9 Users Guide Chapter 4 (ug04.ht)  
Input Files and Output Styles  
Input Files  
The .axiom.input File  
Common Features of Using Output Formats  
Monospace 2D Mathematical Format  
TeX Format  
IBM Script Formula Format  
FORTRAN Format  
HTML Format  
Immediate and Delayed Assignments  
Blocks  
if-then-else  
Loops  
Compiling vs. Interpreting Loops  
return in Loops  
break in Loops  
break vs. => in Loop Bodies  
More Examples of break  
iterate in Loops  
while Loops  
for Loops  
for i in n..m repeat  
for i in n..m by s repeat  
for i in n.. repeat  
for x in l repeat  
“Such that” Predicates  
Parallel Iteration  
Creating Lists and Streams with Iterators  
An Example: Streams of Primes  

10 Users Guide Chapter 6 (ug06.ht)  
User-Defined Functions, Macros and Rules  
Functions vs. Macros  
Macros  
Introduction to Functions  
Declaring the Type of Functions  
One-Line Functions  
Declared vs. Undeclared Functions  
Functions vs. Operations  
Delayed Assignments vs. Functions with No Arguments  
How Axiom Determines What Function to Use  
Compiling vs. Interpreting  
Piece-Wise Function Definitions  
A Basic Example  
Picking Up the Pieces
### Predicates

## 22 NAG Library Routines

### 22.1 nagaux.ht

- NAG On-line Documentation: summary: 2705
- NAG Documentation: keyword in context: 2744
- NAG Documentation: conversion: 2842

### 22.2 nagc.ht

- Zeros of Polynomials: 2845
- Roots of a complex polynomial equation: 2849
- Roots of a real polynomial equation: 2854
- Roots of One or More Transcendental Equations: 2860
- Zero of a continuous function in a given interval: 2864
- Solution of a system of nonlinear equations: 2868
- Solution of a system of nonlinear equations: 2872
- Checks the gradients of a set of non-linear functions: 2878
- Discrete Fourier transform of real or complex data values: 2881
- Discrete Fourier transform of m real data values: 2889
- Discrete Fourier transform of a Hermitian sequence: 2892
- Discrete Fourier transform of m complex data values: 2896
- Circular convolution or correlation of two real vectors: 2899
- Discrete Fourier transforms of m sequences: 2903
- Discrete Fourier transforms of m Hermitian sequences: 2908
- Discrete Fourier transforms of m complex sequences: 2912
- Discrete Fourier transform of bivariate complex data: 2916
- Summation of Series: 2921
- Complex conjugate of a sequence of n data values: 2923
- Complex conjugates of m Hermitian sequences: 2925
- Form real and imaginary parts of m Hermitian sequences: 2927

### 22.3 nagd.ht

- Quadrature: 2930
  - Approximation of the integral over a finite interval: 2943
  - Adaptive integration over a finite integral: 2949
  - Approximate integration with local singular points: 2955
  - Approximate integration over a (semi-)infinite interval: 2961
  - Approximate sine or cosine transform over finite interval: 2967
  - Adaptive integration of weighted function over an interval: 2973
  - Hilbert transform over finite interval: 2979
  - Approximate Sine or Cosine over $[a, \infty]$: 2985
  - Weights and abscissae for Gaussian quadrature formula: 2992
- Multidimensional integrals with finite limits: 2998
- Third-order finite-difference integration: 3003
- Monte Carlo integration over hyper-rectangular regions: 3006
- Ordinary Differential Equations: 3011
- First-order ODE over an interval with initial conditions: 3018
- First-order ODE with initial conditions and user function: 3026

New Foreword

On October 1, 2001 Axiom was withdrawn from the market and ended life as a commercial product. On September 3, 2002 Axiom was released under the Modified BSD license, including this document. On August 27, 2003 Axiom was released as free and open source software available for download from the Free Software Foundation’s website, Savannah.

Work on Axiom has had the generous support of the Center for Algorithms and Interactive Scientific Computation (CAISS) at City College of New York. Special thanks go to Dr. Gilbert Baumslag for his support of the long term goal.

The online version of this documentation is roughly 1000 pages. In order to make printed versions we’ve broken it up into three volumes. The first volume is tutorial in nature. The second volume is for programmers. The third volume is reference material. We’ve also added a fourth volume for developers. All of these changes represent an experiment in print-on-demand delivery of documentation. Time will tell whether the experiment succeeded.

Axiom has been in existence for over thirty years. It is estimated to contain about three hundred man-years of research and has, as of September 3, 2003, 143 people listed in the credits. All of these people have contributed directly or indirectly to making Axiom available. Axiom is being passed to the next generation. I’m looking forward to future milestones.

With that in mind I’ve introduced the theme of the “30 year horizon”. We must invent the tools that support the Computational Mathematician working 30 years from now. How will research be done when every bit of mathematical knowledge is online and instantly available? What happens when we scale Axiom by a factor of 100, giving us 1.1 million domains? How can we integrate theory with code? How will we integrate theorems and proofs of the mathematics with space-time complexity proofs and running code? What visualization tools are needed? How do we support the conceptual structures and semantics of mathematics in effective ways? How do we support results from the sciences? How do we teach the next generation to be effective Computational Mathematicians?

The “30 year horizon” is much nearer than it appears.

Tim Daly

August 2014 Release Notes

This release moves Axiom to the latest GCL version. All unused prior versions were removed.

Most of the work involved in this release has involved CATS, working with Albert Rich to develop Axiom tests.

Noweb was removed. Axiom now uses its own literate tools.

The databases are no longer compressed.

Volume 13: Proving Axiom Correct was started

Makefile.pamphlet
VERSION = August 2014

This release moves Axiom to the latest GCL version. All unused prior versions were removed.

1.1. RELEASENOTES.HT

working with Albert Rich to develop Axiom tests.

Noweb was removed. Axiom now uses its own literate tools.

The databases are no longer compressed.

Volume 13: Proving Axiom Correct was started

Makefile.pamphlet

  \texttt{VERSION = August 2014}
  \texttt{TESTSET defaults to regresstests}
  fix missing dvipdfm
  remove noweb

book/

  new directory containing axiom-developer emails
  reduce and categorize emails for history
  create timeline of people joining/leaving

books/

  axiom.sty
  \texttt{document}
  remove all other sources
  add additional macros
  axbook.tgz
  \texttt{fix sinCosExpandRules}
  dvipdfm.def
  added
  tanglec.c
  \texttt{new C function to handle chunks}
  tangle.lisp
  \texttt{add fastxhtml extraction from bookvol11}
  extract (rename from document)
  \texttt{support new chunk syntax}

ps/

  \texttt{move .ps to .eps}
  \texttt{add new images}

books/Makefile

  handle bookheader.tex
  \texttt{fix broken sed regular expression}
  add bookvol13 (Proving Axiom Correct)

books/bookheader.tex

  \texttt{user underline, colored links}
  \texttt{standardize headers, table of contents}

books/bookvol10 (Jenks)

  \texttt{add condata for MAGCDOC}
  \texttt{add graphics, fix typos, add text}

CHAPTER 1. RELEASE NOTES

May 2012 Release Notes

The primary work of this release is developing the BLAS1 domain. This is a subtask of developing native BLAS and LAPACK support. These are all checked and tested against the original fortran code.

Makefile.pamphlet

VERSION = March 2012
add <<GCLOPTS-CUSTRELOC>> to all stanzas
1.1. RELEASENOTES.HT

- add ubuntu64 with 64 bit patch
- move to GCL Version gcl-2.6.8pre7

books/bookvol10.3
- change HASHEQ to SXHASH

books/bookvol10.4
- add Frederick H. Pitts to credits
- add LAPACK contributors

books/bookvol10.5
- BLAS1 daxpy dcopy ddot dnrm2 drot drotg dscal dswap dzasum dznrm2
- icamax idamax isamax izamax zaxpy
- add LAPACK reference code
- add missing lapack routines

books/bookvol15
- add Frederick H. Pitts to credits
- add LAPACK contributors
- fix parsing for 64 bit systems
- reset si::*system-directory* to the null string

books/bookvol17.1
- update What’s New Page

books/bookvolbib
- BLAS1 drotg references
- add paper references
- fix typo
- update references

books/bookvolbib.bib
- BLAS1 drotg references
- add LAPACK bibtex reference
- update references

books/ps/
- v71mar2012.eps added
- v71releasenotes.eps add release notes

faq
- add FAQ 53: Axiom won’t build on Fedora
- fix FAQ 22: How do I check out the latest source?

lsp/Makefile.pamphlet
- move to GCL Version gcl-2.6.8pre7

readme
- Frederick H. Pitts <fred.pitts@comcast.net>
- add LAPACK contributors
src/algebra/Makefile
  fix MYUP, etc

src/axiom-website/download.html
  add debian binary
  add ubuntu
  update download list
  update download table

src/axiom-website
  releasenotes.html

src/input/Makefile
  add cohen.input
  add example of spad code
  add simplify.input

src/input
  clements.input add example of spad code
  cohen.input Joel Cohen algebra example
  simplify.input added from sci.math.symbolic

src/interp
  buildom.lisp: change HASHEQ to SXHASH
  sys-pkg.lisp: remove HASHEQ

zips/
  gcl-2.6.8pre7.h.linux.defs.patch port to pre7

\autobuttons
\end{page}
March 2012 Release Notes

A new volume, Volume 8.1, the Axiom Gallery shows examples of Axiom graphics. These are test cases being collected to show capabilities of the graphics subsystems.

One of the outstanding graphics bugs was 7217 which gave odd values for graphics labels. This was fixed by picking up Waldek’s patch for coercion to InputForm. This had the unfortunate side effect that a large number of Axiom’s 35,000 test cases needed to be updated.

A particularly interesting article on Literate Programming and Reproducible Research was published in the Journal of Statistical Software and was added to the documentation page. (http://www.jstatsoft.org/v46/i03/paper)

There are two new commands, )tangle and )regress.

A new function, getAncestors was added to the API domain.

The buglist was published and several bugs were added.

New references to Axiom were added to the bibliography, including Dav12, Jen79, Dav80
Several people contributed to this release, including James Davenport, Mark Clements, George Legendre, and Waldek Hebisch

bookvol5.pamphlet
   add )tangle and )regress commands

bookvol10.4.pamphlet
   add Mark Clements, George Legendre
   fix 7217 bugs

books/bookvol5
   add Mark Clements, George Legendre
   fix 7217 bugs

books/bookvol18.1
   A new volume, the Axiom Gallery, showing example graphics

books/bookvolbib
   add additional Axiom literature references

books/ps/
   add v81* for graphics gallery

readme
   add Mark Clements, George Legendre

src/algebra
   Makefile fix GUESS, clique1, and clique2 handling

src/axiom-website/
   add jstat article

src/input/
   add testpackage.input
   update pasta.input graphics test cases
   fix 7216 bugs

\end{verbatim}
\endscroll
\autobuttons
\end{page}
January 2012 Release Notes

January 2012 Release

The Jenks book was updated by adding appendix E, and the graphics images from the center of the book.

These people were added to the credits list:
Guilherme Reis, Michael Albaugh, Roger House to credits

Literate documentation was added to the book 9, the compiler
The axiomgraphs were created for the compile command and the parser.

The website was updated with several changes including a global rewrite of the color and fixes for broken links.

Treeshaking of the compiler and interpreter code continues.

bookvol0.pamphlet
  add Appendix E
  add graphics images from middle of book
bookvol10.4.pamphlet
   add Guilherme Reis, Michael Albaugh, Roger House

books/bookvol5
   localize function names
treeshake interpreter
   add Guilherme Reis, Michael Albaugh, Roger House

books/bookvol9
   add comment graphs
code cleanup
   localize function names
treeshake and document compiler

books/bookvolbib
   add additional Axiom literature references

books/ps/
   add v0root.eps, v0hyper.eps, v0page1.eps, v0page2.eps, v0page3.eps
   add v0page4.eps, v0page5.eps, v0page6.eps, v0page7.eps, v0page8.eps
   v9CommentRecording.eps comment recording chapter
   v9CommentSyntaxChecking.eps comment syntax chapter
   v9comdefine.eps document compiler
   v9compiler.eps document compiler

readme
   add Guilherme Reis, Michael Albaugh, Roger House

src/algebra
   Makefile fix autoload

src/axiom-website/
   global background color change to ECEA81
   axiom.png make background transparent
   books.html fix broken links

November 2011 Release Notes

November 2011 Release

Treeshaking the interpreter and compiler continues and a few more files were merged and removed.

Several books and Makefiles were converted to use lisp tangle rather than noweb. This is part of the general process to remove noweb.

Global function rewrites continue, including removing GETREFV and makeprop.

Work was done to improve OpenMath support. The OpenMath semantics CDs were added and the OpenMath parser was enhanced.

More effort was put into literate work. In particular, an example of a literate program using HTML was created and presented at the Clojure/Conj conference.
books/Makefile
   removed noweb, move to lisp tangle
   fix missing index files on PDfs

books/tangle.lisp
   fix .input file algebra extraction

books/bookvol10.2
   missing/unused function cleanup
   remove makeprop
   remove noweb, move to lisp tangle

books/bookvol10.3
   remove GETREFV
   remove makeprop
   remove noweb, move to lisp tangle

books/bookvol10.4
   remove noweb, move to lisp tangle

books/bookvol10.5
   remove noweb, move to lisp tangle

books/bookvol14
   missing/unused function cleanup
   remove makeprop

books/bookvol15
   OpenMath support
   add OpenMath stubs
   missing/unused function cleanup
   remove makeprop
   remove noweb, move to lisp tangle
   treeshake interpreter

books/bookvol7.1
   fix documentation
   update What’s New Page

books/bookvol9
   missing/unused function cleanup
   remove makeprop
   treeshake and merge c-doc.lisp

books/bookvolbib
   Axiom OpenMath references
   add additional references
   add references
books/ps/
  v71releasenotes.eps add release notes
  v71sept2011.eps added

  fix .input file algebra extraction
  remove noweb, move to lisp tangle

src/axiom-website/documentation.html
  add Alexander quote
  add Knuth quote
  add litprog.html
  add quote

src/axiom-website/download.html
  update to latest release

src/axiom-website/litprog.html
  added
  add quote
  literate program example update

src/interp/Makfile
  remove apply.lisp
  remove c-doc.lisp
  remove noweb, move to lisp tangle
  remove nruntime.lisp

src/interp
  apply.lisp removed, merged with bookvol9
  buildom.lisp remove GETREFV
  c-doc.lisp removed
  c-util.lisp missing/unused function cleanup
  category.lisp remove GETREFV
  functor.lisp missing/unused function cleanup, remove GETREFV
  g-util.lisp missing/unused function cleanup
  i-eval.lisp remove nruntime.lisp
  i-spec1.lisp treeshake interpreter
  i-spec2.lisp fix AN has sqrt: % -> %
  i-spec2.lisp remove makeprop
  nruncomp.lisp remove GETREFV, treeshake compiler
  nrungo.lisp remove nruntime.lisp, treeshake interpreter, remove GETREFV
  nruntime.lisp removed
  parsing.lisp remove makeprop
  sys-pkg.lisp missing/unused function cleanup, remove GETREFV, makeprop
  template.lisp remove GETREFV
  vmlisp.lisp missing/unused function cleanup, remove GETREFV, makeprop

zips
  add cds.tar.gz OpenMath support. add OpenMath CDs
September 2011 Release Notes

This release continues the task of treeshaking the compiler and interpreter. Nine files were merged and removed. In addition, several passes were made for code cleanup.

The Symbolic Ito Calculus package is being added, starting with the BasicStochasticDifferential and StochasticDifferential domains. More work remains to be done.

The GUESS package is being upgraded.

James Cloos and Wilfrid Kendall were added to the credits.

== “What’s New in Axiom” (releaseNotes) 1.1 on page 1
— releasenotes.ht —

This release continues the task of treeshaking the compiler and interpreter. Nine files were merged and removed. In addition, several passes were made for code cleanup.

The Symbolic Ito Calculus package is being added, starting with the BasicStochasticDifferential and StochasticDifferential domains. More work remains to be done.

The GUESS package is being upgraded.
James Cloos and Wilfrid Kendall were added to the credits.

books/bookvol10.3
  add BasicStochasticDifferential and StochasticDifferential
  remove pairp
  start upgrade of GUESS package

books/bookvol10.4
  remove packageTran

books/bookvol10.5
  add StochasticDifferential

books/bookvol15
  add BasicStochasticDifferential domain
  merge nocompile.lisp, as.lisp, nci.lisp
  treeshake interpreter
  remove pairp, nParseAndInterpretString, packageTran
  use qc(ad)r forms

books/bookvol17
  merge nocompile.lisp

books/bookvol17.1
  update What’s New Page

books/bookvol19
  remove pairp, isPackageFunction
  treeshake compiler
  use qc(ad)r forms

books/bookvolbib
  add Kendall Ken99a, Ken99b literature references to Axiom

books/ps/
  v103basicstochasticdifferential.ps added
  v103stochasticdifferential.ps added
  v71july2011.eps
  v71releasenotes.eps add release notes

src/algebra/Makefile
  BasicStochasticDifferential domain
  add StochasticDifferential
  remove upper GUESS package code

src/axiom-website/download.html add Gentoo notes by James Cloos
src/axiom-website/download.html add ubuntu

src/axiom-website/releasenotes.html
src/doc/axiom.sty
  fix defplist

src/input/Makefile
  document finite field bug
  respect the BUILD=fast variable value

  fix broken tests in axiom, cmds, setcmd, unittest1, unittest2
  ffieldbug.input: added

src/interp/Makefile
  remove as.lisp, compiler.lisp, database.lisp, define.lisp, foam_1
  remove g-opt.lisp, nci.lisp, package.lisp, ax.lisp

\end(verbatim)
\endscroll
\autobuttons
\end{page}

July 2011 Release Notes

July 2011 Release

The prior release had a bug that caused it to remember the build location. This was a change introduced by the underlying lisp. This was fixed.

This release continues treeshaking the compiler. The modemap.lisp file has been merged and no longer exists.

This release continues to treeshake the interpreter. The axext_1.lisp file has been removed.

Makefile.pamphlet
  add BUILD=full / BUILD=fast switch

Book Volume 5 [Interpreter]
  treeshake interpreter

⇐ “What’s New in Axiom” (releaseNotes) 1.1 on page 1
   — releasenotes.ht —
July 2011 Release

The prior release had a bug that caused it to remember the build location. This was a change introduced by the underlying lisp. This was fixed.

This release continues treeshaking the compiler. The modemap.lisp file has been merged and no longer exists.

This release continues to treeshake the interpreter. The axext_1.lisp file has been removed.

Makefile.pamphlet
add BUILD=full / BUILD=fast switch

Book Volume 5 (Interpreter)
treeshake interpreter

Book Volume 9 (Compiler)
treeshake compiler

Book Volume 10.3 (Domains)
help and unit tests for RewriteRule

axiom.sty
add /refsdollar and /defsdollar for better cross references

src/interp/Makefile
add (si::reset-sys-paths) per Camm
remove axext_1 aldor support file
remove modemap.lisp
May 2011 Release Notes

This release involved more work treeshaking of the compiler and interpreter. Argument naming conventions were normalized to improve the documentation and clarity.

Time was spent proofreading the books and reducing or eliminating latex warnings. Missing index files were fixed and errors in the Jenks book were fixed.

The website has been updated to make Arthur Ralf’s book available from every page. The website is being rewritten to be IPv6 enabled.

Doug Telford was added to the credits.

Book Volume 0 (Jenks book)
proofread to chapter 1 (pdf page 86)
replace "operator over" by "operate over"
set textlength 400
port changes to Arthur Ralfs HTML version

July 2010 Release Notes

This release concentrated on the work of Albert Rich and his Rubi pattern matching machinery. All of his integrals from his test suite were converted to a regression test suite. This will form a baseline for the pattern work in future releases. David Parnas has a table-based method of specifying programs. Axiom is trying to synthesize this work with the pattern match work to create pattern specifications using tables. Martin Baker added HTML output to the system. Waldek Hebisch implemented the DoubleFloat representation routines. Martin Rubey implemented Dirichlet.

The symbolic version of the fresnel integrals was added as well as a numeric implementation of the fresnelC and fresnelS functions. The output of these numeric functions were validated against Pearcy’s tables, with the comparison as part of the regression tests. Further work on numeric approximation is ongoing and expected in the next release.

These people were added to the credits list:

Albert D. Rich, David Parnas, Martin Baker

May 2010 Release Notes

This release concentrated on adding new algebra.
A new package was added for factoring over finite fields.
A new volume Axiom Numerics was added, including BLAS and LAPACK in lisp.
A new volume Axiom Bibliography was added for literature citations.
GCL was upgraded, thanks to Camm Maquire.

These people were added to the credits list:

Nelson H. F. Beebe, Gaetan Hache, Bill Hart, Kaj Laurson,
Patrice Naudin, Claude Quitte, Steve Toleque

March 2010 Release Notes

March 2010 Release

This release concentrated on treeshaking more code into the volume. Support for last break quit was added. Additional do was added for branch cuts and clifford algebras. The first new volume (10.5) on Numerics was added. An example of unix to fulfill the long-term goal of unicode I/O support.

This release is an interim step in the process of merging the source code into a single volume. Due to the size and complex task it will take several releases.

Three people were added to the credits list:
  John P. Fletcher <J.P.Fletcher@aston.ac.uk>
  Nathaniel Daly <nathaniel.daly@gmail.com>
  Ted Kosan <ted.kosan@gmail.com>

⇐ “What’s New in Axiom” (releaseNotes) 1.1 on page 1 — releasenotes.ht —
volume. Support for \texttt{)set break quit} was added. Additional documentation
was added for branch cuts and clifford algebras. The first draft of a
new volume (10.5) on Numerics was added. An example of unicode was tested
to fulfill the long-term goal of unicode I/O support.

This release is an interim step in the process of merging the interpreter
source code into a single volume. Due to the size and complexity of the
task it will take several releases.

Three people were added to the credits list:
    John P. Fletcher <J.P.Fletcher@aston.ac.uk>
    Nathaniel Daly <nathaniel.daly@gmail.com
    Ted Kosan <ted.kosan@gmail.com>

The Axiom website was completely rewritten based on a new style css
provided by Nate. This change was also made to axiom-developer.com.

There is a new set option "\texttt{)set break quit}" per Ralf Hemmecke.
This will cause the interpreter to quit on failure. Documentation
was added to the books.

books/bookvol4 Axiom Developers Guide
    add \texttt{)set break quit}

books/bookvol5 Axiom Interpreter
    add \texttt{)set break quit}
    add support for IndexedBits
    begin documentation of macex
    merge and remove lisp files from src/interp
    remove non-common lisp macros
    rewrite to common lisp functions

books/bookvol7.1 Axiom Hyperdoc Pages
    add jan2010 what's new page
    books/ps/v71jan2010.eps added
    books/ps/v71releasenotes.eps updated for January 2010

books/bookvol8 Axiom Graphics
    redefine R1 in view3D for ARM processor

books/bookvol10 Axiom Algebra Implementation
    A new section on Elementary Functions branch cuts based on the
    Numerical Mathematics Consortium was added.

books/bookvol10.1 Axiom Algebra Theory
    A new chapter on the Clifford algebra was added.
    A quote on quaternions from Altman was added

books/bookvol10.3 Axiom Domains
    defstream function and KAFILE test bug fixed
1.1. RELEASENOTES.HT

fix IndexedBits range error
remove non-common lisp macros
rewrite to common lisp functions

books/bookvol10.4 Axiom Packages

remove compat.lisp, cparse.lisp, intint.lisp, macex.lisp,
monitor.lisp, pf2sex.lisp, ptrees.lisp, serror.lisp
remove MAKESTRING macro from all files
remove non common lisp macros
remove unused functions

g-error.lisp add )set break quit
htcheck.lisp add README from compat.lisp
nci.lisp pick up functions from intint
patches.lisp move global variables to bookvol15
posit.lisp move position functions to bookvol15
util.lisp move global variables to bookvol15
varini.lisp pick up functions from intint
vmlisp.lisp add )set break quit
January 2010 Release Notes

This release concentrated on treeshaking more code into the Interpreter volume. Ten files have been merged and removed. Call graphs were generated for all C code and added to the documentation. Several new functions were added, including flush, machineFraction, and integerDecode.

This release is an interim step in the process of merging the interpreter source code into a single volume. Due to the size and complexity of the task it will take several releases.

Volume 0: Jenks
Lee Duham fix typos

Volume I: Tutorial
Lee Duham fix typos

— releasesnotes.ht —

This release concentrated on treeshaking more code into the Interpreter volume. Ten files have been merged and removed. Call graphs were generated for all C code and added to the documentation. Several new functions were added, including flush, machineFraction, and integerDecode.
This release is an interim step in the process of merging the interpreter source code into a single volume. Due to the size and complexity of the task it will take several releases.

**Volume 0:** Jenks
- Lee Duhum fix typos

**Volume 1:** Tutorial
- Lee Duhum fix typos

**Volume 5: Interpreter**
- `describe` no longer needs `cat`, `dom`, `pkg` args
- add Lee Duhum to credits list
- add banner and cleanup `globals`
- add `DoubleFloat` trig macros
- support `DFLOAT machineFraction`, `integerDecode`
- do not set `si::*system-directory*` in restart
- fix `)display all output bug`
- merge `fname.lisp`, `alql.lisp`, `i-syscmd`, `i-toplev`, `pathname.lisp`
- merge `daase.lisp`, `exposed.lsp`

**Volume 7: Hyperdoc**
- add call graph for `ex2ht`, `htadd`, `hthits`, `hypertex`, `spadbuf`

**Volume 8: Graphics**
- add call graph for `view2d`, `view3d`, `viewalone`, `viewman`

**Volume 10.2 Categories**
- `latex` cleanup
- `FileCategory` add `flush`

**Volume 10.3 Domains**
- `DoubleFloat` add `dfloat machineFraction`, `integerDecode`
- `DoubleFloat` rewrite `doublefloat` to use typed macros
- `File` add `flush`

**Volume 10.4 Packages**
- document `RepeatedSquaring`
- fix API regression

`lsp/Makefile` add `compiler::link` per Camm Maguire

`src/algebra`
- remove `exposed.lisp`

`src/axiom-website`
- add `fedora 10` `nov2009 build`
- add `nov2009` builds
- move `CVS` instruction to `git`
- `axbook` add Stack and Queue
axbook fix typos

src/input
  add ackerman to test function caching
  add dftrig to test DoubleFloat trig changes
  rewrite dfloat, dop, e1, ei, en, numericgamma using machineFraction
  r20bugs, setcmd, unittest1, unittest2 fix broken tests
  zimmbon fix typo in bibliography

src/interp
  remove alql, cformat, daase, fname, i-sysmc, i-toplev, intfile, pathname, packtran

other src files
  add call graph information edible.c, asq.c
  src/docmsgs/s2-us.msgs remove S2IZ0049D
  src/share/docmsgs/s2-us.msgs removed

\end{verbatim}

November 2009 Release Notes

Summary: November 2009 release

The major changes are:
A new )describe command, boot language removal, and more motion toward a fully literate system.

