takes an integer argument and returns an integer result.

\[
\text{map}(\text{double}, f)
\]

\[
\begin{align*}
4 & 2 \\
2 & 4 & 6 & 10
\end{align*}
\]

Type: Factored Integer

If we want to use an operation that returns an object that has a type different from the operation's argument, the map in Factored cannot be used and we use the one in FactoredFunctions2.

\[
\text{makePoly}(b) = x + b
\]

\[
\begin{align*}
4 & 2 \\
(x + 1)(x + 2)(x + 3)(x + 5)
\end{align*}
\]

Type: Factored Polynomial Integer

In fact, the "2" in the name of the package means that we might be using factored objects of two different types.

\[
g := \text{map}(\text{makePoly}, f)
\]

It is important to note that both versions of map destroy any information known about the bases (the fact that they are prime, for instance).

The flags for each base are set to "nil" in the object returned by map.
\texttt{nthFlag(g,1)}
\texttt{"nil"}

Type: \texttt{Union("nil",...)}

FactoredFunctionUtilities (FRUTIL)

Exports:
mergeFactors refine

--- package FRUTIL FactoredFunctionUtilities ---

)abbrev package FRUTIL FactoredFunctionUtilities
++ Description:
++ spadtype{FactoredFunctionUtilities} implements some utility
++ functions for manipulating factored objects.

FactoredFunctionUtilities(R):Exports == Implementation where
  R: IntegralDomain
  FR ==> Factored R

Exports ==> with
  refine: (FR, R-> FR) -> FR
    ++ refine(u,fn) is used to apply the function \userfun{fn} to
    ++ each factor of \spadvar{u} and then build a new factored
    ++ object from the results. For example, if \spadvar{u} were
    ++ created by calling \spad{nilFactor(10,2)} then
\spad{refine(u,factor)} would create a factored object equal
++ to that created by \spad{factor(100)} or
++ \spad{primeFactor(2,2) * primeFactor(5,2)}.

mergeFactors: (FR,FR) -> FR
++ mergeFactors(u,v) is used when the factorizations of \spadvar{u}
++ and \spadvar{v} are known to be disjoint, e.g. resulting from a
++ content/primitive part split. Essentially, it creates a new
++ factored object by multiplying the units together and appending
++ the lists of factors.

Implementation ==> add
fg: FR
func: R -> FR
fUnion ==> Union("nil", "sqfr", "irred", "prime")
FF ==> Record(flg: fUnion, fctr: R, xpnt: Integer)

Exports ==> with

createZechTable: SUP -> ARR
++ createZechTable(f) generates a Zech logarithm table for the cyclic
++ group representation of a extension of the ground field by the
++ primitive polynomial f(x), i.e. \spad{Z(i)},
++ defined by x**Z(i) = 1+x**i is stored at index i.
++ This is needed in particular
++ to perform addition of field elements in finite fields represented
++ in this way. See \spadtype{FFCGP}, \spadtype{FFCGX}.
createMultiplicationTable: SUP -> V L TERM
++ createMultiplicationTable(f) generates a multiplication
++ table for the normal basis of the field extension determined
++ by f. This is needed to perform multiplications
++ between elements represented as coordinate vectors to this basis.
++ See \spadtype{FFNBP}, \spadtype{FFNBX}.
createMultiplicationMatrix: V L TERM -> M GF
++ createMultiplicationMatrix(m) forms the multiplication table
++ m into a matrix over the ground field.
-- only useful for the user to visualise the multiplication table
-- in a nice form
sizeMultiplication: V L TERM -> NNI
++ sizeMultiplication(m) returns the number of entries
++ of the multiplication table m.
-- the time of the multiplication of field elements depends
-- on this size
createLowComplexityTable: PI -> Union(Vector List TERM,"failed")
++ createLowComplexityTable(n) tries to find
++ a low complexity normal basis of degree n over GF
++ and returns its multiplication matrix
++ Fails, if it does not find a low complexity basis
createLowComplexityNormalBasis: PI -> Union(SUP, V L TERM)
++ createLowComplexityNormalBasis(n) tries to find a
++ a low complexity normal basis of degree n over GF
++ and returns its multiplication matrix
++ If no low complexity basis is found it calls
++ \axiomFunFrom{createNormalPoly}{FiniteFieldPolynomialPackage}(n)
++ to produce a normal polynomial of degree n over GF

)abbrev package FFPOLY FiniteFieldPolynomialPackage
++ Author: A. Bouyer, J. Grabmeier, A. Scheerhorn, R. Sutor, B. Trager
++ Date Created: January 1991
++ Date Last Updated: 1 June 1994
++ References:
++ J. Grabmeier, A. Scheerhorn: Finite Fields in Axiom.
++ Description:
This package provides a number of functions for generating, counting and testing irreducible, normal, primitive, random polynomials over finite fields.

FiniteFieldPolynomialPackage GF : Exports == Implementation where

GF : FiniteFieldCategory

I    ===> Integer
L    ===> List
NNI ===> NonNegativeInteger
PI   ===> PositiveInteger
Rec  ===> Record(expnt:NNI, coeff:GF)
Repr ===> L Rec
SUP  ===> SparseUnivariatePolynomial GF

Exports ==> with

-- qEulerPhiCyclotomic : PI -> PI
-- ++ qEulerPhiCyclotomic(n)$FFPOLY(GF) yields the q-Euler's function
-- ++ of the n-th cyclotomic polynomial over the field GF of
-- ++ order q (cf. [LN] p.122);
-- ++ error if n is a multiple of the field characteristic.

primitive? : SUP -> Boolean
++ primitive?(f) tests whether the polynomial f over a finite field is primitive, i.e. all its roots are primitive.

normal? : SUP -> Boolean
++ normal?(f) tests whether the polynomial f over a finite field is normal, i.e. its roots are linearly independent over the field.

numberOfIrreduciblePoly : PI -> PI
++ numberOfIrreduciblePoly(n)$FFPOLY(GF) yields the number of monic irreducible univariate polynomials of degree n over the finite field GF.

numberOfPrimitivePoly : PI -> PI
++ numberOfPrimitivePoly(n)$FFPOLY(GF) yields the number of primitive polynomials of degree n over the finite field GF.

numberOfNormalPoly : PI -> PI
++ numberOfNormalPoly(n)$FFPOLY(GF) yields the number of normal polynomials of degree n over the finite field GF.

createIrreduciblePoly : PI -> SUP
++ createIrreduciblePoly(n)$FFPOLY(GF) generates a monic irreducible univariate polynomial of degree n over the finite field GF.

createPrimitivePoly : PI -> SUP
++ createPrimitivePoly(n)$FFPOLY(GF) generates a primitive polynomial of degree n over the finite field GF.

createNormalPoly : PI -> SUP
++ createNormalPoly(n)$FFPOLY(GF) generates a normal polynomial of degree n over the finite field GF.

createNormalPrimitivePoly : PI -> SUP
++ createNormalPrimitivePoly(n)$FFPOLY(GF) generates a normal and primitive polynomial of degree n over the field GF.
Note that this function is equivalent to createPrimitiveNormalPoly(n).

createPrimitiveNormalPoly : PI -> SUP
++ createPrimitiveNormalPoly(n)\$FFPOLY(GF) generates a normal and
++ primitive polynomial of degree n over the field GF.
++ polynomial of degree n over the field GF.
nextIrreduciblePoly : SUP -> Union(SUP, "failed")
++ nextIrreduciblePoly(f) yields the next monic irreducible polynomial
++ over a finite field GF of the same degree as f in the following
++ order, or "failed" if there are no greater ones.
++ Error: if f has degree 0.
++ Note that the input polynomial f is made monic.
++ Also, \spad{f < g} if
++ the number of monomials of f is less
++ than this number for g.
++ If f and g have the same number of monomials,
++ the lists of exponents are compared lexicographically.
++ If these lists are also equal, the lists of coefficients
++ are compared according to the lexicographic ordering induced by
++ the ordering of the elements of GF given by lookup.
nextPrimitivePoly : SUP -> Union(SUP, "failed")
++ nextPrimitivePoly(f) yields the next primitive polynomial over
++ a finite field GF of the same degree as f in the following
++ order, or "failed" if there are no greater ones.
++ Error: if f has degree 0.
++ Note that the input polynomial f is made monic.
++ Also, \spad{f < g} if the lookup of the constant term
++ of f is less than
++ this number for g.
++ If these values are equal, then \spad{f < g} if
++ if the number of monomials of f is less than that for g or if
++ the lists of exponents of f are lexicographically less than the
++ corresponding list for g.
++ If these lists are also equal, the lists of coefficients are
++ compared according to the lexicographic ordering induced by
++ the ordering of the elements of GF given by lookup.
nextNormalPoly : SUP -> Union(SUP, "failed")
++ nextNormalPoly(f) yields the next normal polynomial over
++ a finite field GF of the same degree as f in the following
++ order, or "failed" if there are no greater ones.
++ Error: if f has degree 0.
++ Note that the input polynomial f is made monic.
++ Also, \spad{f < g} if the lookup of the coefficient
++ of the term of degree
++ n-1 of f is less than that for g.
++ In case these numbers are equal, \spad{f < g} if
++ if the number of monomials of f is less than that for g or if
++ the list of exponents of f are lexicographically less than the
++ corresponding list for g.
++ If these lists are also equal, the lists of coefficients are
++ compared according to the lexicographic ordering induced by
++ the ordering of the elements of GF given by lookup.

nextNormalPrimitivePoly : SUP -> Union(SUP, "failed")
++ nextNormalPrimitivePoly(f) yields the next normal primitive polynomial
++ over a finite field GF of the same degree as f in the following
++ order, or "failed" if there are no greater ones.
++ Error: if f has degree 0.
++ Note that the input polynomial f is made monic.
++ Also, \spad{f < g} if the lookup of the constant
++ term of f is less than
++ this number for g or if
++ lookup of the coefficient of the term of degree n-1
++ of f is less than this number for g.
++ Otherwise, \spad{f < g}
++ if the number of monomials of f is less than
++ that for g or if the lists of exponents for f are
++ lexicographically less than those for g.
++ If these lists are also equal, the lists of coefficients are
++ compared according to the lexicographic ordering induced by
++ the ordering of the elements of GF given by lookup.
++ This operation is equivalent to nextPrimitiveNormalPoly(f).

nextPrimitiveNormalPoly : SUP -> Union(SUP, "failed")
++ nextPrimitiveNormalPoly(f) yields the next primitive normal polynomial
++ over a finite field GF of the same degree as f in the following
++ order, or "failed" if there are no greater ones.
++ Error: if f has degree 0.
++ Note that the input polynomial f is made monic.
++ Also, \spad{f < g} if the lookup of the
++ constant term of f is less than
++ this number for g, or, in case these numbers are equal, if the
++ lookup of the coefficient of the term of degree n-1
++ of f is less than this number for g.
++ If these numbers are equals, \spad{f < g}
++ if the number of monomials of f is less than
++ that for g, or if the lists of exponents for f are lexicographically
++ less than those for g.
++ If these lists are also equal, the lists of coefficients are
++ coefficients according to the lexicographic ordering induced by
++ the ordering of the elements of GF given by lookup.
++ This operation is equivalent to nextNormalPrimitivePoly(f).

-- random : () -> SUP
-- ++ random()$FFPOLY(GF) generates a random monic polynomial
-- ++ of random degree over the field GF

random : PI -> SUP
++ random(n)$FFPOLY(GF) generates a random monic polynomial
++ of degree n over the finite field GF.

random : (PI, PI) -> SUP
++ random(m,n)$FFPOLY(GF) generates a random monic polynomial
++ of degree d over the finite field GF, d between m and n.

leastAffineMultiple : SUP -> SUP
++ leastAffineMultiple(f) computes the least affine polynomial which
++ is divisible by the polynomial \( f \) over the finite field \( GF \),
++ i.e. a polynomial whose exponents are 0 or a power of \( q \), the
++ size of \( GF \).

\textbf{reducedQPowers:} \( \text{SUP} \rightarrow \text{PrimitiveArray SUP} \)
++ \text{reducedQPowers}(f)
++ generates \( \text{\spad{[x, x**q, x**(q**2), \ldots, x**(q**(n-1))]} } \)
++ reduced modulo \( f \) where \( \text{\spad{q = size()}$GF} \) and \( \text{\spad{n = degree f}} \).

++ FiniteLinearAggregateFunctions2 provides functions involving two
++ FiniteLinearAggregates where the underlying domains might be
++ different. An example of this might be creating a list of rational
++ numbers by mapping a function across a list of integers where the
++ function divides each integer by 1000.

FiniteLinearAggregateFunctions2(S, A, R, B):  
Exports == Implementation where
S, R: Type
A : FiniteLinearAggregate S
B : FiniteLinearAggregate R

Exports ==> with
map : (S -> R, A) -> B
++ map(f,a) applies function f to each member of aggregate
++ \spad{a} resulting in a new aggregate over a
++ possibly different underlying domain.
reduce : ((S, R) -> R, A, R) -> R
++ reduce(f,a,r) applies function f to each
++ successive element of the
++ aggregate \spad{a} and an accumulant initialized to r.
++ For example,
++ \spad{reduce(_,+$Integer,[1,2,3],0)}
++ does \spad{3+(2+(1+0))}. Note that third argument r
++ may be regarded as the
++ identity element for the function f.
scan : ((S, R) -> R, A, R) -> B
++ scan(f,a,r) successively applies
++ \spad{reduce(f,x,r)} to more and more leading sub-aggregates
++ x of aggregate \spad{a}.
++ More precisely, if \spad{a} is \spad{[a1,a2,...]}, then
++ \spad{scan(f,a,r)} returns
++ \spad{[reduce(f,[a1],r),reduce(f,[a1,a2],r),...]}.

  D: Join(IntegralDomain, GcdDomain)
  V: AbelianMonoidRing(D, NonNegativeInteger) -- for example, SUP D

SUP => SparseUnivariatePolynomial

cFunction => (NonNegativeInteger, Vector SUP D) -> D

CoeffAction => (NonNegativeInteger, NonNegativeInteger, V) -> D

Exports == with

  fffg: (List D, cFunction, List NonNegativeInteger) -> Matrix SUP D
++ \text{\textbackslash spad} fffg \text{\textbackslash is the general algorithm as proposed by Beckermann and}
++ Labahn.
++
++ The first argument is the list of \text{c\_\{i,i\}}. These are the only values
The following function could be moved to FFFGF, parallel to \texttt{generalInterpolation}. However, the reason for moving \texttt{generalInterpolation} for fractions to a separate package was the need of a generic signature, hence the extra argument \texttt{VF} to FFFGF. In the special case of rational interpolation, this extra argument is not necessary, since we are always returning a fraction of SUPs, and ignore \texttt{V}. In fact, \texttt{V} is not needed for \texttt{fffg} itself, only if we want to specify a \texttt{CoeffAction}.

Thus, maybe it would be better to move \texttt{fffg} to a separate package?

--- package FFFG FractionFreeFastGaussian ---

\texttt{interpolate}: (List $D$, List $D$, NonNegativeInteger) $\rightarrow$ Fraction SUP $D$
\texttt{generalInterpolation}: (List $D$, CoeffAction, Vector $V$, List NonNegativeInteger) $\rightarrow$ Matrix SUP $D$
++ eta + e.i - [1,1,...,1], where the degree of zero is -1.
++
++ The first argument C is the list of coefficients c_{k,k} in the
++ expansion <x^k> z g(x) = sum_{i=0}^k c_{k,i} <x^i> g(x).
++
++ The second argument, CA(k, 1, f), should return the coefficient of x^k
++ in z^l f(x).

++ with maximal entry \text{maxEta} and sum of entries at most
++ \text{sumEta}.
++
++ The first argument C is the list of coefficients c_{k,k} in the
++ expansion <x^k> z g(x) = sum_{i=0}^k c_{k,i} <x^i> g(x).
++
++ The second argument, CA(k, 1, f), should return the coefficient of x^k
++ in z^l f(x).

\text{generalCoefficient}: (\text{CoeffAction, Vector V,}
\text{NonNegativeInteger, Vector SUP D}) \rightarrow \text{D}
++ \text{generalCoefficient}(action, f, k, p) gives the coefficient of
++ x^k in p(z) \dot f(x), where the action of z^l on a polynomial in x is
++ given by action, i.e., action(k, l, f) should return the coefficient
++ of x^k in z^l f(x).

\text{ShiftAction}: (\text{NonNegativeInteger, NonNegativeInteger, V}) \rightarrow \text{D}
++ \text{ShiftAction}(k, l, g) gives the coefficient of x^k in z^l g(x),
++ where \text{z*(a+b*x+c*x^2+d*x^3+...)} = (b*x+2*c*x^2+3*d*x^3+...). In
++ terms of sequences, z*u(n)=n*u(n).

\text{ShiftC}: \text{NonNegativeInteger} \rightarrow \text{List D}
++ \text{ShiftC} gives the coefficients c_{k,k} in the expansion <x^k> z
++ g(x) = sum_{i=0}^k c_{k,i} <x^i> g(x), where z acts on g(x) by
++ shifting. In fact, the result is [0,1,2,...]

\text{DiffAction}: (\text{NonNegativeInteger, NonNegativeInteger, V}) \rightarrow \text{D}
++ \text{DiffAction}(k, l, g) gives the coefficient of x^k in z^l g(x),
++ where z*(a+b*x+c*x^2+d*x^3+...) = (a*x+b*x^2+c*x^3+...), i.e.,
++ multiplication with x.

\text{DiffC}: \text{NonNegativeInteger} \rightarrow \text{List D}
++ \text{DiffC} gives the coefficients c_{k,k} in the expansion <x^k> z
++ g(x) = sum_{i=0}^k c_{k,i} <x^i> g(x), where z acts on g(x) by
++ shifting. In fact, the result is [0,0,0,...]

\text{qShiftAction}: (\text{D, NonNegativeInteger, NonNegativeInteger, V}) \rightarrow \text{D}
++ \spad{qShiftAction(q, k, l, g)} gives the coefficient of \(x^k\) in \(z^l\) 
++ \(g(x)\), where 
++ \(z*(a+b*x+c*x^2+d*x^3+...)=\) 
++ \((a+q*b*x+q^2*c*x^2+q^3*d*x^3+...).\) In terms of sequences, 
++ \(z*u(n)=q^n*u(n).\)

\[
qShiftC: (D, \text{NonNegativeInteger}) \to \text{List D}
\]
++ \spad{qShiftC} gives the coefficients \(c_{k,k}\) in the expansion \(\langle x^k\rangle z\)
++ \(g(x) = \sum_{i=0}^k c_{k,i} \langle x^i\rangle g(x)\), where \(z\) acts on \(g(x)\) by
++ shifting. In fact, the result is \([1,q,q^2,...]\)

    if not zero? coefficient(b, l) then res := res + coefficient(b, l) * coeffAction(k, l, a)
res

generalInterpolation(C: List D, coeffAction: CoeffAction,
   f: Vector V,
   eta: List NonNegativeInteger): Matrix SUP D ==
  c: cFunction := (x,y) +-> generalCoefficient(coeffAction, f,
          (x-1)::NonNegativeInteger, y)
  fffg(C, c, eta)

-- general - suitable for functions f - trying all possible degree combinations

The following function returns the lexicographically next vector with non-negative components smaller than p with the same sum as v.

— package FFFG FractionFreeFastGaussian —

nextVector!(p: NonNegativeInteger, v: List NonNegativeInteger)
  : Union("failed", List NonNegativeInteger) ==
  n := #v
The following function returns the stream of all possible degree vectors, beginning with v, where the degree vectors are sorted in reverse lexicographic order. Furthermore, the entries are all less or equal to p and their sum equals the sum of the entries of v. We assume that the entries of v are also all less or equal to p.

--- package FFFG FractionFreeFastGaussian ---

vectorStream(p: NonNegativeInteger, v: List NonNegativeInteger) : Stream List NonNegativeInteger == delay
next := nextVector!(p, copy v)
(next case "failed") => empty()$Stream(List NonNegativeInteger)
cons(next, vectorStream(p, next))

---

vectorStream2 skips every second entry of vectorStream.

--- package FFFG FractionFreeFastGaussian ---

vectorStream2(p: NonNegativeInteger, v: List NonNegativeInteger) : Stream List NonNegativeInteger == delay
next := nextVector!(p, copy v)
(next case "failed") => empty()
next2 := nextVector!(p, copy next)
(next2 case "failed") => cons(next, empty())
cons(next2, vectorStream2(p, next2))

This version of generalInterpolation returns a stream of solutions, one for each possible
degree vector. Thus, it only needs to apply the previously defined generalInterpolation to
each degree vector. These are generated by vectorStream and vectorStream2 respectively.

If \( f \) consists of two elements only, we can skip every second degree vector: note that \( \text{fffg} \),
and thus also generalInterpolation, returns a matrix with \( \#f \) columns, each corresponding
to a solution of the interpolation problem. More precisely, the \( i \)th column is a solution with
degrees \( \eta - (1,1,\ldots,1) + e_i \). Thus, in the case of \( 2 \times 2 \) matrices, vectorStream would produce
solutions corresponding to \((d,0),(d-1,1),(d-2,2),(d-3,3),\ldots\), i.e.,
every second matrix is redundant.

Although some redundancy exists also for higher dimensional \( f \), the scheme becomes much
more complicated, thus we did not implement it.

— package FFFG FractionFreeFastGaussian —

\[
\text{generalInterpolation}(C: \text{List D}, \text{coeffAction: CoeffAction},
\text{f: Vector V},
\text{sumEta: NonNegativeInteger},
\text{maxEta: NonNegativeInteger})
: \text{Stream Matrix SUP D} ==
\]

\{
\text{generate an initial degree vector}\}

if \( \#f = 2 \) then
map(x +-> generalInterpolation(C, coeffAction, f, x),
cons(eta, vectorStream2(maxEta, eta)))
$\text{StreamFunctions2(\text{List NonNegativeInteger},}$
\text{Matrix SUP D})
else
map(x +-> generalInterpolation(C, coeffAction, f, x),
cons(eta, vectorStream(maxEta, eta)))
$\text{StreamFunctions2(\text{List NonNegativeInteger},}$
\text{Matrix SUP D})

We need to generate an initial degree vector, being the minimal element in reverse lexicographic order, i.e., \( m, m, \ldots, m, k, 0, 0, \ldots \), where \( m \) is \( \text{maxEta} \) and \( k \) is the remainder of
\( \text{sumEta} \) divided by \( \text{maxEta} \). This is done by the following code:

— generate an initial degree vector —
sum: Integer := sumEta
entry: Integer
eta: List NonNegativeInteger
:= [(if sum < maxEta 
then (entry := sum; sum := 0) 
else (entry := maxEta; sum := sum - maxEta); 
entry::NonNegativeInteger) for i in 1..#f]

We want to generate all vectors with sum of entries being at most sumEta. Therefore the following is incorrect.

--- BUG generate an initial degree vector ---

(\begin{itemize}
    \item (sum > 0) => empty($Stream$(Matrix SUP D))
\end{itemize})

--- package FFFG FractionFreeFastGaussian ---

Package FFFG FractionFreeFastGaussian

--- rational interpolation ---

\begin{verbatim}
interpolate(x: List Fraction D, y: List Fraction D, d: NonNegativeInteger) 
: Fraction SUP D ==
gx := splitDenominator(x)$InnerCommonDenominator(D, Fraction D, _
    List D, _
    List Fraction D)
gy := splitDenominator(y)$InnerCommonDenominator(D, Fraction D, _
    List D, _
    List Fraction D)
r := interpolate(gx.num, gy.num, d)
elt(numer r, monomial(gx.den,1))/(gy.den*elt(denom r, monomial(gx.den,1)))
\end{verbatim}

interpolate(x: List D, y: List D, d: NonNegativeInteger): Fraction SUP D ==
\begin{verbatim}
    -- berechne Interpolante mit Grad d und N-d-1
    if (N := #x) \neq #y then
        error "interpolate: number of points and values must match"
    if N <= d then
        error "interpolate: numerator degree must be smaller than number of data points"
    c: cFunction := (s,u) \to y.s * elt(u.2, x.s) - elt(u.1, x.s)
    eta: List NonNegativeInteger := [d, (N-d)::NonNegativeInteger]
    M := fffg(x, c, eta)
    if zero?(M.(2,1)) then M.(1,2)/M.(2,2)
    else M.(1,1)/M.(2,1)
\end{verbatim}
Because of Lemma 5.3, $M.1.(2,1)$ and $M.1.(2,2)$ cannot both vanish, since $\eta_{\sigma}$ is always $\sigma$-normal by Theorem 7.2 and therefore also para-normal, see Definition 4.2.

Because of Lemma 5.1 we have that $M.1.(*,2)$ is a solution of the interpolation problem, if $M.1.(2,1)$ vanishes.

--- package FFFG FractionFreeFastGaussian ---

recurrence computes the new matrix $M$, according to the following formulas (cf. Table 2 in Beckermann and Labahn):

\[
\begin{align*}
&\text{Increase order } \\
&\text{for } \ell = 1 \ldots m, \ell \neq \pi \\
&M^{(\cdot,\ell)}_{\sigma+1} := \left( M^{(\cdot,\ell)}_{\sigma}(\pi) - M^{(\cdot,\pi)}_{\sigma}(\ell) \right) / d_{\sigma}
\end{align*}
\]

\[
\begin{align*}
&\text{Increase order in column } \pi \\
&M^{(\cdot,\pi)}_{\sigma+1} := (z - c_{\sigma,\pi}) M^{(\cdot,\pi)}_{\sigma}
\end{align*}
\]

\[
\begin{align*}
&\text{Adjust degree constraints:} \\
&M^{(\cdot,\pi)}_{\sigma+1} := \left( M^{(\cdot,\pi)}_{\sigma+1}(\pi) - \sum_{\ell \neq \pi} M^{(\cdot,\ell)}_{\sigma+1}(\ell) \right) / d_{\sigma}
\end{align*}
\]

Since we do not need the matrix $M_{\sigma}$ anymore, we drop the index and update the matrix destructively. In the following, we write $C_k$ for $c_{\sigma,\pi}$.

--- package FFFG FractionFreeFastGaussian ---

-- a major part of the time is spent here

```
recurrence(M: Matrix SUP D, pi: NonNegativeInteger, m: NonNegativeInteger, 

  rPi: D := qelt(r, pi)
  polyf: SUP D := rPi * (z - Ck::SUP D)
  for i in 1..m repeat
    MiPi: SUP D := qelt(M, i, pi)
    newMiPi: SUP D := polyf * MiPi

  -- update columns ^= pi and calculate their sum
  for l in 1..m | l ^= pi repeat
    rl: D := qelt(r, l)
  -- I need the coercion to SUP D, since exquo returns an element of
```
-- Union("failed", SUP D)...
  Mil: SUP D := ((qelt(M, i, l) * rPi - MiPi * rl) exquo d)::SUP D
  qsetelt!(M, i, l, Mil)
  pl: D := qelt(p, l)
  newMiPi := newMiPi - pl * Mil

-- update column pi
  qsetelt!(M, i, pi, (newMiPi exquo d)::SUP D)

    ++ airyBi(x) returns the airybi function applied to x

In case we want to have more special function operators here, do not forget to add them to
the list specop in CommonOperators. Otherwise they will not have the 'special' attribute
and will not be recognised here. One effect could be that

myNewSpecOp(1::Expression Integer)::Expression DoubleFloat

might not re-evaluate the operator.

differentiation of special functions

In the following we define the symbolic derivatives of the special functions we provide. The formulas we use for the Bessel functions can be found in Milton Abramowitz and Irene A. Stegun, eds. (1965). Handbook of Mathematical Functions with Formulas, Graphs, and Mathematical Tables. New York: Dover. ISBN 0-486-61272-4, Equations 9.1.27 and 9.6.26. Up to patch-50 the formula for $K$ missed the minus sign. (Issue #355)

We do not attempt to provide formulas for the derivative with respect to the first argument currently. Instead, we leave such derivatives unevaluated.

---

```plaintext
import Fraction Integer
ahalf: F := recip(2::F)::F
athird: F := recip(2::F)::F
twothirds: F := 2*recip(3::F)::F
```

---

We need to get hold of the differentiation operator as modified by FunctionSpace. Otherwise, for example, display will be ugly. We accomplish that by differentiating an operator, which will certainly result in a single kernel only.

---

```plaintext
dummyArg: SE := new()$SE
opdiff := operator first kernels D((operator(new()$SE)$BasicOperator)
                                  (dummyArg::F), dummyArg)
```

---

The differentiation operator opdiff takes three arguments corresponding to

$F_{i,i}(a_1, a_2, \ldots, a_n)$:

1. $F(a_1, \ldots, dm, \ldots a_n)$, where the $i$\textsuperscript{th} argument is a dummy variable,
2. $dm$, the dummy variable, and
3. $a_i$, the point at which the differential is evaluated.

In the following, it seems to be safe to use the same dummy variable throughout. At least, this is done also in FunctionSpace, and did not cause problems.

The operation symbolicGrad returns the first component of the gradient of op l.
— package FSPECFF FunctionalSpecialFunction —

dm := new()$SE :: F

iBesselJ(l: List F, t: SE): F ==
n := first l; x := second l
differentiate(n, t)*kernel(opdiff, [opBesselJ [dm, x], dm, n])
+ differentiate(x, t) * ahalf * (besselJ (n-1,x) - besselJ (n+1,x))

iBesselY(l: List F, t: SE): F ==
n := first l; x := second l
differentiate(n, t)*kernel(opdiff, [opBesselY [dm, x], dm, n])
+ differentiate(x, t) * ahalf * (besselY (n-1,x) - besselY (n+1,x))

iBesselI(l: List F, t: SE): F ==
n := first l; x := second l
differentiate(n, t)*kernel(opdiff, [opBesselI [dm, x], dm, n])
+ differentiate(x, t)* ahalf * (besselI (n-1,x) + besselI (n+1,x))

iBesselK(l: List F, t: SE): F ==
n := first l; x := second l
differentiate(n, t)*kernel(opdiff, [opBesselK [dm, x], dm, n])
- differentiate(x, t)* ahalf * (besselK (n-1,x) + besselK (n+1,x))

———

For the moment we throw an error if we try to differentiate polygamma with respect to the first argument.

— package FSPECFF FunctionalSpecialFunction —

ipolygamma(l: List F, x: SE): F ==
member?(x, variables first l) =>
  error "cannot differentiate polygamma with respect to the first argument"
n := first l; y := second l
differentiate(y, x)*polygamma(n+1, y)

iBetaGrad1(l: List F): F ==
x := first l; y := second l
Beta(x,y)*(digamma x - digamma(x+y))

iBetaGrad2(l: List F): F ==
x := first l; y := second l
Beta(x,y)*(digamma y - digamma(x+y))

if F has ElementaryFunctionCategory then
  iGamma2(l: List F, t: SE): F ==
a := first l; x := second l
differentiate(a, t)*kernel(opdiff, [opGamma2 [dm, x], dm, a])
Finally, we tell Axiom to use these functions for differentiation. Note that up to patch 50, the properties for the Bessel functions were set using derivative(oppolygamma, [lzero, ipolygammaGrad]), where lzero returned zero always. Trying to replace lzero by a function that returns the first component of the gradient failed, it resulted in an infinite loop for integrate(D(besselJ(a,x),a,a)).

— package FSPECF FunctionalSpecialFunction —

derivative(opabs, (x:F):F +-> abs(x) * inv(x))
derivative(opGamma, (x:F):F +-> digamma x * Gamma x)
derivative(opBeta, [iBetaGrad1, iBetaGrad2])
derivative(opdigamma, (x:F):F +-> polygamma(1, x))

Integral bases for function fields of dimension one

In this package \( R \) is a Euclidean domain and \( F \) is a framed algebra over \( R \). The package provides functions to compute the integral closure of \( R \) in the quotient field of \( F \). It is assumed that \( \text{char}(R/P) = \text{char}(R) \) for any prime \( P \) of \( R \). A typical instance of this is when \( R = K[x] \) and \( F \) is a function field over \( R \).

     x    : Symbol
     cen  : FE
     B    ==> Boolean
     BOP  ==> BasicOperator
PACKAGE FS2EXPXP FUNKTIONSPACE TO EXPONENTIAL EXPANSION

Exports ==>

exprToXXP : (FE,B) -> XResult
++ exprToXXP(fcn, posCheck?) converts the expression \spad{fcn} to
++ an exponential expansion. If \spad{posCheck?} is true,
++ log's of negative numbers are not allowed nor are nth roots of
++ negative numbers with n even. If \spad{posCheck?} is false,
++ these are allowed.

localAbs: FE -> FE
++ localAbs(fcn) = \spad{abs(fcn)} or \spad{sqrt(fcn^2)} depending
++ on whether or not FE has a function \spad{abs}. This should be
++ a local function, but the compiler won't allow it.

Implementation ==> add

   exprToUPS : (FE,B,S) -> Result
      ++ exprToUPS(fcn,posCheck?,atanFlag) converts the expression
      ++ \spad{fcn} to a power series. If \spad{posCheck?} is true,
      ++ log's of negative numbers are not allowed nor are nth roots of
      ++ negative numbers with n even. If \spad{posCheck?} is false,
CHAPTER 7. CHAPTER F

++ these are allowed. \spad{atanFlag} determines how the case
++ \spad{atan(f(x))}, where \spad{f(x)} has a pole, will be treated.
++ The possible values of \spad{atanFlag} are \spad{"complex"},
++ \spad{"real: two sides"}, \spad{"real: left side"},
++ \spad{"real: right side"}, and \spad{"just do it"}.
++ If \spad{atanFlag} is \spad{"complex"}, then no series expansion
++ will be computed because, viewed as a function of a complex
++ variable, \spad{atan(f(x))} has an essential singularity.
++ Otherwise, the sign of the leading coefficient of the series
++ expansion of \spad{f(x)} determines the constant coefficient
++ in the series expansion of \spad{atan(f(x))}. If this sign cannot
++ be determined, a series expansion is computed only when
++ \spad{atanFlag} is \spad{"just do it"}. When the leading term
++ in the series expansion of \spad{f(x)} is of odd degree (or is a
++ rational degree with odd numerator), then the constant coefficient
++ in the series expansion of \spad{atan(f(x))} for values to the
++ left differs from that for values to the right. If \spad{atanFlag}
++ is \spad{"real: two sides"}, no series expansion will be computed.
++ If \spad{atanFlag} is \spad{"real: left side"}, the constant
++ coefficient for values to the left will be used and if \spad{atanFlag}
++ \spad{"real: right side"}, the constant coefficient for values to the
++ right will be used.
++ If there is a problem in converting the function to a power series,
++ a record containing the name of the function that caused the problem
++ and a brief description of the problem is returned.
++ When expanding the expression into a series it is assumed that
++ the series is centered at 0. For a series centered at a, the
++ user should perform the substitution \spad{x -> x + a} before calling
++ this function.

exprToGenUPS : (FE,B,S) -> Result
++ exprToGenUPS(fcn,posCheck?,atanFlag) converts the expression
++ \spad{fcn} to a generalized power series. If \spad{posCheck?}
++ is true, log's of negative numbers are not allowed nor are nth roots
++ of negative numbers with n even. If \spad{posCheck?} is false,
++ these are allowed. \spad{atanFlag} determines how the case
++ \spad{atan(f(x))}, where \spad{f(x)} has a pole, will be treated.
++ The possible values of \spad{atanFlag} are \spad{"complex"},
++ \spad{"real: two sides"}, \spad{"real: left side"},
++ \spad{"real: right side"}, and \spad{"just do it"}.
++ If \spad{atanFlag} is \spad{"complex"}, then no series expansion
++ will be computed because, viewed as a function of a complex
++ variable, \spad{atan(f(x))} has an essential singularity.
++ Otherwise, the sign of the leading coefficient of the series
++ expansion of \spad{f(x)} determines the constant coefficient
++ in the series expansion of \spad{atan(f(x))}. If this sign cannot
++ be determined, a series expansion is computed only when
++ \spad{atanFlag} is \spad{"just do it"}. When the leading term
++ in the series expansion of \spad{f(x)} is of odd degree (or is a
++ rational degree with odd numerator), then the constant coefficient
++ in the series expansion of \spad{atan(f(x))} for values to the
++ left differs from that for values to the right. If \spad{atanFlag}
++ is \spad{"real: two sides"}, no series expansion will be computed.
++ If \spad{atanFlag} is \spad{"real: left side"} the constant
++ coefficient for values to the left will be used and if \spad{atanFlag}
++ \spad{"real: right side"} the constant coefficient for values to the
++ right will be used.
++ If there is a problem in converting the function to a power
++ series, we return a record containing the name of the function
++ that caused the problem and a brief description of the problem.
++ When expanding the expression into a series it is assumed that
++ the series is centered at 0. For a series centered at a, the
++ user should perform the substitution \spad{x -> x + a} before calling
++ this function.

\textbf{localAbs: \texttt{FE} \rightarrow \texttt{FE}}
++ \texttt{localAbs(fcn) = abs(fcn)} or \texttt{sqrt(fcn**2)} depending
++ on whether or not \texttt{FE} has a function \texttt{abs}. This should be
++ a local function, but the compiler won’t allow it.

Description:
\texttt{GaloisGroupFactorizationUtilities} provides functions that will be used by the factorizer.