The )describe command was added.

The )describe function was added to Volume 5 (Interpreter)
The )describe function was documented in Volume 2 (Users Guide)
The Description field for the Categories, Domains, and Packages were cleanup up and reformatted in Volumes 10.2 (Categories) 10.3 (Domains) and 10.4 (Packages)

Boot Language removal

All of the boot-converted lisp files were reformatted from their compiler generated output. These files are being merged into Volume 5 (Interpreters) and Volume 9 (Compiler) as appropriate. This work will continue for the next few releases.

All or portions of the following files were merged into Volume 5 (Interpreter):
astr, cstream.lisp, dq, incl, int-top, i-syscmd, msg, nci, obey, osyscmd, parini, patches, pile, scan
All of the boot-converted lisp files were reformatted from their compiler generated output. These files are being merged into Volume 5 (Interpreter) and Volume 9 (Compiler) as appropriate. This work will continue for the next few releases.

All or portions of the following files were merged into Volume 5 (Interpreter):
- astr, cstream.lisp, dq, incl, int-top, i-syscmd, msg, nci,
- obey, osyscmd, parini, patches, pile, scan

The src/boot subdirectory is gone, including the files:
- Makefile, boot-proclains, boothdr, bootstrap, btinc12, btpile2,
- btscan2, ccl-boostsys, ccl-depsys.lsp, exports.lisp, npextra, ptyout,
- tyextra, typars, typrops, tytree1, sys-pkg, vmlisp, ptrees, wi2

The bootsys image is no longer part of the build process

Patch ports from Fricas and Open-Axiom

The Tuples patch was picked up and applied.
The SXHASH function is the hash default in SetCategory
The function ListOfTerms was renamed to listOfTerms

Input file changes

New input files have been added to show how to compute results using Axiom or to create regression tests for fixes:
- complexfactor, rubey, zimmbron, branchcut, cachedf, finitegraph,
- newtonlisp, nonlinhomodiffeq, distexpr, numericgamma, donsimple
- solverperf, tuplebug, unit-macro, testprob, unittest2

lexp was removed and moved to the LEXP algebra file
dop and gstbl had minor fixes

New Help files and Function examples were added

There are new help files:
- describe, AlgebraicallyClosedField, RationalFunctionSum,
- RadicalSolvePackage, PartialFractionPackage, Product,
- OrderedFreeMonoid

Website update:
The developer.html page was rewritten. An old Scratchpad group
photo was added to the site.

Work continues on re-hosting the axiom-developer.org domain.

We now own axiom-developer.com and axiom-developer.net which will be re-targetted to the new host as soon as it is available.

Interpreter changes:

Axiom will sit in a single package in the near future.
The VMLISP package was partially removed from the system.
Work continues on this path.

The util.ht file is created earlier in the parallel build so there are fewer compiler messages about documentation.

Research:

A Cohen algebra domain is being developed to enable symbolic manipulation of expressions with explanations and controlled simplification.
A major project milestone has been achieved with this release. Axiom is implemented in lisp, removing all code in Boot.

The major effort in this release has been the boot to lisp rewrite. There are several follow-on phases which are "in-process" but only partially complete with this release. These include:

- source cleanup -
  - generating warning-free compiles which involves cleaning up the boot-to-lisp artifacts
  - generating unit tests
  - unit tests are being developed for each of the translated files to ensure that the rewrite does not introduce bugs

- file merge
  - the individual files are being prepared to merge into the interpreter and compiler volumes.

- global variable handling
  - the system uses many globals which are being either explained or rewritten to reduce coupling

- data structure extraction
  - the various data structures used by the compiler and interpreter are being identified and explained

- API vs implementation
  - the functions used externally vs the functions used internally are being identified

- code refactoring
  - the generated lisp code is being rewritten into human form without changing the behavior

The target goal is to have the code cleanly merged into the interpreter and compiler volumes in a logical way that form chapters related to function.

Additional changes in this release include:

- Add Steven Segletes to credits. He was the author of the paper that supplied the coefficients for computing E1. He has contributed a later, unpublished paper which has more accurate coefficients. This is in-plan to implement.

- Barry Trager contributed an example of computing Shannon Matrices. This has been added to the input/regression suite.
1.1. RELEASENOTES.HT

The .dvi files for the interpreter are no longer being built. The individual pamphlets will shortly disappear.

Debugsys is no longer built. I am the only user of it and I can build it when needed.

Bootsys is no longer built. It is no longer needed.

The Makefiles now use the := rather than = assignment limiting re-evals

Parallel Make is now the default since the documentation build is now independent of the interpreter build

\end{verbatim}
\endscroll
\autobuttons
\end{page}
July 2009 Release Notes

The syntactic conversion from the prior #1 form to the +-> form is complete except for the GUESS package. Both forms still work but the #1 form is discouraged.

All algebra files from src/algebra are now in books.

Work has concentrated on the hyperdoc browser.
* The browser files which get autoloded into the interpreter were merged and removed in preparation for being rewritten into book form.
* Glossary files were missing from the build and were added.

Work has started on a new CATS collection of verified algebraic identities, the tspiesz set. See http://sites.google.com/site/tspiesz

Volume 5: Axiom Interpreter
* set message autoload now defaults to off

Volume 7 Axiom Hyperdoc
* htscreen moved to $AXIOM/bin

Volume 10.1 Axiom Algebra Theory
* add chapter on quaternions

Volume 10.3 Domains
* Any now has regression and help files
* MathMLFormat domain moved from Volume 10.4
* TexFormat has regression and help files
* TexFormat fix for horizontal fractions
* Quaternion was added from src/algebra

"What’s New in Axiom" (releaseNotes) 1.1 on page 1
— releasenotes.ht —
* Glossary files were missing from the build and were added.

Work has started on a new CATS collection of verified algebraic identities, the tpiezas set. See http://sites.google.com/site/tpiezas

Volume 5: Axiom Interpreter
* set message autoload now defaults to off

Volume 7 Axiom Hyperdoc
* htsearch moved to $AXIOM/bin

Volume 10.1 Axiom Algebra Theory
* add chapter on quaternions

Volume 10.3 Domains
* Any now has regression and help files
* MathMLFormat domain moved from Volume 10.4
* TexFormat has regression and help files
* TexFormat fix for horizontal fractions
* Quaternion was added from src/algebra

Volume 10.4 Packages
* IntegerNumberTheoryFunctions fix divisors regression
* Waldek’s QUATCT2 algebra was added, including a help file, regression tests and command examples.

Makefile
* make help files in parallel
* make xhtml pages in parallel
* make books documentation in parallel

interpreter
* src/interp/i-output.boot fix horizontal fractions

axiom-website
* download.html add mandriva
* download.html add may2009 binaries

input files
* ffdemo.input fix steps 27, 57 due to divisors change
* numbers.input fix random zero failure
* spline.input explain how to compute 2D splines
* tpiezas001.input CATS tests of algebraic identities
* tpiezas002.input CATS tests of algebraic identities
May 2009 Release Notes

Axiom now supports latex chunk syntax in pamphlets, thus
Axiom pamphlets can now be pure latex.
Axiom can now read pamphlet files and extract latex chunks directly.
All input files were converted to the new format.

This change has several long term implications. Once all of the
pamphlet files are pure latex we no longer need the NOWEAVE function.
Once Axiom can read all of its input formats, that is, )read and )compile
work directly on their pamphlet forms we will no longer need NOTANGLE.
At that point, we no longer need noweb.

This release sees the introduction of new domains and packages
as well as more documentation. The original Jenks books has been
modified to include new documentation, more help files were added,
and the id op function documentation was expanded.

More effort has been applied to collecting interpreter and compiler
code into literate form in book volume 5.

A new effort to collect the compiler code into book volume 9 started.

The compiler was modified (by Waldem) to allow \texttt{\&
\&} in place of \texttt{#} syntax.
This conversion is nearly complete, with only a few packages remaining
to be converted. Lisp code to regression check the algebra changes
written so the generated algebra is parsed and highlighted.

A method for running Axiom on Windows was developed and documented
on the home page of the website.

work directly on their pamphlet forms we will no longer need NOTANGLE. At that point, we no longer need noweb.

This release sees the introduction of new domains and packages as well as more documentation. The original Jenks books has been modified to include new documentation, more help files were added, and the )d op function documentation was expanded.

More effort has been applied to collecting interpreter and compiler code into literate form in book volume 5.

A new effort to collect the compiler code into book volume 9 started.

The compiler was modified (by Waldek) to allow +-> in place of #1 syntax. This conversion is nearly complete, with only a few packages remaining to be converted. Lisp code to regression check the algebra changes was written so the generated algebra is parsed and highlighted.

A method for running Axiom on Windows was developed and documented on the home page of the website.

Unit testing of interpreter and compiler changes was added to the regression testing. This will expand in future versions as changes are made so ensure that things continue to function.

Volume 0: Axiom Jenks and Sutor
   Richard Jenks bio was added

   Section 9: Examples of Domains and Packages expanded
      ApplicationProgramInterface (API)
      Dequeue (DEQUEUE)
      EuclideanGroebnerBasisPackage
      GeneralDistributedMultivariatePolynomial
      GroebnerPackage
      HomogeneousDistributedMultivariatePolynomial
      NottinghamGroup
      Permutation
      RealSolvePackage
      TwoDimensionalViewport

      Cross references were fixed

      More spelling typo fixes

Volume 4: Axiom Developers Guide
   A section was added explaining how to find anonymous function signatures

Volume 5: Axiom Interpreter
   Michael Becker was added to the credit list
\)set debug is now a new top level command to collect all of
the developer-level commands to enable/disable internal messages
and tracing functions.

\defunsec macro was added to handle section titles with docstrings

More interpreter code was moved from other files into this book

All regression test numbering was fixed to conform to the new,
stronger regression test. Thus \(--S\) requires the "of NN" phrase
or a FAILED message will be raised.

The compiler root was moved to volume 9: Axiom Compiler

Volume 7: Axiom Hyperdoc
Fixup verbatim breakage

Volume 7.1: Axiom Hyperdoc Pages
Update What’s New for March 2009

Volume 9: Axiom Compiler
The compiler code is being collected from other parts of the
system into this book. In particular,
  - The root functions for the compiler were added
  - The top level loop code of the compiler was added
  - The next layer of compiler code was added

Volume 10.2: Axiom Algebra Categories
There was a general change to allow +-> syntax in algebra and
this was made to all existing categories

MatrixCategory now has regression test cases, a help page,
and \)d op function examples

Document binomial category

Volume 10.3: Axiom Algebra Domains
There was a general change to allow +-> syntax in algebra and
this was made to all existing domains

SparseMultivariateTaylorSeries now has regression test cases, a help page,
and \)d op function examples

Permutation now has regression test cases, a help page,
and \)d op function examples

The regression tests now conform to the new, stronger
regression test requirements

Volume 10.4: Axiom Algebra Packages
There was a general change to allow +-> syntax in algebra and this was made to some existing packages. There is more to be done.

Bezier package was added, including regression test cases, a help page, and \texttt{\textbackslash d op} function examples

Combinatorial\texttt{Function} now has regression test cases, a help page, and \texttt{\textbackslash d op} function examples

Elementary\texttt{Function} now has regression test cases, a help page, and \texttt{\textbackslash d op} function examples

IntegerCombinatoric\texttt{Functions} now has regression test cases, a help page, and \texttt{\textbackslash d op} function examples

LazardSetSolving\texttt{Package} now has regression test cases, a help page, and \texttt{\textbackslash d op} function examples

The regression tests now conform to the new, stronger regression test requirements

Volume 12: Axiom Crystal
Add Gelernter’s observations on Layout and Linking

Bug fixes
7191: set *system-directory* dynamically (20090413.03.tpd.patch)
7192: \texttt{\textbackslash edit} now works because SPADEDIT added (20090414.02.tpd.patch)
7197: fix hyperdoc/graphics failure (20090530.01.tpd.patch)

Makefile changes
Top Level Makfile
The BOOKS environment shell variable was added to ENV
Makefile.slackware chunk exists
Makefile reports regression failures after builds

lisp/Makfile
Build tangle into the lisp image

src/Makfile
Copy bookvol9, the compiler, to src/interp at build time

src/algebra/Makfile
Add Bezier package
Add LazardSetSolving\texttt{Package}.help
Add Matrix\texttt{Category}.\texttt{input}, .\texttt{help}
Add help, regress for Elementary\texttt{Function}
Add input, help, examples for SparseMultivariate\texttt{TaylorSeries}
Fix LazardSetSolving\texttt{Package} typo
Move egrep to grep -E since egrep might not be installed
Move help to bookvol5
src/doc/Makefile
 Move help to bookvol5

src/input/Makefile
 Add FRAC regression test
 Add unittest* files for regression testing non-algebra changes
 Change input files to latex tangle
 Fix regress format to conform to the new, improved regression testing

src/interp/Makefile
 Build bookvol9, the compiler from book sources
 The old gclweb code was rewritten into tangle.lisp, gclweb was removed
 Move help to bookvol5
 More interpreter code was moved to bookvol5, the interpreter
 Debugsys has been updated to stop loading deleted files
 Several files were merged, rewritten, and removed:
  apply.boot, bootlex.lisp, comp.lisp, compiler.boot, cstream.boot,
  def.lisp, i-util.boot, incl.boot, int-top.boot, metalex.lisp,
  nci.lisp, parse.boot, parsing.lisp, postpar.boot, preparse.lisp,
  server.boot, seq.lisp, sockio.lisp, spad.lisp, spaderror.lisp,
  util.lisp, vmlisp.lisp

faq
faq 50: Cannot find libXpm.a

readme
 Add Michael Becker to credit list

books/
 tangle.lisp lisp version of tangle command
 ps/v71mar2009.ps hypertex march 2009 release notes pic
 ps/v71releasenotes.ps hypertex what's new page pic

src/interp
 Rewrite apply.boot to apply.lisp
 Regression tests, regress.lisp, now checks for the "of NN" phrase

src/algebra
 Add Bezier package to exposed.lsp

src/axiom-website
 Add March 2009 column
 Add slackware column
 Axiom on Windows as html instructions
 Add March release notes
 Add binaries

src/doc/
Add chunk environment to axiom.sty
Old book sources were removed
The spadhelp file was removed and added to the interpreter book

src/input/
All of the .input files were modified to use latex tangle

src/scripts/tex/
axiom.sty contains new latex macros

zips
Old GCL versions were removed
gcl-2.6.8pre.tgz removed
gcl-2.6.7.tgz removed

March 2009 Release Notes

March 2009 Release Notes

There were two major changes in this release.

First is the completion of the first phase of Book Volume 10.4: Axiom Packages, which collects all of the packages into one document. The side effect is to remove almost all of the remaining algebra files leaving src/algebra nearly empty.

Second is the start of Book Volume 5: Axiom Interpreter which will consolidate all of the interpreter functions and document them in book form. A side effect of this consolidation will be the ultimate removal of all boot code, with the further side effect of removing bootstraps from the build step and boot translation time.

While consolidating the interpreter code a parallel effort will be ongoing to build Book Volume 9: Axiom Compiler. The idea is to split the compiler code from the interpreter code so the compiler can be documented and upgraded.
March 2009 Release Notes

There were two major changes in this release.

First is the completion of the first phase of Book Volume 10.4: Axiom Packages, which collects all of the packages into one document. The side effect is to remove almost all of the remaining algebra files leaving src/algebra nearly empty.

Second is the start of Book Volume 5: Axiom Interpreter which will consolidate all of the interpreter functions and document them in book form. A side effect of this consolidation will be the ultimate removal of all boot code, with the further side effect of removing bootsys from the build step and boot translation time.

While consolidating the interpreter code a parallel effort will be ongoing to build Book Volume 9: Axiom Compiler. The idea is to split the compiler code from the interpreter code so the compiler can be documented and upgraded.

Book Volume 0: Axiom Jenks book
Add }include documentation

The original book did not document the }include command. This is now documented.

Add UnivariateSkewPolynomial

This domain was added to the domain examples

Book Volume 4: Axiom Developers Guide
Hyperdoc

A Hyperdoc tutorial on making new pages was written

A tutorial on spadhelp was added

Book Volume 5: Axiom Interpreter
Command Handling

The top level commands that start with open parenthesis are all kept in the $setOptions data structure. This structure was documented. Each command has a handler routine which was integrated with the
1.1. RELEASENOTES.HT

structure in the proper place.

New latex macros

The \defun and \defmacro macros were added to ensure that there is a uniform handling of subsections and cross references for all functions and macros.

The \defdollar macro was added to handle $\$foo$ variables in both index and cross reference.

The \cmdhead macro was added to provide uniform handling of each of the top level commands in the $\$setOptions$ data structure.

Unit testing

To ensure that changes did not break behavior two new regression test routines were added, unittest1 and setcmd. These test the top level command behavior.

Trace functions added

The trace.boot code was added.

Book Volume 7: Axiom Hyperdoc
Documentation

Add Scott Morrison’s original hypertex plan notes

Book Volume 10.1: Axiom Algebra Theory
Documentation

Add tutorial chapter on Singular Value Decomposition

Book Volume 10.3 Axiom Domains
Algebra fixes

Johannes Grabmeier fixed the outputFixed behavior in Float.

A regression test chunk was added to the Float domain.

UnivariateSkewPolynomial was documented. A regression test, help file, and examples were added.

Heap was documented. A regression test, help file, and examples were added.

Dequeue was documented. A regression test, help file, and examples were added.
Queue was documented. A regression test, help file, and examples were added.

ArrayStack was documented. A regression test, help file, and examples were added.

Stack was documented. A regression test, help file, and examples were added.

NottinghamGroup was added, including regression and help files. Originally written by Martin Rubey.

Regression tests

The )sys rm now uses the -f flag to force deletion on all regression test files

Book Volume 10.4 Axiom Packages
New Algebra

All packages were moved into this volume. Almost all of the remaining algebra files were deleted.

ApplicationProgramInterface (API) was added. It exposes the Axiom internal functions at the algebra level.

UnivariateSkewPolynomial now has help, input, and examples

Documentation

The nag man pages were added to the related domain documentation

Export lists were added for all packages.

Regression tests

The )sys rm now uses the -f flag to force deletion on all regression test files.

Boot to Lisp rewrite

Deleted boot files

setvars.boot is gone. The code has been rewritten and added to book volume 5. The code was rewritten and/or reformatted. All compile-time warnings were eliminated.

setvart.boot is gone. The code has been rewritten and added to book volume 5. The code was rewritten and/or reformatted. All compile-time warnings were eliminated.
trace.boot is gone. The code has been rewritten and added to book volume 5. The code was rewritten and/or reformatted. All compile-time warnings were eliminated.

Regression test cleanup

)set break resume

A subtle bug in regression testing caused by early exit of a test left some of the regression tests reporting success when there should have been failure. This was fixed by adding a )set break resume command to allow Axiom to continue the testing in the presence of an internal fault.

new

setcmd.input was added to regression test changes to the )set top level command

unittest1.input was added to regression test other top level commands

dop.input was added to unit test )d op example output

frame.input was added to unit test frame handling

removed

bags.input was distributed among the algebra regression test files and bags.input was removed.

Bug fixes

Bug 7183. The library handling code was repaired. Functions which do not exist were removed (e.g. input-libraries). The element values of the data structure are now pathnames.

Bug 7182. )set mes auto did not indicate the current value.

Bug 7180: )set compiler input add foo triggers a call to open-library which was a CCL function and no longer implemented. The elements of the data structure were changed.

Bug 7179. Suprious sensitivity to )abb in documentation caused breakage because this was assumed to be an )abbreviation command.

Bug 7178. Missing function inspect in ArrayStack

Bug 7177. Missing function map! in ArrayStack
Bug 7176. Missing function parts in ArrayStack

Bug 7175. Missing function map in ArrayStack

Bug 7174. Missing function map! in Stack

Bug 7173. Missing function parts in Stack

Bug 7172. map was missing from Stack(Integer)

Bug 7170: )d op output failure due to X in algebra comments. The X symbol is now a marker for )d op examples and the use of X in comments is ambiguous.

Bug 7141: )cd relative does not work

Interpreter (src/interp)
  Documentation

  document mmCost calculation

Help files
  Documentation

  The help file list is now dynamically generated from the algebra books.

readme
  Quote

  Add Doron Zeilberger quote about builders of CA systems.

Website
  Download

  Add fedora10 as a supported platform

  Add vector as a supported platform

Lisp
  New patch

  read-char-no-hang was changed by Camm to ignore newlines but Axiom's browser needs them to be recognized. A patch was added to back out Camm's change.

\end{verbatim}
\endscroll
\autobuttons
\end{page}
January 2009 Release Notes

One major theme of this release was restructuring the system to move all domains to literate form in book volume 10.3

A second major theme was the first Axiom youtube tutorial video.

Book Volume 0: Axiom Reference

Remove obsolete references to SmallFloat

Book Volume 1: Axiom Tutorial

Remove obsolete references to SmallFloat

Book Volume 4: Axiom Developers Guide
Add section on generating graphviz graphs

Book Volume 7.1: Axiom Hyperdoc

Give a complete path to htadd

Book Volume 10.3 Axiom Domains

All domains have been removed from the algebra subdirectory and are now in literate form in book volume 10.3. Some domains include a help file, a regression test suite, and --X function examples for the )display command. Future work will extend this set.

Each domain has a fully indexed list of functions exported. This allows hyperlinked access to functions.

Each domain includes a graph segment that shows the list of categories, domains, and packages that provide immediate support in the prior build layer.

Each domain includes a dotabb chunk which contains the source code necessary to recreate the graph.

Domains which were associated with other domains in the same original spad file have hyperlinks to connect them.

Book Volume 11: Axiom Browser

Lighten Bayou theme background image

Axiom Website (src/axiom-website)

The axiom website is now under git control. The source tree is in src/axiom-website in the distribution.

The build order graph exists. It contains a graph of all the constraints for each level. A line in the graph connects each category, domain, and package to every category, domain, and package in the prior layer that is required for the build. Multilayer constraints are not shown (although the data is in src/algebra/Makefile chunks) because the graph would be too complex.

http://axiom-developer.org/axiom-website/hp.svg

The Computer Algebra Test Suite (CATS) has a new test suite for ordinary differential equations (kamke*)

http://axiom-developer.org/axiom-website/CATS
The Ubuntu download now advises XTerm.metaSendsEscape: true due to misconfiguration of the meta key in emacs.
http://axiom-developer.org/axiom-website/documentation.html

A new binary for vector linux was added
http://axiom-developer.org/axiom-website/download.html

A new binary for doyen thumbdrive was added
(work by Jose Alfredo Portes)
http://axiom-developer.org/axiom-website/download.html

The screenshots were recreated so the sources would be available.
for matrixinmatrix.jpg, heatequation.jpg, axiomfirefox.jpg
http://axiom-developer.org/axiom-website/screenshots.html

The Axiom Information Sources video page was added, including a link to the youtube video, a local copy, and the supporting PDF.
http://axiom-developer.org/axiom-website/videos.html

A broken link to Book Volume 0: Axiom Reference was fixed.

Algebra (src/algebra)

All domains were removed from spad files and moved to Book Volume 10.3 Axiom Domains

The Makefile now contains the information necessary to construct the build order graph as literate chunks.

The layers were restructured. Files were moved to ensure that each file was at its lowest possible layer.

The Guess package was added. However, due to nonstandard package files the guess function does not yet work properly. These packages are being rewritten.

The Guess package has circular references. A new clique mechanism was added to the Makefile to handle this.

Automatic regression test files associated with the algebra sources were reviewed for conforming to regression standards.

integer.spad was reverted to remove an algebra change that causes a regression (cherry picked from Fricas in 2007)

Interpreter (src/interp)

Tim Lahey added to )credits
Karl Hegbloom added to )credits

htcheck.boot moves util.ht to the mnt/doc directory

setq.lisp no longer had redundant release data information

nrunfast.boot Float has exp : Float -> Float now works
This change was cherry-picked from Fricas.

Testing (src/input)

All regression test files were reviewed and cleaned to conform to a standard setup.

A parallel build race condition was fixed in the Makefile

xpbwpoly.input was removed as it is now associated with its source domain and automatically generated.

hyperbolicrules.input was added

Tim Lahey submitted a fix for bugs in schaum17.input

A cherry-picked patch from Fricas in 2007 was removed because it causes an algebra regression. The regression test file was corrected.

fixed.input was converted to a regression test file

Build process

The lsp/Makefile was updated for GCL pre3 patches

An ubuntu64 chunk was added as a system target

src/Makefile outputs util.ht before compiles (bug 7146)

books/Makefile uses bash SHELL to fix echo behavior. The standard sh echo behaves badly.

books/Makefile now has amssymb in preamble for toc.tex

GCL (zips)

Axiom now includes GCL pre3, the latest snapshot of GCL. This can be chosen as an option for building in the top level Makefile.pamphlet
The lisp/Makefile was updated for GCL pre3 patches

faq

FAQ 49: How do I get the lastest GCL?

readme

Tim Lahey added
Karl Hegbloom added

The date information for releases was removed as it is available elsewhere

A John Gorka quote was added:
"What matters the most is what you do for free" -- John Gorka

November 23, 2008 Release Notes

Axiom website

New patch tracking has been added:
* <http://axiom-developer.org/axiom-website/patches.html>

Volumes have been significantly updated:

Book Volume 10.2 Axiom Categories completed

The effort here is to create fully indexed, cross-referenced, graphical documentation for Axiom categories in a standalone form. This is a "live" literate document which contains the actual source code used to build the system.

1.1. RELEASENOTES.HT

Book Volume 10.3 Axiom Domains started

This volume will contain the Axiom domains.

Rosetta documentation

Fix the Magnus URL

Input Files

There is a new effort to automatically extract the algebra examples in order to regression test the user API to the algebra. In addition there is ongoing test work.