\texttt{GaloisGroupFactorizationUtilities}(R,UP,F): Exports == Implementation where
\texttt{R} : Ring
\texttt{UP} : UnivariatePolynomialCategory R
\texttt{F} : Join(FloatingPointSystem,RetractableTo(R),Field,TranscendentalFunctionCategory,ElementaryFunctionCategory)
\texttt{N} ==> NonNegativeInteger
\texttt{P} ==> PositiveInteger
\texttt{Z} ==> Integer

Exports ==>
\begin{verbatim}
beauzamyBound: UP -> Z -- See [1]
  ++ beauzamyBound(p) returns a bound on the larger coefficient of any
  ++ factor of p.
bombieriNorm: UP -> F -- See [1]
  ++ bombieriNorm(p) returns quadratic Bombieri's norm of p.
bombieriNorm: (UP,P) -> F -- See [2] and [3]
  ++ bombieriNorm(p,n) returns the nth Bombieri's norm of p.
  ++ rootBound(p) returns a bound on the largest norm of the complex roots
  ++ of p.
singleFactorBound: (UP,N) -> Z -- See [6]
  ++ singleFactorBound(p,r) returns a bound on the infinite norm of
  ++ the factor of p with smallest Bombieri's norm. r is a lower bound
  ++ for the number of factors of p. p shall be of degree higher or equal
  ++ to 2.
singleFactorBound: UP -> Z -- See [6]
  ++ singleFactorBound(p,r) returns a bound on the infinite norm of
  ++ the factor of p with smallest Bombieri's norm. p shall be of degree
  ++ higher or equal to 2.
norm: (UP,P) -> F
  ++ norm(f,p) returns the lp norm of the polynomial f.
quadraticNorm: UP -> F
  ++ quadraticNorm(f) returns the l2 norm of the polynomial f.
infinityNorm: UP -> F
  ++ infinityNorm(f) returns the maximal absolute value of the coefficients
  ++ of the polynomial f.
height: UP -> F
  ++ height(p) returns the maximal absolute value of the coefficients of
  ++ the polynomial p.
length: UP -> F
  ++ length(p) returns the sum of the absolute values of the coefficients
  ++ of the polynomial p.
\end{verbatim}

--- package GALFACT GaloisGroupFactorizer ---

)abbrev package GALFACT GaloisGroupFactorizer  
++ Author: Frederic Lehobey  
++ Date Created: 28 June 1994  
++ Date Last Updated: 11 July 1997  
++ References:  
++ Factorization: Sharp Bounds, Efficient Algorithms,  
++ J. Symbolic Computation (1993) 15, 393-413  
++ [2] John Brillhart, Note on Irreducibility Testing,  
++ [3] David R. Musser, On the Efficiency of a Polynomial Irreducibility Test,  
++ Description:  
++ \spadtype{GaloisGroupFactorizer} provides functions to factor resolvents.  
-- improvements to do :  
-- + reformulate the lifting problem in completeFactor -- See [1] (hard)  
-- + implement algorithm RC -- See [1] (easy)  
-- + use Dedekind's criterion to prove sometimes irreducibility (easy)  
-- or even to improve early detection of true factors (hard)  
-- + replace Sets by Bits

Exports == with  
  makeFR: FinalFact -> Factored UP  
    ++ makeFR(flist) turns the final factorization of henselFact into a  
    ++ \spadtype{Factored} object.  
  degreePartition: DDLlist -> Multiset N  
    ++ degreePartition(ddfactorization) returns the degree partition of  
    ++ the polynomial f modulo p where ddfactorization is the distinct
++ degree factorization of f computed by ddFact for some prime p.

musserTrials:: () -> P
++ musserTrials() returns the number of primes that are tried in
++ \spadfun{modularFactor}.

musserTrials:: P -> P
++ musserTrials(n) sets to n the number of primes to be tried in
++ \spadfun{modularFactor} and returns the previous value.

stopMusserTrials:: () -> P
++ stopMusserTrials() returns the bound on the number of factors for
++ which \spadfun{modularFactor} stops to look for an other prime. You
++ will have to remember that the step of recombining the extraneous
++ factors may take up to \spad{2**stopMusserTrials()} trials.

stopMusserTrials:: P -> P
++ stopMusserTrials(n) sets to n the bound on the number of factors for
++ which \spadfun{modularFactor} stops to look for an other prime. You
++ will have to remember that the step of recombining the extraneous
++ factors may take up to \spad{2**n} trials. Returns the previous
++ value.

numberOfFactors:: DDList -> N
++ numberOfFactors(ddfactorization) returns the number of factors of
++ the polynomial f modulo p where ddfactorization is the distinct
++ degree factorization of f computed by ddFact for some prime p.

modularFactor:: UP -> MFact
++ modularFactor(f) chooses a "good" prime and returns the factorization
++ of f modulo this prime in a form that may be used by
++ completeHensel. If prime is zero
++ it means that f has been proved to be irreducible over the integers
++ or that f is a unit (i.e. 1 or -1).
++ f shall be primitive (i.e. content(p)=1) and square free (i.e.
++ without repeated factors).

useSingleFactorBound?: () -> Boolean
++ useSingleFactorBound?() returns \spad{true} if algorithm with single
++ factor bound is used for factorization, \spad{false} for algorithm
++ with overall bound.

useSingleFactorBound: Boolean -> Boolean
++ useSingleFactorBound(b) chooses the algorithm to be used by the
++ factorizers: \spad{true} for algorithm with single
++ factor bound, \spad{false} for algorithm with overall bound.
++ Returns the previous value.

useEisensteinCriterion?: () -> Boolean
++ useEisensteinCriterion?() returns \spad{true} if factorizers
++ check Eisenstein's criterion before factoring.

useEisensteinCriterion: Boolean -> Boolean
++ useEisensteinCriterion(b) chooses whether factorizers check
++ Eisenstein's criterion before factoring: \spad{true} for
++ using it, \spad{false} else. Returns the previous value.

eisensteinIrreducible?: UP -> Boolean
++ eisensteinIrreducible?(p) returns \spad{true} if p can be
++ shown to be irreducible by Eisenstein's criterion,
++ \spad{false} is inconclusive.
tryFunctionalDecomposition?: () -> Boolean
++ tryFunctionalDecomposition?() returns \spad{true} if
++ factorizers try functional decomposition of polynomials before
++ factoring them.
tryFunctionalDecomposition: Boolean -> Boolean
++ tryFunctionalDecomposition(b) chooses whether factorizers have
++ to look for functional decomposition of polynomials
++ (\spad{true}) or not (\spad{false}). Returns the previous value.
factor: UP -> Factored UP
++ factor(p) returns the factorization of p over the integers.
factor: (UP,N) -> Factored UP
++ factor(p,r) factorizes the polynomial p using the single factor bound
++ algorithm and knowing that p has at least r factors.
factor: (UP,List N) -> Factored UP
++ factor(p,listOfDegrees) factorizes the polynomial p using the single
++ factor bound algorithm and knowing that p has for possible
++ splitting of its degree listOfDegrees.
factor: (UP,List N,N) -> Factored UP
++ factor(p,listOfDegrees,r) factorizes the polynomial p using the single
++ factor bound algorithm, knowing that p has for possible
++ splitting of its degree listOfDegrees and that p has at least r
++ factors.
factor: (UP,N,N) -> Factored UP
++ factor(p,d,r) factorizes the polynomial p using the single
++ factor bound algorithm, knowing that d divides the degree of all
++ factors of p and that p has at least r factors.
factorSquareFree: UP -> Factored UP
++ factorSquareFree(p) returns the factorization of p which is supposed
++ not having any repeated factor (this is not checked).
factorSquareFree: (UP,N) -> Factored UP
++ factorSquareFree(p,r) factorizes the polynomial p using the single
++ factor bound algorithm and knowing that p has at least r factors.
++ f is supposed not having any repeated factor (this is not checked).
factorSquareFree: (UP,List N) -> Factored UP
++ factorSquareFree(p,listOfDegrees) factorizes the polynomial p using
++ the single factor bound algorithm and knowing that p has for possible
++ splitting of its degree listOfDegrees.
++ f is supposed not having any repeated factor (this is not checked).
factorSquareFree: (UP,List N,N) -> Factored UP
++ factorSquareFree(p,listOfDegrees,r) factorizes the polynomial p using
++ the single factor bound algorithm, knowing that p has for possible
++ splitting of its degree listOfDegrees and that p has at least r
++ factors.
++ f is supposed not having any repeated factor (this is not checked).
factorSquareFree: (UP,N,N) -> Factored UP
++ factorSquareFree(p,d,r) factorizes the polynomial p using the single
++ factor bound algorithm, knowing that d divides the degree of all
++ factors of p and that p has at least r factors.
++ f is supposed not having any repeated factor (this is not checked).
factorOfDegree: (P,UP) -> Union(UP,"failed")
++ factorOfDegree(d,p) returns a factor of p of degree d.
factorOfDegree: (P,UP,N) -> Union(UP,"failed")
++ factorOfDegree(d,p,r) returns a factor of p of degree
++ d knowing that p has at least r factors.
factorOfDegree: (P,UP,List N) -> Union(UP,"failed")
++ factorOfDegree(d,p,listOfDegrees) returns a factor
++ of p of degree d knowing that p has for possible splitting of its
++ degree listOfDegrees.
factorOfDegree: (P,UP,List N,N) -> Union(UP,"failed")
++ factorOfDegree(d,p,listOfDegrees,r) returns a factor
++ of p of degree d knowing that p has for possible splitting of its
++ degree listOfDegrees, and that p has at least r factors.
factorOfDegree: (P,UP,List N,N,Boolean) -> Union(UP,"failed")
++ factorOfDegree(d,p,listOfDegrees,r,sqf) returns a
++ factor of p of degree d knowing that p has for possible splitting of
++ its degree listOfDegrees, and that p has at least r factors.
++ If \spad{sqf=true} the polynomial is assumed to be square free (i.e.
++ without repeated factors).
henselFact: (UP,Boolean) -> FinalFact
++ henselFact(p,sqf) returns the factorization of p, the result
++ is a Record such that \spad{contp=}content p,
++ \spad{factors=}List of irreducible factors of p with exponent.
++ If \spad{sqf=true} the polynomial is assumed to be square free (i.e.
++ without repeated factors).
btwFact: (UP,Boolean,Set N,N) -> FinalFact
++ btwFact(p,sqf,pd,r) returns the factorization of p, the result
++ is a Record such that \spad{contp=}content p,
++ \spad{factors=}List of irreducible factors of p with exponent.
++ If \spad{sqf=true} the polynomial is assumed to be square free (i.e.
++ without repeated factors).
++ pd is the \spadtype{Set} of possible degrees. r is a lower bound for
++ the number of factors of p. Please do not use this function in your
++ code because its design may change.

++ Author: Frederic Lehobey
++ Date Created: 30 June 1994
++ Date Last Updated: 15 July 1994
++ Description:
++ \spadtype{GaloisGroupPolynomialUtilities} provides useful
++ functions for univariate polynomials which should be added to
++ \spadtype{UnivariatePolynomialCategory} or to \spadtype{Factored}

GaloisGroupPolynomialUtilities(R,UP): Exports == Implementation where
R : Ring
UP : UnivariatePolynomialCategory R
N ==> NonNegativeInteger
P ==> PositiveInteger

Exports => with
- monic?: UP -> Boolean
  ++ monic?(p) tests if p is monic (i.e. leading coefficient equal to 1).
- unvectorise: Vector R -> UP
  ++ unvectorise(v) returns the polynomial which has for coefficients the
  ++ entries of v in the increasing order.
reverse: UP -> UP
++ reverse(p) returns the reverse polynomial of p.
scaleRoots: (UP,R) -> UP
++ scaleRoots(p,c) returns the polynomial which has c times the roots
++ of p.
shiftRoots: (UP,R) -> UP
++ shiftRoots(p,c) returns the polynomial which has for roots c added
++ to the roots of p.
degreePartition: Factored UP -> Multiset N
++ degreePartition(f) returns the degree partition (i.e. the multiset
++ of the degrees of the irreducible factors) of
++ the polynomial f.
factorOfDegree: (P, Factored UP) -> UP
++ factorOfDegree(d,f) returns a factor of degree d of the factored
++ polynomial f. Such a factor shall exist.
factorsOfDegree: (P, Factored UP) -> List UP
++ factorsOfDegree(d,f) returns the factors of degree d of the factored
++ polynomial f.

Exports ==> with

  reset: () -> Void
  setCurve: PolyRing -> PolyRing
  homogenize: (PolyRing,Integer) -> PolyRing
  printInfo: List Boolean -> Void
    ++ printInfo(lbool) prints some information coming from various
    ++ package and domain used by this package.
  theCurve: () -> PolyRing
    ++ theCurve returns the specified polynomial for the package.
  genus: () -> NNI
    ++ genus returns the genus of the curve defined by the polynomial
    ++ given to the package.
  genusNeg: () -> INT
  desingTree: () -> List DesTree
    ++ desingTree returns the desingularisation trees at all singular
    ++ points of the curve defined by the polynomial given to the package.
  desingTreeWoFullParam : () -> List Tree
    ++ desingTreeWoFullParam returns the desingularisation trees at all
    ++ singular points of the curve defined by the polynomial given to
    ++ the package. The local parameterizations are not computed.
  setSingularPoints: List ProjPt -> List ProjPt
    ++ setSingularPoints(lpt) sets the singular points to be used.
    ++ Beware: no attempt is made to check if the points are singular
    ++ or not, nor if all of the singular points are present. Hence,
    ++ results of some computation may be false. It is intended to be used
    ++ when one wants to compute the singular points are computed by other
    ++ means than to use the function singularPoints.
  singularPoints: () -> List(ProjPt)
    ++ rationalPoints() returns the singular points of the
+ curve defined by the polynomial given to the package.
+ If the singular points lie in an extension of the specified ground
+ field an error message is issued specifying the extension degree
+ needed to find all singular points.

parametrize: (PolyRing,Plc) -> PCS
+ parametrize(f,pl) returns a local parametrization of f at the place
+ pl.

lBasis: DIVISOR -> Record(num:List PolyRing, den: PolyRing)
+ lBasis computes a basis associated to the specified divisor

findOrderOfDivisor: (DIVISOR,Integer,Integer) -> 
+ Record(ord:Integer,num:PolyRing,den:PolyRing,upTo:Integer)

interpolateForms: (DIVISOR,NNI) -> List(PolyRing)
+ interpolateForms(d,n) returns a basis of the interpolate forms of
+ degree n of the divisor d.

interpolateFormsForFact: (DIVISOR,List PolyRing) -> List(PolyRing)

eval: (PolyRing,Plc) -> K
+ eval(f,pl) evaluate f at the place pl.

eval: (PolyRing,PolyRing,Plc) -> K
+ eval(f,g,pl) evaluate the function f/g at the place pl.

eval: (FRACPOLY,Plc) -> K
+ eval(u,pl) evaluate the function u at the place pl.

evalIfCan: (PolyRing,Plc) -> Union(K,"failed")
+ evalIfCan(f,pl) evaluate f at the place pl
+ (returns "failed" if it is a pole).

evalIfCan: (PolyRing,PolyRing,Plc) -> Union(K,"failed")
+ evalIfCan(f,g,pl) evaluate the function f/g at the place pl
+ (returns "failed" if it is a pole).

evalIfCan: (FRACPOLY,Plc) -> Union(K,"failed")
+ evalIfCan(u,pl) evaluate the function u at the place pl
+ (returns "failed" if it is a pole).

intersectionDivisor: PolyRing -> DIVISOR
+ intersectionDivisor(pol) compute the intersection divisor
+ (the Cartier divisor) of the form pol with the curve. If some
+ intersection points lie in an extension of the ground field,
+ an error message is issued specifying the extension degree
+ needed to find all the intersection points.
+ (If pol is not homogeneous an error message is issued).
adjunctionDivisor: () -> DIVISOR
++ adjunctionDivisor computes the adjunction divisor of the plane
++ curve given by the polynomial crv.

placesAbove: ProjPt -> List Plc

pointDominateBy : Plc -> ProjPt
++ pointDominateBy(pl) returns the projective point dominated
++ by the place pl.

if K has Finite then --should we say LocallyAlgebraicallyClosedField??

rationalPlaces: () -> List Plc
++ rationalPlaces returns all the rational places of the
++ curve defined by the polynomial given to the package.

rationalPoints: () -> List(ProjPt)

LPolynomial: () -> SparseUnivariatePolynomial Integer
++ Returns the L-Polynomial of the curve.

LPolynomial: PI -> SparseUnivariatePolynomial Integer
++ LPolynomial(d) returns the L-Polynomial of the curve in
++ constant field extension of degree d.

classNumber: () -> Integer
++ Returns the class number of the curve.

placesOfDegree: PI -> List Plc
++ placesOfDegree(d) returns all places of degree d of the
++ curve.

numberOfPlacesOfDegree: PI -> Integer
++ returns the number of places of the given degree

numberRatPlacesExtDeg: PI -> Integer
++ numberRatPlacesExtDeg(n) returns the number of rational
++ places in the constant field extension of degree n

numberPlacesDegExtDeg: (PI, PI) -> Integer
++ numberRatPlacesExtDegExtDeg(d, n) returns the number of
++ places of degree d in the constant field extension of
++ degree n

ZetaFunction: () -> UTSZ
++ Returns the Zeta function of the curve. Calculated by
++ using the L-Polynomial

ZetaFunction: PI -> UTSZ
++ Returns the Zeta function of the curve in constant field
++ extension. Calculated by using the L-Polynomial

====================================================================
GenExEuclid examples
====================================================================

The equation Af+Bg=h and its generalization to n polynomials
is solved for solutions over the R, euclidean domain.

A table containing the solutions of Af+Bg=x**k is used.

The operations are performed modulus a prime which are in principle
big enough, but the solutions are tested and, in case of failure, a
hensel lifting process is used to get to the right solutions. It will
be used in the factorization of multivariate polynomials over finite
field, with R=F[x].

C == with
  reduction: (BP,R) -> BP
    ++ reduction(p,prime) reduces the polynomial p modulo prime of R.
    ++ Note that this function is exported only because it’s conditional.
  compBound: (BP,L BP) -> NNI
    ++ compBound(p,lp)
    ++ computes a bound for the coefficients of the solution
    ++ polynomials.
    ++ Given a polynomial right hand side p,
    ++ and a list lp of left hand side polynomials.
    ++ Exported because it depends on the valuation.
  tablePow : (NNI,R,L BP) -> Union(Vector(L BP),"failed")
    ++ tablePow(maxdeg,prime,lpol) constructs the table with the
    ++ coefficients of the Extended Euclidean Algorithm for lpol.
    ++ Here the right side is \spad{x**k}, for k less or equal to maxdeg.
    ++ The operation returns "failed" when the elements
    ++ are not coprime modulo prime.
solveid : (BP,R,Vector L BP) -> Union(L BP,"failed")
  ++ solveid(h,table) computes the coefficients of the
  ++ extended euclidean algorithm for a list of polynomials
  ++ whose tablePow is table and with right side h.

  testModulus : (R, L BP) -> Boolean
  ++ testModulus(p,lp) returns true if the the prime p
  ++ is valid for the list of polynomials lp, i.e. preserves
  ++ the degree and they remain relatively prime.

Rationalization of several types of genus 0 integrands;
This internal package rationalises integrands on curves of the form:

\[ y^2 = a x^2 + b x + c \]
\[ y^2 = (a x + b) / (c x + d) \]
\[ f(x, y) = 0 \] where \( f \) has degree 1 in \( x \)

The rationalization is done for integration, limited integration,
extended integration and the risch differential equation;

package GRAY GrayCode

GrayCode examples

GrayCode provides a function for efficiently running through all subsets of a finite set, only changing one element by another one.

See Also:
  o )show GrayCode
GrayCode (GRAY)

Exports:
  firstSubsetGray  nextSubsetGray

— package GRAY GrayCode —

)abbrev package GRAY GrayCode
++ Authors: Johannes Grabmeier, Oswald Gschnitzer
++ Date Created: 7 August 1989
++ Date Last Updated: 23 August 1990
++ References:
++ Henryk Minc: Evaluation of Permanents,
++ Nijenhuis and Wilf : Combinatorical Algorithms, Academic
++ S.G.Williamson, Combinatorics for Computer Science,
++ Description:
++ GrayCode provides a function for efficiently running
++ through all subsets of a finite set, only changing one element
++ by another one.

GrayCode: public == private where

  PI ==> PositiveInteger
  I  ==> Integer
  V  ==> Vector

public ==> with

  nextSubsetGray: (V V I,PI) -> V V I
  ++ nextSubsetGray(ww,n) returns a vector vv whose components
  ++ have the following meanings:
  ++ vv.1: a vector of length n whose entries are 0 or 1. This
  ++ can be interpreted as a code for a subset of the set 1,...,n;
  ++ vv.1 differs from ww.1 by exactly one entry;
++ vv.2.1 is the number of the entry of vv.1 which
++ will be changed next time; \br
++ vv.2.1 = n+1 means that vv.1 is the last subset;
++ trying to compute nextSubsetGray(vv) if vv.2.1 = n+1
++ will produce an error! \br
++
++ The other components of vv.2 are needed to compute
++ nextSubsetGray efficiently.
++ Note that this is an implementation of [Williamson, Topic II, 3.54,
++ p. 112] for the special case r1 = r2 = \ldots = rn = 2;
++ Note that nextSubsetGray produces a side-effect, i.e.
++ nextSubsetGray(vv) and vv := nextSubsetGray(vv)
++ will have the same effect.

firstSubsetGray: PI -> V V I
++ firstSubsetGray(n) creates the first vector ww to start a
++ loop using nextSubsetGray(ww,n)

private ==> add

--- GroebnerFactorizationPackage.help ---

GroebnerFactorizationPackage provides the function "groebnerFactor" which uses the factorization routines of Axiom to factor each polynomial under consideration while doing the groebner basis algorithm. Then it writes the ideal as an intersection of ideals determined by the irreducible factors. Note that the whole ring may occur as well as other redundancies. We also use the fact, that from the second factor on we can assume that the preceding factors are not equal to 0 and we divide all polynomials.
under considerations by the elements of this list of "nonZeroRestrictions".

The result is a list of groebner bases, whose union of solutions of the corresponding systems of equations is the solution of the system of equation corresponding to the input list. The term ordering is determined by the polynomial type used.

Suggested types include
- DistributedMultivariatePolynomial
- HomogeneousDistributedMultivariatePolynomial
- GeneralDistributedMultivariatePolynomial

Solving systems of polynomial equations with the Groebner basis algorithm can often be very time consuming because, in general, the algorithm has exponential run-time. These systems, which often come from concrete applications, frequently have symmetries which are not taken advantage of by the algorithm. However, it often happens in this case that the polynomials which occur during the Groebner calculations are reducible. Since Axiom has an excellent polynomial factorization algorithm, it is very natural to combine the Groebner and factorization algorithms.