* New input files (Jakubi, Maltey, Rubey, Page, Daly)
  dhmatrix, reclos2
* Changed input files (Hebisch, Daly)
  sae, r20bugs

Build changes

* Testing is now run in parallel

\end{verbatim}
\end{scroll}
\autobuttons
\end{page}
September 23, 2008 Release Notes

Axiom website
The effort here is to improve the support for offline literate documentation. The primary changes are the inclusion of graphs and additional book volumes.

* <http://axiom-developer.org/axiom-website/documentation.html>
  Contains the new algebra volumes and subvolumes.
* <http://axiom-developer.org/axiom-website/bookvol10.2abb.html>
  Contains a "clickable" graph that indexes into the algebra.

Graphviz, PDF, and HTML integration
The effort here is to unify these three technologies in a way that simplifies the user interface and improves documentation.
* Graphviz is used if available but not required
* Algebra graphs are automatically generated at build time from algebra source files
* Graphviz graphs now properly hyperlink into PDF files allowing any node in a graph to link to any document page

Book volume 0 (Jenks and Sutor)
* [http://axiom-developer.org/axiom-website/bookvol0.pdf](http://axiom-developer.org/axiom-website/bookvol0.pdf)
* replace \over with \frac

Book volume 7.1 (Hyperdoc pages)
The effort here is to create a literate document that contains all of the "live" pages used in hyperdoc. The PDF is being constructed so that a user can effectively "browse" the static hyperdoc pages, which are included, without a running Axiom.
* The source for all of the pages is now contained in this book.
* Hyperdoc now fetches the pages directly from the book.
* The hyper page directory and all files are gone.
* Some of the static page images are now inside the PDF
* Pages have href links allowing "in-pdf" navigation of pages

Book volume 10 (Algebra)
The effort here is to create a way to describe and deeply document the algebra. This volume was split to better handle the structure of Axiom's information.
* Split into 5 volumes
  - 10 Implementation
  - 10.1 Theory
  - 10.2 Categories
  - 10.3 Domains
  - 10.4 Packages

Book volume 10.2 (Algebra Categories)
The effort here is to create fully indexed, cross-referenced, graphical documentation for Axiom categories in a standalone
form. This is a "live" literate document which contains the actual source code used to build the system.

* Contains 60 categories so far
* Has partial graphs for each category
* Has list of exported functions
* Has information about source of functions
* Has index cross reference by function and category
* Has PDF href links so that URLs work:
  <http://axiom-developer.org/axiom-website/bookvol10.2.pdf#nameddest=AGG>
* Has forward/backward links between categories
* Automatically generates "clickable" graphs:
  <http://axiom-developer.org/axiom-website/bookvol10.2abb.html>
* Graph clicking automatically opens to the proper source code

New algebra examples (Daly, Tsikas)
The effort here is to create "real time" documentation that gives the end user an example of how to construct the proper arguments and call a function. This puts examples into the system so users don't need to consult other documents.

* )d op someop shows examples of function usage
* about 100 new function examples were added
* new comment syntax added to allow automatic API testing

Input Files
There is a new effort to automatically extract the algebra examples in order to regression test the user API to the algebra. In addition there is ongoing test work.

* New input files (Hemmecke, Stumbo, Cyganski, Daly)
  bini, biquat, ifthenelse, liu, overload, sqrt3, typetower
* Changed input files (Hemmecke, Stumbo, Cyganski, Daly)
  bern, function, linalg, regset, test, tutchap2

Build changes
* graphics does not depend on compress, done at build time
* firefox html pages are now built before tests are run
Algebra changes

* FLAGG (FiniteLinearAggregate) -- removed a duplicate function

Interpreter changes (Page)

* add cost function to bottomUp output

July 23, 2008 Release Notes

The July 2008 release marks the second large-scale change to literate Axiom distribution. The original change was to make file into a pamphlet document. This second change draws Axiom tighter collections, called books (for obvious reasons).

There is a new "books" directory which contains 14 books, and which are new:

bookvol0: The reconstructed Jenks and Sutor book
bookvol1: The published tutorial volume
bookvol2: Users Guide
bookvol3: Programmers Guide
bookvol4: Developers Guide
bookvol5: Interpreter
bookvol6: Command
bookvol7: Hyperdoc

⇐ “What’s New in Axiom” (releaseNotes) 1.1 on page 1
The July 2008 release marks the second large-scale change toward a literate Axiom distribution. The original change was to make every file into a pamphlet document. This second change draws Axiom into tighter collections, called books (for obvious reasons).

There is a new “books” directory which contains 14 books, most of which are new:

- bookvol0: The reconstructed Jenks and Sutor book
- bookvol1: The published tutorial volume
- bookvol2: Users Guide
- bookvol3: Programmers Guide
- bookvol4: Developers Guide
- bookvol5: Interpreter
- bookvol6: Command
- bookvol7: Hyperdoc
- bookvol7.1 Hyperdoc Pages
- bookvol8: Graphics
- bookvol9: Compiler
- bookvol10: Algebra
- bookvol11: Browser
- bookvol12: Crystal

All of these books now exist. Portions of the current system have been moved completely into book form (Graphics and Hyperdoc) so the old files have been removed from the src tree. Both Graphics and Hyperdoc are now built directly from their book. Work will follow on other parts of the system.

These books are online at: <http://axiom.axiom-developer.org/axiom-website/documentation.html>

There is an interesting side-effect of using literate technology. Once you combine C and .h files into a single document so that each file is a separate chunk it becomes obvious that there is no need for local include files. The lines that read:

```c
#include "foo.h"
```

become

```c
begin{chunk}{foo.h}
```

and get expanded inline. Once you do this it also becomes obvious that many include files get included multiple times (a clear waste of disk I/O and preparser time). Further it becomes clear that there
is no need for creating tiny .o files since all of the source can be combined into one C file using chunks.

These approaches were used to reduce the compile-time overhead for both the graphics and the hyperdoc functions.

In addition to consolidating the source files for Graphics into bookvol8 there were several other changes:

* the functions for graphics, that is, viewman, view2d, view3d and viewalone are now built as single C files.
* the graphics code was reorganized into chapters of related code
* there is the beginnings of documentation
* there is the beginnings of a test suite based on the CRC Handbook of Curves and Surfaces
* the book is hyperlinked (Bill Page, Frederic Lehbey, Anatoly Raportirenko)
* redundant code was eliminated
* the code is fully indexed
* the src/graph subdirectory is gone

In addition to consolidating the source files for Hyperdoc into bookvol7 there were several other changes:

* the functions for hyperdoc, that is, spadbuf, ex2ht, htadd, hthits and hypertex are now built as single C files
* the hyperdoc code was reorganized into chapters of related code
* there is the beginnings of documentation
* redundant code was eliminated
* scroll wheel handling was added (Gregory Vanuxen)
* the book is hyperlinked (Bill Page, Frederic Lehbey, Anatoly Raportirenko)
* the code is fully indexed
* )hd now works to start or restart Hyperdoc (Jose Alfredo Portes)
* the src/hyper subdirectory is gone

In addition to consolidating the hyperdoc pages into bookvol7.1 there were several other changes:

* the pages are hyperlinked
* new latex macros were written to simplify page handling
* images of hyperdoc pages were added
* forward and backward hyperlinks between pages images works making it possible to "browse" the hyperdoc pages using only the single PDF file (Bill Page, Frederic Lehbey, Anatoly Raportirenko)
* the pages are fully indexed
* the src/hyper/pages subdirectory is gone

A combined table of contents PDF is now automatically generated which covers all of the volumes. This makes it easier to find the topic of interest.

In addition there were several other changes.

* Some fixes were made for different platforms
  In particular, Fedora9 breaks the build and needs work

* The configure script was replaced by instructions
  The standard (export AXIOM) works everywhere so the configure script is useless for guessing.

* the FAQ was updated about git
  Since the May 2008 release the primary Gold source code platform is github. The FAQ was updated to reflect this.

* the FAQ was updated about X11
  X11 has moved yet again so more notes are needed

* move axbook to books
  The hyperlinked version of Jenks is now built from the books dir

* add Ralf Hemmecke's documentation to ax.boot
* add Monoid multiply to DirectProduct (Ralf Hemmecke)
* add Monoid multiply regression test
May 27, 2008 Release Notes

COMPUTER ALGEBRA TEST SUITE

A large part of the effort for these two months has involved detailed test cases of Axiom’s integration routines against Schaum’s Handbook of Mathematical Formulas. Of the 619 integrals, the detailed results are:

- 419 Schaums and Axiom agree
- 137 No closed form solution
- 60 Cannot simplify
- 2 Typos found in Schaums
- 1 Axiom bug

The Axiom bug was in src/algebra/intef.spad.pamphlet. There was a fix applied to this code for a previously identified bug but the previous fix was incorrect.

In addition, there were
src/input/danzwill2.input.pamphlet added for the MIT Integration tests
src/input/mapleok.input.pamphlet to fix typos
src/input/kamke1.input.pamphlet had ode97 removed due to running time
src/input/kamke2.input.pamphlet ode104, ode105 removed for running time

**DOCUMENTATION**

\begin{verbatim}
Summary: March 2008 release

Axiom is now available at github, a git-based code repository. This site will have the Gold version of Axiom, that is, only code that changes at each two-month release. To get a clone type:

git-clone git://github.com/daly/axiom.git

USER VISIBLE CHANGES

One primary focus of this release has been extending the Firefox toward being a full Axiom user interface (as opposed to a simple hyperdoc replacement). The Firefox console page has new, AJAX based, dropdown menus which are planned to be dynamically updated to display available functions for the last computed type. This should make it much easier to find the applicable functions by category and type. They are currently static in this release.

* Firefox Pages
  o Dropdown menus were added to the Axiom console page
  o More hyperdoc pages were translated to Firefox/html
  o Bitmaps and graphics are now properly handled in pages
  o A minor mathml fix was applied (for invisible times)

* Refcard
  o An Axiom reference card of Axiom commands was created (src/doc/refcard)

* Examples
  o It is often difficult to figure the exact arguments required to call any given function in Axiom. The )display operation command used to only show the available modemaps. This command has now been changed.
    )display operation foo
    now shows examples of function calls for foo.

* Help
  o The plot routines have new help files and documentation

PORTING

o Axiom was ported to MAC-OSX

o The binary download page now has binaries for Ubuntu, OpenSUSE, Redhat9, Redhat72, Debian, MACOSX at
\end{verbatim}
<http://axiom.axiom-developer.org/axiom-website/download.html>

- Binaries for the this release will be available shortly.

**INTERNALS**

* Compiler changes
  - hashtables were used to speed up compiles

* Algebra changes
  - There are new special functions, \( E_i, E_n, E_{i1}, E_{i2}, E_{i3}, E_{i4}, E_{i5}, E_{i6} \)
  - The prime and BasicSieve functions are faster
  - The Brent/Pollard algorithm was documented
  - Bad gcd reductions are checked (heugcd regression test file added)
  - The plot routines have new help files and documentation

* Makefile changes
  - Bi-capital SVN copies are no longer made

* Interpreter changes
  - Book Volume 5 has new documentation on the display function
  - The display function code has been translated and moved to book volume 5
  - \( \pi \) has a higher internal precision
  - Mappings are now properly hashed for Aldor

**CATS (Computer Algebra Test Suite)**

- The differential equations regression tests are being checked against Mathematica, Maple, and Maxima. This has happened for the kamke2.input regression test file and will happen for the other regression tests.

- Complex Gamma, \( \log\Gamma \), and \( \log(\Gamma) \) have additional tests and documentation.
January 25, 2008 Release Notes

Summary: January 2008 release

There have been two major concentrations of effort in this release.

The first concentration is on the new Firefox Hyperdoc and the second concentration was the verification of Axiom against published standards.

Firefox Hyperdoc

The Firefox Hyperdoc has been integrated with the rest of the interpreter. The new )browse command causes Axiom to listen and serve hyperdoc pages on port 8085.

The interpreter was changed to add the )browse command. As a
CHAPTER 1. RELEASE NOTES

side-effect new documentation was added to the interpreter volume (bookvol5) to explain top-level command handling. In addition, lisp and boot code was rewritten as part of the literate change.

New sections were added to cover the beginning of the Computer Algebra Test Suite (CATS) subsection which brings a focus on compliance with published standards.

Arthur Ralf's mathml-enabled version of the Jenks book is fully integrated into the Firefox Hyperdoc. Arthur also fixed some rendering and ambiguity issues.

axbook.tgz fix the user/group settings
axserver.spad fix lastType output re: errors
bookvol5 browse and top-level command handling
bookvol11 add standards compliance for gamma
gammacomplexinverse.png added
gammacomplex.png added
gammareal3.png added
loggamma.png added
mathml.spad fix ambiguity bug in mathml output
mathml.spad fix hex(10) mathml rendering
mathml.spad fix F,3 mathml rendering
mathml.spad remove code to eat %%
psi.png added

Standards Verification

The Computer Algebra Test Suite (CATS) effort checks the results that Axiom generates against published results. Axiom has an extensive set of regression tests (the KAMKE suite) for ordinary differential equations, for integration (the SCHAUM suite), and for numeric special functions (the ABRAMOWITZ suite). In addition, results have been checked against Mathematica, Maple, and Maxima.

asinatan.input regression for the functions asin and atan
asinhatanh.input regression for the functions asinh and atanh
besselk.input regression for the function besselK
e1.input regression for the function E1
en.input regression for the function En
exp.input regression for the function exp
gamma.input regression for the function gamma
log.input regression for the functions log
pfaffian.input regression for the function pfaffian
seccsc.input regression for the functions sec and csc
sincos.input regression for the functions sin and cos
1.1. RELEASENOTES.HT

sinhcosh.input regression for the functions sinh and cosh
tancot.input regression for the functions tan and cot
tanhcoth.input regression for the functions tanh and coth

New Functions Added

Axiom is missing various special functions found in other computer algebra systems. This release adds two new ones, the Exponential Integral E1 and the higher order Exponential Integral En. These have been tested against the published results.

special.spad E1 added
special.spad En added

Bugs Fixed

There are 15 bug fixes in this release:

bug 7015: fix hex(10) mathml rendering
bug 7016: remove code to eat %%
bug 7019: fix F,3 mathml rendering
bug 7023: discardGraph free corrected
bug 7042: ignore regression test gensym
bug 7045: wrong Makefile for Xpm fix
bug 7052: spurious remake of axbook
bug 7054: /home/silver path in bookvol11
bug 7057: ambiguity in mathml
bug 7089/343: FreeAbelianGroup order
bug 7090/355 handle besselK
bug 7093: Function name fix
bug 7100/149: numlock in hyperdoc
bug 7101/204: MoreSystemCommand unnecessary loading
bug 7102/412: Equality testing in TableAggregate

Regression test fixes

As changes happen in the system the regression tests are updated to reflect the new conditions. Changing the category of PositiveInteger caused (a + -bi) to print as (a - bi). New builds raised gensym faults which were fixed. And new builds change random numbers so the tests that depend on them are marked "ok" despite failures due to randomness.
The FreeAbelianGroup bug is tested.

- acplot.spad: Fix output form of negative numbers
- calculus2.input: Fix function names
- classtalk.input: Ignore gensyms
- collect.input: Fix function names
- dfloat.input: Handle negative number output
- easter.input: Fix function names
- elemnum.input: Handle negative number output
- exlap.input: Fix function names
- exsum.input: Fix function names
- free.input: Added to test bug
- grpthry.input: Mark random generation failures ok
- grpthry.input: Fix function names
- ic0.input: Mark random generation failures ok
- intg0.input: Ignore gensyms
- is.input: Type declare function
- kamke3.input: Mark random generation failures ok
- knot2.input: Fix function names
- lodo.spad: Ignore regression test gensym
- maplecok.input: Ignore gensyms
- mathml.input: Handle new mathml sub/sup change
- ndftip.input: Fix missing blank lines
- pmint.input: Rewritten
- repa6.input: Fix function names
- r20bugs.input: Change spacing
- sf.spad: Fix output form of negative numbers
- tbagg.input: Regression for equality testing in TableAggregate

Algebra file changes

The fundamental change was a supposedly transparent move of the category for PositiveInteger. This had the effect of changing the output form and broke several regression tests. Some mathml issues were fixed. The new functions E1 and En were added. The FreeAbelianGroup bug was fixed.

- axserver.spad: Fix lastType output re: errors
- acplot.spad: Fix output form of negative numbers
- combfunc.spad: Fix bold font handling
- integer.spad: Category change for PositiveInteger
- sf.spad: Fix output form of negative numbers
- spf.spad: Handle besselK
- op.spad: Handle besselK
- combfunc.spad: Handle besselK
- free.spad: Fix FreeAbelianGroup bug
- special.spad: Add E1
special.spad  add En
mathml.spad  fix ambiguity bug in mathml output
mathml.spad  fix hex(10) mathml rendering
mathml.spad  fix F,3 mathml rendering
mathml.spad  remove code to eat %%

Interpreter changes

The primary changes are the addition of bookvol11 for the Firefox
Hyperdoc and the literate documentation of the top level command
handling in bookvol5 (the interpreter) along with rewrites of the
lisp/boot code.

boottfuns.lisp move $systemCommands to bookvol5
bookvol5      browse and top-level command handling
bookvol11     added
http.lisp     mathObject2String for hex(10)
incl.boot     move incBiteOff to bookvol5
intint.lisp   move setCurrentLine to bookvol5
int-top.boot   move ncloopCommand, etc. to bookvol5
i-syscmd.boot move $SYSCOMMANDS to bookvol5
Makefile      wrong Makefile for Xpm fix
makegraph.c   discardGraph free corrected
nci.lisp      move ncloopInclude to bookvol5
setq.lisp     move command initialization to bookvol5

Documentation changes

bookvol5      explain top level input handling (lisp/boot rewrite)
combfunc.spad  fix bold font handling
axiom.sty      add binom

November 23, 2007 Release Notes

Summary: November 2007 release

All of the golden sources are up to date.
savannah.nongnu.org/projects/axiom CVS
sourceforge.net/projects/axiom CVS
arch@axiom-developer.org ARCH (axiom--main--1--patch-54)
git@axiom-developer.org GIT

ADD NEW CREDITS
New patches were posted by Arthur and Alfredo so their tlas were
added to the changelog

20071001 acr Arthur C. Ralfs <arthur@mathbrane.ca>
20070914 jap Jose Alfredo Portes <doyenatccny@gmail.com>

PORT TO DIFFERENT SYSTEMS
As part of the new axiom website there is a binary release page. The stanzas for these supported systems were added.

20071119 tpd Makefile.pamphlet add fedora6,7,8 stanzas

NEW Axiom WEBSITE: http://axiom-developer.org STARTED. The new Axiom website (currently at axiom.axiom-developer.org) has been started. It will include the binary release page.

REMOVE OLD REGRESSION SYSTEM
The previous regression test system was removed. A new combined regression test and help documentation system was built to replace this mechanism.

20070901 tpd src/input/Makefile remove ALGEBRA variable
20070901 tpd src/algebra/perm.spad remove TEST mechanism
20070901 tpd src/algebra/view2d.spad remove TEST mechanism
20070901 tpd src/algebra/fr.spad remove TEST mechanism

FIX BOOK DOCUMENTATION
Minor typos have been discovered in the book during documentation.

20070905 tpd src/doc/book remove duplicate upperCase, lowerCase typo
20070903 tpd src/doc/bookvol4 fix typos
20070902 tpd src/doc/book MultiSet -> Multiset
20080829 tpd src/doc/book.pamphlet correct typo

FIX BUGS
Various bugs have been found and fixed.

20071101 tpd src/interp/i-output.boot fix bugs 7010 (209), 7011
20070920 tpd src/input/Makefile add bug101.input regression test
20070920 tpd src/input/bug101.input test laplace(log(z),z,w) bug 101
20070920 wxh src/algebra/laplace.spad fix laplace(log(z),z,w) bug 101
20070916 tpd src/input/Makefile add bug103.input regression test
20070916 tpd src/input/bug103.input test solve(z^2, z) bug fix
20070916 tpd src/algebra/polycat.spad solve(z^2, z) bug fix
20070916 tpd src/algebra/caten minor edit for regression cleanup
20070914 tpd merge bug100 branch
20070915 tpd src/input/Makefile add bug100.input regression test
20070915 tpd src/input/bug100.input test integrate((z^a+1)^b, z) infinite loop
20070915 wxh src/algebra/intef.spad fix integrate((z^a+1)^b, z) infinite loop
20070915 tpd src/algebra/caten minor edit for regression cleanup
20070914 wxh src/hyper/hyper fix bad bracing of )hd change
20070914 tpd src/algebra/fraction.spad remove double )spool command
20070914 tpd src/algebra/kl.spad remove double )spool command
1.1. RELEASENOTES.HT

20070914 tpd src/algebra/lindspad remove double )spool command
20070914 tpd src/algebra/radix.spad remove double )spool command

ENABLE DYNAMIC RESTART OF HYPERDOC
Hyperdoc can now be started dynamically or restarted if killed.

20070914 jap adapt changes for )hd restart to Axiom sources
20070914 wxh src/sman/bookvol6 enable restart of hyperdoc with )hd
20070914 wxh src/include/sman.h1 enable restart of hyperdoc with )hd
20070914 wxh src/hyper/hyper enable restart of hyperdoc with )hd

SET UP THE NEW FIREFOX BASED HYPERDOC
Hyperdoc is going away. A new version of hyperdoc is being built
which uses html/javascript/mathml. These files change the interpreter
and algebra to support the new hyperdoc machinery.

20071019 acr src/interp/http.lisp use new return values
20071019 acr src/algebra/axserver.spad use new return values
20071014 acr src/algebra/axserver.spad use getContentType(pathvar)
20071013 acr license/license.ralfs license rewrite
20071013 acr src/interp/http.lisp faster page service
20071013 acr src/algebra/axserver.spad faster page service
20071001 tpd src/algebra/exposed.lisp add ([AxiomServer] . AXSERV) to basic
20071001 tpd src/algebra/Makdefile add axserver.spad
20071001 acr src/algebra/axserver.spad axserver socket connection code
20071001 tpd src/interp/Makdefile add http.lisp
20071001 acr src/interp/http.lisp axserver socket connection code
20071001 acr license/license.ralfs added

REGRESSION TEST CALCULUS
A new regression test suite for calculus is being built. The first
of these files has been added to the system.

20070913 tpd src/input/Makdefile schaum1.input added
20070913 tpd src/input/schaum1.input added

REGRESSION TEST ORDINARY DIFFERENTIAL EQUATIONS
A regression test suite for ordinary differential equations was built.

20071005 tpd src/input/Makdefile kamke7.input regression test added
20071005 tpd src/input/kamke7.input ODE regression test added
20071005 tpd src/input/Makdefile kamke6.input regression test added
20071005 tpd src/input/kamke6.input ODE regression test added
20071005 tpd src/input/Makdefile kamke5.input regression test added
20071005 tpd src/input/kamke5.input ODE regression test added
20071005 tpd src/input/Makdefile kamke4.input regression test added
REGRESSION TEST PFAFFIAN
Martin added the pfaffian regression test. It was added and removed due to documentation license issues. New documentation is being written.

ADD PORTIONS OF THE GUESS PACKAGE
The newton.spad file is actually part of the ffgg.spad file so it was removed. The very top level spad functions in GUESS still do not work properly.

FIX BUILD PROCESS
The build process was not properly suppressing output by default.

ADD ALDOR RELEASE
The aldor release has been added to zips. It will soon be part of the build mechanism but separately maintained like GCL.
20070901 tpd zips/aldor.20070901.tgz added

ADD )HELP FACILITY
The )help facility was recovered. The documentation is now integrated into the spad files and used both for help documentation and algebra regression testing.

Feature Complete Release Feb 2005

The February 2005 release is the first complete release of the Axiom system since it was first made available as open source. This release includes the full complement of algebra, the graphics subsystem, and the hyperdoc system.
This full release runs on Linux and Solaris 9. The algebra runs on Windows.
This release includes the full complement of algebra, the graphics subsystem, and the hyperdoc system.

This full release runs on Linux and Solaris 9. The algebra runs on Windows.
Chapter 2

Special hyperdoc pages

2.1 util.ht

This file contains macros for the Axiom HyperDoc hypertext facility. Most of the macros for the system are here though there may be some in individual .ht files that are of a local nature.

Names of software and facilities

--- util.ht ---

\newcommand{\Browse}{Browse}
\newcommand{\Language}{Axiom}
\newcommand{\SpadName}{\Language}
\newcommand{\LangName}{\Language}
\newcommand{\HyperName}{HyperDoc}
\newcommand{\Clef}{Clef}
\newcommand{\Lisp}{Common LISP}
\newcommand{\naglib}{NAG Foundation Library}
\newcommand{\GoBackToWork}
{\vspace{2}\newline
\{Click on \ \UpButton{} \ to go back to what you were doing.\}}

---

Special hooks to Unix

All unix commands should be done as macros defined here so we don’t have to go hunting when moving between Unix versions.
HyperDoc menu macros

% Example:
%
% \beginmenu
% \menulink{Thing One}{PageOne} la da di da da ...
% \menulink{Thin Two}{PageTwo} do da day ...
% \item \ACmdMacro{Thing Three} la di da ...
% \endmenu
%
% The menu environment

\newcommand{\beginmenu} \beginitems[MenuDotBitmap] \endmenu
\newcommand{\endmenu} \enditems

% This is the usual format for a menu item.