GroebnerFactorizationPackage exports the groebnerFactorize operation which implements a modified Groebner basis algorithm. In this algorithm, each polynomial that is to be put into the partial list of the basis is first factored. The remaining calculation is split into as many parts as there are irreducible factors. Call these factors p1,...,pN. In the branches corresponding to p2,...,pN, the factor p1 can be divided out, and so on. This package also contains operations that allow you to specify the polynomials that are not zero on the common roots of the final Groebner basis.

Here is an example from chemistry. In a theoretical model of the cyclohexan C6H12, the six carbon atoms each sit in the center of gravity of a tetrahedron that has two hydrogen atoms and two carbon atoms at its corners. We first normalize and set the length of each edge to 1. Hence, the distances of one fixed carbon atom to each of its immediate neighbours is 1. We will denote the distances to the other three carbon atoms by x, y and z.

A. Dress developed a theory to decide whether a set of points and distances between them can be realized in an n-dimensional space. Here, of course, we have n = 3.

```
mfzn : SQMATRIX(6,DMP([x,y,z],Fraction INT)) := _
  [ [0,1,1,1,1,1], [1,0,1,8/3,x,8/3], [1,1,0,1,8/3,y],_
    [1,8/3,1,0,1,8/3], [1,x,8/3,1,0,1], [1,8/3,y,8/3,1,0] ]
  +0 1 1 1 1 1 +
  |     |     |
  | 8 8 |
```
Type: SquareMatrix(6,DistributedMultivariatePolynomial([x,y,z],
Fraction Integer))

For the cyclohexan, the distances have to satisfy this equation.

\[
\begin{align*}
\text{eq} &:= \text{determinant mfn}\n\begin{array}{cccccccc}
2 & 2 & 2 & 2 & 2 & 2 & 2 & 388 & 250 & 25 & 2 & 250 & 14575 \\
- x y + & x y - & x + & x y - & x y - & x y - & x - & y - & y + ----
\end{array} \\
3 & 9 & 3 & 9 & 27 & 9 & 27 & 81 \\
\text{Type: DistributedMultivariatePolynomial([x,y,z],Fraction Integer)}
\end{align*}
\]

They also must satisfy the equations given by cyclic shifts of the indeterminates.

\[
\text{groebnerFactorize } \{\text{eq,eval(eq, [x,y,z],[y,z,x])}, \
\text{eval(eq,[x,y,z],[z,x,y])}\} \\
\{ 22 & 22 & 22 & 121 \\
x z - & x z + & x + y z - & y + y z + & y z + & y z + & y z + & y + z + & z + -- \\
3 & 3 & 3 & 3 & 3 & 3 & 3 & 3 & 9 & 9 & 9 & 9 & 27 \\
2 & 2 & 2 & 2 & 2 & 2 & 2 & 388 & 250 & 25 & 2 & 250 & 14575 \\
y z - & y z + & y z + & y z + & y z + & y z + & y z + & y + z + & z + -- \\
3 & 3 & 3 & 9 & 9 & 9 & 9 & 9 & 27 & 27 & 27 & 27 & 81 \\
\}, \\
21994 & 2 & 21994 & 4427 & 463 \\
x + y - & y - & y + & z - & - - \\
5625 & 5625 & 675 & 87 \\
2 & 1 & 11 & 5 & 265 & 2 & 38 & 265 \\
x + & x z - & x + & z + & y - & z, z - & z + - - \\
2 & 2 & 6 & 18 & 3 & 9
\]
The union of the solutions of this list is the solution of our original problem. If we impose positivity conditions, we get two relevant ideals. One ideal is zero-dimensional, namely \( x = y = z = \frac{11}{3} \), and this determines the "boat" form of the cyclohexan. The other ideal is one-dimensional, which means that we have a solution space given by one parameter. This gives the "chair" form of the cyclohexan. The parameter describes the angle of the "back of the chair."

\textbf{groebnerFactorize} has an optional Boolean-valued second argument. When it is true partial results are displayed, since it may happen that the calculation does not terminate in a reasonable time. See the source code for \texttt{GroebnerFactorizationPackage} in \texttt{groebf.spad.pamphlet} for more details about the algorithms used.

There are 6 Groebner Basis Polynomials.

THE GROEBNER BASIS POLYNOMIALS

There are 6 Groebner Basis Polynomials.

THE GROEBNER BASIS POLYNOMIALS

Groebner Package computes groebner bases for polynomial ideals. The basic computation provides a distinguished set of generators for polynomial ideals over fields. This basis allows an easy test for membership: the operation normalForm returns zero on ideal members. When the provided coefficient domain, Dom, is not a field, the result is equivalent to considering the extended ideal with Fraction(Dom) as coefficients, but considerably more efficient since all calculations are performed in Dom.

Additional arguments "info" and "redcrit" can be given to provide incremental information during computation.

Argument "info" produces a computational summary for each s-polynomial. Argument "redcrit" prints out the reduced critical pairs.

The term ordering is determined by the polynomial type used.

Suggested types include
Example to call groebner:

```
s1:DMP[w,p,z,t,s,b]RN:= 45*p + 35*s - 165*b - 36
s2:DMP[w,p,z,t,s,b]RN:= 35*p + 40*z + 25*t - 27*s
s3:DMP[w,p,z,t,s,b]RN:= 15*w + 25*p*s + 30*z - 18*t - 165*b**2
s4:DMP[w,p,z,t,s,b]RN:= -9*w + 15*p*t + 20*z*s
s5:DMP[w,p,z,t,s,b]RN:= w*p + 2*z*t - 11*b**3
s6:DMP[w,p,z,t,s,b]RN:= 99*w - 11*b*s + 3*b**2
s7:DMP[w,p,z,t,s,b]RN:= b**2 + 33/50*b + 2673/10000

sn7:=[s1,s2,s3,s4,s5,s6,s7]

groebner(sn7,info)
```

groebner calculates a minimal Groebner Basis
all reductions are TOTAL reductions

To get the reduced critical pairs do:

```
groebner(sn7,"redcrit")
```

You can get other information by calling:

```
groebner(sn7,"info")
```

which returns:

```
ci => Leading monomial for critpair calculation
tci => Number of terms of polynomial i

cj => Leading monomial for critpair calculation
tcj => Number of terms of polynomial j

c => Leading monomial of critpair polynomial
tc => Number of terms of critpair polynomial

rc => Leading monomial of redcritpair polynomial
trc => Number of terms of redcritpair polynomial

tF => Number of polynomials in reduction list F
tD => Number of critpairs still to do
```

Guess examples
====================================================================

The packages defined in this file enable {Axiom} to guess formulas for
sequences of, for example, rational numbers or rational functions,
given the first few terms. It extends and complements Christian
Krattenthaler’s program Rate and the relevant parts of Bruno Salvy and
Paul Zimmermann’s GFUN.

This package implements guessing of sequences. Packages for the
most common cases are provided as GuessInteger, GuessPolynomial, etc.

See Also:

- shiftHP

The original code would not compile. This is a temporary replacement with changes marked with my initials. I will pick up the latest version sometime in the future and hope it compiles.

++ Author: P. Gianni
++ Date Created: 1983
++ Date Last Updated: Sept. 1990
++ Description:
++ This is an inner package for factoring multivariate polynomials
++ over various coefficient domains in characteristic 0.
++ The univariate factor operation is passed as a parameter.
++ Multivariate hensel lifting is used to lift the univariate
++ factorization

-- Both exposed functions call mFactor. This deals with issues such as
-- monomial factors, contents, square-freeness etc., then calls intfact.
-- This uses intChoose to find a "good" evaluation and factorise the
-- corresponding univariate, and then uses MultivariateLifting to find
-- the multivariate factors.

Exports == with

  setFieldInfo: (V L TERM,GF) -> Void
    ++ setFieldInfo(m,p) initializes the field arithmetic, where m is
    ++ the multiplication table and p is the respective normal element
    ++ of the ground field GF.
  random : PI -> VGF
    ++ random(n) creates a vector over the ground field with random entries.
  index : (PI,PI) -> VGF
    ++ index(n,m) is a index function for vectors of length n over
    ++ the ground field.
  pol : VGF -> SUP GF
    ++ pol(v) turns the vector \spad{[v_0,...,v_n]} into the polynomial
    ++ \spad{v_0+v_1*x+ ... + v_n*x^n}.
  xn : NNI -> SUP GF
    ++ xn(n) returns the polynomial \spad{x^n-1}.
  dAndcExp : (VGF,NNI,SI) -> VGF
    ++ dAndcExp(v,n,k) computes \spad{v^{n^k}} interpreting v as an element of
    ++ normal basis field. A divide and conquer algorithm similar to the
    ++ one from D.R.Stinson,
    ++ "Some observations on parallel Algorithms for fast exponentiation in
    ++ GF(2^n)", Siam J. Computation, Vol.19, No.4, pp.711-717, August 1990
    ++ is used. Argument k is a parameter of this algorithm.
  repSq : (VGF,NNI) -> VGF
    ++ repSq(v,e) computes \spad{v^{e}} by repeated squaring,
    ++ interpreting v as an element of a normal basis field.
  expPot : (VGF,SI,SI) -> VGF
++ expPot(v,e,d) returns the sum from \( i = 0 \) to
++ \( e - 1 \) of \( v^{q^i \cdot d} \), interpreting
++ \( v \) as an element of a normal basis field and where \( q \) is
++ the size of the ground field.
++ Note that for a description of the algorithm, see
++ T. Itoh and S. Tsujii,
++ "A fast algorithm for computing multiplicative inverses in GF\( (2^m) \)
++ using normal bases",

qPot : (VGF,I) -> VGF
++ qPot(v,e) computes \( v^{q^e} \), interpreting \( v \) as an element of
++ normal basis field, \( q \) the size of the ground field.
++ This is done by a cyclic \( e \)-shift of the vector \( v \).

CHAPTER 10. CHAPTER I

charpol : MK -> SUK
  ++ charpol(m) computes the characteristic polynomial of a matrix
  ++ m with entries in K.
  ++ This function returns a polynomial
  ++ over K, while the general one (that is in EiegenPackage) returns
  ++ Fraction P K

solve1 : (SUK, Par) -> List F
  ++ solve1(pol, eps) finds the roots of the univariate polynomial
  ++ polynomial pol to precision eps. If K is \spad{Fraction Integer}
  ++ then only the real roots are returned, if K is
  ++ \spad{Complex Fraction Integer} then all roots are found.

innerEigenvectors : (MK, Par, UFactor) -> List(outForm)
  ++ innerEigenvectors(m,eps,factor) computes explicitly
  ++ the eigenvalues and the correspondent eigenvectors
  ++ of the matrix m. The parameter eps determines the type of
  ++ the output, factor is the univariate factorizer to be used
  ++ to reduce the characteristic polynomial into irreducible factors.

====================================================================
InnerNumericFloatSolvePackage examples
====================================================================

This is an internal package for computing approximate solutions to systems of polynomial equations. The parameter K specifies the coefficient field of the input polynomials and must be either Fraction(Integer) or Complex(Fraction Integer).

The parameter F specifies where the solutions must lie and can be one of the following: Float, Fraction(Integer), Complex(Float), or Complex(Fraction Integer). The last parameter specifies the type of the precision operand and must be either Fraction(Integer) or Float.

IntegerCombinatoricFunctions package provides some standard functions in combinatorics.

The binomial(n, r) returns the number of subsets of r objects taken among n objects, i.e. \( \frac{n!}{r! \cdot (n-r)!} \)

The binomial coefficients are the coefficients of the series expansion of a power of a binomial, that is

\[
\begin{align*}
\sum_{k=0}^{n} & \binom{n}{k} x^k = (1 + x)^n
\end{align*}
\]

This leads to the famous Pascal triangle. First we expose the OutputForm domain, which is normally hidden, so we can use it to format the lines.

Next we define a function that will output the list of binomial coefficients right justified with proper spacing:

\[
\text{pascalRow}(n) = [\text{right}(\binom{n}{i}, 4) \text{ for } i \text{ in } 0..n]
\]

and now we format the whole line so that it looks centered:

\[
\text{displayRow}(n) = \text{output center blankSeparate pascalRow}(n)
\]

and we compute the triangle

\[
\text{for } i \text{ in } 0..7 \text{ repeat displayRow } i
\]

giving the pretty result:
OutputForm
Compiling function displayRow with type NonNegativeInteger -> Void

1
 1 1
 1 2 1
 1 3 3 1
 1 4 6 4 1
 1 5 10 10 5 1
 1 6 15 20 15 6 1
 1 7 21 35 35 21 7 1

PollardSmallFactor

This is Brent's optimization of Pollard's rho factoring. Brent's algorithm is about 24 percent faster than Pollard's. Pollard's algorithm has complexity $O(p^{1/2})$ where $p$ is the smallest prime factor of the composite number $N$.

Pollard's idea is based on the observation that two numbers $x$ and $y$ are congruent modulo $p$ with probability 0.5 after $1.177 \sqrt{p}$ numbers have been randomly chosen. If we try to factor $n$ and $p$ is a factor of $n$, then

$$1 < \gcd(|x - y|, n) \leq n$$
since \( p \) divides both \( |x - y| \) and \( n \).

Given a function \( f \) which generates a pseudo-random sequence of numbers we allow \( x \) to walk the sequence in order and \( y \) to walk the sequence at twice the rate. At each cycle we compute \( \gcd(|x - y|, n) \). If this GCD ever equals \( n \) then \( x = y \) which means that we have walked "all the way around the pseudo-random cycle" and we terminate with failure.

This algorithm returns failure on all primes but also fails on some composite numbers.

Quoting Brent’s back-tracking idea:

The best-known algorithm for finding GCDs is the Euclidean algorithm which takes \( O(\log N) \) times as long as one multiplication mod \( N \). Pollard showed that most of the GCD computations in Floyd’s algorithm could be dispensed with.

... The idea is simple: if \( P_F \) computes \( \gcd(z_1, N), \gcd(z_2, N), \ldots \), then we compute

\[
q_i = \prod_{j=1}^{i} z_j \pmod{N}
\]

and only compute \( \gcd(q_i, N) \) when \( i \) is a multiple of \( m \), where \( \log N << m << N^{1/4} \). Since \( q_{i+1} = q_i \times z_{i+1} \pmod{N} \), the work required for each GCD computation in algorithm \( P_F \) is effectively reduced to that for a multiplication mod \( N \) in the modified algorithm. The probability of the algorithm failing because \( q_i = 0 \) increases, so it is best not to choose \( m \) too large. This problem can be minimized by backtracking to the state after the previous GCD computation and setting \( m = 1 \).

Brent incorporates back-tracking, omits the random choice of \( u \), and makes some minor modifications. His algorithm (p192-183) reads:

\[
y := x_0; r := 1; q := 1;
\]

repeat \( x := y; \)
  for \( i := 1 \) to \( r \) do \( y := f(y); k := 0; \)
   repeat \( y_s := y; \)
     for \( i := 1 \) to \( \min(m, r - k) \) do
       begin \( y := f(y); q := q \times |x - y| \pmod{N} \)
       end;

   \( G := \gcd(q, N); k := k + m \)
   until \( (k \geq r) \) or \( (G > 1) \);

until \( G > 1 \);

if \( G = N \) then
  repeat \( y_s := f(y_s); G := \gcd(|y - yx|, N) \)
  until \( G > 1 \);

if \( G = N \) then failure else success
Here we use the function 
\[(y \ast y + 5 :: I) \text{ rem } n\]
as our pseudo-random sequence with a random starting value for y.

On possible optimization to explore is to keep a hash table for the computed values of the function \(y_{i+1} := f(y_i)\) since we effectively walk the sequence several times. And we walk the sequence in a loop many times. But because we are generating a very large number of numbers the array can be a simple array of fixed size that captures the last n values. So if we make a fixed array F of, say \(2^q\) elements we can store \(f(y_i)\) in \(F[y_i \text{ mod } 2^q]\).

One property that this algorithm assumes is that the function used to generate the numbers has a long, hopefully complete, period. It is not clear that the recommended function has that property.

```haskell
-- package INTFACT IntegerFactorizationPackage --

PollardSmallFactor(n:I):Union(I,"failed") ==
  -- Use the Brent variation
  x0 := random()$I
  m := 100 :: I
  y := x0 rem n
  r:I := 1
  q:I := 1
  G:I := 1
  until G > 1 repeat
    x := y
    for i in 1..convert(r)@Integer repeat
      y := (y\ast y + 5 :: I) \text{ rem } n
      k:I := 0
      until (k>r) or (G>1) repeat
        yss := y
        for i in 1..convert(min(m,r-k))@Integer repeat
          y := (y\ast y + 5 :: I) \text{ rem } n
          q := q*abs(x-y) \text{ rem } n
          G := gcd(q,n)
          k := k+m
        r := 2*r
      if G=n then
        until G>1 repeat
          yss := (yss\ast yss + 5 :: I) \text{ rem } n
          G := gcd(abs(x-yss),n)
        G=n => "failed"
      G
```

---
BasicSieve

We create a list of prime numbers up to the limit given. The prior code used a circular list but tests of that list show that on average more than 50 the required prime numbers. Overall this is a small percentage of the time needed to factor.

This loop uses three pieces of information

1. n which is the number we are testing
2. d which is the current prime to test
3. lim which is the upper limit of the primes to test

We loop d over the list of primes. If the remaining number n is smaller than the square of d then n must be prime and if it is not one, we add it to the list of primes. If the remaining number is larger than the square of d we remove all factors of d, reducing n each time. Then we add a record of the new factor and its multiplicity, m. We continue the loop until we run out of primes.

Annoyingly enough, primes does not return an ordered list so we fix this.

The sieve works up to a given limit, reducing out the factors that it finds. If it can find all of the factors than it returns a factored result where the first element is the unit 1. If there is still a part of the number unfactored it returns the number and a list of the factors found and their multiplicity.

Basically we just loop thru the prime factors checking to see if they are a component of the number, n. If so, we remove the factor from the number n (possibly m times) and continue thru the list of primes.

This package tests for linear dependence over the integers.

The elements \( v_1, \ldots, v_N \) of a module \( M \) over a ring \( R \) are said to be
linearly dependent over \( R \) if there exist \( c_1, \ldots, c_N \) in \( R \), not all 0, such that \( c_1 v_1 + \ldots + c_N v_N = 0 \). If such \( c_i \)'s exist, they form what is called a linear dependence relation over \( R \) for the \( v_i \)'s.

The package IntegerLinearDependence provides functions for testing whether some elements of a module over the integers are linearly dependent over the integers, and to find the linear dependence relations, if any.

Consider the domain of two by two square matrices with integer entries.

\[
M := \text{SQMATRIX}(2, \text{INT})
\]

\[
\text{SquareMatrix}(2, \text{Integer})
\]

\[
\text{Type: Domain}
\]

Now create three such matrices.

\[
m1 := \text{squareMatrix} \begin{bmatrix} 1 & 2 \\ 0 & -1 \end{bmatrix}
\]

\[
\text{Type: SquareMatrix}(2, \text{Integer})
\]

\[
m2 := \text{squareMatrix} \begin{bmatrix} 2 & 3 \\ 1 & -2 \end{bmatrix}
\]

\[
\text{Type: SquareMatrix}(2, \text{Integer})
\]

\[
m3 := \text{squareMatrix} \begin{bmatrix} 3 & 4 \\ 2 & -3 \end{bmatrix}
\]

\[
\text{Type: SquareMatrix}(2, \text{Integer})
\]

This tells you whether \( m_1, m_2 \) and \( m_3 \) are linearly dependent over the integers.

\[
\text{linearlyDependentOverZ? vector } [m1, m2, m3]
\]

\[
\text{true}
\]

\[
\text{Type: Boolean}
\]

Since they are linearly dependent, you can ask for the dependence relation.

\[
c := \text{linearDependenceOverZ} \text{ vector } [m1, m2, m3] [1, -2, 1]
\]

\[
\text{Type: Union(Vector Integer, ...)}
\]

This means that the following linear combination should be 0.

\[
c.1 \times m1 + c.2 \times m2 + c.3 \times m3
\]
When a given set of elements are linearly dependent over \( \mathbb{R} \), this also means that at least one of them can be rewritten as a linear combination of the others with coefficients in the quotient field of \( \mathbb{R} \).

To express a given element in terms of other elements, use the operation `solveLinearlyOverQ`.

\[
\text{solveLinearlyOverQ(vector } [m1, m3], m2) = \begin{bmatrix} 1 & 1 \\ -1 & -1 \\ 2 & 2 \end{bmatrix}
\]

Type: Union(Vector Fraction Integer,...)

This package provides various number theoretic functions on the integers.

The IntegerNumberTheoryFunctions package contains a variety of operations of interest to number theorists. Many of these operations deal with divisibility properties of integers. (Recall that an integer a divides an integer b if there is an integer c such that b = a * c.)

The operation divisors returns a list of the divisors of an integer.

\[
\text{div}144 := \text{divisors}(144) \\
[1,2,3,4,6,8,9,12,16,18,24,36,48,72,144] \\
\text{Type: List Integer}
\]

You can now compute the number of divisors of 144 and the sum of the divisors of 144 by counting and summing the elements of the list we just created.

\[
\#(\text{div}144) \\
15 \\
\text{Type: PositiveInteger}
\]

\[
\text{reduce}(+,\text{div}144) \\
403 \\
\text{Type: PositiveInteger}
\]

Of course, you can compute the number of divisors of an integer n, usually denoted \(d(n)\), and the sum of the divisors of an integer n, usually denoted \(\sigma(n)\), without ever listing the divisors of n.

In Axiom, you can simply call the operations \text{numberOfDivisors} and \text{sigma}.
CHAPTER 10. CHAPTER I

sumOfDivisors.

numberOfDivisors(144)
15
Type: PositiveInteger

sumOfDivisors(144)
403
Type: PositiveInteger

The key is that d(n) and sigma(n) are "multiplicative functions.
This means that when n and m are relatively prime, that is, when
n and m have no prime factor in common, then d(nm) = d(n) d(m) and
sigma(nm) = sigma(n) sigma(m). Note that these functions are trivial to
calculate when n is a prime power and are computed for general n from the
prime factorization of n. Other examples of multiplicative functions
are sigma_k(n), the sum of the k-th powers of the divisors of n and
varphi(n), the number of integers between 1 and n which are prime to n.
The corresponding Axiom operations are called sumOfKthPowerDivisors and
eulerPhi.

An interesting function is mu(n), the Moebius mu function, defined as
follows: mu(1) = 1, mu(n) = 0, when n is divisible by a square, and
mu = (-1)^k, when n is the product of k distinct primes. The corresponding
Axiom operation is moebiusMu. This function occurs in the following theorem:

Theorem: (Moebius Inversion Formula):
Let f(n) be a function on the positive integers and let F(n)
be defined by
F(n) = \sum_{d | n} f(n)
the sum of f(n) over d | n where the sum is taken over the
positive divisors of n. Then the values of f(n) can be recovered
from the values of F(n): f(n) = \sum_{d | n} \mu(n) F(n/d) where
again the sum is taken over the positive divisors of n.

When f(n) = 1, then F(n) = d(n). Thus, if you sum mu(d).d(n/d) over
the positive divisors d of n, you should always get 1.

f1(n)==reduce(+,[moebiusMu(d)*numberOfDivisors(quo(n,d)) for d in divisors(n)])
Type: Void

f1(200)
1
Type: PositiveInteger

f1(846)
1
Type: PositiveInteger
Similarly, when \( f(n) = n \), then \( F(n) = \sigma(n) \). Thus, if you sum
\( \mu(d) \cdot \sigma(n/d) \) over the positive divisors \( d \) of \( n \), you should always get \( n \).

\[
f_2(n) = \text{reduce}(+, [\mu(d) \cdot \sum \text{divisors}(\text{quo}(n,d))]
\text{for } d \text{ in } \text{divisors}(n))
\]

Type: Void

\[
f_2(200) = 200
\]

Type: PositiveInteger

\[
f_2(846) = 846
\]

Type: PositiveInteger

The Fibonacci numbers are defined by
\( F(1) = F(2) = 1 \) and
\( F(n) = F(n-1) + F(n-2) \) for \( n = 3,4,... \).

The operation fibonacci computes the \( n \)-th Fibonacci number.

\[
fibonacci(25) = 75025
\]

Type: PositiveInteger

\[
[fibonacci(n) \text{ for } n \text{ in } 1..15]
[1,1,2,3,5,8,13,21,34,55,89,144,233,377,610]
\]

Type: List Integer

Fibonacci numbers can also be expressed as sums of binomial coefficients.

\[
fib(n) = \text{reduce}(+, [\binomial(n-1-k,k) \text{ for } k \text{ in } 0..\text{quo}(n-1,2)])
\]

Type: Void

\[
fib(25) = 75025
\]

Type: PositiveInteger

\[
[fib(n) \text{ for } n \text{ in } 1..15]
[1,1,2,3,5,8,13,21,34,55,89,144,233,377,610]
\]

Type: List Integer

Quadratic symbols can be computed with the operations legendre and
jacobi. The Legendre symbol \( a/p \) is defined for integers \( a \) and \( p \) with
\( p \) an odd prime number. By definition,

\[
(a/p) = +1, \text{ when } a \text{ is a square } (\text{mod } p),
(a/p) = -1, \text{ when } a \text{ is not a square } (\text{mod } p), \text{ and}
(a/p) = 0, \text{ when } a \text{ is divisible by } p.
\]
You compute \((a/p)\) via the command `legendre(a,p)`.

\[
\begin{align*}
\text{legendre}(3,5) & \quad -1 \quad \text{Type: Integer} \\
\text{legendre}(23,691) & \quad -1 \quad \text{Type: Integer}
\end{align*}
\]

The Jacobi symbol \((a/n)\) is the usual extension of the Legendre symbol, where \(n\) is an arbitrary integer. The most important property of the Jacobi symbol is the following: if \(K\) is a quadratic field with discriminant \(d\) and quadratic character \(\chi\), then \(\chi(n) = (d/n)\). Thus, you can use the Jacobi symbol to compute, say, the class numbers of imaginary quadratic fields from a standard class number formula.

This function computes the class number of the imaginary quadratic field with discriminant \(d\).

\[
\begin{align*}
\text{h}(d) & \quad = \quad \text{quo}(\text{reduce}(+, [\text{jacobi}(d,k) \text{ for } k \text{ in } 1..\text{quo}(-d, 2)])), 2\text{-jacobi}(d,2)) \\
& \quad \text{Type: Void}
\end{align*}
\]

\[
\begin{align*}
\text{h}(-163) & \quad 1 \quad \text{Type: PositiveInteger} \\
\text{h}(-499) & \quad 3 \quad \text{Type: PositiveInteger} \\
\text{h}(-1832) & \quad 26 \quad \text{Type: PositiveInteger}
\end{align*}
\]

====================================================================

The inverse function

====================================================================

The inverse function is derived from the Extended Euclidean Algorithm. If we divide one integer by another nonzero integer we get an integer quotient plus a remainder which is, in general, a rational number. For instance,

\[
13/5 = 2 + 3/5
\]

where 2 is the quotient and 3/5 is the remainder.

If we multiply thru by the denominator of the remainder we get an answer in integer terms which no longer involves division:

\[
13 = 2(5) + 3
\]
This gives a method of dividing integers. Specifically, if \( a \) and \( b \) are positive integers, there exist unique non-negative integers \( q \) and \( r \) so that
\[
a = qb + r, \quad \text{where } 0 \leq r < b
\]
\( q \) is called the quotient and \( r \) the remainder.

The greatest common divisor of integers \( a \) and \( b \), denoted by \( \gcd(a, b) \), is the largest integer that divides (without remainder) both \( a \) and \( b \). So, for example:
\[
\gcd(15, 5) = 5, \\
\gcd(7, 9) = 1, \\
\gcd(12, 9) = 3, \\
\gcd(81, 57) = 3.
\]

The \( \gcd \) of two integers can be found by repeated application of the division algorithm, this is known as the Euclidean Algorithm. You repeatedly divide the divisor by the remainder until the remainder is 0. The \( \gcd \) is the last non-zero remainder in this algorithm. The following example shows the algorithm.

Finding the \( \gcd \) of 81 and 57 by the Euclidean Algorithm:
\[
81 = 1(57) + 24 \\
57 = 2(24) + 9 \\
24 = 2(9) + 6 \\
9 = 1(6) + 3 \\
6 = 2(3) + 0
\]
So the greatest common divisor, the \( \text{GCD}(81,51) = 3 \).

If the \( \gcd(a, b) = r \) then there exist integers \( s \) and \( t \) so that
\[
s(a) + t(b) = r
\]
By back substitution in the steps in the Euclidean Algorithm, it is possible to find these integers \( s \) and \( t \). We shall do this with the above example:

Starting with the next to last line, we have:
\[
3 = 9 - 1(6)
\]
From the line before that, we see that 6 = 24 - 2(9), so:
\[
3 = 9 - 1(24 - 2(9)) = 3(9) - 1(24)
\]
From the line before that, we have 9 = 57 - 2(24), so:
\[
3 = 3( 57 - 2(24)) - 1(24) = 3(57) - 7(24)
\]
And, from the line before that $24 = 81 - 1(57)$, giving us:

$$3 = 3(57) - 7(81 - 1(57)) = 10(57) - 7(81)$$

So we have found $s = -7$ and $t = 10$.

The Extended Euclidean Algorithm computes the GCD(a,b) and the values for $s$ and $t$.

Suppose we were doing arithmetics modulo 26 and we needed to find the inverse of a number mod 26. This turned out to be a difficult task (and not always possible). We observed that a number $x$ had an inverse mod 26 (i.e., a number $y$ so that $xy = 1 \mod 26$) if and only if $\gcd(x, 26) = 1$. In the general case the inverse of $x$ exists if and only if $\gcd(x, n) = 1$ and if it exists then there exist integers $s$ and $t$ so that

$$sx + tn = 1$$

But this says that $sx = 1 + (-t)n$, or in other words,

$$sx \equiv 1 \mod n$$

So, $s$ (reduced mod $n$ if need be) is the inverse of $x$ mod $n$.

The extended Euclidean algorithm calculates $s$ efficiently.

```
Finding the inverse mod n
```

We will number the steps of the Euclidean algorithm starting with step 0. The quotient obtained at step $i$ will be denoted by $q_i$ and an auxiliary number, $s_i$. For the first two steps, the value of this number is given:

- $s(0) = 0$
- $s(1) = 1$

For the remainder of the steps, we recursively calculate

$$s(i) = s(i-2) - s(i-1) q(i-2) \mod n$$

The algorithm starts by "dividing" $n$ by $x$. If the last non-zero remainder occurs at step $k$, then if this remainder is 1, $x$ has an inverse and it is $s(k+2)$. If the remainder is not 1, then $x$ does not have an inverse.

For example, find the inverse of 15 mod 26.

```
Step 0: 26 = 1(15) + 11 $s(0) = 0$
Step 1: 15 = 1(11) + 4 $s(1) = 1$
Step 2: 11 = 2(4) + 3 $s(2) = 0 - 1(1) \mod 26 = 25$
Step 3: 4 = 1(3) + 1 $s(3) = 1 - 25(1) \mod 26 = -24 \mod 26 = 2$
Step 4: 3 = 3(1) + 0 $s(4) = 25 - 2(2) \mod 26 = 21$
```

$s(5) = 2 - 21(1) \mod 26 = -19 \mod 26 = 7$
Notice that $15(7) = 105 = 1 + 4(26) = 1 \pmod{26}$.

Using the half extended Euclidean algorithm we compute $1/a \mod b$.

```lisp
inverse: (INT, INT) -> INT
Type: Void
inverse(a, b) ==
borg: INT := b
cl: INT := 1
d1: INT := 0
while b ~= 0 repeat
  q := a quo b
  r := a-q*b
  print [a, "=", q, "*", b, "+", r]
  (a, b) := (b, r)
  (c1, d1) := (d1, c1-q*d1)
a ~= 1 => error("moduli are not relatively prime")
positiveRemainder(c1, borg)
Type: Void
```

```lisp
inverse(15, 26)
[15,"=",0,"*",26,"+",15]
[4,"=",1,"*",3,"+",1]
[3,"=",3,"*",1,"+",0]

7
Type: PositiveInteger
```

The Chinese Remainder Algorithm

The Chinese Remainder Theorem says that given $n$ moduli $m_i$ for $(1 \leq i \leq n)$ of pairwise coprime integers and a set of congruential equations $x \equiv c_i \pmod{m_i}$ $(1 \leq i \leq n)$ for an arbitrary integer $x$, there is a unique solution $c$ for $x \mod M$, say $x \equiv c \pmod{M}$.

If the upper bound $B$ of the absolute value of $x$ is known, that is, if $|x| \leq B$ then the number of moduli can be chosen such that $B < M/2$. If $c$ is the absolutely least residue modulo $M$ then $c$ and $x$ coincide so $x$ is uniquely determined.

Let $m_1, m_2, \ldots, m_r$ be positive integers that are pairwise relatively prime.
Let $x_1, x_2, \ldots, x_r$ be integers with $0 \leq x_i < m_i$. Then, there is exactly one $x$ in the interval $0 \leq x < m_1 \ldots m_2 \ldots m_r$ that satisfies the remainder equations

$$\text{irem}(x, m_i) = x_i, \ i = 1, 2, \ldots, r$$

where $\text{irem}$ is the positive integer remainder function.

For example, let $x_1 = 4$, $m_1 = 5$, $x_2 = 2$, $m_2 = 3$. We know that

$$\text{irem}(x, m_1) = x_1$$
$$\text{irem}(x, m_2) = x_2$$

where $0 \leq x_1 < m_1$ and $0 \leq x_2 < m_2$.

By the extended Euclidean Algorithm there are integers $c$ and $d$ such that

$$c \cdot m_1 + d \cdot m_2 = 1$$

In this case we are looking for an integer such that

$$\text{irem}(x, 5) = 4,$$
$$\text{irem}(x, 3) = 2$$

The algorithm we use is to first compute the positive integer remainder of $x_1$ and $m_1$ to get a new $x_1$:

$$x_1 = \text{positiveRemainder}(x_1, m_1)$$
$$4 = \text{positiveRemainder}(4, 5)$$

Next compute the positive integer remainder of $x_2$ and $m_2$ to get a new $x_2$:

$$x_2 = \text{positiveRemainder}(x_2, m_2)$$
$$2 = \text{positiveRemainder}(2, 3)$$

Then we compute $x_1 + m_1 \ldots \text{positiveRemainder}(((x_2-x_1)\cdot\text{inverse}(m_1,m_2)), m_2)$ or

$$4 + 5 \cdot \text{positiveRemainder}(((2-4)\cdot\text{inverse}(5,3)), 3)$$

or

$$4 + 5 \cdot \text{positiveRemainder}(-2\cdot2), 3)$$

or

$$4 + 5 \cdot 2$$

or

$$14$$

This function has a restricted signature which only allows for computing the Chinese remainder of two numbers and two moduli.

package INTHEORY IntegerNumberTheoryFunctions —

)abbrev package INTHEORY IntegerNumberTheoryFunctions
++ Author: Michael Monagan, Martin Brock, Robert Sutor, Timothy Daly
++ Date Created: June 1987
++ References: Knuth, The Art of Computer Programming Vol.2
++ Description:
++ This package provides various number theoretic functions on the integers.

IntegerNumberTheoryFunctions(): Exports == Implementation where
+ I ==> Integer +
+ RN ==> Fraction I +
+ SUP ==> SparseUnivariatePolynomial +
\textbf{NNI} \Rightarrow \textbf{NonNegativeInteger}

\textbf{Exports} \Rightarrow \textbf{with}

bernoulli : I \rightarrow \text{RN}
++ \texttt{bernoulli(n)} returns the nth Bernoulli number.
++ this is \texttt{B(n,0)}, where \texttt{B(n,x)} is the \texttt{n}th Bernoulli
++ polynomial.

\textbf{chineseRemainder:} (I,I,I,I) \rightarrow I
++ \texttt{chineseRemainder(x1,m1,x2,m2)} returns \(w\), where \(w\) is such that
++ \texttt{w = x1 \mod m1} and \texttt{w = x2 \mod m2}. Note that \texttt{m1} and
++ \texttt{m2} must be relatively prime.

divisors : I \rightarrow \text{List I}
++ \texttt{divisors(divisors(n))} returns a list of the divisors of \(n\).

euler : I \rightarrow I
++ \texttt{euler(n)} returns the \(n\)th Euler number. This is
++ \texttt{2^n E(n,1/2)}, where \texttt{E(n,x)} is the \(n\)th Euler polynomial.

eulerPhi : I \rightarrow I
++ \texttt{eulerPhi(n)} returns the number of integers between 1 and \(n\)
++ (including 1) which are relatively prime to \(n\). This is the Euler phi
++ function \texttt{\phi(n)} is also called the totient function.

fibonacci : I \rightarrow I
++ \texttt{fibonacci(n)} returns the \(n\)th Fibonacci number. The Fibonacci
++ numbers \texttt{F[n]} are defined by \texttt{F[0] = F[1] = 1} and
++ \texttt{F[n] = F[n-1] + F[n-2]}.
++ The algorithm has running time \texttt{O(log(n)^3)}.
++ Reference: Knuth, The Art of Computer Programming

harmonic : I \rightarrow \text{RN}
++ \texttt{harmonic(n)} returns the nth harmonic number. This is
++ \texttt{H[n] = sum(1/k, k=1..n)}.

jacobi : (I,I) \rightarrow I
++ \texttt{Jacobi(a,b)} returns the Jacobi symbol \texttt{J(a/b)}.
++ When \(b\) is odd, \texttt{J(a/b) = product(L(a/p) for p in factor b)}.
++ Note that by convention, 0 is returned if \texttt{gcd(a,b) = 1}.
++ Iterative \texttt{O(log(b)^2)} version coded by Michael Monagan June 1987.

legendre : (I,I) \rightarrow I
++ \texttt{legendre(a,p)} returns the Legendre symbol \texttt{L(a/p)}.
++ \texttt{L(a/p) = (-1)**((p-1)/2) mod p} (\(p\) prime), which is 0 if \texttt{a}
++ is 0, 1 if \texttt{a} is a quadratic residue \texttt{mod p} and -1 otherwise.
++ Note that because the primality test is expensive,
++ if it is known that \(p\) is prime then use \texttt{Jacobi(a,p)}.

moebiusMu : I \rightarrow I
++ \texttt{mu(n)} returns the Moebius function \texttt{\mu(n)}.
++ \texttt{\mu(n)} is either \(-1, 0\) or \(1\) as follows:
++ \texttt{\mu(n) = 0} if \(n\) is divisible by a square > 1,
++ \texttt{\mu(n) = (-1)^k} if \(n\) is square-free and has \(k\) distinct
++ prime divisors.

numberOfDivisors : I \rightarrow I
++ \texttt{numberOfDivisors(n)} returns the number of integers between 1 and \(n\)
++ (inclusive) which divide \(n\). The number of divisors of \(n\) is often
++ denoted by \spad{\tau(n)}.

\hfill sumOfDivisors : I \to I
++ \spad{\text{sumOfDivisors(n)}} returns the sum of the integers between 1 and n
++ (inclusive) which divide n. The sum of the divisors of n is often
++ denoted by \spad{\sigma(n)}.

\hfill sumOfKthPowerDivisors : (I,NNI) \to I
++ \spad{\text{sumOfKthPowerDivisors(n,k)}} returns the sum of the \spad{k}\text{th}
++ powers of the integers between 1 and n (inclusive) which divide n.
++ the sum of the \spad{k}\text{th} powers of the divisors of n is often denoted
++ by \spad{\sigma_k(n)}.