\newcommand{\menuitemstyle}[1] {MenuDotBitmap#1}

%% Often-used menu item forms

% These two simply do links
\newcommand{\menudownlink}[2] {\item\downlink{menuitemstyle(#1)}{#2}}
\newcommand{\menuuplink}[2] {\item\uplink{menuitemstyle(#1)}{#2}}

% This will cause lower level links to have a HOME button
\newcommand{\menumemolink}[2] {\item\memolink{menuitemstyle(#1)}{#2}}

% This opens a new window for the linked page.
\newcommand{\menumwindowlink}[2] {\item\windowlink{menuitemstyle(#1)}{#2}}

% These execute lisp commands in various flavors
\newcommand{\menulispcommand}[2]
Bitmaps and bitmap manipulation macros

— util.ht —

\newcommand{\htbmdir}{\env{AXIOM}/doc/bitmaps}
\newcommand{\htbmfile}[1]{\htbmdir /#1.bitmap}
\newcommand{\htbitmap}[1]{\inputbitmap{\htbmfile{#1}}}
\newcommand{\ControlBitmap}[1]{\controlbitmap{\htbmfile{#1}}}

% next group of bitmaps frequently appear in the titlebar
\newcommand{\ContinueBitmap}{\ControlBitmap{continue}}
\newcommand{\DoItBitmap}{\ControlBitmap{doit}}
\newcommand{\ExitBitmap}{\ControlBitmap{exit3d}}
\newcommand{\HelpBitmap}{\ControlBitmap{help3d}}
\newcommand{\ReturnBitmap}{\ControlBitmap{home3d}}
\newcommand{\NoopBitmap}{\ControlBitmap{noop3d}}
\newcommand{\UpBitmap}{\ControlBitmap{up3d}}
\newcommand{\MenuDotBitmap}{\htbitmap{menudot}}

% Including control panel pixmaps for help pages:
\newcommand{\helpbit}[1]{1}
{\centerline{\inputpixmap{\env{AXIOM}/doc/pixmaps/#1}}}

---------
HyperDoc button objects

— util.ht —

\newcommand{\ContinueButton}[1]{\downlink{Click here}{#1} to continue.}
\newcommand{\ExitButton}[1]{\memolink{\ExitBitmap}{#1}}
\newcommand{\HelpButton}[1]{\memolink{\HelpBitmap}{#1}}
\newcommand{\StdHelpButton}{\HelpButton{ugHyperPage}}
\newcommand{\StdExitButton}{\ExitButton{ProtectedQuitPage}}
\newcommand{\UpButton}{\upbutton{UpBitmap}{UpPage}}
\newcommand{\ReturnButton}{\returnbutton{\ReturnBitmap}{ReturnPage}}
\newcommand{\on}[1]{{\inputbox[1]{#1}{\htbmfile{pick}}
\htbmfile{unpick}}}
\newcommand{\off}[1]{{\inputbox[0]{#1}{\htbmfile{pick}}
\htbmfile{unpick}}}

Standard HyperDoc button configurations

— util.ht —

\newcommand{\autobutt}[1]{\helppage{#1}}
\newcommand{\autobuttons}{}
\newcommand{\exitbuttons}{}
\newcommand{\autobuttLayout}[1]{\centerline{#1}}
\newcommand{\autobuttMaker}[1]{\autobuttLayout{\HelpButton{#1}}}
\newcommand{\riddlebuttons}[1]{\autobuttLayout{\link{\HelpBitmap}{#1}}}

% Macro for downward compatibility (?).
\newcommand{\simplebox}[2]{{\inputbox[1][#1][#2]{\htbitmap{xbox}}{\htbitmap{xopenbox}}}}

HyperDoc graphics macros

— util.ht —

% Including viewport bitmaps within \HyperName pages:
2.1. UTIL.HT

% Creating a real live viewport:
\newcommand{\viewportbutton}[2]{\unixcommand{#1}{viewalone #2}}
\newcommand{\axiomViewportbutton}[2]{\unixcommand{#1}{viewalone \$AXIOM/doc/viewports/{#2}}}
\newcommand{\spadviewportbutton}[2]{\axiomViewportbutton{#1}{#2}}

% Making active viewport buttons:
\newcommand{\viewportasbutton}[1]{\unixcommand{\inputimage{{#1}.view/image}}{viewalone {#1}}}
\newcommand{\axiomViewportasbutton}[1]{\unixcommand{\inputimage{\env{AXIOM}/doc/viewports/{#1}.view/image}}{viewalone \$AXIOM/doc/viewports/{#1}}}
\newcommand{\spadviewportasbutton}[1]{\axiomViewportasbutton{#1}}

Axiom – The Scientific Computation System

Axiom is now free and open source software released under the Modified BSD license. For further information visit http://axiom.axiom-developer.org
AXIOM was originally developed by the Research Division of the International Business Machines Corporation, Yorktown Heights, New York, USA.
System Commands

System commands are used to perform Axiom environment management and change Axiom system variables.

- **Commands**  System commands that control your environment.
- **Settings**   Change an Axiom variable.

<= “Root Page” (RootPage) 3.1 on page 117  
=> “Commands” (ugSysCmdPage) 19 on page 2538

The “Settings” link is implemented in lisp.

— rootpage.ht —
System commands are used to perform Axiom environment management and change Axiom system variables.

System commands that control your environment.

Change an Axiom variable.

AssociationList

⇒ “Table” (TableXmpPage) 3.106 on page 1298
⇒ “List” (ListXmpPage) 3.64 on page 866

The \spadtype{AssociationList} constructor provides a general structure for associative storage. This type provides association lists in which data objects can be saved according to keys of any type. For a given association list, specific types must be chosen for the keys and entries. You can think of the representation of an association list as a list of records with key and entry fields.
Association lists are a form of table and so most of the operations available for \spadtype{Table} are also available for \spadtype{AssociationList}. They can also be viewed as lists and can be manipulated accordingly.

\begin{verbatim}
\spad{Data := Record(monthsOld : Integer, gender : String)}
\end{verbatim}

This is a \spadtype{Record} type with age and gender fields.

\begin{verbatim}
\spad{al := AssociationList(String,Data)}
\end{verbatim}

In this expression, \spad{al} is declared to be an association list whose keys are strings and whose entries are the above records.

\begin{verbatim}
\spad{al := table()}
\end{verbatim}

The \spadfunFrom{table}{AssociationList} operation is used to create an empty association list.

\begin{verbatim}
\spad{al."bob" := [407,"male"]}
\end{verbatim}

You can use assignment syntax to add things to the association list.

\begin{verbatim}
\spad{al."judith" := [366,"female"]}
\end{verbatim}

Perhaps we should have included a species field.

\begin{verbatim}
\spad{al."smokie" := [200,"female"]}
\end{verbatim}

Now look at what is in the association list.

\begin{verbatim}
\spad{al}
\end{verbatim}

Note that the last-added \{key, entry\} pair is at the beginning of the list.

\begin{verbatim}
\spad{al."katie" := [23,"female"]}
\end{verbatim}

You can reset the entry for an existing key.

\begin{verbatim}
\spad{al}"katie" := [23,"female"]
\end{verbatim}
Use \spadfunFrom{delete}{AssociationList} to destructively remove an element of the association list.

Use \spadfunFrom{delete}{AssociationList} to return a copy of the association list with the element deleted. The second argument is the index of the element to delete.

\spadpaste{delete!(al,1) \free{al6}\bound{al7}}

For more information about tables, see \downlink{`Table'}{TableXmpPage}\ignore{Table}.

For more information about lists, see \downlink{`List'}{ListXmpPage}\ignore{List}.

3.4 array1.ht

OneDimensionalArray

⇒ “Vector” (VectorXmpPage) 3.114 on page 1351
⇒ “FlexibleArray” (FlexibleArrayXmpPage) 3.39 on page 472

To create a one-dimensional array, apply the operation \spadfun{oneDimensionalArray} to a list.
\spadpaste{oneDimensionalArray [i**2 for i in 1..10]}

Another approach is to first create \spad{a}, a one-dimensional array of 10 \spad{0}'s. \spad{OneDimensionalArray} has the convenient abbreviation \spad{ARRAY1}.
\spadpaste{a : ARRAY1 INT := new(10,0)}

Set each \spad{i}th element to \spad{i}, then display the result.
\spadpaste{a}
3.4. **ARRAY1.HT**

\spadpaste{for i in 1..10 repeat a.i := i; a\bound{a1}\free{a}}

\xtc{
Square each element by mapping the function
\texttt{$i \mapsto i^2$} onto each element.
}\{
\spadpaste{map!(i +-> i ** 2,a); a\bound{a3}\free{a2}}
\}

\xtc{
Reverse the elements in place.
}\{
\spadpaste{reverse! a\bound{a4}\free{a3}}
\}

\xtc{
Swap the \spad{4}th and \spad{5}th element.
}\{
\spadpaste{swap!(a,4,5); a\bound{a5}\free{a4}}
\}

\xtc{
Sort the elements in place.
}\{
\spadpaste{sort! a \bound{a6}\free{a5}}
\}

\xtc{
Create a new one-dimensional array \spad{b} containing the
last 5 elements of \spad{a}.
}\{
\spadpaste{b := a(6..10)\bound{b}\free{a6}}
\}

\xtc{
Replace the first 5 elements of \spad{a} with those of \spad{b}.
}\{
\spadpaste{copyInto!(a,b,1)\free{b}}
\}

TwoDimensionalArray

⇒ “The Any Domain” (ugTypesAnyNonePage) 7 on page 1668
⇒ “Matrix” (MatrixXmpPage) 3.75 on page 984
⇒ “OneDimensionalArray” (OneDimensionalArrayXmpPage) 3.4 on page 138

The \spadtype{TwoDimensionalArray} domain is used for storing data in
a \twodim{} data structure indexed by row and by column. Such an
array is a homogeneous data structure in that all the entries of the
array must belong to the same Axiom domain (although see
\downlink{``The Any Domain''}{ugTypesAnyNonePage} in Section 2.6
\ignore{ugTypesAnyNone}). Each array has a fixed
number of rows and columns specified by the user and arrays are not
extensible. In Axiom, the indexing of two-dimensional arrays is
one-based. This means that both the ‘‘first’’ row of an array and the
‘‘first’’ column of an array are given the index \spad{1}. Thus, the
entry in the upper left corner of an array is in position
\spad{(1,1)}.

The operation \spadfunFrom{new}{TwoDimensionalArray} creates an array
with a specified number of rows and columns and fills the components
of that array with a specified entry. The arguments of this operation
specify the number of rows, the number of columns, and the entry.

This creates a five-by-four array of integers, all of whose entries are
zero.

This creates a five-by-four array of integers, all of whose entries are
zero.

The entries of this array can be set to other integers using
the operation \spadfunFrom{setelt}{TwoDimensionalArray}.
Issue this to set the element in the upper left corner of this array to \spad{17}.

\spadpaste{setelt(arr,1,1,17) \free{arr}\bound{arr1}}
\xtc{
Now the first element of the array is \spad{17}.
}{
\spadpaste{arr \free{arr1}}
}
\xtc{
Likewise, elements of an array are extracted using the operation \spadfunFrom{elt}{TwoDimensionalArray}.
}{
\spadpaste{elt(arr,1,1) \free{arr1}}
}
\xtc{
Another way to use these two operations is as follows. This sets the element in position \spad{(3,2)} of the array to \spad{15}.
}{
\spadpaste{arr(3,2) := 15 \free{arr1}\bound{arr2}}
}
\xtc{
This extracts the element in position \spad{(3,2)} of the array.
}{
\spadpaste{arr(3,2) \free{arr2}}
}

The operations \spadfunFrom{elt}{TwoDimensionalArray} and \spadfunFrom{setelt}{TwoDimensionalArray} come equipped with an error check which verifies that the indices are in the proper ranges. For example, the above array has five rows and four columns, so if you ask for the entry in position \spad{(6,2)} with \spad{arr(6,2)} Axiom displays an error message.

If there is no need for an error check, you can call the operations \spadfunFrom{qelt}{TwoDimensionalArray} and \spadfunFromX{qsetelt}{TwoDimensionalArray} which provide the same functionality but without the error check. Typically, these operations are called in well-tested programs.

\xtc{
The operations \spadfunFrom{row}{TwoDimensionalArray} and \spadfunFrom{column}{TwoDimensionalArray} extract rows and columns, respectively, and return objects of \spadtype{OneDimensionalArray} with the same underlying element type.
}{
\spadpaste{row(arr,1) \free{arr2}}
}
\xtc{
}
\spadpaste{column(arr,1) \free{arr2}}
You can determine the dimensions of an array by calling the operations \texttt{\texttt{\texttt{nrows}}} and \texttt{\texttt{\texttt{ncols}}}, which return the number of rows and columns, respectively.

\begin{verbatim}
\spadpaste{nrows(arr) \free{arr2}}
\end{verbatim}

\begin{verbatim}
\spadpaste{ncols(arr) \free{arr2}}
\end{verbatim}

To apply an operation to every element of an array, use \texttt{\texttt{map}}. This creates a new array. This expression negates every element.

\begin{verbatim}
\spadpaste{map(-,arr) \free{arr2}}
\end{verbatim}

This creates an array where all the elements are doubled.

\begin{verbatim}
\spadpaste{map((x \mapsto x + x),arr) \free{arr2}}
\end{verbatim}

To change the array destructively, use \texttt{\texttt{map!}} instead of \texttt{\texttt{map}}. If you need to make a copy of any array, use \texttt{\texttt{copy}}.

\begin{verbatim}
\spadpaste{arrc := copy(arr) \bound{arrc}\free{arr2}}
\end{verbatim}

\begin{verbatim}
\spadpaste{map!(-,arrc) \free{arrc}}
\end{verbatim}

\begin{verbatim}
\spadpaste{arrc \free{arrc}}
\end{verbatim}

\begin{verbatim}
\spadpaste{arr \free{arr2}}
\end{verbatim}
Use `\spadfunFrom{member?}{TwoDimensionalArray}` to see if a given element is in an array.

```spad
\spadpaste{member?(17,arr) \free{arr2}}
\xtc{
\spadpaste{member?(10317,arr) \free{arr2}}
\xtc{
To see how many times an element appears in an array, use
\spadfunFrom{count}{TwoDimensionalArray}.

```spad
\spadpaste{count(17,arr) \free{arr2}}
\xtc{
\spadpaste{count(0,arr) \free{arr2}}
\xtc{
For more information about the operations available for `TwoDimensionalArray`, issue `\spadcmd{)show TwoDimensionalArray}`.
For information on related topics, see `Matrix` and `OneDimensionalArray`.
```

3.7 **bbtree.ht**

**BalancedBinaryTree**

— bbtree.ht —

\begin{page}{BalancedBinaryTreeXmpPage}{BalancedBinaryTree}
\beginscroll
\spadtype{BalancedBinaryTrees(S)} is the domain of balanced binary trees with elements of type \spad{S} at the nodes. A binary tree is either \spadfun{empty} or else consists of a \spadfun{node} having a \spadfun{value} and two branches, each branch a binary tree. A balanced binary tree is one that is balanced with respect its leaves. One with \texttt{\$2^k\$} leaves is perfectly ‘‘balanced’’: the tree has minimum depth, and the \spadfun{left} and \spadfun{right} branch of every interior node is identical in shape.

Balanced binary trees are useful in algebraic computation for so-called ‘‘divide-and-conquer’’ algorithms. Conceptually, the data for a problem is initially placed at the root of the tree. The original data is then split into two subproblems, one for each subtree. And so on. Eventually, the problem is solved at the leaves
of the tree. A solution to the original problem is obtained by some mechanism that can reassemble the pieces. In fact, an implementation of the Chinese Remainder Algorithm using balanced binary trees was first proposed by David Y. Y. Yun at the IBM T. J. Watson Research Center in Yorktown Heights, New York, in 1978. It served as the prototype for polymorphic algorithms in Axiom.

In what follows, rather than perform a series of computations with a single expression, the expression is reduced modulo a number of integer primes, a computation is done with modular arithmetic for each prime, and the Chinese Remainder Algorithm is used to obtain the answer to the original problem.

We illustrate this principle with the computation of $12^2 = 144$.$12 \times 2 = 144$.

\begin{verbatim}
A list of moduli.
\}
\spadpaste{lm := [3,5,7,11] \bound{lm}}
\}
\xtc{The expression \spad{modTree(n, lm)}
creates a balanced binary tree with leaf values
\spad{n \mod m} for each modulus \spad{m} in \spad{lm}.
\}
\spadpaste{modTree(12,lm) \free{lm}}
\}
\xtc{Operation \spad{modTree} does this using operations on balanced binary trees.
We trace its steps.
Create a balanced binary tree \spad{t} of zeros with four leaves.
\}
\spadpaste{t := balancedBinaryTree(#lm, 0) \bound{t} \free{lm}}
\}
\xtc{The leaves of the tree are set to the individual moduli.
\}
\spadpaste{setleaves!(t, lm) \bound{t1} \free{t}}
\}
\xtc{Use \spad{mapUp} to do a bottom-up traversal of \spad{t}, setting each interior node to the product of the values at the nodes of its children.
\}
\spadpaste{mapUp!(t, *) \bound{t2} \free{t1}}
\}
\xtc{The value at the node of every subtree is the product of the moduli of the leaves of the subtree.
\}
\end{verbatim}
3.7. BBTREE.HT

}\{ 
\spadpaste{t \text{ free}(t2)}
\}

3.8. BINARY.HT

\begin{verbatim}
(10) 144
Type: PositiveInteger
\end{verbatim}

3.8 binary.ht

BinaryExpansion

All rational numbers have repeating binary expansions. Operations to access the individual bits of a binary expansion can be obtained by converting the value to \texttt{RadixExpansion(2)}. More examples of expansions are available in \texttt{DecimalExpansion}, \texttt{HexadecimalExpansion}, and \texttt{RadixExpansion}.

The expansion (of type \texttt{BinaryExpansion}) of a rational number is returned by the \texttt{binary} operation:

- \begin{itemize}
  - \texttt{r := binary(22/7)}
    \texttt{Arithmetic is exact.}
  - \texttt{r + binary(6/7)}
    The period of the expansion can be short or long ...
  - \texttt{binary(1/1007)}
    These numbers are bona fide algebraic objects.
\end{itemize}

\begin{itemize}
  - \texttt{p := binary(1/4) *x**2 + binary(2/3) *x + binary(4/9)}
\end{itemize}
All rational numbers have repeating binary expansions. Operations to access the individual bits of a binary expansion can be obtained by converting the value to \spadtype{RadixExpansion(2)}. More examples of expansions are available in \downlink{`DecimalExpansion'}{DecimalExpansionXmpPage} \ignore{DecimalExpansion}, \downlink{`HexadecimalExpansion'}{HexExpansionXmpPage} \ignore{HexadecimalExpansion}, and \downlink{`RadixExpansion'}{RadixExpansionXmpPage} \ignore{RadixExpansion}.

BasicOperator

A basic operator is an object that can be symbolically applied to a list of arguments from a set, the result being a kernel over that set or an expression. In addition to this section, please see \downlink{`Expression'}{ExpressionXmpPage}\ignore{Expression} and \downlink{`Kernel'}{KernelXmpPage}\ignore{Kernel} for additional information and examples.

You create an object of type \axiomType{BasicOperator} by using the \axiomFunFrom{operator}{BasicOperator} operation. This first form of this operation has one argument and it must be a symbol. The symbol should be quoted in case the name has been used as an identifier to which a value
has been assigned.

A frequent application of \axiomType{BasicOperator} is the creation of an operator to represent the unknown function when solving a differential equation.

Let \axiom{y} be the unknown function in terms of \axiom{x}.

\begin{spad}
\texttt{y := operator 'y \bound{y}}
\end{spad}

This is how you enter the equation \axiom{y'' + y' + y = 0}.

\begin{spad}
\texttt{deq := D(y x, x, 2) + D(y x, x) + y x = 0\bound{e1}\free{y}}
\end{spad}

To solve the above equation, enter this.

\begin{spad}
\texttt{solve(deq, y, x) \free{e1}\free{y}}
\end{spad}

See \downlink{``Solution of Differential Equations''}{ugProblemDEQPage} in Section 8.10\ignore{ugProblemDEQ} for this kind of use of \axiomType{BasicOperator}.

Use the single argument form of \axiomFunFrom{operator}{BasicOperator} (as above) when you intend to use the operator to create functional expressions with an arbitrary number of arguments.

\begin{spad}
\texttt{nary? y \free{y}}
\end{spad}

Use the two-argument form when you want to restrict the number of arguments in the functional expressions created with the operator.

\begin{spad}
\texttt{opOne := operator('opOne, 1) \bound{opOne}}
\end{spad}
You can attached named properties to an operator. These are rarely used at the top-level of the Axiom interactive environment but are used with Axiom library source code.

By default, an operator has no properties.

The interface for setting and getting properties is somewhat awkward because the property values are stored as values of type `axiomType{None}`.

Attach a property by using `axiomFunFrom{setProperty}{BasicOperator}`.

You can also use a string as the name to be tested against.
We know the property value has type \axiomType{String}.

Use \axiomFunFrom{deleteProperty!}{BasicOperator} to destructively remove a property.

Use \axiomFunFrom{deleteProperty!}{BasicOperator} to destructively remove a property.

```
spadpaste{properties y \free{y spy}}
spadpaste{property(y, "use") :: None pretend String \free{y spy}}
deleteProperty!(y, "use") \free{y spy}\bound{dpy}
spadpaste{properties y \free{dpy}}
```

BinarySearchTree

— bstree.ht —

\spadtype{BinarySearchTree(R)} is the domain of binary trees with elements of type \spad{R}, ordered across the nodes of the tree. A non-empty binary search tree has a value of type \spad{R}, and \spadfun{right} and \spadfun{left} binary search subtrees. If a subtree is empty, it is displayed as a period (‘.’).

\xtc{
Define a list of values to be placed across the tree.
The resulting tree has \spad{8} at the root; all other elements are in the left subtree.
A convenient way to create a binary search tree is to apply the operation \texttt{binarySearchTree} to a list of elements.

Another approach is to first create an empty binary search tree of integers.

Insert the value \texttt{8}. This establishes \texttt{8} as the root of the binary search tree. Values inserted later that are less than \texttt{8} get stored in the \texttt{left} subtree, others in the \texttt{right} subtree.

Insert the value \texttt{3}. This number becomes the root of the \texttt{left} subtree of \texttt{t1}.

For optimal retrieval, it is thus important to insert the middle elements first.

The leaves of the binary search tree are those which have empty \texttt{left} and \texttt{right} subtrees.

The operation \texttt{split(k,t)} returns a \texttt{record} containing the two subtrees: one with all elements ‘‘less’’ than \texttt{k}, another with elements ‘‘greater’’ than \texttt{k}.

Define \texttt{insertRoot} to insert new elements by creating a new node.
The new node puts the inserted value between its 'less' tree and 'greater' tree.

\begin{spadsrc}
insertRoot(x, t) ==
  a := split(x, t)
  node(a.less, x, a.greater)
\end{spadsrc}

Function \userfun{buildFromRoot} builds a binary search tree from a list of elements \spad{ls} and the empty tree \spad{emptybst}.

\begin{spadpaste}
buildFromRoot ls == reduce(insertRoot,ls,emptybst)
\end{spadpaste}

Apply this to the reverse of the list \spad{lv}.

\begin{spadpaste}
rt := buildFromRoot reverse lv
\end{spadpaste}

Have Axiom check that these are equal.

\begin{spadpaste}
(t = rt)@Boolean
\end{spadpaste}

\end{verbatim}
The \texttt{CardinalNumber} domain can be used for values indicating the cardinality of sets, both finite and infinite. For example, the \texttt{dimension} operation in the category \texttt{VectorSpace} returns a cardinal number.

The non-negative integers have a natural construction as cardinals:
\[
0 = \#\emptyset, \quad 1 = \{0\}, \quad 2 = \{0, 1\}, \quad \ldots, \quad n = \{i \mid 0 \leq i < n\}.
\]

The fact that \texttt{0} acts as a zero for the multiplication of cardinals is equivalent to the axiom of choice.

Cardinal numbers can be created by conversion from non-negative integers:
\begin{verbatim}
\spadtype{CardinalNumber} c0 := 0 :: CardinalNumber
\spadtype{CardinalNumber} c1 := 1 :: CardinalNumber
\spadtype{CardinalNumber} c2 := 2 :: CardinalNumber
\spadtype{CardinalNumber} c3 := 3 :: CardinalNumber
\end{verbatim}
They can also be obtained as the named cardinal \texttt{Aleph}(n).
\begin{verbatim}
\spad{A0 := Aleph 0}
\end{verbatim}

\begin{page}{CardinalNumberXmpPage}{CardinalNumber}
\beginscroll

CartesianTensor

--- carten.ht ---

\begin{verbatim}
\spadtype{CartesianTensor(i0,dim,R)} provides Cartesian tensors with components belonging to a commutative ring \spad{R}. Tensors can be described as a generalization of vectors and matrices. This gives a concise \textit{tensor algebra} for multilinear objects supported by the \spad{CartesianTensor} domain. You can form the inner or outer product of any two tensors and you can add or subtract tensors with the same number of components. Additionally, various forms of traces and transpositions are useful.

The \spad{CartesianTensor} constructor allows you to specify the minimum index for subscripting. In what follows we discuss in detail how to manipulate tensors.

Here we construct the domain of Cartesian tensors of dimension 2 over the integers, with indices starting at 1.\}{
\spadpaste{CT := CARTEN(i0 := 1, 2, Integer) \bound{CT i0}}}

\subsection*{Forming tensors}

Scalars can be converted to tensors of rank zero.\}{
\spadpaste{t0: CT := 8 \free{CT}\bound{t0}}}
\end{verbatim}
Vectors (mathematical direct products, rather than one dimensional array structures) can be converted to tensors of rank one.

```spad
v: DirectProduct(2, Integer) := directProduct [3,4] 
Tv: CT := v 
```

Matrices can be converted to tensors of rank two.

```spad
m: SquareMatrix(2, Integer) := matrix [[1,2],[4,5]] 
m: SquareMatrix(2, Integer) := matrix [[2,3],[0,1]] 
```

In general, a tensor of rank \(k\) can be formed by making a list of rank \(k-1\) tensors or, alternatively, a \(k\)-deep nested list of lists.