++ Author: Michael Monagan, James Davenport
++ Date Created: August 1987
++ Date Last Updated: 31 May 1993
++ References:
++ J. H. Davenport ‘‘Primality testing revisited’’ Technical Report TR2/93
++ (ATR/6) (NP2556) Numerical Algorithms Group, Inc., Downer’s Grove, IL, USA
++ and Oxford, UK, August 1993
++ Description:
++ The \spadtype{IntegerPrimesPackage} implements a modification of
++ Rabin’s probabilistic
++ primality test and the utility functions \spadfun{nextPrime},
++ \spadfun{prevPrime} and \spadfun{primes}.

IntegerPrimesPackage(I:IntegerNumberSystem): with
  prime?: I -> Boolean
  nextPrime: I -> I
  prevPrime: I -> I
  primes: (I,I) -> List I

  ++ \spad{prime?(n)} returns true if n is prime and false if not.
  ++ The algorithm used is Rabin’s probabilistic primality test
  ++ If \spad{prime? n} returns false, n is proven composite.
  ++ If \spad{prime? n} returns true, prime? may be in error
  ++ however, the probability of error is very low.
  ++ and is zero below 25*10**9 (due to a result of Pomerance et al),
  ++ below 10**12 and 10**13 due to results of Pinch,
  ++ and below 341550071728321 due to a result of Jaeschke.
  ++ Specifically, this implementation does at least 10 pseudo prime
  ++ tests and so the probability of error is \spad{< 4**(-10)}.
  ++ The running time of this method is cubic in the length
  ++ of the input n, that is \spad{O((log n)**3)}, for n<10**20.
  ++ beyond that, the algorithm is quartic, \spad{O((log n)**4)}.
  ++ Two improvements due to Davenport have been incorporated
  ++ which catches some trivial strong pseudo-primes, such as
  ++ [Jaeschke, 1991] 1377161253229053 * 413148375987157, which
  ++ the original algorithm regards as prime
  nextPrime: I -> I
  ++ \spad{nextPrime(n)} returns the smallest prime strictly larger than n
  prevPrime: I -> I
  ++ \spad{prevPrime(n)} returns the largest prime strictly smaller than n
  primes: (I,I) -> List I
  ++ \spad{primes(a,b)} returns a list of all primes p with
  ++ \spad{a <= p <= b}
smallPrimes

This is a table of all of the primes in \([2..10000]\). It is used by the prime? function to check
for primality. It is used by the primes function to generate arrays of primes in a given range.
Changing the range included in this table implies changing the value of the nextSmallPrime
variable. There is a constant in the function squareFree from IntegerFactorizationPackage
that is the square of the upper bound of the table range, in this case 10000000.

IntegerRoots examples
====================================================================

The IntegerRoots package computes square roots and nth roots of
integers efficiently.

See Also:
- \texttt{show IntegerRoots}

---

**IntegerRoots (IROOT)**

Exports:

\begin{itemize}
  \item \texttt{approxSqrt}
  \item \texttt{approxNthRoot}
  \item \texttt{perfectNthPower?}
  \item \texttt{perfectNthRoot}
  \item \texttt{perfectSqrt}
  \item \texttt{perfectSquare?}
\end{itemize}

---

\texttt{\textbackslash abbrev package IROOT IntegerRoots}

++ Author: Michael Monagan
++ Date Created: November 1987
++ Description:
++ The \texttt{IntegerRoots} package computes square roots and
++ \texttt{n}th roots of integers efficiently.

\texttt{IntegerRoots(I:IntegerNumberSystem): Exports == Implementation where
  NNI \rightarrow \text{NonNegativeInteger}}

Exports == with

\begin{itemize}
  \item \texttt{perfectNthPower? (I, NNI) \rightarrow Boolean}
    \begin{itemize}
      \item \texttt{\textbackslash spad{perfectNthPower?(n,r)}} returns true if \texttt{n} is an \texttt{\textbackslash spad{r}}th power and false otherwise
    \end{itemize}
  \item \texttt{perfectNthRoot (I, NNI) \rightarrow \text{Union(I,\	extbackslash \textquoteleft\textbackslash failed\textquoteright)}}
    \begin{itemize}
      \item \texttt{\textbackslash spad{perfectNthRoot(n,r)}} returns the \texttt{\textbackslash spad{r}}th root of \texttt{n} if \texttt{n} is an \texttt{\textbackslash spad{r}}th power and returns "\texttt{failed}" otherwise
    \end{itemize}
  \item \texttt{perfectNthRoot: I \rightarrow Record(base:I, exponent:NNI)}
    \begin{itemize}
      \item \texttt{\textbackslash spad{perfectNthRoot(n)}} returns \texttt{\textbackslash spad{[x,r]}} where \texttt{\textbackslash spad{n = x^r}}
    \end{itemize}
\end{itemize}
++ and r is the largest integer such that n is a perfect \( \sqrt[r]{n} \)
approxNthRoot: (I,NNI) -> I
++ \( \text{approxNthRoot}(n,r) \) returns an approximation x
++ to \( n^{\frac{1}{r}} \) such that \( -1 < x - n^{\frac{1}{r}} < 1 \)
perfectSquare?: I -> Boolean
++ \( \text{perfectSquare?}(n) \) returns true if n is a perfect square
++ and false otherwise
perfectSqrt: I -> Union(I,"failed")
++ \( \text{perfectSqrt}(n) \) returns the square root of n if n is a
++ perfect square and returns "failed" otherwise
approxSqrt: I -> I
++ \( \text{approxSqrt}(n) \) returns an approximation x
++ to \( \sqrt{n} \) such that \( -1 < x - \sqrt{n} < 1 \).
++ Compute an approximation s to \( \sqrt{n} \) such that
++ \( -1 < s - \sqrt{n} < 1 \)
++ A variable precision Newton iteration is used.
++ The running time is \( O(\log(n)^2) \).

IntegralBasisTools (IBATOOL)

Exports:
diagonalProduct  divideIfCan!  idealiser  idealiserMatrix  leastPower
matrixGcd        moduleSum

--- package IBATOOL IntegralBasisTools ---

)abbrev package IBATOOL IntegralBasisTools
++ Author: Victor Miller, Barry Trager, Clifton Williamson
++ Date Created: 11 April 1990
++ Date Last Updated: 20 September 1994
++ Description:
++ This package contains functions used in the packages
++ FunctionFieldIntegralBasis and NumberFieldIntegralBasis.

IntegralBasisTools(R,UP,F): Exports == Implementation where
  R : EuclideanDomain with
    squareFree: $ -> Factored $
    ++ squareFree(x) returns a square-free factorisation of x
  UP : UnivariatePolynomialCategory R
  F : FramedAlgebra(R,UP)
  Mat ==> Matrix R
  NNI ==> NonNegativeInteger
Ans ==> Record(basis: Mat, basisDen: R, basisInv: Mat)

Exports ==> with

  diagonalProduct: Mat -> R
  ++ diagonalProduct(m) returns the product of the elements on the
  ++ diagonal of the matrix m

matrixGcd: (Mat,R,NNI) -> R
  ++ matrixGcd(mat,sing,n) is \texttt{gcd(sing,g)} where \texttt{gcd(g)} is the
  ++ gcd of the entries of the \texttt{spad(n)}-by-\texttt{spad(n)} upper-triangular
  ++ matrix \spad{mat}.

divideIfCan_!: (Matrix R,Matrix R,R,Integer) -> R
  ++ divideIfCan!(matrix,matrixOut,prime,n) attempts to divide the
  ++ entries of \spad{matrix} by \spad{prime} and store the result in
  ++ \spad{matrixOut}. If it is successful, 1 is returned and if not,
  ++ \spad{prime} is returned. Here both \spad{matrix} and
  ++ \spad{matrixOut} are \spad{n}-by-\spad{n} upper triangular matrices.

leastPower: (NNI,NNI) -> NNI
  ++ leastPower(p,n) returns e, where e is the smallest integer
  ++ such that \spad{p ** e >= n}

idealiser: (Mat,Mat) -> Mat
  ++ idealiser(m1,m2) computes the order of an ideal defined by m1 and m2

idealiser: (Mat,Mat,R) -> Mat
  ++ idealiser(m1,m2,d) computes the order of an ideal defined by m1 and m2
  ++ where d is the known part of the denominator

idealiserMatrix: (Mat, Mat) -> Mat
  ++ idealiserMatrix(m1, m2) returns the matrix representing the linear
  ++ conditions on the Ring associated with an ideal defined by m1 and m2.

moduleSum: (Ans,Ans) -> Ans
  ++ moduleSum(m1,m2) returns the sum of two modules in the framed
  ++ algebra \spad{F}. Each module \spad{mi} is represented as follows:
  ++ \spad{F} is a framed algebra with \spad{R}-module basis \spad{w1,w2,...,wn} and
  ++ \spad{spad(mi)} is a record \spad{[basis,basisDen,basisInv]}. If
  ++ \spad{spad(basis)} is the matrix \spad{[aij, i = 1..n, j = 1..n]}, then
  ++ a basis \spad{v1,...,vn} for \spad{spad(mi)} is given by
  ++ \spad{spad(vi = (1/basisDen) * sum(aij * wj, j = 1..n)}, i.e. the
  ++ \spad{spad(i)}th row of \spad{basis} contains the coordinates of the
  ++ \spad{spad(i)}th basis vector. Similarly, the \spad{spad(i)}th row of the
  ++ matrix \spad{spad(basisInv)} contains the coordinates of \spad{spad(wi)} with
  ++ respect to the basis \spad{spad(v1,...,vn}): if \spad{spad(basisInv)} is the
  ++ matrix \spad{spad((bij, i = 1..n, j = 1..n))}, then
  ++ \spad{spad(wi = sum(bij * vj, j = 1..n))}.

  interpolateForms: (DIVISOR,NNI,PolRing,List PolRing) -> List(PolRing)
    interpolateForms(D,n,pol,base) compute the basis of the sub-vector
    space \( W \) of \( V = \langle \text{base} \rangle \), such that for all \( G \) in \( W \), the
    divisor \( (G) \geq D \). All the elements in base must be homogeneous
    polynomial of degree \( n \). Typically, base is the set of all monomial
    of degree \( n \); in that case, interpolateForms(D,n,pol,base)
    returns the basis of the vector space of all forms of degree \( d \) that
    interpolated \( D \). The argument \( \text{pol} \) must be the same polynomial that
    defined the curve form which the divisor \( D \) is defined.

IrrRepSymNatPackage examples

IrrRepSymNatPackage contains functions for computing
the ordinary irreducible representations of symmetric groups on
n letters \{1,2,...,n\} in Young’s natural form and their dimensions.

These representations can be labelled by number partitions of n,
i.e. a weakly decreasing sequence of integers summing up to n, e.g.

Note that whenever a \spadtype{List Integer} appears in a signature,
a partition required.

g := locallaplace(x::F, t, tt, vv := new()$SE, vvv := vv::F)
(x := intlaplace(f, ss, g, vv, vvv)) case F => x::F
oplap(f, tt, ss)

Use linearity
(u := mkPlus f) case List(F) =>
  +/[locallaplace(g, t, tt, s, ss) for g in u::List(F)]
(rec := splitConstant(f, t)).const ^= 1 =>
  rec.const * locallaplace(rec.nconst, t, tt, ss)

laplace(t^n*f(t),t,s) = (-1)^n*D(laplace(f(t),t,s), s, n)

(v := atn(f, t)) case Record(coef:F, deg:PI) =>
  vv := v::Record(coef:F, deg:PI)
  is?(la := locallaplace(vv.coef, t, tt, s, ss), oplap) => oplap(f,tt,ss)
  (-1$Integer)**(vv.deg) * differentiate(la, s, vv.deg)

Complex shift rule
(w := aexp(f, t)) case Record(coef:F, coef1:F, coef0:F) =>
  ww := w::Record(coef:F, coef1:F, coef0:F)
  exp(ww.coef0) * locallaplace(ww.coef,t,tt,s,ss - ww.coef1)

Try base cases
(x := lapkernel(f, t, tt, ss)) case F => x::F

The following does not seem to help computing transforms, but
-- quite frequently leads to loops, so I (wh) disabled it for now
-- last chance option: try to use the fact that
-- laplace(f(t),t,s) = s laplace(g(t),t,s) - g(0) where dg/dt = f(t)
-- elem?(int := lfintegrate(f, t)) and (rint := retractIfCan int) case F =>
-- fint := rint :: F
-- to avoid infinite loops, we don’t call laplace recursively
-- if the integral has no new logs and f is an algebraic function
-- empty?(logpart int) and algebraic?(f, t) => oplap(fint, tt, ss)
-- ss * locallaplace(fint, t, tt, s, ss) - eval(fint, tt = 0)
-- oplap(f, tt, ss)

A package for solving polynomial systems by means of Lazard triangular sets. This package provides two operations. One for solving in the sense of the regular zeros, and the other for solving in the sense of the Zariski closure. Both produce square-free regular sets. Moreover, the decompositions do not contain any redundant component. However, only zero-dimensional regular sets are normalized, since normalization may be time consuming in positive dimension.

The decomposition process is that of

The LazardSetSolvingPackage package constructor solves polynomial systems by means of Lazard triangular sets. However one condition is relaxed: Regular triangular sets whose saturated ideals have positive dimension are not necessarily normalized.

The decompositions are computed in two steps. First the algorithm of Moreno Maza (implemented in the RegularTriangularSet domain constructor) is called. Then the resulting decompositions are
converted into lists of square-free regular triangular sets and the redundant components are removed. Moreover, zero-dimensional regular triangular sets are normalized.

Note that the way of understanding triangular decompositions is detailed in the example of the RegularTriangularSet constructor.

The LazardSetSolvingPackage constructor takes six arguments. The first one, \( R \), is the coefficient ring of the polynomials; it must belong to the category \( \text{GcdDomain} \). The second one, \( E \), is the exponent monoid of the polynomials; it must belong to the category \( \text{OrderedAbelianMonoidSup} \). The third one, \( V \), is the ordered set of variables; it must belong to the category \( \text{OrderedSet} \). The fourth one is the polynomial ring; it must belong to the category \( \text{RecursivePolynomialCategory}(R,E,V) \). The fifth one is a domain of the category \( \text{RegularTriangularSetCategory}(R,E,V,P) \) and the last one is a domain of the category \( \text{SquareFreeRegularTriangularSetCategory}(R,E,V,P) \). The abbreviation for LazardSetSolvingPackage is \( \text{LAZM3PK} \).

For the purpose of solving zero-dimensional algebraic systems, see also \( \text{LexTriangularPackage} \) and \( \text{ZeroDimensionalSolvePackage} \). These packages are easier to call than \( \text{LAZM3PK} \). Moreover, the \( \text{ZeroDimensionalSolvePackage} \) package provides operations to compute either the complex roots or the real roots.

We illustrate now the use of the LazardSetSolvingPackage package constructor with two examples (Butcher and Vermeer).

Define the coefficient ring.

\[
R := \text{Integer}
\]

Define the list of variables,

\[
ls : \text{List Symbol} := [b1,x,y,z,t,v,u,w]
\]

and make it an ordered set:

\[
V := \text{OVAR}(ls)
\]

then define the exponent monoid.

\[
E := \text{IndexedExponents}(V)
\]

Define the polynomial ring.

\[
P := \text{NSMP}(R, V)
\]
Let the variables be polynomial.

\begin{verbatim}
b1: P := 'b1
x: P := 'x
y: P := 'y
z: P := 'z
t: P := 't
u: P := 'u
v: P := 'v
w: P := 'w
\end{verbatim}

Now call the \tt{RegularTriangularSet} domain constructor.

\begin{verbatim}
T := REGSET(R,E,V,P)
\end{verbatim}

Define a polynomial system (the Butcher example).

\begin{verbatim}
p0 := b1 + y + z - t - w
p1 := 2*z*u + 2*y*v + 2*t*w - 2*w**2 - w - 1
p2 := 3*z*u**2 + 3*y*v**2 - 3*t*w**2 + 3*w**3 + 3*w**2 - t + 4*w
p3 := 6*x*z*v - 6*t*u**2 + 6*u**3 - 3*t*w + 6*u**2 - t + 4*w
p4 := 4*z*u**3 + 4*y*v**3 + 4*t*w**3 - 4*u**4 - 6*u**3 + 4*t*u - 10*u**2 - w - 1
p5 := 8*x*z*v**2 + 8*y*v**2 - 8*t*u**2 - 4*t*w**3 - 4*t**2 - 14*u**2 - 3*t**2 - 1
p6 := 12*x*z*v**2 + 12*t*w**3 - 12*u**4 + 12*t**2 + 16*u**3 + 8*t**2 - 14*w**2 - w - 1
p7 := -24*t**2 - 24*u**4 - 24*t**2 + 36*u**3 + 8*t**2 + 26*u**2 + 7*w + 1
lp := [p0, p1, p2, p3, p4, p5, p6, p7]
\end{verbatim}
First of all, let us solve this system in the sense of Lazard by means of the REGSET constructor:

\[
lts := \text{zeroSetSplit}(lp, false) \{\{w + 1, u, v, t + 1, b1 + y + z + 2\}, \{w + 1, v, t + 1, z, b1 + y + 2\},
\{w + 1, t + 1, z, y, b1 + 2\}, \{w + 1, u, t + 1, y, z, b1 + 2\},
\{w + 1, u, t + 1, y, x, b1 + z + 2\},
\{144u + 216u + 96u + 6u - 11u - 1, 12u + 9u + 1\}u - 72u - 108u - 42u - 9u - 3u,
\{12u + 9u + 1\}v + 36u + 54u + 18u , 24u + 24u + 8u)t - 24u - 36u - 26u - 7u - 1, 2(12v - 12v )z + (12w v + 12w + 4)t + (3w - 5)v + 36w + 42w + 6w + 16w,
\{2v + 2u z + 2w t - 2w - w - 1, 6v x + (- 6w - 3w - 1)t + 6w + 6w + 4w, b1 + y + z - t - w\}\}
\]

We can get the dimensions of each component of a decomposition as follows.

[coHeight(ts) for ts in lts]
[3,3,3,2,0]

The first five sets have a simple shape. However, the last one, which has dimension zero, can be simplified by using Lazard triangular sets.

Thus we call the SquareFreeRegularTriangularSet domain constructor,

\[
\text{ST := SREGSET}(R,E,V,P)
\]

and set the LAZM3PK package constructor to our situation.

\[
\text{pack := LAZM3PK}(R,E,V,P,T,ST)
\]
We are ready to solve the system by means of Lazard triangular sets:

\[
\text{zeroSetSplit}(lp,\text{false})\text{pack}
\]

\[
\{w + 1, t + 1, z, y, b1 + 2\}, \{w + 1, v, t + 1, z, b1 + y + 2\}, \{w + 1, u, v, t + 1, y + z, x, b1 + 2\},
\]

\[
\{w + 1, u, t + 1, y, x, b1 + z + 2\},
\]

\[
5 \quad 4 \quad 3 \quad 2 \quad 4 \quad 3 \quad 2
\]

\[
\{144w + 216w + 96w + 6w - 11w - 1, u - 24w - 36w - 14w + w + 1,
\]

\[
4 \quad 3 \quad 2 \quad 4 \quad 3 \quad 2
\]

\[
3v - 48w - 60w - 10w + 8w + 2, t - 24w - 36w - 14w - w + 1,
\]

\[
4 \quad 3 \quad 2
\]

\[
486z - 2772w - 4662w - 2055w + 30w + 127,
\]

\[
4 \quad 3 \quad 2
\]

\[
2916y - 22752w - 30312w - 8220w + 2064w + 1561,
\]

\[
4 \quad 3 \quad 2
\]

\[
356x - 3696w - 4536w - 968w + 822w + 371,
\]

\[
4 \quad 3 \quad 2
\]

\[
2916b1 - 30600w - 46692w - 20274w - 8076w + 593\}
\]

We see the sixth triangular set is nicer now: each one of its polynomials has a constant initial.

We follow with the Vermeer example. The ordering is the usual one for this system.