```spad
t1: CT := [2, 3] 
t2: CT := [t1, t1] 
t3: CT := [t2, t2] 
```
3.13. CARTEN.HT

\tt: CT := [t3, t3]; tt := [tt, tt] \free{CT t3}\bound{tt}
\tt{rank tt \free{tt}}

\subsubsection{Multiplication}
%\head{subsection}{Multiplication}{ugxCartenMult}

Given two tensors of rank \spad{k1} and \spad{k2}, the outer
\spadfunFrom{product}{CartesianTensor} forms a new tensor of rank
\spad{k1+k2}.
\tt{Here}
\spad{Tmn(i,j,k,l) = T_m(i,j) \ T_n(k,l).}
\spad{Tmn := product(Tm, Tn)\free{Tm Tn}\bound{Tmn}}

The inner product (\spadfunFrom{contract}{CartesianTensor}) forms a tensor
\spadfunFrom{contract}{CartesianTensor} of rank \spad{k1+k2-2}.
This product generalizes the vector dot product and matrix-vector product
by summing component products along two indices.
\tt{Here we sum along the second index of \spad{Tm} and the
first index of \spad{Tv}.}
\spad{Tmv(i) = sum Tm(i,j) * Tv(j) for j in 1..dim.}
\spad{Tmv := contract(Tm,2,Tv,1)\free{Tm Tv}\bound{Tmv}}

The multiplication operator \spadopFrom{*}{CartesianTensor} is scalar
multiplication or an inner product depending on the ranks of the
arguments.
\tt{If either argument is rank zero it is treated as scalar multiplication.
Otherwise, \spad{a*b} is the inner product summing the last index of
\spad{a} with the first index of \spad{b}.}
\spad{Tm*Tv \free{Tm Tv}}
This definition is consistent with the inner product on matrices and vectors.

\[ T_{mv} = m * v \]

\subsubsection{Selecting Components}
\%\head{subsection}{Selecting Components}{ugxCartenSelect}

\labelSpace{2pc}
\xtc{
For tensors of low rank (that is, four or less), components can be selected by applying the tensor to its indices.
}{
\spadpaste{t0()} \free{t0}}
\xtc{
}{
\spadpaste{t1(1+1)} \free{t1}}
\xtc{
}{
\spadpaste{t2(2,1)} \free{t2}}
\xtc{
}{
\spadpaste{t3(2,1,2)} \free{t3}}
\xtc{
}{
\spadpaste{Tmn(2,1,2,1)} \free{Tmn}}
\xtc{
A general indexing mechanism is provided for a list of indices.
}{
\spadpaste{t0[]} \free{t0}}
\xtc{
}{
\spadpaste{t1[2]} \free{t1}}
\xtc{
}{
\spadpaste{t2[2,1]} \free{t2}}
\xtc{
The general mechanism works for tensors of arbitrary rank, but is somewhat less efficient since the intermediate index list must be created.
}{
}
A “contraction” between two tensors is an inner product, as we have seen above.
You can also contract a pair of indices of a single tensor.
This corresponds to a “trace” in linear algebra.
The expression \( \text{contract}(t, k1, k2) \) forms a new tensor by summing the diagonal given by indices in position \( k1 \) and \( k2 \).
This is the tensor given by
\[
\sum_{k=1}^{\dim} T_{mn}(k,k,i,j).
\]
Since \( T_{mn} \) is the outer product of matrix \( m \) and matrix \( n \), the above is equivalent to this.

\[
\text{trace}(m) \ast n
\]
\spadpaste{contract(Tmn,2,4) = m * transpose(n) \free{Tmn m n}}
}\xtc{
}\spadpaste{contract(Tmn,3,4) = trace(n) * m \free{Tmn m n}}
}

\subsubsection{Transpositions}
%\head{subsection}{Transpositions}{ugxCartenTranspos}

You can exchange any desired pair of indices using the \spadfunFrom{transpose}{CartesianTensor} operation.

\xtc{
Here the indices in positions one and three are exchanged, that is,
\texht{$tT_{mn}(i,j,k,l) = T_{mn}(k,j,i,l).$}{% \spad{tTmn(i,j,k,l) = Tmn(k,j,i,l).}}}
}\spadpaste{tTmn := transpose(Tmn,1,3) \free{tTmn}}
\xtc{
If no indices are specified, the first and last index are exchanged.
}\spadpaste{transpose Tmn \free{Tmn}}
\xtc{
This is consistent with the matrix transpose.
}\spadpaste{transpose Tm = transpose m \free{Tm m}}

If a more complicated reordering of the indices is required, then the \spadfunFrom{reindex}{CartesianTensor} operation can be used. This operation allows the indices to be arbitrarily permuted.
\xtc{
This defines
\texht{$rT_{mn}(i,j,k,l) = T_{mn}(i,l,j,k).$}{% \spad{rTmn(i,j,k,l) = Tmn(i,l,j,k).}}}
}\spadpaste{rTmn := reindex(Tmn, [1,4,2,3]) \free{rTmn}}

\subsubsection{Arithmetic}
%\head{subsection}{Arithmetic}{ugxCartenArith}

\xtc{
Tensors of equal rank can be added or subtracted so arithmetic expressions can be used to produce new tensors.
Two specific tensors have properties which depend only on the dimension.

The Kronecker delta satisfies
\[
\begin{array}{|c|}
\hline
i=j & 1 \\
\hline
i\neq j & 0 \\
\hline
\end{array}
\]

This can be used to reindex via contraction.

The Levi Civita symbol determines the sign of a permutation of indices.
\[
\epsilon(i_1, \ldots, i_{\text{dim}}) = +1 \text{ if } i_1, \ldots, i_{\text{dim}} \text{ is an even permutation of } i_0, \ldots, i_0+\text{dim}-1
\]
= -1 if $i_1, \ldots, i_{\text{dim}}$ is an odd permutation of $i_0, \ldots, i_0+\text{dim}-1$
= 0 if $i_1, \ldots, i_{\text{dim}}$ is not a permutation of $i_0, \ldots, i_0+\text{dim}-1$

This property can be used to form determinants.

\spadpaste{contract(epsilon*Tm*epsilon, 1,2) = 2 * determinant m \free{epsilon Tm m}}

\subsubsection{Properties of the CartesianTensor domain}

\spadtype{GradedModule(R,E)} denotes “\spad{E}-graded \spad{R}-module”,
that is, a collection of \spad{R}-modules indexed by an abelian monoid \spad{E}.

An element \spad{g} of \spad{G[s]} for some specific \spad{s}
in \spad{E} is said to be an element of \spad{G} with
\spadfunFrom{degree}{GradedModule} \spad{s}.

Sums are defined in each module \spad{G[s]} so two elements of
\spad{G} can be added if they have the same degree.

Morphisms can be defined and composed by degree to give the
mathematical category of graded modules.

\spadtype{GradedAlgebra(R,E)} denotes “\spad{E}-graded \spad{R}-algebra.”

A graded algebra is a graded module together with a degree preserving
\spad{R}-bilinear map, called the \spadfunFrom{product}{GradedAlgebra}.

\begin{verbatim}
degree(product(a,b))= degree(a) + degree(b)
product(r*a,b) = product(a,r*b) = r*product(a,b)
product(a1+a2,b) = product(a1,b) + product(a2,b)
product(a,b1+b2) = product(a,b1) + product(a,b2)
product(a,product(b,c)) = product(product(a,b),c)
\end{verbatim}

The domain \spadtype{CartesianTensor(i0, dim, R)} belongs
to the category \spadtype{GradedAlgebra(R, NonNegativeInteger)}.
The non-negative integer \spadfunFrom{degree}{GradedAlgebra} is the tensor rank
and the graded algebra \spadfunFrom{product}{GradedAlgebra} is the tensor outer product.
The graded module addition captures the notion that
only tensors of equal rank can be added.

If \spad{V} is a vector space of dimension \spad{dim} over \spad{R},
then the tensor module \spad{T[k](V)} is defined as
\begin{verbatim}
\[ T[0](V) = R \]
\[ T[k](V) = T[k-1](V) \ast V \]

where \texttt{\spad{*}} denotes the \texttt{\spad{R}}-module tensor
\texttt{\spadfunFrom{product}{GradedAlgebra}}.
\texttt{\spadtype{CartesianTensor(i0,dim,R)}} is the graded algebra in which
the degree \texttt{\spad{k}} module is \texttt{\spad{T[k](V)}}.

\subsubsection{Tensor Calculus}

It should be noted here that often tensors are used in the context of
tensor-valued manifold maps. This leads to the notion of covariant
and contravariant bases with tensor component functions transforming
in specific ways under a change of coordinates on the manifold. This
is no more directly supported by the \texttt{\spad{CartesianTensor}} domain
than it is by the \texttt{\spad{Vector}} domain. However, it is possible
to have the components implicitly represent component maps by choosing
a polynomial or expression type for the components. In this case, it
is up to the user to satisfy any constraints which arise on the basis
of this interpretation.

3.14 cclass.ht

CharacterClass

--- cclass.ht ---

\begin{page}{CharacterClassXmpPage}{CharacterClass}
\beginscroll

The CharacterClass domain allows classes of characters to be defined and manipulated efficiently.

\xtc{Character classes can be created by giving either a string or a list of characters.}
\spadpaste{cl1 := charClass [char "a", char "e", char "i", char "o", char "u", char "y"] \bound{cl1}}
\xtc{}
\spadpaste{cl2 := charClass "bcdfghjklmnpqrstuvwxyz" \bound{cl2}}
\xtc{A number of character classes are predefined for convenience.}
\spadpaste{digit()}\}
\xtc{\}
\spadpaste{hexDigit()}\}
\xtc{\}
\spadpaste{upperCase()}\}
\xtc{\}
\spadpaste{lowerCase()}\}
\xtc{\}
\spadpaste{alphabetic()}\}
\xtc{\}
\spadpaste{alphanumeric()}}
You can quickly test whether a character belongs to a class.
\spadpaste{member?(char "a", cl1) \free{cl1}}
\spadpaste{member?(char "a", cl2) \free{cl2}}

Classes have the usual set operations because the \spadtype{CharacterClass} domain belongs to the category \spadtype{FiniteSetAggregate(Character)}.
\spadpaste{intersect(cl1, c12) \free{cl1 cl2}}
\spadpaste{union(cl1,cl2) \free{cl1 cl2}}
\spadpaste{difference(cl1,cl2) \free{cl1 cl2}}
\spadpaste{intersect(complement(cl1),cl2) \free{cl1 cl2}}

You can modify character classes by adding or removing characters.
\spadpaste{insert!(char "a", cl2) \free{cl2}\bound{cl22}}
\spadpaste{remove!(char "b", cl2) \free{cl22}\bound{cl23}}

For more information on related topics, see \downlink{`Character'}{CharacterXmpPage} and \downlink{`String'}{StringXmpPage}.

The Quaternion Numbers as a Clifford Algebra

⇒ “Quaternion” (QuaternionXmpPage) 3.89 on page 1134

— clif.ht —

This is the field over which we will work, rational functions with integer coefficients.
\spadpaste{K := Fraction Polynomial Integer \free{K}}

We use this matrix for the quadratic form.
\spadpaste{m := matrix [[-1,0],[0,-1]] \free{m}}

The resulting domain is the quaternions.
\spadpaste{H := CliffordAlgebra(2, K, quadraticForm m) \free{K m}}

We use Hamilton’s notation for \spad{i}, \spad{j}, \spad{k}.
\spadpaste{i: H := e(1) \free{H}}
\spadpaste{j: H := e(2) \free{H}}
\spadpaste{k: \( H := i * j \) \( \free{H, i, j} \) \( \bound{k} \) }
\xtc{}
\{\spadpaste{x := a + b * i + c * j + d * k \( \free{i, j, k} \) \( \bound{x} \) }
\xtc{}
\{\spadpaste{y := e + f * i + g * j + h * k \( \free{i, j, k} \) \( \bound{y} \) }
\xtc{}
\{\spadpaste{x + y \( \free{x, y} \) }
\xtc{}
\{\spadpaste{x * y \( \free{x, y} \) }
\xtc{}
See \downlink{`Quaternion'}{QuaternionXmpPage} \ignore{Quaternion} for examples of Axiom's constructor implementing quaternions.

The Exterior Algebra on a Three Space

\begin{page}{ugxCliffordExteriorPage}{The Exterior Algebra on a Three Space}
\begin{scroll}

\labelSpace{4pc}
\xtc{This is the field over which we will work, rational functions with integer coefficients.}
\{\spadpaste{K := Fraction Polynomial Integer \text{\textbackslash bound}{K}}\}
\xtc{\}
\end{scroll}
\end{page}
If we chose the three by three zero quadratic form, we obtain the exterior algebra on $\text{e}(1), \text{e}(2), \text{e}(3)$.

\spad{Ext := CliffordAlgebra(3, K, quadraticForm 0) \free{K}}

This is a three dimensional vector algebra.
We define $\text{i}$, $\text{j}$, $\text{k}$ as the unit vectors.

\spad{i: Ext := e(1) \free{Ext}\bound{i}}
\spad{j: Ext := e(2) \free{Ext}\bound{j}}
\spad{k: Ext := e(3) \free{Ext}\bound{k}}

Now it is possible to do arithmetic.

\spad{x := x1*i + x2*j + x3*k \free{i j k}\bound{x}}
\spad{y := y1*i + y2*j + y3*k \free{i j k}\bound{y}}

On an $\text{spad{n}}$ space, a grade $\text{spad{p}}$ form has a dual $\text{spad{n-p}}$ form. In particular, in three space the dual of a grade two element identifies $\text{e1*e2->e3, e2*e3->e1, e3*e1->e2}$.

\spad{dual2 a == coefficient(a,[2,3]) * i + coefficient(a,[3,1]) * j + coefficient(a,[1,2]) * k \free{i j k}\bound{dual2}}

The vector cross product is then given by this.

\spad{dual2(x*y) \free{x y dual2}}

3.16 complex.ht

Complex

The \spadtype{Complex} constructor implements complex objects over a
commutative ring \spad{R}. Typically, the ring \spad{R} is \spadtype{Integer},
\spadtype{Fraction Integer}, \spadtype{Float} or \spadtype{DoubleFloat}. \spad{R}
can also be a symbolic type, like \spadtype{Polynomial Integer}. For more information
about the numerical and graphical aspects of complex numbers, see "Numeric Functions"
in Section 8.1.

Complex objects are created by the \spad{complex} operation.

\begin{verbatim}
a := complex(4/3,5/2)
b := complex(4/3,-5/2)
\end{verbatim}

The standard arithmetic operations are available.

\begin{verbatim}
a + b
a - b
a * b
\end{verbatim}

If \spad{R} is a field, you can also divide the complex objects.

\begin{verbatim}
a / b
\end{verbatim}

Use a conversion (``Conversion'' in Section 2.7) to view the
last object as a fraction of complex integers.
\spad{b := \text{complex}(4/3,-5/2)}

The standard arithmetic operations are available.

\spad{a + b}

\spad{a - b}

\spad{a * b}

If \spad{R} is a field, you can also divide the complex objects.

\spad{a / b}

Use a conversion \downlink{``Conversion''}{ugTypesConvertPage} in Section 2.7\ignore{ugTypesConvert} to view the last object as a fraction of complex integers.

\spad{\text{\%} :: \text{Fraction Complex Integer}}

The predefined macro \spad{\text{\%i}} is defined to be \spad{\text{\text{complex}(0,1)}}.

\spad{3.4 + 6.7 \times \text{\%i}}

You can also compute the \spad{\text{conjugate}}{Complex} and \spad{\text{norm}}{Complex} of a complex number.

\spad{\text{conjugate a}}

\spad{\text{norm a}}

The \spad{\text{real}}{Complex} and \spad{\text{imag}}{Complex} operations are provided to extract the real and imaginary parts, respectively.

\spad{\text{real a}}
The domain \spadtype{Complex Integer} is also called the Gaussian integers. If \spad{R} is the integers (or, more generally, a \spadtype{EuclideanDomain}), you can compute greatest common divisors.
\spad{gcd(13 - 13\%i,31 + 27\%i)}
You can also compute least common multiples.
\spad{lcm(13 - 13\%i,31 + 27\%i)}
You can \spadfunFrom{factor}{Complex} Gaussian integers.
\spad{factor(13 - 13\%i)}

\spad{factor complex(2,0)}

ContinuedFraction

Continued fractions have been a fascinating and useful tool in mathematics for well over three hundred years. Axiom implements continued fractions for fractions of any Euclidean domain. In practice, this usually means rational numbers. In this section we demonstrate some of the operations available for manipulating both finite and infinite continued fractions. It may be helpful if you review 'Stream' to remind yourself of some of the operations with streams.

The ContinuedFraction domain is a field and therefore you can add, subtract, multiply and divide the fractions. The continuedFraction operation converts its fractional argument to a continued fraction.

\[ \frac{c := \text{continuedFraction}(314159/100000)}{\frac{3 + \frac{1}{7 + \frac{1}{}}}{}{}} \]

This display is a compact form of the bulkier

\[
\frac{3 + \frac{1}{7 + \frac{1}{}}}{}
\]

Continued fractions have been a fascinating and useful tool in mathematics for well over three hundred years. Axiom implements
continued fractions for fractions of any Euclidean domain. In practice, this usually means rational numbers. In this section we demonstrate some of the operations available for manipulating both finite and infinite continued fractions. It may be helpful if you review \downlink{`Stream'}{StreamXmpPage}\ignore{Stream} to remind yourself of some of the operations with streams.

The \spadtype{ContinuedFraction} domain is a field and therefore you can add, subtract, multiply and divide the fractions.

% This display is a compact form of the bulkier
\texht{\narrowDisplay{3 + \frac{1}{7 + \frac{1}{15 + \frac{1}{1 + \frac{1}{25 + \frac{1}{1 + \frac{1}{7 + \frac{1}{4}}}}}}}}}

You can write any rational number in a similar form. The fraction will be finite and you can always take the ''numerators'' to be \spad{1}. That is, any rational number can be written as a simple, finite continued fraction of the form

\texht{a_1 + \frac{1}{\ldots + \frac{1}{a_n}}}

\begin{verbatim}
a(1) + 1

\begin{verbatim}
\end{verbatim}

The \texttt{$a_i$} are called partial quotients and the operation \spadfunFrom{partialQuotients}{ContinuedFraction} creates a stream of them.
\end{verbatim}

By considering more and more of the fraction, you get the \spadfunFrom{convergents}{ContinuedFraction}. For example, the first convergent is \texttt{$a_1$}, the second is \texttt{$a_1 + 1/a_2$} and so on.
\end{verbatim}

Since this is a finite continued fraction, the last convergent is the original rational number, in reduced form. The result of \spadfunFrom{approximants}{ContinuedFraction} is always an infinite stream, though it may just repeat the \texttt{"last"} value.
\end{verbatim}

Inverting \spad{c} only changes the partial quotients of its fraction by inserting a \spad{0} at the beginning of the list.
3.17. CONTFRAC.HT

\spadpaste{pq := partialQuotients(1/c) \free{c}\bound{pq}}
}
\xtc{
Do this to recover the original continued fraction from this list of
partial quotients.
The three-argument form of the
\spadfunFrom{continuedFraction}{ContinuedFraction} operation takes an
element which is the whole part of the fraction, a stream of elements
which are the numerators of the fraction, and a stream of elements which
are the denominators of the fraction.
}
\spadpaste{continuedFraction(first pq,repeating [1],rest pq) \free{pq}}
}
\xtc{
The streams need not be finite for
\spadfunFrom{continuedFraction}{ContinuedFraction}.
Can you guess which irrational number has the following continued
fraction?
See the end of this section for the answer.
}
\spadpaste{z:=continuedFraction(3,repeating [1],repeating [3,6]) \bound{z}}
}
%

In 1737 Euler discovered the infinite continued fraction expansion
\begin{verbatim}
    e - 1  1
----- = ---------------------------------
    2  1 + 1
           6 + 1
                 10 + 1
                     14 + ...
\end{verbatim}

We use this expansion to compute rational and floating point
approximations of \spad{e}.\footnote{For this and other interesting
expansions, see C. D. Olds, \it Continued Fractions,}
134--139.}
By looking at the above expansion, we see that the whole part is \texttt{0} and the numerators are all equal to \texttt{1}. This constructs the stream of denominators.

\begin{verbatim}
\spadpaste{dens:Stream Integer := cons(1,generate((x+-x+4),6))}
\end{verbatim}

Therefore this is the continued fraction expansion for \( (e - 1) / 2 \).

\begin{verbatim}
\spadpaste{cf := continuedFraction(0,repeating [1],dens)}
\end{verbatim}

These are the rational number convergents.

\begin{verbatim}
\spadpaste{ccf := convergents cf} \end{verbatim}

You can get rational convergents for \spad{e} by multiplying by \spad{2} and adding \spad{1}.

\begin{verbatim}
\spadpaste{eConvergents := [2*e + 1 for e in ccf]} \end{verbatim}

You can also compute the floating point approximations to these convergents.

\begin{verbatim}
\spadpaste{eConvergents :: Float} \end{verbatim}

In about 1658, Lord Brouncker established the following expansion for \( 4 / \pi \).

\begin{verbatim}
1 + \frac{1}{2 + \frac{9}{2 + \frac{25}{2 + \frac{49}{2 + \frac{81}{\ddots}}}}} \end{verbatim}
Let's use this expansion to compute rational and floating point approximations for $\pi$.

\begin{verbatim}
1 + 1
-----------------------
2 + 9
-------------------
2 + 25
---------------
2 + 49
-----------
2 + 81
-------
2 + ...
\end{verbatim}

As you can see, the values are converging to $\pi = 3.14159265358979323846...$, but not very quickly.

You need not restrict yourself to continued fractions of integers. Here is an expansion for a quotient of Gaussian integers.

\begin{verbatim}
continuedFraction((-122 + 597*\%i)/(4 - 4*\%i))
\end{verbatim}

This is an expansion for a quotient of polynomials in one variable with rational number coefficients.
\spadpaste{r : Fraction UnivariatePolynomial(x,Fraction Integer)
\bound{rdec}}
}
\xtc{
\spadpaste{r := ((x - 1) * (x - 2)) / ((x-3) * (x-4)) \free{rdec}
\bound{r}}
}
\xtc{
}\{\spadpaste{continuedFraction r \free{r}}
\}

To conclude this section, we give you evidence that
\texht{narrowDisplay{z =\begin{verbatim}3 + 1
-----------------------
3 + 1
-------------------
6 + 1
---------------
3 + 1
-------------
6 + 1
-------
3 + ...
\end{verbatim}}
}
is the expansion of \texht{\sqrt{11}}{the square root of \spad{11}}.\%
\xtc{

3.19 cycles.ht

CycleIndicators

— cycles.ht —
This section is based upon the paper
J. H. Redfield, ‘‘The Theory of Group-Reduced Distributions’’,
and is an application of group theory to enumeration problems.
It is a development of the work by P. A. MacMahon on the

The theory is based upon the power sum symmetric functions
\[ \sum_{i=1}^{n} x_i \]
which are the sum of the \[ x_i \] powers of the variables.
The cycle index of a permutation is an expression that specifies
the sizes of the cycles of a permutation, and
may be represented as a partition.
A partition of a non-negative integer \[ n \] is a collection
of positive integers called its parts whose sum is \[ n \].
For example, the partition
\[ (3^2 \ 2 \ 1^2) \]
will be used to represent
\[ (s_3)^2 s_2 (s_1)^2 \]
and will indicate that the permutation has two cycles of length 3,
one of length 2 and two of length 1.
The cycle index of a permutation group is the sum of the cycle indices
of its permutations divided by the number of permutations.
The cycle indices of certain groups are provided.

We first expose something from the library.
}{
\spadpaste{expose EVALCYC}
}

The operation \spadfun{complete} returns the cycle index of the
symmetric group of order \spad{n} for argument \spad{n}.
Alternatively, it is the \[ n \] complete homogeneous symmetric
function expressed in terms of power sum symmetric functions.
}{
\spadpaste{complete 1}
}{
\spadpaste{complete 2}
}{
\spadpaste{complete 3}
}{
\spadpaste{complete 7}
}
The operation \texttt{elementary} computes the \texttt{elementary symmetric function} for argument \texttt{n.}
\begin{verbatim}
\spad{elementary 7}
\end{verbatim}

The operation \texttt{alternating} returns the cycle index of the alternating group having an even number of even parts in each cycle partition.
\begin{verbatim}
\spad{alternating 7}
\end{verbatim}

The operation \texttt{cyclic} returns the cycle index of the cyclic group.
\begin{verbatim}
\spad{cyclic 7}
\end{verbatim}

The operation \texttt{dihedral} is the cycle index of the dihedral group.
\begin{verbatim}
\spad{dihedral 7}
\end{verbatim}

The operation \texttt{graphs} for argument \texttt{n} returns the cycle index of the group of permutations on the edges of the complete graph with \texttt{n} nodes induced by applying the symmetric group to the nodes.
\begin{verbatim}
\spad{graphs 5}
\end{verbatim}

The cycle index of a direct product of two groups is the product of the cycle indices of the groups. Redfield provided two operations on two cycle indices which will be called \texttt{cup} and \texttt{cap} here. The \texttt{cup} of two cycle indices is a kind of scalar product that combines monomials for permutations with the same cycles. The \texttt{cap} operation provides the sum of the coefficients of the result of the \texttt{cup} operation which will be an integer that enumerates what Redfield called group-reduced distributions.

We can, for example, represent \texttt{complete 2 * complete 2} as the set of objects \texttt{a a b b} and \texttt{complete 2 * complete 1 * complete 1} as \texttt{c c d e.}

This integer is the number of different sets of four pairs.
For example,
\begin{verbatim}
a a b b  a a b b a a b b  
c c d e  c d e c e d  d e c c
\end{verbatim}

This integer is the number of different sets of four pairs no two pairs being equal.

In this case the configurations enumerated are easily constructed, however the theory merely enumerates them providing little help in actually constructing them.

Here are the number of 6-pairs, first from \spad{a a a b b c}, second from \spad{d d e e f g}.

Here it is again, but with no equal pairs.

The number of 6-triples, first from \spad{a a a b b c}, second from \spad{d d e e f g}, third from \spad{h h i i j j}.

The number of 6-triples, first from \spad{a a a b b c}, second from \spad{d d e e f g}, third from \spad{h h i i j j}.
The cycle index of vertices of a square is dihedral 4.
\spadpaste{square:=dihedral 4}
\xtc{
The number of different squares with 2 red vertices and 2 blue vertices.
\spadpaste{cap(complete 2**2,square)}
\xtc{
The number of necklaces with 3 red beads, 2 blue beads and 2 green beads.
\spadpaste{cap(complete 3*complete 2**2,dihedral 7)}
\xtc{
The number of graphs with 5 nodes and 7 edges.
\spadpaste{cap(graphs 5,complete 7*complete 3)}
\xtc{
The cycle index of rotations of vertices of a cube.
\spadpaste{s(x) == powerSum(x)}
\xtc{
\spadpaste{cube:=(1/24)*(s 1**8+9*s 2**4 + 8*s 3**2*s 1**2+6*s 4**2)}
\xtc{
The number of cubes with 4 red vertices and 4 blue vertices.
\spadpaste{cap(complete 4**2,cube)}
\xtc{
The number of labeled graphs with degree sequence \spad{2 2 2 1 1} with no loops or multiple edges.
\spadpaste{cap(complete 2**3*complete 1**2,wreath(elementary 4,elementary 2))}
\xtc{
Again, but with loops allowed but not multiple edges.
\spadpaste{cap(complete 2**3*complete 1**2,wreath(elementary 4,complete 2))}
\xtc{
Again, but with multiple edges allowed, but not loops
Again, but with both multiple edges and loops allowed.

Having constructed a cycle index for a configuration we are at liberty to evaluate the \( s_i \) components any way we please. For example we can produce enumerating generating functions.

This is done by providing a function \( f \) on an integer \( i \) to the value required of \( s_i \), and then evaluating \( \text{eval}(f, \text{cycleindex}) \).

For the integers 0 and 1, or two colors.

For the integers \( 0, 1, 2, \ldots \) we have this.
\texttikz{\text{The coefficient of $x^n$ is the number of graphs with 5 nodes and $n$ edges.}}\{\text{eval(ZeroOrOne, graphs 5) free(zo)}\}\\
\texttikz{The coefficient of $x^n$ is the number of necklaces with $n$ red beads and $n-8$ green beads.} \{\text{eval(ZeroOrOne,dihedral 8) free(zo)}\}\\
\texttikz{The coefficient of $x^n$ is the number of partitions of $n$ into 4 or fewer parts.} \{\text{eval(Integers,complete 4) free(i)}\}\\
\texttikz{The coefficient of $x^n$ is the number of partitions of $n$ into 4 boxes containing ordered distinct parts.} \{\text{eval(Integers,elementary 4) free(i)}\}\\
\texttikz{The coefficient of $x^n$ is the number of different cubes with $n$ red vertices and $8-n$ green ones.} \{\text{eval(ZeroOrOne,cube) free(zo)}\}\\
\texttikz{The coefficient of $x^n$ is the number of different cubes with integers on the vertices whose sum is $n$.} \{\text{eval(Integers,cube) free(i)}\}\\
\texttikz{The coefficient of $x^n$ is the number of graphs with 5 nodes and with integers on the edges whose sum is $n$. In other words, the enumeration is of multigraphs with 5 nodes and $n$ edges.} \{\text{eval(Integers,graphs 5) free(i)}\}\\
\texttikz{Graphs with 15 nodes enumerated with respect to number of edges.}
Necklaces with 7 green beads, 8 white beads, 5 yellow beads and 10 red beads.

The operation \texttt{SFunction} is the S-function or Schur function of a partition written as a descending list of integers expressed in terms of power sum symmetric functions.

In this case the argument partition represents a tableau shape. For example \texttt{[3,2,2,1]} represents a tableau with three boxes in the first row, two boxes in the second and third rows, and one box in the fourth row.

counts the number of different tableaux of shape \texttt{[3, 2, 2, 1]} filled with objects with an ascending order in the columns and a non-descending order in the rows.

This is the number filled with \texttt{[a a b b c c d d].}

The configurations enumerated above are:

\begin{verbatim}
a a b  a a c  a a d 
b c  b b  b b 
c d  c d  c c 
d  d  d 
\end{verbatim}

This is the number of tableaux filled with \texttt{[1..8].}

The coefficient of $x^n$ is the number of column strict reverse plane partitions of \texttt{n} of shape \texttt{[3 2 2 1].}

Decimal Expansion

All rationals have repeating decimal expansions. Operations to access the individual digits of a decimal expansion can be obtained by converting the value to `RadixExpansion(10)`.

More examples of expansions are available in `BinaryExpansion`, `HexadecimalExpansion`, and `RadixExpansion`. Issue the system command `show DecimalExpansion` to display the full list of operations defined by `DecimalExpansion`.

The operation `decimal` is used to create this expansion of type `DecimalExpansion`.