Define the polynomial system.

\[
f0 := (w - v) ** 2 + (u - t) ** 2 - 1
\]

\[
t - 2u t + v - 2w v + u + w - 1
\]

\[
f1 := t ** 2 - v ** 3
\]

\[
t - v
\]

\[
f2 := 2 * t * (w - v) + 3 * v ** 2 * (u - t)
\]

\[
(- 3v - 2v + 2w)t + 3u v
\]

\[
f3 := (3 * z * v ** 2 - 1) * (2 * z * t - 1)
\]

\[
2 \quad 2
\]
First of all, let us solve this system in the sense of Kalkbrener by means of the REGSET constructor:

```latex
zeroSetSplit(lf, true)$T
```

We have obtained one regular chain (i.e. regular triangular set) with dimension 1. This set is in fact a characterist set of the (radical of) the ideal generated by the input system \( \text{lf} \). Thus we have only the generic points of the variety associated with \( \text{lf} \) (for the elimination ordering given by \( \text{ls} \)).

So let us get now a full description of this variety.

Hence, we solve this system in the sense of Lazard by means of the REGSET constructor:
zeroSetSplit(1, false)$T$

\[
\begin{align*}
&\{ \\
&\quad \begin{array}{cccccc}
6 & 3 & 2 & 4 \\
729u & + & (-1458w + 729w - 4158w - 1685)u \\
+ & \\
6 & 5 & 4 & 3 & 2 & 2 & 8 \\
(729w - 1458w - 2619w - 4892w - 297w + 5814w + 427)u & + & 729w \\
+ & \\
7 & 6 & 5 & 4 & 3 & 2 \\

+ \\
\}
\end{align*}
\]
We retrieve our regular chain of dimension 1 and we get three regular chains of dimension 0 corresponding to the degenerated cases. We want now to simplify these zero-dimensional regular chains by using Lazard triangular sets. Moreover, this will allow us to prove that the above decomposition has no redundant component.

Generally, decompositions computed by the REGSET constructor do not have redundant components. However, to be sure that no redundant component occurs one needs to use the SREGSET or LAZM3PK constructors.

So let us solve the input system in the sense of Lazard by means of the LAZM3PK constructor:

```plaintext
zeroSetSplit(lf,false)$pack
[
  
  6 3 2 4
  729u + (- 1458w + 729w - 4158w - 1685)u
  +
  6 5 4 3 2 2 8
  (729w - 1458w - 2619w - 4892w - 297w + 5814w + 427)u + 729w
  +
  7 6 5 4 3 2
  216w - 2900w - 2376w + 3870w + 4072w - 1188w - 1656w + 529

  4 3 2 2
  2187u + (- 4374w - 972w - 12474w - 2868)u + 2187w - 1944w
  +
  4 3 2
  - 10125w - 4800w + 2501w + 4968w - 1587
* v
+ 
```
\[
\begin{align*}
& (1944w - 108w )u + 972w + 3024w - 1080w + 496w + 1116w, \\
& (3v + 2v - 2w)t - 3u v, ((4v - 4w)t - 6u v )z + (2t + 3v )z - 1, \\
& (81w + 18w + 28, 729u - 1890w - 533, 81v + (- 162w + 27)v - 72w - 112, \\
& 11881t + (972w + 2997)u v + (- 11448w - 11536)u, \\
& 641237934604288z \\
& + (78614584763904w + 26785578742272)u + 236143618655616w \\
& + 70221988585728 \\
& * v \\
& + (35852025318432w + 10192213759488)u + 142598803536000w \\
& + 54166419595008 \\
& * z \\
& + (32655103844499w - 44224572465882)u v \\
& + (43213900115457w - 32432039102070)u.
\end{align*}
\]
Due to square-free factorization, we obtained now four zero-dimensional regular chains. Moreover, each of them is normalized (the initials are constant). Note that these zero-dimensional components may be investigated further with the ZeroDimensionalSolvePackage package constructor.

++ [1] D. LAZARD "A new method for solving algebraic systems of
++ Description:
++ A package for solving polynomial systems by means of Lazard triangular
++ sets. This package provides two operations. One for solving in the sense
++ of the regular zeros, and the other for solving in the sense of
++ the Zariski closure. Both produce square-free regular sets.
++ Moreover, the decompositions do not contain any redundant component.
++ However, only zero-dimensional regular sets are normalized, since
++ normalization may be time consumming in positive dimension.
++ The decomposition process is that of [2].

LexTriangularPackage.help

LexTriangularPackage examples

A package for solving polynomial systems with finitely many solutions.

The decompositions are given by means of regular triangular sets.
The computations use lexicographical Groebner bases. The main operations
are lexTriangular and squareFreeLexTriangular. The second one provide
decompositions by means of square-free regular triangular sets.

Both are based on the lexTriangular method described in
D. LAZARD "Solving Zero-dimensional Algebraic Systems"

They differ from the algorithm described in
M. MORENO MAZA and R. RIODBQ "Computations of gcd over
algebraic towers of simple extensions"
by the fact that multiplicities of the roots are not kept. With the squareFreeLexTriangular operation all multiplicities are removed. With the other operation some multiplicities may remain. Both operations admit an optional argument to produce normalized triangular sets.

The LexTriangularPackage package constructor provides an implementation of the lexTriangular algorithm (D. Lazard "Solving Zero-dimensional Algebraic Systems", J. of Symbol. Comput., 1992). This algorithm decomposes a zero-dimensional variety into zero-sets of regular triangular sets. Thus the input system must have a finite number of complex solutions. Moreover, this system needs to be a lexicographical Groebner basis.

This package takes two arguments: the coefficient-ring R of the polynomials, which must be a GcdDomain and their set of variables given by ls a List Symbol. The type of the input polynomials must be NewSparseMultivariatePolynomial(R,V) where V is OrderedVariableList(ls). The abbreviation for LexTriangularPackage is LEXTRIPK. The main operations are lexTriangular and squareFreeLexTriangular. The later provide decompositions by means of square-free regular triangular sets, built with the SquareFreeRegularTriangularSet constructor, whereas the former uses the RegularTriangularSet constructor. Note that these constructors also implement another algorithm for solving algebraic systems by means of regular triangular sets; in that case no computations of Groebner bases are needed and the input system may have any dimension (i.e. it may have an infinite number of solutions).

The implementation of the lexTriangular algorithm provided in the LexTriangularPackage constructor differs from that reported in "Computations of gcd over algebraic towers of simple extensions" by M. Moreno Maza and R. Rioboo (in proceedings of AAECC11, Paris, 1995). Indeed, the squareFreeLexTriangular operation removes all multiplicities of the solutions (i.e. the computed solutions are pairwise different) and the lexTriangular operation may keep some multiplicities; this later operation runs generally faster than the former.

The interest of the lexTriangular algorithm is due to the following experimental remark. For some examples, a triangular decomposition of a zero-dimensional variety can be computed faster via a lexicographical Groebner basis computation than by using a direct method (like that of SquareFreeRegularTriangularSet and RegularTriangularSet). This happens typically when the total degree of the system relies essentially on its smallest variable (like in the Katsura systems). When this is not the case, the direct method may give better timings (like in the Rose system).

Of course, the direct method can also be applied to a lexicographical Groebner basis. However, the lexTriangular algorithm takes advantage of the structure of this basis and avoids many unnecessary computations.
which are performed by the direct method.

For this purpose of solving algebraic systems with a finite number of solutions, see also the ZeroDimensionalSolvePackage. It allows to use both strategies (the lexTriangular algorithm and the direct method) for computing either the complex or real roots of a system.

Note that the way of understanding triangular decompositions is detailed in the example of the RegularTriangularSet constructor.

Since the LexTriangularPackage package constructor is limited to zero-dimensional systems, it provides a zeroDimensional? operation to check whether this requirement holds. There is also a groebner operation to compute the lexicographical Groebner basis of a set of polynomials with type NewSparseMultivariatePolynomial(R,V). The elimination ordering is that given by ls (the greatest variable being the first element of ls). This basis is computed by the FLG algorithm (Faugere et al. "Efficient Computation of Zero-Dimensional Groebner Bases by Change of Ordering", J. of Symbol. Comput., 1993) implemented in the LinGroebnerPackage package constructor.

Once a lexicographical Groebner basis is computed, then one can call the operations lexTriangular and squareFreeLexTriangular. Note that these operations admit an optional argument to produce normalized triangular sets. There is also a zeroSetSplit operation which does all the job from the input system; an error is produced if this system is not zero-dimensional.

Let us illustrate the facilities of the LexTriangularPackage constructor by a famous example, the cyclic-6 root system.

Define the coefficient ring.

\begin{verbatim}
R := Integer
   Type: Domain
\end{verbatim}

Define the list of variables,

\begin{verbatim}
ls : List Symbol := [a,b,c,d,e,f]
   Type: List Symbol
\end{verbatim}

and make it an ordered set.

\begin{verbatim}
V := OVAR(ls)
   OrderedVariableList [a,b,c,d,e,f]
   Type: Domain
\end{verbatim}

Define the polynomial ring.
\[ P := \text{NSMP}(R, V) \]
\[ \text{NewSparseMultivariatePolynomial}(\text{Integer}, \text{OrderedVariableList} \ [a,b,c,d,e,f]) \]
\[ \text{Type: Domain} \]

Define the polynomials.

- \[ p_1: P := a*b*c*d*e*f - 1 \]
  \[ \text{Type: NewSparseMultivariatePolynomial}(\text{Integer}, \text{OrderedVariableList} \ [a,b,c,d,e,f]) \]

- \[ p_2: P := a*b*c*d*e + a*b*e*f + a*d*e*f + b*c*d*e + c*d*e*f \]
  \[ (((e + f)d + f e)c + f e d)b + f e d c)a + f e d c b \]
  \[ \text{Type: NewSparseMultivariatePolynomial}(\text{Integer}, \text{OrderedVariableList} \ [a,b,c,d,e,f]) \]

- \[ p_3: P := a*b*c*d + a*b*c*f + a*b*e*f + a*d*e*f + b*c*d*e + c*d*e*f \]
  \[ (c + f)b + f e)a + d c b + e d c + f e d \]
  \[ \text{Type: NewSparseMultivariatePolynomial}(\text{Integer}, \text{OrderedVariableList} \ [a,b,c,d,e,f]) \]

- \[ p_4: P := a*b*c + a*b*f + a*e*f + b*c*d + c*d*e + d*e*f \]
  \[ (b + f)a + c b + d c + e d + f e \]
  \[ \text{Type: NewSparseMultivariatePolynomial}(\text{Integer}, \text{OrderedVariableList} \ [a,b,c,d,e,f]) \]

- \[ p_5: P := a*b + a*f + b*c + c*d + d*e + e*f \]
  \[ a + b + c + d + e + f \]
  \[ \text{Type: NewSparseMultivariatePolynomial}(\text{Integer}, \text{OrderedVariableList} \ [a,b,c,d,e,f]) \]

- \[ p_6: P := a*b + c*d + e*f \]
  \[ a + b + c + d + e + f \]
  \[ \text{Type: NewSparseMultivariatePolynomial}(\text{Integer}, \text{OrderedVariableList} \ [a,b,c,d,e,f]) \]

\[ l p := [p_1, p_2, p_3, p_4, p_5, p_6] \]
\[ [f e d c b a - 1, ((((e + f)d + f e)c + f e d)b + f e d c)a + f e d c b, ((d + f)c + f e)b + f e d c)a + e d c b + f e d c, (c + f)b + f e)a + d c b + e d c + f e d, (b + f)a + c b + d c + e d + f e, a + b + c + d + e + f] \]
\[ \text{Type: List NewSparseMultivariatePolynomial}(\text{Integer}, \text{OrderedVariableList} \ [a,b,c,d,e,f]) \]

Now call LEXTRIPK.

\[ \text{lextripack} := \text{LEXTRIPK}(R, l s) \]
\[ \text{LexTriangularPackage}(\text{Integer}, [a,b,c,d,e,f]) \]
\[ \text{Type: Domain} \]
Compute the lexicographical Groebner basis of the system. This may take between 5 minutes and one hour, depending on your machine.

\[
lg := \text{groebner(lp)}; \text{lextripack}\\
[a + b + c + d + e + f,\\

Note that the first set of the decomposition is normalized (all initials are integer numbers) but not the second one (normalized triangular sets are defined in the description of the NormalizedTriangularSetCategory constructor).

So apply now lexTriangular to produce normalized triangular sets.

```plaintext

Thus the solutions given by lts are pairwise different.

We count them as follows.

reduce(+,[degree(ts) for ts in lts])

156

Type: PositiveInteger

We can investigate the triangular decomposition lts by using the
ZeroDimensionalSolvePackage.

This requires to add an extra variable (smaller than the others) as follows.

ls2 : List Symbol := concat(ls,new()$Symbol)

[a,b,c,d,e,f,%A]

Type: List Symbol

Then we call the package.
zdpack := ZDSOLVE(R,ls,ls2)
(20) ZeroDimensionalSolvePackage(Integer,[a,b,c,d,e,f],[a,b,c,d,e,f,%A])
Type: Domain

We compute a univariate representation of the variety associated with
the input system as follows.

concat [univariateSolve(ts)$zdpack for ts in lts]

The image contains a mathematical expression and some text. The mathematical expression seems to be a series of complex numbers or polynomials. The text on the image is as follows:

```

complexRoots = [3 2]
  a + b^2 - c^2 + d^2 + e^2 + f^2 + g^2 + h^2 + i^2 + j^2 + k^2 + l^2 + m^2 + n^2 + o^2 + p^2 + q^2 + r^2 + s^2 + t^2 + u^2 + v^2 + w^2 + x^2 + y^2 + z^2

coordinates = [7 6 5 4 3 2]