```
r := decimal(22/7)
Arithmetic is exact.
```

The period of the expansion can be short or long...

```
{decimal(1/i) for i in 350..354}
```

or very long.

```
decimal(1/2049)
```

The operation `spadfunFrom(decimal)` is used to create...
this expansion of type \spadtype{DecimalExpansion}.
){
\spadpaste{r := decimal(22/7) \bound{r}}

3.22 derham.ht

DeRhamComplex

--- derham.ht ---

The domain constructor \spadtype{DeRhamComplex} creates the class of differential forms of arbitrary degree over a coefficient ring. The De Rham complex constructor takes two arguments: a ring, \spad{coefRing}, and a list of coordinate variables.

\xtc{}
This is the ring of coefficients.
\{\spadpaste{coefRing := Integer \bound{coefRing}}\}
\xtc{}
These are the coordinate variables.
This is the De Rham complex of Euclidean three-space using coordinates \(x, y\) and \(z\).

This complex allows us to describe differential forms having expressions of integers as coefficients. These coefficients can involve any number of variables, for example, \(f(x,t,r,u,z)\).

As we've chosen to work with ordinary Euclidean three-space, expressions involving these forms are treated as functions of \(x, y\) and \(z\) with the additional arguments \(t, r\) and \(u\) regarded as symbolic constants.

Here are some examples of coefficients.

\[
R := \text{Expression (}\text{coefRing})
\]

\[
f := x^2y^2z - 5x^3y^2z^5
\]

\[
g := z^2y\cos(z) - 7\sin(x^3y^2)z^2
\]

\[
h := xy^2z - 2x^3y^2z^2
\]

We now define the multiplicative basis elements for the exterior algebra over \(R\).

\[
dx := \text{generator(1)}
\]

\[
dy := \text{generator(2)}
\]

\[
dz := \text{generator(3)}
\]
This is an alternative way to give the above assignments.

\begin{verbatim}
\spadpaste{[dx,dy,dz] := [generator(i)\der for i in 1..3] \free{der}
\bound{dxyz}}
\end{verbatim}

Now we define some one-forms.

\begin{verbatim}
\spadpaste{alpha : \der := f*dx + g*dy + h*dz \bound{alpha}
\free{der f g h dxyz}}
\end{verbatim}

\begin{verbatim}
\spadpaste{beta : \der := \cos(tan(x*y*z)+x*y*z)*dx + x*dy
\bound{beta}\free{der f g h dxyz}}
\end{verbatim}

A well-known theorem states that the composition of
\spadfunFrom{exteriorDifferential}{DeRhamComplex}
with itself is the zero map for continuous forms.
Let's verify this theorem for \spad{alpha}.

\begin{verbatim}
\spadpaste{exteriorDifferential alpha; \free{alpha}\bound{ed}}
\end{verbatim}

We suppressed the lengthy output of the last expression, but nevertheless, the
composition is zero.

\begin{verbatim}
\spadpaste{exteriorDifferential \% \free{ed}}
\end{verbatim}

Now we check that \spadfunFrom{exteriorDifferential}{DeRhamComplex}
is a "graded derivation" \spad{D,} that is, \spad{D} satisfies:
\begin{verbatim}
D(a*b) = D(a)*b + (-1)**degree(a)*a*D(b)
\end{verbatim}

\begin{verbatim}
\spadpaste{gamma := alpha * beta \bound{gamma}\free{alpha}\free{beta}}
\end{verbatim}

We try this for the one-forms \spad{alpha} and \spad{beta}.

\begin{verbatim}
\spadpaste{exteriorDifferential(gamma) - (exteriorDifferential(alpha)*beta - alpha * exteriorDifferential(beta)) \free{alpha beta gamma}}
\end{verbatim}
Now we define some "basic operators" (see \downlink{`Operator'}\ignore{OperatorXmpPage}).

\spadpaste{a : BOP := operator('a) \bound{ao}}

\xtc{
\spadpaste{b : BOP := operator('b) \bound{bo}}
}
\xtc{
\spadpaste{c : BOP := operator('c) \bound{co}}
}

We also define some indeterminate one- and two-forms using these operators.

\spadpaste{sigma := a(x,y,z) * dx + b(x,y,z) * dy + c(x,y,z) * dz \bound{sigma}\free{ao bo co dxyz}}

\xtc{
\spadpaste{theta := a(x,y,z) * dx * dy + b(x,y,z) * dx *
dz + c(x,y,z) * dy * dz \bound{theta}\free{ao bo co dxyz}}
}

This allows us to get formal definitions for the "gradient" ... \ldots

\spadpaste{totalDifferential(a(x,y,z))\$der \free{ao der}}

the "curl" ... \ldots

\spadpaste{exteriorDifferential sigma \free{sigma}}

... \ldots

\spadpaste{exteriorDifferential theta \free{theta}}

Note that the De Rham complex is an algebra with unity. This element \spad{1} is the basis for elements for zero-forms, that is, functions in our space.

\spadpaste{one : der := 1 \bound{one}\free{der}}
To convert a function to a function lying in the De Rham complex, multiply the function by "one."

\spadpaste{g1 : der := a([x,t,y,u,v,z,e]) * one \free{der one ao}\bound{g1}}

A current limitation of Axiom forces you to write functions with more than four arguments using square brackets in this way.

\spadpaste{h1 : der := a([x,y,x,t,x,z,y,r,u,x]) * one \free{der one ao}\bound{h1}}

Now note how the system keeps track of where your coordinate functions are located in expressions.

\spadpaste{exteriorDifferential g1 \free{g1}}

\spadpaste{exteriorDifferential h1 \free{h1}}

In this example of Euclidean three-space, the basis for the De Rham complex consists of the eight forms: \spad{1}, \spad{dx}, \spad{dy}, \spad{dz}, \spad{dx*dy}, \spad{dx*dz}, \spad{dy*dz}, and \spad{dx*dy*dz}.

\spadpaste{coefficient(gamma, dx*dy) \free{gamma dxyz}}

\spadpaste{coefficient(gamma, one) \free{gamma one}}

\spadpaste{coefficient(g1,one) \free{g1 one}}

In this example of Euclidean three-space, the basis for the De Rham complex consists of the eight forms: \spad{1}, \spad{dx}, \spad{dy}, \spad{dz}, \spad{dx*dy}, \spad{dx*dz}, \spad{dy*dz}, and \spad{dx*dy*dz}.

\spadpaste{coefficient(gamma, dx*dy) \free{gamma dxyz}}

\spadpaste{coefficient(gamma, one) \free{gamma one}}

\spadpaste{coefficient(g1,one) \free{g1 one}}

Axiom provides two kinds of floating point numbers. The domain \texttt{Float} (abbreviation \texttt{FLOAT}) implements a model of arbitrary precision floating point numbers. The domain \texttt{DoubleFloat} (abbreviation \texttt{DFLOAT}) is intended to make available hardware floating point arithmetic in Axiom. The actual model of floating point \texttt{DoubleFloat} that provides is system-dependent. For example, on the IBM system 370 Axiom uses IBM double precision which has fourteen hexadecimal digits of precision or roughly sixteen decimal digits.

Arbitrary precision floats allow the user to specify the precision at which arithmetic operations are computed. Although this is an attractive facility, it comes at a cost.

The usual arithmetic and elementary functions are available for \texttt{DoubleFloat}. Use \texttt{show DoubleFloat} to get a list of...
Arbitrary-precision floating-point arithmetic typically takes twenty to two hundred times more time than hardware floating point.

The usual arithmetic and elementary functions are available for \spad{DoubleFloat}. Use \spad{)show DoubleFloat} to get a list of operations or the Hyperdoc \Browse{} facility to get more extensive documentation about \spad{DoubleFloat}.

\xtc{
  By default, floating point numbers that you enter into Axiom are of type \spad{Float}.
}{
\spad{2.71828}
}

You must therefore tell Axiom that you want to use \spad{DoubleFloat} values and operations. The following are some conservative guidelines for getting Axiom to use \spad{DoubleFloat}.

\xtc{
  To get a value of type \spad{DoubleFloat}, use a target with \spad{)spadSyntax}, \ldots
}{
\spad{2.71828@DoubleFloat}
}

\xtc{
  a conversion, \ldots
}{
\spad{2.71828 :: DoubleFloat}
}

\xtc{
  or an assignment to a declared variable.
}{
\spad{eApprox : DoubleFloat := 2.71828 \bound{eApprox}}
}

\xtc{
  You also need to declare functions that work with \spad{DoubleFloat}.
}{
\spad{avg : List DoubleFloat -> DoubleFloat \bound{avgDec}}
}

\xtc{
}{
\begin{spadsrc}\begin{verbatim}
bound{avg}free{avgDec}
\end{verbatim}\end{spadsrc}

avg 1 ==
  empty? 1 => 0 :: DoubleFloat
reduce(_+,1) / #1
\end{spadsrc}
}

xtc{
}\spadpaste{avg [] \free{avg}}
}

xtc{
}\spadpaste{avg [3.4,9.7,-6.8] \free{avg}}
}

xtc{Use package-calling for operations from \spadtype{DoubleFloat} unless the arguments themselves are already of type \spadtype{DoubleFloat}.}
}

\spadpaste{cos(3.1415926)\$DoubleFloat}
}

\spadpaste{cos(3.1415926 :: DoubleFloat)}
}

By far, the most common usage of \spadtype{DoubleFloat} is for functions to be graphed.
For more information about Axiom's numerical and graphical facilities, see \downlink{``Graphics''}{ugGraphPage} in Section 7. \ignore{ugGraph}, \downlink{``Numeric Functions''}{ugProblemNumericPage} in Section 8.1\ignore{ugProblemNumeric}, and \downlink{`Float'}{FloatXmpPage}\ignore{Float}.

\begin{page}{DistributedMultivariatePolyXmpPage}
{DistributedMultivariatePoly}
\beginscroll
\texht{
Homo-gen-eous-Dis-tributed-Multi-var-i-ate-Pol-y-nomial
}
\spadtype{DistributedMultivariatePoly} and
\spadtype{HomogeneousDistributedMultivariatePoly}, abbreviated
\spadtype{DMP} and \spadtype{HDMP}, respectively, are very similar to
\spadtype{MultivariatePolynomial} except that they are represented and
displayed in a non-recursive manner.
\xtc{
}(d1,d2,d3) : DMP([z,y,x],FRAC INT) \bound{d1dec d2dec d3dec})
}
\xtc{
The constructor
\spadtype{DMP} orders its monomials lexicographically while
\spadtype{HDMP} orders them by total order refined by reverse
lexicographic order.
}(d1 := -4*z + 4*y**2*x + 16*x**2 + 1 \bound{d1}\free{d1dec})
}
\xtc{
}(d2 := 2*z*y**2 + 4*x + 1 \bound{d2}\free{d2dec})
}
\xtc{
}(d3 := 2*z*x**2 - 2*y**2 - x \bound{d3}\free{d3dec})
}
These constructors are mostly used in \texttt{Gröbner} basis calculations.

\spadpaste{groebner [d1,d2,d3] ree{d1 d2 d3}}

Note that we get a different \texttt{Gröbner} basis when we use the \spadtype{HDMP} polynomials, as expected.

\spadpaste{groebner [n1,n2,n3] ree{n}}

\spadtype{GeneralDistributedMultivariatePoly} is somewhat more flexible in the sense that as well as accepting a list of variables to specify the variable ordering, it also takes a predicate on exponent vectors to specify the term ordering. With this polynomial type the user can experiment with the effect of using completely arbitrary term orderings. This flexibility is mostly important for algorithms such as \texttt{Gröbner} basis calculations which can be very sensitive to term ordering.

For more information on related topics, see \downlink{``Polynomials''}{ugIntroVariablesPage} in Section 1.9\ignore{ugIntroVariables}, \downlink{``Conversion''}{ugTypesConvertPage} in Section 2.7\ignore{ugTypesConvert}, \downlink{`Polynomial'}{PolynomialXmpPage}\ignore{Polynomial}, \downlink{`UnivariatePolynomial'}{UnivariatePolyXmpPage}\ignore{UnivariatePolynomial}, and \downlink{`MultivariatePolynomial'}{MultivariatePolyXmpPage}\ignore{MultivariatePolynomial}.

3.25 eq.ht

Equation

--- eq.ht ---

The \texttt{Equation} domain provides equations as mathematical objects. These are used, for example, as the input to various \texttt{solve} operations.

\begin{verbatim}
\spadcommand{eq1 := 3*x + 4*y = 5 \bound{eq1}}
\spadcommand{eq2 := 2*x + 2*y = 3 \bound{eq2}}
\end{verbatim}

The left- and right-hand sides of an equation are accessible using the operations \texttt{lhs} and \texttt{rhs}.

\begin{verbatim}
\spadcommand{lhs eq1 \free{eq1}}
\spadcommand{rhs eq1 \free{eq1}}
\end{verbatim}
Arithmetic operations are supported and operate on both sides of the equation. 

\spadpaste{eq1 + eq2 \free{eq1 eq2}} 
\xtc{
\spadpaste{eq1 * eq2 \free{eq1 eq2}} 
}\xtc{
\spadpaste{2*eq2 - eq1 \free{eq1 eq2}} 
}\xtc{
Equations may be created for any type so the arithmetic operations will be defined only when they make sense. For example, exponentiation is not defined for equations involving non-square matrices. 
\spadpaste{eq1**2 \free{eq1}} 
}\xtc{
Note that an equals symbol is also used to test for equality of values in certain contexts. For example, \spad{x+1} and \spad{y} are unequal as polynomials. 
\spadpaste{if x+1 = y then "equal" else "unequal"} 
\xtc{
\spadpaste{eqpol := x+1 = y \bound{eqpol}} 
}\xtc{
If an equation is used where a \spad{Boolean} value is required, then it is evaluated using the equality test from the operand type. 
\spadpaste{if eqpol then "equal" else "unequal" \free{eqpol}} 
}\xtc{
If one wants a \spad{Boolean} value rather than an equation, all one has to do is ask! 
\spadpaste{eqpol::Boolean \free{eqpol}}}

3.27 evalex.ht

Example of Standard Evaluation

--- evalex.ht ---

\begin{page}{PrefixEval}{Example of Standard Evaluation}
\beginscroll
We illustrate the general evaluation of \texttt{\em a} for some prefix operator \texttt{\em op} and operand \texttt{\em a} by the example: \texttt{\em \cos(2)}.

The evaluation steps are as follows:

1. \texttt{\em a} evaluates to a value of some type.

2. \texttt{\em op} is chosen based on the type of \texttt{\em a}.

3. If the argument type of the function is different from that of \texttt{\em a},
then the system coerces

\begin{verbatim}
\%\downlink{coerces}{Coercion} \begin{enumerate}
\item \texttt{\em a} to the argument type.
\end{enumerate}
\end{verbatim}

4. The function is then applied to the value of \texttt{\em a} to produce the value

\begin{verbatim}
Try it:
\example{\cos(2)}
\endscroll
\autobuttons
\end{page}
Example of Standard Evaluation

--- evalex.ht ---

We illustrate the general evaluation of $a \ op \ b$ for some infix operator $\ op$ with operands $a$ and $b$ by the example: $2 + 3.4$. The evaluation steps are as follows:

1. $a$ and $b$ are evaluated, each producing a value and a type.
   
   Example: $2$ evaluates to $2$ of type `Integer'; $3.4$ evaluates to $3.4$ of type `Float'.

2. Axiom then chooses a function $\ op$ based on the types of $a$ and $b$.
   
   Example: The function $+: (D,D) \to D$ is chosen requiring a common type $D$ for both arguments to $+$. An operation called $\ resolve$ determines the 'smallest common type' $\ Float$.

3. If the argument types for the function are different from those of $a$ and $b$, then the system coerces $a$ and $b$ to the argument types.
Example: The integer 2 is coerced to the float 2.0.

The function is then applied to the values of a and b to produce the value for a op b.

Example: The function +: (D,D) -> D, where D = spadtype(Float) is applied to 2.0 and 3.4 to produce 5.4.

Try it:

\example{2 + 3.4}

Try it:

\example{2 + 3.4}

---

3.28 exdiff.ht

Computing Derivatives

--- exdiff.ht ---

To compute a derivative, you must specify an expression and a variable of differentiation.

For example, to compute the derivative of sin(x) * exp(x**2) with respect to the variable x, issue the following command:

\spadpaste{differentiate(sin(x) * exp(x**2),x)}
\begin{patch}{ExDiffBasicPatch1}
\begin{paste}{ExDiffBasicFull1}{ExDiffBasicEmpty1}
\pastebutton{ExDiffBasicFull1}{\hidepaste}
\indentrel{3}\begin{verbatim}
2 2
x x
(1) 2x %e sin(x) + cos(x)%e
\end{verbatim}
\indentrel{-3}\end{paste}\end{patch}

\begin{patch}{ExDiffBasicEmpty1}
\begin{paste}{ExDiffBasicEmpty1}{ExDiffBasicPatch1}
\pastebutton{ExDiffBasicEmpty1}{\showpaste}
\indentrel{3}\spadcommand{differentiate(sin(x) * exp(x**2),x)}
\end{paste}\end{patch}

Derivatives of Functions of Several Variables

\begin{page}{ExDiffSeveralVariables}
{Derivatives of Functions of Several Variables}
\beginscroll
Partial derivatives are computed in the same way as derivatives of functions of one variable: you specify the function and a variable of differentiation. For example:
\spadpaste{differentiate(sin(x) * tan(y)/(x**2 + y**2),x)}
\spadpaste{differentiate(sin(x) * tan(y)/(x**2 + y**2),y)}
\endscroll
\autobuttons
\end{page}

\begin{patch}{ExDiffSeveralVariablesPatch1}
\begin{paste}{ExDiffSeveralVariablesFull1}{ExDiffSeveralVariablesEmpty1}
\pastebutton{ExDiffSeveralVariablesFull1}{\hidepaste}
\indentrel{3}\spadcommand{differentiate(sin(x) * tan(y)/(x**2 + y**2),x)}
\indentrel{-3}\end{paste}\end{patch}
(1) \[ y + 2x y + x \]

\text{Type: Expression Integer}

\begin{verbatim}
(2) 2 2 2
2 2
(y + x )\sin(x)\tan(y) - 2y \sin(x)\tan(y)
+ 
2 2
(y + x )\sin(x)
/ 
4 2 2 4
y + 2x y + x
\end{verbatim}

\text{Type: Expression Integer}

---

### Derivatives of Higher Order

To compute a derivative of higher order (e.g. a second or third derivative), pass the order as the third argument of the function 'differentiate'.

---

---
For example, to compute the fourth derivative of $\exp(x^2)$, issue the following command:
\spadpaste{differentiate(exp(x**2),x,4)}
\endscroll
\autobuttons
\end{page}

\begin{patch}{ExDiffHigherOrderPatch1}
\begin{paste}{ExDiffHigherOrderFull1}{ExDiffHigherOrderEmpty1}
\pastebutton{ExDiffHigherOrderFull1}{\hidepaste}
\tab{5}\spadcommand{differentiate(exp(x**2),x,4)}
\indentrel{3}\begin{verbatim}
2
4 2 x
(1) (16x + 48x + 12)\%e
\end{verbatim}
\indentrel{-3}\end{paste}\end{patch}

\begin{patch}{ExDiffHigherOrderEmpty1}
\begin{paste}{ExDiffHigherOrderEmpty1}{ExDiffHigherOrderPatch1}
\pastebutton{ExDiffHigherOrderEmpty1}{\showpaste}
\tab{5}\spadcommand{differentiate(exp(x**2),x,4)}\end{paste}\end{patch}

---

Multiple Derivatives I

— exdiff.ht —

\begin{page}{ExDiffMultipleI}{Multiple Derivatives I}
\beginscroll
When given a function of several variables, you may take derivatives repeatedly and with respect to different variables. The following command differentiates the function $\sin(x)/(x^2 + y^2)$ first with respect to $x$ and then with respect to $y$:
\spadpaste{differentiate(sin(x)/(x**2 + y**2),[x,y])}
As you can see, we first specify the function and then a list of the variables of differentiation. Variables may appear on the list more than once. For example, the following command differentiates the same function with respect to $x$ and then twice with respect to $y$:
\spadpaste{differentiate(sin(x)/(x**2 + y**2),[x,y,y])}
\endscroll
\autobuttons
\begin{patch}{ExDiffMultipleIPatch1}
\begin{paste}{ExDiffMultipleIFull1}{ExDiffMultipleIEmpty1}

Multiple Derivatives II

You may also compute multiple derivatives by specifying a list of variables together with a list of multiplicities. For example, to differentiate \( \cos(z)/(x^2 + y^3) \) first with respect to \( x \), then twice with respect to \( y \), then three times with respect to \( z \), issue the following command:

\[
\text{differentiate}(\cos(z)/(x^2 + y^3), [x,y,z],[1,2,3])
\]

Derivatives of Functions Involving Formal Integrals
When a function does not have a closed-form antiderivative, Axiom returns a formal integral. A typical example is

\begin{spad}
f := \int \sqrt{1 + t^3} \, dt\end{spad}

This formal integral may be differentiated, either by itself or in any combination with other functions:

\begin{spad}
differentiate(f, t)\end{spad}

\begin{spad}
differentiate(f * t^2, t)\end{spad}

}\end{scroll}

\begin{spad}
t^3
\int \\frac{1}{\sqrt{1 + t^3}} \, dt
\text{Type: Union(Expression Integer,...)}
\end{spad}

(1) \, \frac{1}{2} \ln |1 + \sqrt{2}t^3| + 1 \, dt

\begin{spad}
differentiate(f, t)
\text{Type: Expression Integer}
\end{spad}

(2) \, t + 1

\begin{spad}
differentiate(f, t)
\text{Type: Expression Integer}
\end{spad}
Exit

--- exit.ht ---

A function that does not return directly to its caller has \spadtype{Exit} as its return type.
The operation \spadfun{error} is an example of one which does not return to its caller.
Instead, it causes a return to top-level.

\begin{spadsrc}
  gasp(): Exit ==
  \begin{verbatim}
  free n
  n := n + 1
  error "Oh no!"
  \end{verbatim}
\end{spadsrc}
The return type of \spadfun{half} is determined by resolving the types of the two branches of the \spad{if}.

\begin{spadsrc}
\begin{verbatim}
half(k) ==
  if odd? k then gasp()
  else k quo 2
\end{verbatim}
\end{spadsrc}

Because \spadfun{gasp} has the return type \spadtype{Exit}, the type of \spad{if} in \spadfun{half} is resolved to be \spadtype{Integer}.

\begin{spadpaste}
\spad{half 4}
\end{spadpaste}

\begin{spadpaste}
\spad{half 3}
\end{spadpaste}

For functions which return no value at all, use \spadtype{Void}. See \downlink{``User-Defined Functions, Macros and Rules''}{ugUserPage} in Section 6 and \downlink{`Void'}{VoidXmpPage} for more information.

Integral of a Rational Function with a Real Parameter

When real parameters are present, the form of the integral can depend on the signs of some expressions. Rather than query the user or make sign assumptions, Axiom returns all possible answers.

\begin{verbatim}
  integrate(1/(x**2 + a),x)
\end{verbatim}

The integrate command generally assumes that all parameters are real.

\begin{verbatim}
  \(\begin{array}{l}
  \frac{2}{a} - \frac{a}{x} + 2a x \\
    \log(x) + \frac{2}{a} \tan^{-1}\left(\frac{x + a}{\sqrt{-a}}\right)
\end{array}\)
\end{verbatim}

Type: Union(List Expression Integer,...)
Integral of a Rational Function with a Complex Parameter

If the parameter is complex instead of real, then the notion of sign is undefined and there is a unique answer. You can request this answer by prepending the word ‘complex’ to the command name:

\spadpaste{complexIntegrate(1/(x**2 + a),x)}

\vspace*{10pt}

Two Similar Integrands Producing Very Different Results
The following two examples illustrate the limitations of table based approaches. The two integrands are very similar, but the answer to one of them requires the addition of two new algebraic numbers. This one is the easy one:
\begin{verbatim}
integrate(x**3 / (a+b*x)**(1/3),x)
\end{verbatim}

The next one looks very similar but the answer is much more complicated. Only an algorithmic approach is guaranteed to find what new constants must be added in order to find a solution:
\begin{verbatim}
integrate(1 / (x**3 * (a+b*x)**(1/3)),x)
\end{verbatim}

\begin{verbatim}
(1)
(120b x - 135a b x + 162a b x - 243a )b x + a
4
440b
Type: Union(Expression Integer,...)
\end{verbatim}

\begin{verbatim}
(2)
2 2
2b x \3
*
332 32 3
log(\a \b x + a + \a \b x + a + a)
+
\end{verbatim}
An Integral Which Does Not Exist

Most computer algebra systems use heuristics or table-driven approaches to integration. When these systems cannot determine the answer to an integration problem, they reply "I don’t know". Axiom uses a complete algorithm for integration. It will conclusively prove that an integral cannot be expressed in terms of elementary functions. When Axiom returns an integral sign, it has proved that no answer exists as an elementary function.