a + b + c + d + e + f + g + h + i + j + k + l + m + n + o + p + q + r + s + t + u + v + w + x + y + z
```

The text appears to be discussing complex roots and coordinates, possibly in a mathematical or computational context.

Type: List Record(complexRoots: SparseUnivariatePolynomial Integer,
coordinates: List Polynomial Integer)

Since the univariateSolve operation may split a regular set, it
returns a list. This explains the use of concat.

Look at the last item of the result. It consists of two parts. For
any complex root ? of the univariate polynomial in the first part, we
get a tuple of univariate polynomials (in a, ..., f respectively) by
replacing %A by ? in the second part. Each of these tuples t
describes a point of the variety associated with lp by equaling to
zero the polynomials in t.

Note that the way of reading these univariate representations is
explained also in the example illustrating the ZeroDimensionalSolvePackage
constructor.

Now, we compute the points of the variety with real coordinates.

concat [realSolve(ts)$zdpack for ts in lts]

++ Author: Marc Moreno Maza
++ Date Created: 08/02/1999
++ Date Last Updated: 08/02/1999
++ References:
++ algebraic towers of simple extensions"
++ Description:
++ A package for solving polynomial systems with finitely many solutions.
++ The decompositions are given by means of regular triangular sets.
++ The computations use lexicographical Groebner bases.
++ The main operations are lexTriangular
++ and squareFreeLexTriangular. The second one provide decompositions by
++ means of square-free regular triangular sets.
++ Both are based on the lexTriangular method described in [1].
++ They differ from the algorithm described in [2] by the fact that
++ multiplicities of the roots are not kept.
++ With the squareFreeLexTriangular operation all multiplicities are removed.
++ With the other operation some multiplicities may remain. Both operations
++ admit an optional argument to produce normalized triangular sets.

Exports == with

zeroDimensional? : LP -> B
++ \axiom{zeroDimensional?(lp)} returns true iff
++ \axiom{lp} generates a zero-dimensional ideal
++ w.r.t. the variables involved in \axiom{lp}.
fglmIfCan : LP -> Union(LP, "failed")
++ \axiom{fglmIfCan(lp)} returns the lexicographical Groebner
++ basis of \axiom{lp} by using the FGLM strategy,
++ if \axiom{zeroDimensional?(lp)} holds .
groebner : LP -> LP
++ \axiom{groebner(lp)} returns the lexicographical Groebner
++ basis of \axiom{lp}. If \axiom{lp} generates a zero-dimensional
++ ideal then the FGLM strategy is used, otherwise
++ the Sugar strategy is used.
lexTriangular : (LP, B) -> List TS
++ \axiom{lexTriangular(base, norm?)} decomposes the variety
++ associated with \axiom{base} into regular chains.
++ Thus a point belongs to this variety iff it is a regular
++ zero of a regular set in in the output.
++ Note that \axiom{base} needs to be a lexicographical Groebner basis
++ of a zero-dimensional ideal. If \axiom{norm?} is \axiom{true}
++ then the regular sets are normalized.
squareFreeLexTriangular : (LP, B) -> List TS
++ \axiom{squareFreeLexTriangular(base, norm?)} decomposes the variety
++ associated with \axiom{base} into square-free regular chains.
++ Thus a point belongs to this variety iff it is a regular
++ zero of a regular set in in the output.
++ Note that \texttt{base} needs to be a lexicographical Groebner basis
++ of a zero-dimensional ideal. If \texttt{base} is \texttt{true}
++ then the regular sets are normalized.

\texttt{zeroSetSplit: (LP, B) -> List TS}
++ \texttt{zeroSetSplit(lp, \texttt{true})} decomposes the variety
++ associated with \texttt{lp} into regular chains.
++ Thus a point belongs to this variety iff it is a regular
++ zero of a regular set in in the output.
++ Note that \texttt{lp} needs to generate a zero-dimensional ideal.
++ If \texttt{norm?} is \texttt{true} then the regular sets are normalized.

\texttt{zeroSetSplit: (LP, B) -> List ST}
++ \texttt{zeroSetSplit(lp, \texttt{true})} decomposes the variety
++ associated with \texttt{lp} into square-free regular chains.
++ Thus a point belongs to this variety iff it is a regular
++ zero of a regular set in in the output.
++ Note that \texttt{lp} needs to generate a zero-dimensional ideal.
++ If \texttt{norm?} is \texttt{true} then the regular sets are normalized.

)abbrev package LOP LinesOpPack
++ Authors: G. Hache
++ Date Created: 21 sept 1994
++ Date Last Updated: May 2010 by Tim Daly
++ Description:
++ A package that exports several linear algebra operations over lines
++ of matrices. Part of the PAFF package.

LinesOpPack(K):P==T where

K:Field

P== with
    rowEchWoZeroLinesWoVectorise: Matrix(K) -> Matrix(K)
    rowEchWoZeroLines: Matrix(K) -> Matrix(K)
    reduceRow: List(List(K)) -> List(List(K))
        ++ reduceRow: if the input is considered as a matrix, the output would
        ++ be the row reduction matrix. It’s almost the rowEchelon form
        ++ except that no permuation of lines is performed.
    quotVecSpaceBasis: (List(List(K)),List(List(K))) -> List(List(K))
        ++ quotVecSpaceBasis(b1,b2) returns a basis of V1/V2 where
        ++ V1 and V2 are vector space with basis b1 and b2 resp. and
        ++ V2 is suppose to be include in V1; Note that if
        ++ it is not the case then it returns the basis of V1/W
        ++ where W = intersection of V1 and V2
    reduceLineOverLine: (List(K),List(K),K) -> List(K)
        ++ reduceLineOverLine(v1,v2,a) returns v1-a*v1 where
        ++ v1 and v2 are considered as vector space.
    reduceRowOnList: (List(K),List(List(K))) -> List(List(K))
        ++ reduceRowOnList(v,lvec) applies a row reduction on each of the
        ++ element of lv using v according to a pivot in v which is set to
        ++ be the first non nul element in v.

ListFunctions2 (LIST2)

Exports:
- map
- reduce
- scan

---

)abbrev package LIST2 ListFunctions2
++ Description:
**ListFunctions2** implements utility functions that operate on two kinds of lists, each with a possibly different type of element.

**ListFunctions2**(*A*: Type, *B*: Type): public == private where

*LA* ==&gt; List *A*

*LB* ==&gt; List *B*

*O2* ==&gt; FiniteLinearAggregateFunctions2(*A*, *LA*, *B*, *LB*)

public ==&gt; with

scan: ((*A*, *B*) &rarr; *B*, *LA*, *B*) &rarr; *LB*

++ scan(*fn*, *u*, *ident*) successively uses the binary function
++ \spad{fn} to reduce more and more of list \spad{u}.
++ \spad{ident} is returned if the \spad{u} is empty.
++ The result is a list of the reductions at each step. See
++ \spadfun{reduce} for more information. Examples:
++ \spad{scan(*fn*, [{1, 2}], 0) = \{fn(2, fn(1, 0)), fn(1, 0)\}} and
++ \spad{scan(*, [{2, 3}], 1) = \{2 * 1, 3 * (2 * 1)\}}.

reduce: ((*A*, *B*) &rarr; *B*, *LA*, *B*) &rarr; *B*

++ reduce(*fn*, *u*, *ident*) successively uses the binary function
++ \spad{fn} on the elements of list \spad{u} and the result
++ of previous applications. \spad{ident} is returned if the
++ \spad{u} is empty. Note the order of application in
++ the following examples:
++ \spad{reduce(*fn*, [{1, 2, 3}], 0) = fn(3, fn(2, fn(1, 0)))} and
++ \spad{reduce(*, [{2, 3}], 1) = 3 * (2 * 1)}.

map: (*A* &rarr; *B*, *LA*) &rarr; *LB*

++ map(*fn*, *u*) applies \spad{fn} to each element of
++ list \spad{u} and returns a new list with the results.
++ For example \spad{map(square, [{1, 2, 3}]) = \{1, 4, 9\}}.

private ==&gt; add

ListToMap examples
====================================================================

ListToMap allows mappings to be described by a pair of lists of equal lengths. The image of an element x, which appears in position n in the first list, is then the n-th element of the second list. A default value or default function can be specified to be used when x does not appear in the first list. In the absence of defaults, an error will occur in that case.

match

— package LIST2MAP ListToMap —

)abbrev package LIST2MAP ListToMap
++ Author: Manuel Bronstein
++ Date Created: 22 Mar 1988
++ Change History: 11 Oct 1989
++ Description:
++ \spadtype{ListToMap} allows mappings to be described by a pair of
++ lists of equal lengths. The image of an element \spad{x},
++ which appears in position \spad{n} in the first list, is then
++ the \spad{n}th element of the second list. A default value or
++ default function can be specified to be used when \spad{x}
++ does not appear in the first list. In the absence of defaults,
++ an error will occur in that case.

ListToMap(A:SetCategory, B:Type):Exports == Implementation where
LA ==> List A
LB ==> List B
AB ==> (A -> B)

Exports == with
match: (LA, LB) -> AB
++ match(la, lb) creates a map with no default source or target values
++ defined by lists la and lb of equal length.
++ The target of a source value \spad{x} in la is the
++ value y with the same index lb.
++ Error: if la and lb are not of equal length.
++ Note that when this map is applied, an error occurs when
++ applied to a value missing from la.
match: (LA, LB, A) -> B
  ++ match(la, lb, a) creates a map
  ++ defined by lists la and lb of equal length, where \spad{a} is used
  ++ as the default source value if the given one is not in \spad{la}.
  ++ The target of a source value \spad{x} in la is the
  ++ value y with the same index lb.
  ++ Error: if la and lb are not of equal length.
match: (LA, LB, B) -> AB
  ++ match(la, lb, b) creates a map
  ++ defined by lists la and lb of equal length, where \spad{b} is used
  ++ as the default target value if the given function argument is
  ++ not in \spad{la}.
  ++ The target of a source value \spad{x} in la is the
  ++ value y with the same index lb.
  ++ Error: if la and lb are not of equal length.
match: (LA, LB, A, B) -> B
  ++ match(la, lb, a, b) creates a map
  ++ defined by lists la and lb of equal length.
  ++ and applies this map to a.
  ++ The target of a source value \spad{x} in la is the
  ++ value y with the same index lb.
  ++ Argument b is the default target value if a is not in la.
  ++ Error: if la and lb are not of equal length.
match: (LA, LB, AB) -> AB
  ++ match(la, lb, f) creates a map
  ++ defined by lists la and lb of equal length.
  ++ The target of a source value \spad{x} in la is the
  ++ value y with the same index lb.
  ++ Argument \spad{f} is used as the
  ++ function to call when the given function argument is not in
  ++ \spad{la}.
  ++ The value returned is \spad{f} applied to that argument.
match: (LA, LB, A, AB) -> B
  ++ match(la, lb, a, f) creates a map
  ++ defined by lists la and lb of equal length.
  ++ and applies this map to a.
  ++ The target of a source value \spad{x} in la is the
  ++ value y with the same index lb.
  ++ Argument \spad{f} is a default function to call if a is not in la.
  ++ The value returned is then obtained by applying f to argument a.

package LPARSPT LocalParametrizationOfSimplePointPackage

)abbrev package LPARSPT LocalParametrizationOfSimplePointPackage
++ Author: Gaetan Hache
++ Date Created: 17 nov 1992
++ Date Last Updated: May 2010 by Tim Daly
++ Description:
++ This package is part of the PAFF package
LocalParametrizationOfSimplePointPackage(K,symb,PolyRing,E,ProjPt,PCS,Plc):_
Exports == Implementation where
K:Field
  symb: List(Symbol)
E : DirectProductCategory(#symb,NonNegativeInteger)
OV ==> OrderedVariableList(symb)
PolyRing : PolynomialCategory(K,E,OV)
ProjPt : ProjectiveSpaceCategory(K)
PCS : LocalPowerSeriesCategory(K)
Plc : PlacesCategory(K,PCS)
PI ==> PositiveInteger
NNI ==> NonNegativeInteger
PPFC1 ==> PolynomialPackageForCurve(K,PolyRing,E,#symb,ProjPt)
PackPoly ==> PackageForPoly(K,PolyRing,E,#symb)
UP ==> SparseUnivariatePolynomial(K)
UPUP ==> SparseUnivariatePolynomial(UP)
Exports == with

printInfo: Boolean -> Boolean
  ++ printInfo(b) set a flag such that when true (b <- true) prints
  ++ some information during some critical computation.
printInfo: () -> Boolean
  ++ returns the value of the \spad{printInfo} flag.

pointToPlace: (ProjPt,PolyRing) -> Plc
  ++ pointToPlace(pt,pol) takes for input a simple point pt on the curve
  ++ defined by pol and set the local parametrization of the point.

localParamOfSimplePt: (ProjPt,PolyRing,Integer) -> List PCS
  ++ localParamOfSimplePt(pt,pol,n) computes the local parametrization
  ++ of the simple point pt on the curve defined by pol. This local
  ++ parametrization is done according to the standard open affine
  ++ plane set by n

pointDominateBy : Plc -> ProjPt
  ++ pointDominateBy(pl) returns the projective point dominated
  ++ by the place pl.

localize: (PolyRing,ProjPt,PolyRing,Integer) -> _
  Record(fnc:PolyRing,crv:PolyRing,chart:List(Integer))
  ++ localize(f,pt,crv,n) returns a record containing the polynomials f
  ++ and crv translate to the origin with respect to pt. The last
++ element of the records, consisting of three integers contains
++ information about the local parameter that will be used
++ (either x or y): the first integer correspond to the variable
++ that will be used as a local parameter.

CHAPTER 14. CHAPTER M

— MakeFunction.help —

====================================================================
MakeFunction examples
====================================================================

Tools for making interpreter functions from top-level expressions
Transforms top-level objects into interpreter functions.

It is sometimes useful to be able to define a function given by
the result of a calculation.

Suppose that you have obtained the following expression after several
computations and that you now want to tabulate the numerical values of
f for x between -1 and +1 with increment 0.1.

\[
\begin{align*}
\text{expr} & := (x - \exp x + 1)^2 \times (\sin(x^2) \times x + 1)^3 \\
& \quad \times (\exp(\exp x) + (-2x - 2x)\exp + x + 2x + x)\sin(x) \\
& \quad + 2 \times 2 \times 4 \times 3 \times 2 \times 4 \times 3 \times 2 \times 2 \\
& \quad \times (3\exp(x) + (-6x - 6x)\exp + 3x + 6x + 3x)\sin(x) \\
& \quad + x \times 2 \times 3 \times 3 \times 2 \times 3 \times 2 \times 2 \\
& \quad \times (3\exp(x) + (-6x - 6)\exp + 3x + 6x + 3x)\sin(x) + \exp \\
& \quad \times (-2x - 2)\exp + x + 2x + 1.
\end{align*}
\]

Type: Expression Integer

You could, of course, use the function eval within a loop and evaluate
expr twenty-one times, but this would be quite slow. A better way is
to create a numerical function f such that f(x) is defined by the
expression expr above, but without retyping expr! The package
MakeFunction provides the operation function which does exactly this.

Issue this to create the function f(x) given by expr.

\[
\text{function}(\text{expr}, f, x) \\
f
\]

Type: Symbol

To tabulate expr, we can now quickly evaluate f 21 times.

\[
\text{tbl} := [f(0.1 \times i - 1) \text{ for } i \text{ in } 0..20];
\]

Type: List Float

Use the list [x1,...,xn] as the third argument to function to create a
multivariate function f(x1,...,xn).
\[ e := (x - y + 1)^2 \cdot (x^2 \cdot y + 1)^2 \]
\[ x^4 + 4x^3 + 5x^2 + 4x + 3y + 2x + 3y + 2 \]
\[ + 4x + 3y + 2 \]
\[ + 2x + 4x + 2x - 2x - 2y + x + 2x + 1 \]
\[ \text{Type: Polynomial Integer} \]

\[ \text{function(e, g, [x, y])} \]
\[ g \]
\[ \text{Type: Symbol} \]

In the case of just two variables, they can be given as arguments without making them into a list.

\[ \text{function(e, h, x, y)} \]
\[ h \]
\[ \text{Type: Symbol} \]

Note that the functions created by function are not limited to floating point numbers, but can be applied to any type for which they are defined.

\[ m1 := \text{squareMatrix} [ [1, 2], [3, 4] ] \]
\[ +1 2+ \]
\[ +3 4+ \]
\[ \text{Type: SquareMatrix(2,Integer)} \]

\[ m2 := \text{squareMatrix} [ [1, 0], [-1, 1] ] \]
\[ +1 0+ \]
\[ +1 1+ \]
\[ \text{Type: SquareMatrix(2,Integer)} \]

\[ \text{h(m1, m2)} \]
\[ +7836 8960 + \]
\[ +17132 19588+ \]
\[ \text{Type: SquareMatrix(2,Integer)} \]

Various Currying operations.

Function are objects of type Mapping. In this section we demonstrate some library operations from the packages MappingPackage1, MappingPackage2, and MappingPackage3 that manipulate and create functions. Some terminology: a nullary function takes no arguments, a unary function takes one argument, and a binary function takes two arguments.

We begin by creating an example function that raises a rational number to an integer exponent.

\[
power(q: \text{FRAC INT}, n: \text{INT}): \text{FRAC INT} = q^n\]

\[
power(2,3)\]

\[
\text{Type: Fraction Integer}\]

The twist operation transposes the arguments of a binary function. Here \(\text{rewop}(a, b) = \text{power}(b, a)\).

\[
\text{rewop} := \text{twist power}\]

\[
\text{theMap(MAPPKG3;twist;MM;5!0)}\]

\[
\text{Type: ((Integer,Fraction Integer) \to Fraction Integer)}\]

This is \(2^3\).

\[
\text{rewop}(3, 2)\]

\[
8\]

\[
\text{Type: Fraction Integer}\]

Now we define square in terms of power.

\[
square: \text{FRAC INT} \to \text{FRAC INT}\]

\[
\text{Type: Void}\]

The curryRight operation creates a unary function from a binary one by providing a constant argument on the right.

\[
square := \text{curryRight(power, 2)}\]

\[
\text{theMap(MAPPKG3;curryRight;MM;1!0,0)}\]

\[
\text{Type: (Fraction Integer \to Fraction Integer)}\]
Likewise, the curryLeft operation provides a constant argument on the left.

```
    square 4
    16
    Type: Fraction Integer
```

The constantRight operation creates (in a trivial way) a binary function from a unary one: constantRight(f) is the function g such that g(a,b) = f(a).

```
squirrel:= constantRight(square)$MAPPKG3(FRAC INT,FRAC INT,FRAC INT)
theMap(MAPPKG3;constantRight;MM;3!0)
    Type: ((Fraction Integer,Fraction Integer) -> Fraction Integer)
```

Likewise, constantLeft(f) is the function g such that g(a,b) = f(b).

```
squirrel(1/2, 1/3)
    1
    -
    4
    Type: Fraction Integer
```

The curry operation makes a unary function nullary.

```
sixteen := curry(square, 4/1)
    theMap(MAPPKG2;curry;MAM;2!0,0)
    Type: (() -> Fraction Integer)
```

```
sixteen()
    16
    Type: Fraction Integer
```

The * operation constructs composed functions.

```
square2:=square*square
    theMap(MAPPKG3;*;MMM;6!0,0)
    Type: (Fraction Integer -> Fraction Integer)
```

```
square2 3
    81
    Type: Fraction Integer
```

Use the ** operation to create functions that are n-fold iterations of other functions.

```
sc(x: FRAC INT): FRAC INT == x + 1
    Type: Void
```
This is a list of Mapping objects.

\[
\text{incfns := } [\text{sc**i for i in 0..10}]
\text{[theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),}
\text{theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),}
\text{theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),}
\text{theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),}
\text{theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),}
\text{theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),}
\text{theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),}
\text{theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),}
\text{theMap(MAPPKG1;**;MNniM;6!0,0)]}
\text{Type: List (Fraction Integer -> Fraction Integer)}
\]

This is a list of applications of those functions.

\[
[f 4 for f in incfns]
[4,5,6,7,8,9,10,11,12,13,14]
\text{Type: List Fraction Integer}
\]

Use the recur operation for recursion:

\[
g := \text{recur } f \text{ means } g(n,x) == f(n,f(n-1,...f(1,x))).
\]

\[
times(n:NNI, i:INT):INT == n*i
\text{Type: Void}
\]

\[
r := \text{recur(times)}
\text{theMap(MAPPKG1;recur;2M;7!0,0)}
\text{Type: ((NonNegativeInteger,Integer) -> Integer)}
\]

This is a factorial function.

\[
\text{fact := curryRight(r, 1)}
\text{theMap(MAPPKG3;curryRight;MBM;1!0,0)}
\text{Type: (NonNegativeInteger -> Integer)}
\]

\[
\text{fact 4}
24
\text{Type: PositiveInteger}
\]

Constructed functions can be used within other functions.

\[
mto2ton(m, n) ==
\text{raiser := square"n}
\text{raiser m}
\text{Type: Void}
\]

This is 3^{(2^3)}.

\[
mto2ton(3, 3)
6561
\text{Type: Fraction Integer}
\]
Here shiftfib is a unary function that modifies its argument.

```lisp
shiftfib(r: List INT) : INT ==
t := r.1
r.1 := r.2
r.2 := r.2 + t
t
Type: Void
```

By currying over the argument we get a function with private state.

```lisp
fibinit: List INT := [0, 1]
[0,1]
Type: List Integer

fibs := curry(shiftfib, fibinit)
theMap(MAPPKG2;curry;MAM;2!0,0)
Type: (() -> Integer)

[fibs() for i in 0..30]
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610, 987, 1597,
2584, 4181, 6765, 10946, 17711, 28657, 46368, 75025, 121393, 196418,
317811, 514229, 832040]
Type: List Integer
```

MappingPackage2.help

MappingPackage examples

Various Currying operations.

Function are objects of type Mapping. In this section we demonstrate some library operations from the packages MappingPackage1, MappingPackage2, and MappingPackage3 that manipulate and create functions. Some terminology: a nullary function takes no arguments, a unary function takes one argument, and a binary function takes two arguments.

We begin by creating an example function that raises a rational number to an integer exponent.

\[
power(q: \text{FRAC INT}, n: \text{INT}): \text{FRAC INT} = q^{*n}
\]

\[
power(2, 3)
\]

\[
8
\]

The twist operation transposes the arguments of a binary function. Here rewop(a, b) is power(b, a).

\[
rewop := \text{twist power}
\]

\[
\text{theMap(MAPPGK3; twist; MM; 5!0)}
\]

\[
\text{Type: ((Integer, Fraction Integer) -> Fraction Integer)}
\]

This is 2^3.

\[
rewop(3, 2)
\]

\[
8
\]

Now we define square in terms of power.

\[
square: \text{FRAC INT} -> \text{FRAC INT}
\]

\[
\text{Type: Void}
\]

The curryRight operation creates a unary function from a binary one by providing a constant argument on the right.

\[
square := \text{curryRight(power, 2)}
\]

\[
\text{theMap(MAPPKG3; curryRight; MBM; 1!0, 0)}
\]

\[
\text{Type: (Fraction Integer -> Fraction Integer)}
\]

Likewise, the curryLeft operation provides a constant argument on the
The constantRight operation creates (in a trivial way) a binary function from a unary one: constantRight(f) is the function g such that g(a,b) = f(a).

\[\text{squirrel} := \text{constantRight(square)} \]\n
\[\text{theMap(MAPPKG3;constantRight;MM;3!0)}\]

Type: \((\text{Fraction Integer},\text{Fraction Integer}) \rightarrow \text{Fraction Integer}\)

Likewise, constantLeft(f) is the function g such that g(a,b) = f(b).

\[\text{squirrel}(1/2, 1/3)\]

\[1 - \frac{1}{4}\]

Type: Fraction Integer

The curry operation makes a unary function nullary.

\[\text{sixteen} := \text{curry(square, 4/1)}\]

\[\text{theMap(MAPPKG2;curry;MAM;2!0,0)}\]

Type: \((\text{} \rightarrow \text{Fraction Integer})\)

\[\text{sixteen}()\]

\[16\]

Type: Fraction Integer

The * operation constructs composed functions.

\[\text{square2} := \text{square*square}\]

\[\text{theMap(MAPPKG3;*;MMM;6!0,0)}\]

Type: \((\text{Fraction Integer} \rightarrow \text{Fraction Integer})\)

\[\text{square2} 3\]

\[81\]

Type: Fraction Integer

Use the ** operation to create functions that are \(n\)-fold iterations of other functions.

\[\text{sc}(x: \text{FRAC INT}): \text{FRAC INT} \equiv x + 1\]

Type: Void

This is a list of Mapping objects.
incfns := [sc**i for i in 0..10]
[theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),
 theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),
 theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),
 theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),
 theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),
 theMap(MAPPKG1;**;MNniM;6!0,0)]
Type: List (Fraction Integer -> Fraction Integer)

This is a list of applications of those functions.

[f 4 for f in incfns]
[4,5,6,7,8,9,10,11,12,13,14]
Type: List Fraction Integer

Use the recur operation for recursion:

g := recur f means g(n,x) == f(n,f(n-1,...f(1,x))).
times(n:NNI, i:INT):INT == n*i
Type: Void
r := recur(times)
theMap(MAPPKG1;recur;2M;7!0,0)
Type: ((NonNegativeInteger,Integer) -> Integer)

This is a factorial function.

fact := curryRight(r, 1)
theMap(MAPPKG3;curryRight;MBM;1!0,0)
Type: (NonNegativeInteger -> Integer)

fact 4
24
Type: PositiveInteger

Constructed functions can be used within other functions.

mto2ton(m, n) ==
raiser := square^n
raiser m
Type: Void

This is 3**(2^3).
mto2ton(3, 3)
6561
Type: Fraction Integer

Here shiftfib is a unary function that modifies its argument.
shiftfib(r: List INT) : INT ==
  t := r.1
  r.1 := r.2
  r.2 := r.2 + t
  t

Type: Void

By currying over the argument we get a function with private state.

fibinit: List INT := [0, 1]

Type: List Integer

fibs := curry(shiftfib, fibinit)

theMap(MAPPKG2; curry; MAM; 2!0, 0)

Type: () -> Integer

[fibs() for i in 0..30]
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610, 987, 1597, 2584, 4181, 6765, 10946, 17711, 28657, 46368, 75025, 121393, 196418, 317811, 514229, 832040]

Type: List Integer