```
integrate(log(1 + sqrt(a*x + b)) / x, x)
```

— exint.ht —

Details for integrating a function with a Hidden Algebraic Relation

--- exint.ht ---

Steps taken for integration of:
\begin{verbatim}
\em f := \tan(\atan(x)/3))
\end{verbatim}
\begin{itemize}
\item 1. Replace \em f by an equivalent algebraic function \em g
satisfying the algebraic relation:
\begin{verbatim}
\em g**3 - 3*x*g - 3*g + x = 0
\end{verbatim}
\item 2. Integrate \em g using using this algebraic relation; this produces:
\begin{verbatim}
(24g**2 - 8)log(3g**2 - 1) + (81x**2 + 24)g**2 + 72xg - 27x**2 - 16
/ (54g**2 - 18)
\end{verbatim}
\item 3. Rationalize the denominator, producing:
\begin{verbatim}
(8log(3g**2-1) - 3g**2 + 18xg + 15)/18
\end{verbatim}
\item 4. Replace \em g by the initial \em f to produce the final result:
\begin{verbatim}
(8log(3tan(atan(x/3))**2-1) - 3tan(atan(x/3))**2 - 
\end{verbatim}

3.31  exlimit.ht

Computing Limits

⇒ “notitle” (ExLimitTwoSided) 3.31 on page 420
⇒ “notitle” (ExLimitOneSided) 3.31 on page 419
--- exlimit.ht ---

\begin{page}{ExLimitBasic}{Computing Limits}
To compute a limit, you must specify a functional expression, a variable, and a limiting value for that variable. For example, to compute the limit of \((x^2 - 3x + 2)/(x^2 - 1)\) as \(x\) approaches 1, issue the following command:

\[
\text{limit}((x^2 - 3x + 2)/(x^2 - 1), x = 1)
\]

\% answer := -1/2

Since you have not specified a direction, Axiom will attempt to compute a two-sided limit. Sometimes the limit when approached from the left is different from the limit from the right.

\[
\text{limit}((x^2 - 3x + 2)/(x^2 - 1), x = 1)
\]

\% answer := -1/2

Limits of Functions with Parameters

You may also take limits of functions with parameters. The limit will be expressed in terms of those parameters. Here’s an example:

\[
\text{limit}((x^2 - 3x + 2)/(x^2 - 1), x = 1)
\]
3.31. EXLIMIT.HT

One-sided Limits

-- exlimit.ht --

\begin{page}{ExLimitOneSided}{One-sided Limits}
\beginscroll

If you have a function which is only defined on one side of a particular value, you may wish to compute a one-sided limit. For instance, the function \spad{\log(x)} is only defined to the right of zero, i.e. for \spad{x > 0}.

Thus, when computing limits of functions involving \spad{\log(x)}, you probably will want a 'right-hand' limit.

Here's an example:
\spadpaste{limit(x * \log(x),x = 0,"right")}

% answer := 0

When you do not specify \spad{right} or \spad{left} as an optional fourth argument, the function \spadfun{limit} will try to compute a two-sided limit.

In the above case, the limit from the left does not exist, as Axiom will indicate when you try to take a two-sided limit:
\spadpaste{limit(x * \log(x),x = 0)}

% answer := [left = "failed",right = 0]
\endscroll
Two-sided Limits

--- exlimit.ht ---

A function may be defined on both sides of a particular value, but will
tend to different limits as its variable tends to that value from the
left and from the right.

We can construct an example of this as follows:
Since $\sqrt{y^2}$ is simply the absolute value of $y$, the function $\sqrt{y^2}/y$ is simply the sign (+1 or -1) of the real number $y$. Therefore, $\sqrt{y^2}/y = -1$ for $y < 0$ and $\sqrt{y^2}/y = +1$ for $y > 0$.

Watch what happens when we take the limit at $y = 0$.

```
limit(sqrt(y**2)/y,y = 0)
```

% answer := [left = -1, right = 1]

The answer returned by Axiom gives both a 'left-hand' and a 'right-hand' limit.

Here's another example, this time using a more complicated function:

```
limit(sqrt(1 - cos(t))/t,t = 0)
```

% answer := [left = -sqrt(1/2), right = sqrt(1/2)]

[endscroll]

Real Limits vs. Complex Limits

--- exlimit.ht ---

\begin{page}{ExLimitRealComplex}{Real Limits vs. Complex Limits}
\beginscroll
When you use the function \spadfun{limit}, you will be taking the limit of a real function of a real variable.
For example, you can compute
\spadpaste{limit(z * sin(1/z),z = 0)}
Axiom returns \spad{0} because as a function of a real variable
\spad{sin(1/z)} is always between \spad{-1} and \spad{1}, so \spad{z * sin(1/z)}
tends to \spad{0} as \spad{z} tends to \spad{0}.
However, as a function of a complex variable, \spad{sin(1/z)} is badly behaved around \spad{0}.
(one says that \spad{sin(1/z)} has an 'essential singularity' at \spad{z = 0}).
When viewed as a function of a complex variable, \spad{z * sin(1/z)}
does not approach any limit as \spad{z} tends to \spad{0} in the complex plane.
Axiom indicates this when we call the function \spadfun{complexLimit}:
\spadpaste{complexLimit(z * sin(1/z),z = 0)}

Complex Limits at Infinity

— exlimit.ht —

\begin{page}{ExLimitComplexInfinite}{Complex Limits at Infinity}
\beginscroll
You may also take complex limits at infinity, i.e. limits of a function of \spad{z} as \spad{z} approaches infinity on the Riemann sphere. Use the symbol \spad{\%infinity} to denote 'complex infinity'. Also, to compute complex limits rather than real limits, use the function \spadfun{complexLimit}. Here is an example:
\spadpaste{complexLimit((2 + z)/(1 - z),z = \%infinity)}
In many cases, a limit of a real function of a real variable will exist when the corresponding complex limit does not.
For example:
\spadpaste{limit(sin(x)/x,x = \%plusInfinity)}
\spadpaste{complexLimit(sin(x)/x,x = \%infinity)}

Basic Arithmetic Operations on Matrices

--- exmatrix.ht ---

\begin{page}{ExMatrixBasicFunction}
{Basic Arithmetic Operations on Matrices}
\beginscroll
You can create a matrix using the function \spadfun{matrix}. The function takes a list of lists of elements of the ring and produces a matrix whose \spad{i}th row contains the elements of the \spad{i}th list. For example:
\spadpaste{m1 := matrix([[1,-2,1],[4,2,-4]]) \bound{m1}}
\spadpaste{m2 := matrix([[1,0,2],[20,30,10],[0,200,100]]) \bound{m2}}
\spadpaste{m3 := matrix([[1,2,3],[2,4,6]]) \bound{m3}}
Some of the basic arithmetic operations on matrices are:
\spadpaste{m1 + m3 \free{m1} \free{m3}}
\spadpaste{100 * m1 \free{m1}}
\spadpaste{m1 * m2 \free{m1} \free{m2}}
\spadpaste{-m1 + m3 * m2 \free{m1} \free{m2} \free{m3}}
You can also multiply a matrix and a vector provided that the matrix and vector have compatible dimensions.
\spadpaste{m3 *vector([1,0,1]) \free{m3}}
However, the dimensions of the matrices must be compatible in order for Axiom to perform an operation - otherwise an error message will occur.

3.32. **EXMATRIX.HT**

Constructing new Matrices

---

**exmatrix.ht**

A number of functions exist for constructing new matrices from existing ones.

If you want to create a matrix whose entries are 0 except on the main diagonal you can use \spadfun{diagonalMatrix}. This function takes a list of ring elements as an argument and returns a square matrix which has these elements on the main diagonal.

Consider the following example:

\spadpaste{diagonalMatrix([1,2,3,2,1])}

The function \spadfun{subMatrix}\(\{\text{a},\text{j},\text{k},\text{l}\}\) constructs a new matrix consisting of rows \text{a} through \text{j} and columns \text{k} through \text{l}. 

---
The function \spadfunX{setsubMatrix} returns the submatrix of \spad{a} starting at row \spad{i} and column \spad{k} with the elements of the matrix \spad{b}.

\spad{b:=matrix([[0,1,2,3,4],[5,6,7,8,9],[10,11,12,13,14]]) \free{b}} changes the submatrix of \spad{b} consisting of the first 3 rows and columns to its transpose.

Rank of a Matrix

--- exmatrix.ht ---

The function \texttt{rank} gives you the rank of a matrix:

\spadpaste{rank(matrix([[0,4,1],[5,3,-7],[-5,5,9]]))}

(1) 2
Type: PositiveInteger
3.33 expr.ht

Expression

\begin{page}{ExpressionXmpPage}{Expression}
\beginscroll
\axiomType{Expression} is a constructor that creates domains whose objects can have very general symbolic forms. Here are some examples:
\xtc{
This is an object of type \axiomType{Expression Integer}. 
}\spadpaste{\sin(x) + 3*\cos(x)**2}
\xtc{
This is an object of type \axiomType{Expression Float}. 
}\spadpaste{\tan(x) - 3.45*x}
\xtc{
This object contains symbolic function applications, sums, products, square roots, and a quotient. 
}\spadpaste{((\tan \sqrt{7} - \sin \sqrt{11})**2 / (4 - \cos(x - y)))}
As you can see, \axiomType{Expression} actually takes an argument domain.
The \{it coefficients\} of the terms within the expression belong to the argument domain. \axiomType{Integer} and \axiomType{Float}, along with \axiomType{Complex Integer} and \axiomType{Complex Float} are the most common coefficient domains.
\xtc{
The choice of whether
3.33. **EXPR.HT**

... which are not valid on complex ones.

Many potential coefficient domains, such as \(\textbf{AlgebraicNumber}\), are not usually used because \(\textbf{Expression}\) can subsume them.

Note that we sometimes talk about ‘‘an object of type \(\textbf{Expression}\).’’ This is not really correct because we should say, for example, ‘‘an object of type \(\textbf{Expression\ Integer}\)’’ or ‘‘an object of type \(\textbf{Expression\ Float}\).’’

By a similar abuse of language, when we refer to an ‘‘expression’’ in this section we will mean an object of type \(\textbf{Expression\ R}\) for some domain \(\textbf{R}\).

The Axiom documentation contains many examples of the use of \(\textbf{Expression}\).

For the rest of this section, we’ll give you some pointers to those examples plus give you some idea of how to manipulate expressions.

It is important for you to know that \(\textbf{Expression}\) creates domains that have category \(\textbf{Field}\). Thus you can invert any non-zero expression and you shouldn’t expect an operation like \(\textbf{factor}\) to give you much information.

You can imagine expressions as being represented as quotients of ‘‘multivariate’’ polynomials where the ‘‘variables’’ are kernels (see \texttt{Kernel\ XmpPage}\).

A kernel can either be a symbol such as \(\textbf{x}\) or a symbolic function application like \(\textbf{sin(x + 4)}\).

The second example is actually a nested kernel since the argument to \(\textbf{sin}\) contains the kernel \(\textbf{x}\).
Actually, the argument to \axiomFun{sin} is an expression, and so the structure of \axiomType{Expression} is recursive. \downlink{'Kernel'}{KernelXmpPage}\ignore{Kernel} demonstrates how to extract the kernels in an expression.

Use the Hyperdoc Browse facility to see what operations are applicable to expression. At the time of this writing, there were 262 operations with 147 distinct name in \axiomType{Expression Integer}. For example, \axiomFunFrom{numer}{Expression} and \axiomFunFrom{denom}{Expression} extract the numerator and denominator of an expression.

\xtc{
}\spadpaste{e := (\sin(x) - 4)**2 / ( 1 - 2*y*sqrt(- y) ) \bound{e}}
}
\xtc{
}\spadpaste{numer e \free{e}}
}
\xtc{
}\spadpaste{denom e \free{e}}
}
\xtc{Use \axiomFunFrom{D}{Expression} to compute partial derivatives.
}{
}\spadpaste{D(e, x) \free{e}}
}
\xtc{See \downlink{``Derivatives''}{ugIntroCalcDerivPage} in Section 1.12 \ignore{ugIntroCalcDeriv} for more examples of expressions and derivatives.
}{
}\spadpaste{D(e, [x, y], [1, 2]) \free{e}}
}

See \downlink{``Limits''}{ugIntroCalcLimitsPage} in Section 1.10\ignore{ugIntroCalcLimits} and \downlink{``Series''}{ugIntroSeriesPage} in Section 1.11 \ignore{ugIntroSeries} for more examples of expressions and calculus. Differential equations involving expressions are discussed in \downlink{''Solution of Differential Equations''}{ugProblemDEQPage} in Section 8.10\ignore{ugProblemDEQ}. Chapter 8 has many advanced examples: see \downlink{``Integration''}{ugProblemIntegrationPage} in Section 8.8\ignore{ugProblemIntegration} for a discussion of Axiom's integration facilities.
When an expression involves no "symbol kernels" (for example, \texttt{axiom(x)}), it may be possible to numerically evaluate the expression.

\texttt{axiomFun}\{complexNumeric\}.

\texttt{spadpaste}\{complexNumeric(cos(2 - 3*\%i))\}

If you know it will be real, use \texttt{axiomFun}\{numeric\}.

\texttt{spadpaste}\{numeric(tan 3.8)\}

The \texttt{axiomFun}\{numeric\} operation will display an error message if the evaluation yields a value with a non-zero imaginary part. Both of these operations have an optional second argument \texttt{axiom(n)} which specifies that the accuracy of the approximation be up to \texttt{axiom(n)} decimal places.

When an expression involves no "symbolic application" kernels, it may be possible to convert it to a polynomial or rational function in the variables that are present.

\texttt{spadpaste}\{e2 := cos(x**2 - y + 3) \texttt{\bound{e2}}\}

\texttt{spadpaste}\{e3 := asin(e2) - \%pi/2 \texttt{\free{e2}\bound{e3}}\}

\texttt{spadpaste}\{e3 :: Polynomial Integer \texttt{\free{e3}}\}

This also works for the polynomial types where specific variables and their ordering are given.

\texttt{spadpaste}\{e3 :: DMP([x, y], Integer) \texttt{\free{e3}}\}

Finally, a certain amount of simplification takes place as expressions are constructed.

\texttt{spadpaste}\{sin \%pi\}

\texttt{spadpaste}
For simplications that involve multiple terms of the expression, use \axiomFun{simplify}.

\spadpaste{\tan(x)**6 + 3*\tan(x)**4 + 3*\tan(x)**2 + 1 \bound{tan6}}

See \downlink{``Rules and Pattern Matching''}{ugUserRulesPage} in Section 6.21\ignore{ugUserRules} for examples of how to write your own rewrite rules for expressions.

Plotting Functions of One Variable

To plot a function \( y = f(x) \), you need only specify the function and the interval on which it is to be plotted.

\begin{verbatim}
\graphpaste{draw(sin(tan(x)) - tan(sin(x)),x = 0..6)}
\end{verbatim}

Plotting Parametric Curves

To plot a parametric curve defined by \( x = f(t) \), \( y = g(t) \), specify the functions \( f(t) \) and \( g(t) \) as arguments of the function `curve`, then give the interval over which \( t \) is to range.

\begin{verbatim}
\graphpaste{draw(curve(9 * sin(3*t/4),8 * sin(t)),t = -4*\%pi..4*\%pi)}
\end{verbatim}
Plotting Using Polar Coordinates

— explot2d.ht —

To plot the function \( r = f(\theta) \) in polar coordinates, use the option \( \texttt{coordinates == polar} \). As usual, call the function 'draw' and specify the function \( f(\theta) \) and the interval over which \( \theta \) is to range.

\begin{spadgraph}
\texttt{draw(sin(4*t/7),t = 0..14*\%pi,coordinates == polar)}
\end{spadgraph}
3.35. EXPL0T3D.HT

Plotting Plane Algebraic Curves

--- explot2d.ht ---

\begin{page}{ExPlot2DAlgebraic}{Plotting Plane Algebraic Curves}
\beginscroll
Axiom can also plot plane algebraic curves (i.e. curves defined by an equation \emph{f(x,y) = 0}) provided that the curve is non-singular in the region to be sketched. Here's an example:
\graphpaste{draw(y**2 + y - (x**3 - x) = 0, x, y, range == [-2..2,-2..1])}
Here the region of the sketch is \{\em \(-2 \leq x \leq 2, -2 \leq y \leq 1\)\}.

3.35 exp0t3d.ht

Plotting Functions of Two Variables

--- explot3d.ht ---

\begin{page}{ExPlot3DFunctions}{Plotting Functions of Two Variables}
\beginscroll
To plot a function \emph{z = f(x,y)}, you need only specify the function and the intervals over which the dependent variables will range.
\end{scroll}
\autobuttons
\end{page}
For example, here's how you plot the function $z = \cos(x \cdot y)$ as the variables $x$ and $y$ both range between -3 and 3:

\graphpaste{draw(cos(x*y),x = -3..3,y = -3..3)}
\endscroll
\autobuttons
\end{page}

Plotting Parametric Surfaces

— explot3d.ht —

\begin{page}{ExPlot3DParametricSurface}{Plotting Parametric Surfaces}
\beginscroll
To plot a parametric surface defined by $x = f(u,v)$, $y = g(u,v)$, and $z = h(u,v)$ as arguments of the function `surface', then give the intervals over which $u$ and $v$ are to range. With parametric surfaces, we can create some interesting graphs. Here's an egg:
\graphpaste{draw(surface(5*sin(u)*cos(v),4*sin(u)*sin(v),3*cos(u)), u=0..\%pi,v=0..2*\%pi)}
Here's a cone:
\graphpaste{draw(surface(u*cos(v),u*sin(v),u),u=0..4,v=0..2*\%pi)}
\endscroll
\autobuttons
\end{page}
Plotting Parametric Curves

--- explot3d.ht ---

To plot a parametric curve defined by \( x = f(t) \), \( y = g(t) \), \( z = h(t) \), specify the functions \( f(t) \), \( g(t) \), and \( h(t) \) as arguments of the function 'curve', then give the interval over which \( t \) is to range.

Here is a spiral:
\[
\text{graphpaste}{\text{draw}(\text{curve}(\cos(t),\sin(t),t),t=0..6)}
\]

Here is the twisted cubic curve:
\[
\text{graphpaste}{\text{draw}(\text{curve}(t,t**2,t**3),t=-3..3)}
\]
Exposure

Exposure determines what part of the Axiom library is available to you when using Axiom.
At any time during your interactive Axiom session, each constructor is either exposed or unexposed.
If a constructor is exposed, its operations are available to the interpreter and therefore to you.
If a constructor is unexposed, the operations are not seen by the interpreter and thus not available to you.

If you are a beginner, you may only want basic parts of the library exposed.
If you are an expert, you may want to have all parts of the
library exposed.
If you have an application that requires
only a segment of the library, you may want to arrange to expose
only that segment for your use.
\par
\endscroll

\endmenu
\end{page}

---

**System Defined Exposure Groups**

— expose.ht —

\begin{page}{ExposureSystem}{System Defined Exposure Groups}
\beginscroll
Exposure is defined by \em groups.\par
Groups have names.\par
Seven exposure groups are system-defined: \beginmenu
\item \em current The currently active exposure group
\item \em basic The default value of \em current
\item \em category Category constructors not in \em basic
\item \em domain Domain constructors not in \em basic
\item \em package Package constructors not in \em basic
\item \em default Default constructors not in \em basic
\item \em hidden All constructors not in \em basic
\item \em naglink All constructors used in the Axiom NAG Link
\endmenu
\par
When you first use Axiom, the \em current exposure group is
set to \em basic and \em naglink. Using Hyperdoc or the system command
\em expose, you may
change the current exposure group by
adding or dropping constructors or by setting \em current
to an exposure group you have created.
\endscroll
Additional Information:
\beginmenu
\menulink{What}{ExposureDef}\tab{8}What is an exposure group?
What is an Exposure Group?

An exposure group is a list of constructors to be exposed. Those constructors on the list are exposed; those not on the list are not exposed. The library contains 4 kinds of constructors intuitively described as follows:

- **domain**: Describes computational objects and functions defined on these objects
- **package**: Describes functions which will work over a variety of domains
- **category**: Names a set of operations for a category
- **default**: Provides default functions for a category

An exposure group is defined by three lists:

- **groups**: A list of other (more basic) groups
- **additions**: A list of explicit constructors to be included
- **subtractions**: A list of explicit constructors to be dropped

You can define your own exposure groups: give them names and define the three above lists to be anything you like. Using Hyperdoc, you can conveniently edit your exposure groups, install them as the current exposure, and so on.
Details on Exposure

--- expose.ht ---

Exposure is generally defined by the set of domain and package constructors you want to have available. Category and default constructors are generally implied. A category constructor is exposed if mentioned by \emph{any} other constructor (including another category). A default constructor is exposed if its corresponding category constructor is exposed.

\par
If you explicitly add a domain or package constructor, its name will be put in an \emph{Additions} list. The system will also add automatically to the \emph{Additions} list any category explicitly exported by that domain or package. If that category has a corresponding default constructor, that default constructor will also be added as well.

\par
If you like, you can explicitly drop a constructor. Any such name is added to the \emph{Subtractions} list. The system will drop this name from the \emph{Additions} list if it appears.

\par
If the package or domain takes arguments from an unexported domain or declares that its arguments can come from a domain which is a member of an unexported category, these constructors will \emph{not} be added.

---

3.37 \texttt{exseries.ht}

Converting Expressions to Series

--- exseries.ht ---

You can convert a functional expression to a power series by using the function \texttt{series}. Here's an example:
\spadpaste{series(sin(a*x),x = 0)}

This causes $\sin(a*x)$ to be expanded in powers of $(x - 0)$, that is, in powers of $x$.

You can have $\sin(a*x)$ expanded in powers of $(a - \pi/4)$ by issuing the following command:

\spadpaste{series(sin(a*x),a = \pi/4)}

\begin{patch}{ExSeriesConvertPatch1}
\begin{paste}{ExSeriesConvertFull1}{ExSeriesConvertEmpty1}
\pastebutton{ExSeriesConvertFull1}\hidepaste
\tab{5}\spadcommand{series(sin(a*x),x = 0)}
\indentrel{3}\begin{verbatim}

Manipulating Power Series

Once you have created a power series, you can perform arithmetic operations on that series. First compute the Taylor expansion of \(1/(1-x)\):

\[
f := \text{series}(1/(1-x), x = 0) \quad \text{bound}(f)
\]

Now compute the square of that series:
It’s as easy as 1, 2, 3,...
Functions on Power Series

-- exseries.ht --

The usual elementary functions (\em log, \em exp, trigonometric functions, etc.) are defined for power series.
You can create a power series:
% Warning: currently there are (interpretor) problems with converting % rational functions and polynomials to power series.
spadpaste{f := series(1/(1-x),x = 0) \bound{f1}}
and then apply these functions to the series:
spadpaste{g := log(f) \free{f1} \bound{g}}
spadpaste{exp(g) \free{g}}

\begin{patch}{ExSeriesFunctionsPatch1}
\begin{paste}{ExSeriesFunctionsFull1}{ExSeriesFunctionsEmpty1}

\end{patch}
\end{page}

Substituting Numerical Values in Power Series

---

Substituting Numerical Values in Power Series
Here’s a way to obtain numerical approximations of e from the Taylor series expansion of exp(x).

First you create the desired Taylor expansion:

\begin{verbatim}
f := taylor(exp(x))
\end{verbatim}

Now you evaluate the series at the value 1.0:

\begin{verbatim}
eval(f,1.0)
\end{verbatim}

You get a sequence of partial sums.
3.38  exsum.ht

Summing the Entries of a List I

In Axiom, you can create lists of consecutive integers by giving the
first and last entries of the list.
Here’s how you create a list of the integers between $\{1\}$ and $\{15\}$:
\[
\{i \text{ for } i \text{ in } 1..15\}
\]
To sum the entries of a list, simply put $\{+/\}$ in front of the list.
For example, the following command will sum the integers from 1 to 15:
\[
\text{reduce(}+\text{,}\{i \text{ for } i \text{ in } 1..15\})
\]
### Summing the Entries of a List II

In Axiom, you can also create lists whose elements are some expression \( f(n) \) as the parameter \( n \) ranges between two integers. For example, the following command will create a list of the squares of the integers between 5 and 20:

\[
\text{\texttt{[n**2 for n in 5..20]}}
\]

You can also compute the sum of the entries of this list:

\[
\text{\texttt{reduce(+, [n**2 for n in 5..20])}}
\]

---

\[
\text{\texttt{[25, 36, 49, 64, 81, 100, 121, 144, 169, 196, 225, 256, 289, 324, 361, 400]}}
\]

Type: List PositiveInteger

\end{patch}

---

Approximating $e$

— exsum.ht —

\begin{page}{ExSumApproximateE}{Approximating e}
\beginscroll
You can obtain a numerical approximation of the number $e$ by summing the entries of the following list:
\spadpaste{reduce(+,[1.0/factorial(n) \text{ for } n \text{ in } 0..20])}
\endscroll
\autobuttons
\end{page}
Closed Form Summations

In a previous example, we found the sum of the squares of the integers between $5$ and $20$.

We can also use Axiom to find a formula for the sum of the squares of the integers between $a$ and $b$, where $a$ and $b$ are integers which will remain unspecified:

```axiom
s := sum(k^2, k = a..b)
```

`(sum(k^2, k = a..b))` returns the sum of `(k^2)` as the index `k` runs from `a` to `b`.

Let's check our answer in one particular case by substituting specific values for `a` and `b` in our formula:

```axiom
eval(s, [a, b], [1, 25])
```

```axiom
reduce(+, [i^2 for i in 1..25])
```

Type: Fraction Polynomial Integer

(1)

\[ 3^2 b + 3^2 b + b^2 - 2a^2 + 3a - a \]

\[ 6 \]

Type: Fraction Polynomial Integer
Sums of Cubes

--- exsum.ht ---

Here's a cute example.
First compute the sum of the cubes from $1$ to $n$:
\[
\text{sum}(k^3, k = 1..n)
\]
Then compute the square of the sum of the integers from $1$ to $n$:
\[
\text{sum}(k, k = 1..n)^2
\]
The answers are the same.

\begin{verbatim}
\spadcommand{sum(k**3,k = 1..n)}
\verbatimverbatim
4 3 2
n + 2n + n
(1)
\end{verbatimverbatim}
Type: Fraction Polynomial Integer

\begin{verbatim}
\spadcommand{sum(k,k = 1..n) ** 2}
\verbatimverbatim
4 3 2
n + 2n + n
(2)
\end{verbatimverbatim}
Type: Fraction Polynomial Integer
Sums of Polynomials

3.39 farray.ht

FlexibleArray

⇒ “notitle” (OneDimensionalArrayXmpPage) 3.4 on page 138
⇒ “notitle” (VectorXmpPage) 3.114 on page 1351

— farray.ht —
Flexible arrays are an attempt to provide a data type that has the best features of both one-dimensional arrays (fast, random access to elements) and lists (flexibility).

When necessary for expansion, a new, larger block of storage is allocated and the elements from the old storage area are copied into the new block.

Flexible arrays have available most of the operations provided by\spadtype{OneDimensionalArray}
(see \downlink{‘OneDimensionalArray’}{OneDimensionalArrayXmpPage} \ignore{OneDimensionalArray} and \downlink{‘Vector’}{VectorXmpPage} \ignore{Vector}).

Since flexible arrays are also of category \spadtype{ExtensibleLinearAggregate}, they have operations \spadfun{concat}, \spadfun{delete}, \spadfun{insert}, \spadfun{merge}, \spadfun{remove}, \spadfun{removeDuplicates}, and \spadfun{select}.

In addition, the operations \spadfun{physicalLength} and \spadfun{physicalLength} provide user-control over expansion and contraction.

A convenient way to create a flexible array is to apply the operation \spadfun{flexibleArray} to a list of values.

\spadpaste{flexibleArray [i for i in 1..6]}

Create a flexible array of six zeroes.
\spadpaste{f : FARRAY INT := new(6,0}\bound{f}}

For \(i=1\ldots6\), set the \(i\)th element to \(i\).
Display \spad{f}.
\spad{for i in 1..6 repeat f.i := i; f\bound{f1}}

Initially, the physical length is the same as the number of elements.
\spad{physicalLength f\free{f1}}
Add an element to the end of \spad{f}.
}\{
\spadpaste{concat!(f,11)\bound{f2}\free{f1}}
}\
\xtc{
See that its physical length has grown.
}\{
\spadpaste{physicalLength f\free{f2}}
}\
\xtc{
Make \spad{f} grow to have room for \spad{15} elements.
}\{
\spadpaste{physicalLength!(f,15)\bound{f3}\free{f2}}
}\
\xtc{
Concatenate the elements of \spad{f} to itself.  
The physical length allows room for three more values at the end.
}\{
\spadpaste{concat!(f,f)\bound{f4}\free{f3}}
}\
\xtc{
Use \spadfunX{insert} to add an element to the front of a flexible array.
}\{
\spadpaste{insert!(22,f,1)\bound{f5}\free{f4}}
}\
\xtc{
Create a second flexible array from \spad{f} consisting of the elements from index 10 forward.
}\{
\spadpaste{g := f(10..)\bound{g}\free{f5}}
}\
\xtc{
Insert this array at the front of \spad{f}.
}\{
\spadpaste{insert!(g,f,1)\bound{g1}\free{g f5}}
}\
\xtc{
Merge the flexible array \spad{f} into \spad{g} after sorting each in place.
}\{
\spadpaste{merge!(sort! f, sort! g)\bound{f6}\free{g f5}}
}\
\xtc{
Remove duplicates in place.  
}\{
\spadpaste{removeDuplicates! f\bound{f7}\free{f6}}
}\}
\xtc{
Remove all odd integers.  
}{
\spadpaste{select!(i +-> even? i,f8)\bound{f8}\free{f7}}
\xtc{
All these operations have shrunk the physical length of \spad{f}.
}\{
\spadpaste{physicalLength f\free{b8}}
\xtc{
To force Axiom not to shrink flexible arrays call the
\spadfun{shrinkable} operation with the argument \axiom{false}.
You must package call this operation.

\spadcommand{physicalLength f}
The \spadtype{File(S)} domain provides a basic interface to read and write values of type \spad{S} in files.
Before working with a file, it must be made accessible to Axiom with the \spadfunFrom{open}{File} operation.

\spadpaste{ifile:File List Integer:=open("/tmp/jazz1","output")
\bound{ifile}}

The \spadfunFrom{open}{File} function arguments are a \spadtype{FileName} and a \spadtype{String} specifying the mode.

If a full pathname is not specified, the current default directory is assumed.

The mode must be one of \spad{"input"} or \spad{"output"}. If it is not specified, \spad{"input"} is assumed.

Once the file has been opened, you can read or write data.

\spadpaste{write!(ifile, [-1,2,3]) \free{ifile1}\bound{ifile1}}
\spadpaste{write!(ifile, [10,-10,0,111]) \free{ifile1}\bound{ifile2}}
\spadpaste{write!(ifile, [7]) \free{ifile2}\bound{ifile3}}

You can change from writing to reading (or vice versa) by reopening a file.

\spadpaste{reopen!(ifile, "input") \free{ifile3}\bound{ifile4}}
\spadpaste{read! ifile \free{ifile4}\bound{ifile5}}
\spadpaste{read! ifile \free{ifile5}\bound{ifile6}}

The \spadfunFrom{read}{File} operation can cause an error if one tries to read more data than is in the file.

To guard against this possibility the \spadfunFrom{readIfCan}{File} operation should be used.

\spadpaste{readIfCan! ifile \free{ifile6}\bound{ifile7}}

You can find the current mode of the file, and the file's name.

\spadpaste{iomode ifile \free{ifile}}

When you are finished with a file, you should close it.

\spadpaste{close! ifile \free{ifile}\bound{ifileA}}

\noOutputXtc{\spadpaste{)system rm /tmp/jazz1 \free{ifileA}}}

A limitation of the underlying LISP system is that not all values can be represented in a file.
In particular, delayed values containing compiled functions cannot be saved.

Axiom provides two kinds of floating point numbers. The domain Float (abbreviation FLOAT) implements a model of arbitrary precision floating point numbers. The domain DoubleFloat (abbreviation DFLOAT) is intended to make available hardware floating point arithmetic in Axiom. The actual model of floating point that DoubleFloat provides is system-dependent.

For example, on the IBM system 370 Axiom uses IBM double precision which has fourteen hexadecimal digits of precision or roughly sixteen decimal digits. Arbitrary precision floats allow the user to specify the precision at which arithmetic operations are computed. Although this is an attractive facility, it comes at a cost. Arbitrary-precision floating-point arithmetic typically takes twenty to two hundred times more time than hardware floating point.

For more information about Axiom’s numeric and graphic facilities, see `Graphics’ in Section 7, `Numeric Functions’ in Section 8.1, and `DoubleFloat'.

\section{Introduction to Float}

— float.ht —

\begin{page}{ugxFloatIntroPage}{Introduction to Float}
\beginscroll

Scientific notation is supported for input and output of floating point numbers. A floating point number is written as a string of digits containing a decimal point optionally followed by the letter ‘‘\tt E’’, and then the exponent.

We begin by doing some calculations using arbitrary precision floats. The default precision is twenty decimal digits.
A decimal base for the exponent is assumed, so the number \spad{1.234E2} denotes $1.234 \cdot 10^2$. 

The normal arithmetic operations are available for floating point numbers.

Output Functions

A number of operations exist for specifying how numbers of type \texttt{Float} are to be displayed.
By default, spaces are inserted every ten digits in the output for readability.\footnote{Note that you cannot include spaces in the input form of a floating point number, though you can use underscores.}

Output spacing can be modified with the \spadfunFrom{outputSpacing}{Float} operation.
This inserts no spaces and then displays the value of \spad{x}.
\begin{verbatim}
outputSpacing 0; x := sqrt 0.2 \bound{x}\bound{os0}
\end{verbatim}
By default, the system displays floats in either fixed format or scientific format, depending on the magnitude of the number.

A particular format may be requested with the operations \spadfunFrom{outputFloating}{Float} and \spadfunFrom{outputFixed}{Float}.

Additionally, you can ask for \spad{n} digits to be displayed after the decimal point.

This resets the output printing to the default behavior.

An Example: Determinant of a Hilbert Matrix

--- float.ht ---

Consider the problem of computing the determinant of a \texttt{10} by \texttt{10} Hilbert matrix. The $\eth{(i,j)}$ entry of a Hilbert matrix is given by $1/(i+j+1)$.

First do the computation using rational numbers to obtain the exact result.

\begin{verbatim}
\spad{\texttt{a: Matrix Fraction Integer := matrix \lbrack \lbrack 1/(i+j+1) for j in 0..9 \rbrack for i in 0..9 \rbrack}}
\end{verbatim}

This version of \texttt{determinant\{Matrix\}} uses Gaussian elimination.

\spad{\texttt{d:= determinant a \free{a} \bound{d}}}
Now use hardware floats. Note that a semicolon (;) is used to prevent the display of the matrix.

\spadpaste{b: Matrix DoubleFloat := matrix [[1/(i+j+1\$DoubleFloat) for j in 0..9] for i in 0..9]; \bound{b}}

The result given by hardware floats is correct only to four significant digits of precision.
In the jargon of numerical analysis, the Hilbert matrix is said to be ‘ill-conditioned.’

\spadpaste{determinant b \free{b}}

Now repeat the computation at a higher precision using \spadtype{Float}.

\spadpaste{digits 40 \bound{d40}}

\spadpaste{c: Matrix Float := matrix [[1/(i+j+1\$Float) for j in 0..9] for i in 0..9]; \free{d40} \bound{c}}

\spadpaste{determinant c \free{c}}

Reset \spadfunFrom{digits}{Float} to its default value.

\spadpaste{digits 20}

Reset \spadfunFrom{digits}{Float} to its default value.

3.42  FNAME.HT

---

3.42  fname.ht

FileName

--- fname.ht ---

The \spadtype{FileName} domain provides an interface to the computer’s file system.
Functions are provided to manipulate file names and to test properties of files.

The simplest way to use file names in the Axiom interpreter is to rely on conversion to and from strings.
The syntax of these strings depends on the operating system.
\xtc{
}\spadpaste{fn: FileName \bound{fndecl}}
}\xtc{
On AIX, this is a proper file syntax:
}\{\spadpaste{fn := "/spad/src/input/fname.input" \free{fndecl}\bound{fn}}
}\}

Although it is very convenient to be able to use string notation for file names in the interpreter, it is desirable to have a portable way of creating and manipulating file names from within programs.
\xtc{
A measure of portability is obtained by considering a file name to consist of three parts: the \{it directory\}, the \{it name\}, and the \{it extension\}.
}\{\spadpaste{directory fn \free{fn}}
}\xtc{
}\spadpaste{name fn \free{fn}}
}\xtc{
}\spadpaste{extension fn \free{fn}}
}\}

The meaning of these three parts depends on the operating system. For example, on CMS the file \spad{"SPADPROF INPUT M"} would have directory \spad{"M"}, name \spad{"SPADPROF"}, and extension \spad{"INPUT"}.
\xtc{
It is possible to create a filename from its parts.
}\{\spadpaste{fn := filename("/u/smwatt/work", "fname", "input") \free{fndecl}\bound{fn1}}
}\xtc{
When writing programs, it is helpful to refer to directories via variables.
}\{\spadpaste{objdir := "/tmp" \bound{objdir}}
}\xtc{
}\{\spadpaste{fn := filename(objdir, "table", "spad") \free{fndecl, objdir}\bound{fn2}}
}
If the directory or the extension is given as an empty string, then a default is used. On AIX, the defaults are the current directory and no extension.

```spadpaste
fn := filename("", "letter", ") \free{fndecl}\bound{fn3}
```

Three tests provide information about names in the file system.

The \spadfunFrom{exists?}{FileName} operation tests whether the named file exists.

```spadpaste
exists? "/etc/passwd"
```

The operation \spadfunFrom{readable?}{FileName} tells whether the named file can be read. If the file does not exist, then it cannot be read.

```spadpaste
readable? "/etc/passwd"
```

Likewise, the operation \spadfunFrom{writable?}{FileName} tells whether the named file can be written. If the file does not exist, the test is determined by the properties of the directory.

```spadpaste
writable? "/etc/passwd"
```

```spadpaste
writable? "/dev/null"
```

```spadpaste
writable? "/etc/DoesNotExist"
```

```spadpaste
writable? "/tmp/DoesNotExist"
```
The \spadfunFrom{new}{FileName} operation constructs the name of a new writable file. The argument sequence is the same as for \spadfunFrom{filename}{FileName}, except that the name part is actually a prefix for a constructed unique name.

The resulting file is in the specified directory with the given extension, and the same defaults are used.

\spadpaste{fn := new(objdir, "xxx", "yy")}

Factored

Factored creates a domain whose objects are kept in factored form as long as possible. Thus certain operations like \(*\) (multiplication) and \(\text{gcd}\) are relatively easy to do. Others, such as addition, require somewhat more work, and the result may not be completely factored unless the argument domain \(\mathbb{R}\) provides a \texttt{factor} operation. Each object consists of a unit and a list of factors, where each factor consists of a member of \(\mathbb{R}\) (the base), an exponent, and a flag indicating what is known about the base. A flag may be one of "nil", "sqfr", "irred" or "prime", which mean that nothing is known about the base, it is square-free, it is irreducible, or it is prime, respectively. The current restriction to factored objects of integral domains allows simplification to be performed without worrying about multiplication order.

Decomposing Factored Objects

In this section we will work with a factored integer.

\begin{spad}
g := \text{factor}(4312)\end{spad}

Let's begin by decomposing \( g \) into pieces. The only possible units for integers are 1 and -1.

\begin{spad}
\text{unit}(g)
\end{spad}

There are three factors.

\begin{spad}
\text{numberOfFactors}(g)
\end{spad}

We can make a list of the bases, ...

\begin{spad}
\text{nthFactor}(g, i) \text{ for } i \text{ in } 1 \ldots \text{numberOfFactors}(g)
\end{spad}

and the exponents, ...

\begin{spad}
\text{nthExponent}(g, i) \text{ for } i \text{ in } 1 \ldots \text{numberOfFactors}(g)
\end{spad}

and the flags. You can see that all the bases (factors) are prime.

\begin{spad}
\text{nthFlag}(g, i) \text{ for } i \text{ in } 1 \ldots \text{numberOfFactors}(g)
\end{spad}

A useful operation for pulling apart a factored object into a list of records of the components is \text{factorList}.

\begin{spad}
\text{factorList}(g)
\end{spad}

If you don't care about the flags, use \text{factors}.

\begin{spad}
\text{factors}(g)
\end{spad}

Neither of these operations returns the unit.

\begin{spad}
\text{first}(\text{factors})(g)
\end{spad}

\begin{spad}
\text{factor}(g)
\end{spad}

Let's begin by decomposing \( g \) into pieces. The only possible units for integers are 1 and -1.

\begin{spad}
\text{unit}(g) \text{ free}(g)
\end{spad}

There are three factors.
We can make a list of the bases, \ldots
\spadpaste{[nthFactor(g,i) for i in 1..numberOfFactors(g)] \free{g}}
and the exponents, \ldots
\spadpaste{[nthExponent(g,i) for i in 1..numberOfFactors(g)] \free{g}}
and the flags.
You can see that all the bases (factors) are prime.
\spadpaste{[nthFlag(g,i) for i in 1..numberOfFactors(g)] \free{g}}
A useful operation for pulling apart a factored object into a list of records of the components is \spadfunFrom{factorList}{Factored}.
\spadpaste{factorList(g) \free{g}}
If you don’t care about the flags, use \spadfunFrom{factors}{Factored}.
\spadpaste{factors(g) \free{g}\bound{prev1}}
Neither of these operations returns the unit.
\spadpaste{first(\%).factor \free{prev1}}

Expanding Factored Objects

Recall that we are working with this factored integer.
\begin{verbatim}
g := factor(4312) \bound{g}
\end{verbatim}
To multiply out the factors with their multiplicities, use
expand.
\begin{verbatim}
expand(g)
\end{verbatim}
If you would like, say, the distinct factors multiplied
together but with multiplicity one, you could do it this way.
\begin{verbatim}
reduce(*,[t.factor for t in factors(g)])
\end{verbatim}
(1) \(2 \cdot 7 \cdot 11\)  
Type: Factored Integer

\begin{verbatim}
(2) 4312
Type: PositiveInteger
\end{verbatim}

(2) 4312  
Type: PositiveInteger

(3) 154
Type: PositiveInteger
Arithmetic with Factored Objects

We're still working with this factored integer.
\{ \spad{g := \text{factor}(4312)} \}

We'll also define this factored integer.
\{ \spad{f := \text{factor}(246960)} \}

Operations involving multiplication and division are particularly easy with factored objects.
\begin{itemize}
  \item \spad{f \ast g}
  \item \spad{f \ast 500}
  \item \spad{\gcd(f, g)}
  \item \spad{\lcm(f, g)}
\end{itemize}

If we use addition and subtraction things can slow down because we may need to compute greatest common divisors.
\begin{itemize}
  \item \spad{f + g}
  \item \spad{f - g}
\end{itemize}

Test for equality with 0 and 1 by using \code{zero?} and \code{one?}, respectively.
\begin{itemize}
  \item \spad{\text{zero?}(\text{factor}(0))}
  \item \spad{\text{zero?}(g)}
  \item \spad{\text{one?}(\text{factor}(1))}
  \item \spad{\text{one?}(f)}
\end{itemize}

Another way to get the zero and one factored objects is to use package calling (see "\texttt{Package Calling and Target Types}" in Section 2.9).
\begin{itemize}
  \item \spad{0$\text{Factored}(\text{Integer})$}
  \item \spad{1$\text{Factored}(\text{Integer})$}
\end{itemize}
Operations involving multiplication and division are particularly easy with factored objects.

\[
\text{gcd}(f,g)\]

If we use addition and subtraction things can slow down because we may need to compute greatest common divisors.

Test for equality with \spad{0} and \spad{1} by using \spadfunFrom{zero?}{Factored} and \spadfunFrom{one?}{Factored}, respectively.

Another way to get the zero and one factored objects is to use
package calling
(see "Package Calling and Target Types")
{ugTypesPkgCallPage} in Section 2.9\ignore{ugTypesPkgCall}).

Creating New Factored Objects

The \spadfunFrom{map}{Factored} operation is used to iterate across the unit and bases of a factored object. See `FactoredFunctions2` for a discussion of \spadfunFrom{map}{Factored}.

The following four operations take a base and an exponent and create a factored object. They differ in handling the flag component.

\begin{itemize}
\item \texttt{nilFactor(24,2)}
\end{itemize}
This factor has no associated information.

\begin{itemize}
\item \texttt{nthFlag(9,1)}
\end{itemize}
This factor is asserted to be square-free.

\begin{itemize}
\item \texttt{sqrfactor(30,2)}
\end{itemize}
This factor is asserted to be irreducible.

\begin{itemize}
\item \texttt{irreducibleFactor(13,10)}
\end{itemize}
This factor is asserted to be prime.

\begin{itemize}
\item \texttt{primeFactor(11,5)}
\end{itemize}
A partial inverse to \spadfunFrom{factorList}{Factored} is \spadfunFrom{makeFR}{Factored}.

\begin{itemize}
\item \texttt{h := factor(-720)}
\end{itemize}
The first argument is the unit and the second is a list of records as returned by \spadfunFrom{factorList}{Factored}.

\begin{itemize}
\item \texttt{h = makeFR(unit(h),factorList(h))}
\end{itemize}
This factor has no associated information.

FactoredFunctions2

The \texttt{FactoredFunctions2} package implements one operation, \texttt{map}, for applying an operation to every base in a factored object and to the unit.

\begin{verbatim}
  \spadfunFrom{map}{FactoredFunctions2}
\end{verbatim}

Actually, the \texttt{map} operation used in this example comes from \texttt{Factored} itself, since \texttt{double} takes an integer argument and returns an integer result.

\begin{verbatim}
  map(double, f)
\end{verbatim}

If we want to use an operation that returns an object that has a type different from the operation's argument, the \texttt{map} in \texttt{Factored} cannot be used and we use the one in \texttt{FactoredFunctions2}.

\begin{verbatim}
  \spadfunFrom{makePoly}{FactoredFunctions2}
\end{verbatim}

In fact, the '~2' in the name of the package means that we might be using factored objects of two different types.

\begin{verbatim}
  g := map(makePoly, f)
\end{verbatim}

It is important to note that both versions of \texttt{map} destroy any information known about the bases (the fact that they are prime, for instance). The flags for each base are set to `nil' in the object returned by \texttt{map}.

\begin{verbatim}
  nthFlag(g, 1)
\end{verbatim}

For more information about factored objects and their use, see \enquote{Factored} and \enquote{Computation of Galois Groups}' in Section 8.13.
Actually, the \spadfunFrom{map}{FactoredFunctions2} operation used in this example comes from \spadtype{Factored} itself, since \userfun{double} takes an integer argument and returns an integer result.

If we want to use an operation that returns an object that has a type different from the operation's argument, the \spadfunFrom{map}{FactoredFunctions2} in \spadtype{Factored} cannot be used and we use the one in \spadtype{FactoredFunctions2}.

In fact, the ''2'' in the name of the package means that we might be using factored objects of two different types.

It is important to note that both versions of \spadfunFrom{map}{FactoredFunctions2} destroy any information known about the bases (the fact that they are prime, for instance).

The flags for each base are set to ''nil'' in the object returned by \spadfunFrom{map}{FactoredFunctions2}.

For more information about factored objects and their use, see \downlink{`Factored'}{FactoredXmpPage} and \downlink{``Computation of Galois Groups''}{ugProblemGaloisPage} in Section 8.13\ignore{ugProblemGalois}.

⇒ “notitle” (PartialFractionXmpPage) 3.86 on page 1088

\begin{page}{FractionXmpPage}{Fraction}
\beginscroll

The \spad{Fraction} domain implements quotients. The elements must belong to a domain of category \spad{IntegralDomain}: multiplication must be commutative and the product of two non-zero elements must not be zero. This allows you to make fractions of most things you would think of, but don’t expect to create a fraction of two matrices! The abbreviation for \spad{Fraction} is \spad{FRAC}.

\xtc{
Use \spad{opFrom{/}{Fraction}} to create a fraction.
}{
\spad{a := 11/12 \text{ free}{a}}
}
\xtc{
}{
\spad{b := 23/24 \text{ free}{b}}
}
\xtc{
The standard arithmetic operations are available.
}{
\spad{3 - a*b**2 + a + b/a \text{ free}{a} \text{ free}{b}}
}
\xtc{
Extract the numerator and denominator by using \spad{numer}{Fraction} and \spad{denom}{Fraction}, respectively.
}{
\spad{numer(a) \text{ free}{a}}
}
\xtc{
}{
\spad{denom(b) \text{ free}{b}}
}
Operations like \spad{max}{Fraction}, \spad{min}{Fraction}, \spad{negative?}{Fraction}, \spad{positive?}{Fraction} and \spad{zero?}{Fraction} are all available if they are provided for
the numerators and denominators. See \downlink{'Integer'}{IntegerXmpPage} for examples.

Don’t expect a useful answer from \spadfun{factor}{Fraction}, \spadfun{gcd}{Fraction} or \spadfun{lcm}{Fraction} if you apply them to fractions.

FullPartialFracExpansion

⇒ “notitle” (PartialFractionXmpPage) 3.86 on page 1088

The domain \spadtype{FullPartialFracExpansion} implements
factor-free conversion of quotients to full partial fractions.

Our examples will all involve quotients of univariate polynomials
with rational number coefficients.

\spadpaste{Fx := FRAC UP(x, FRAC INT) \bound{Fx}}
Here is a simple-looking rational function.
\begin{spad}
f : Fx := 36 / (x**5-2*x**4-2*x**3+4*x**2+x-2) \end{spad}
\begin{spad}
g := fullPartialFraction f \end{spad}
\begin{spad}
Use a coercion to change it back into a quotient.
\end{spad}
\begin{spad}
g :: Fx \end{spad}
\begin{spad}
Full partial fractions differentiate faster than rational
functions.
\end{spad}
\begin{spad}
g5 := D(g, 5) \end{spad}
\begin{spad}
f5 := D(f, 5) \end{spad}
\begin{spad}
We can check that the two forms represent the same function.
\end{spad}
\begin{spad}
g5::Fx - f5 \end{spad}
\begin{spad}
Here are some examples that are more complicated.
\end{spad}
\begin{spad}
f : Fx := (x**5 * (x-1)) / ((x**2 + x + 1)**2 * (x-2)**3) \end{spad}
\begin{spad}
g := fullPartialFraction f \end{spad}
\begin{spad}
g :: Fx - f \end{spad}
\begin{spad}
f : Fx := (2*x**7-7*x**5+26*x**3+8*x) /
\( (x^8-5x^6+6x^4+4x^2-8) \) 
\free{Fx} \bound{f3} 
\xtc{} 
\spadpaste{g := fullPartialFraction f \free{f3} \bound{g3}} 
\xtc{} 
\spadpaste{g :: Fx - f \free{f3 g3 Fx}} 
\xtc{} 
\spadpaste{f:Fx := x^3 / (x^21 + 2x^20 + 4x^19 + 7x^18 + 10x^17 + 17x^16 + 22x^15 + 30x^14 + 36x^13 + 40x^12 + 47x^11 + 46x^10 + 49x^9 + 43x^8 + 38x^7 + 32x^6 + 23x^5 + 19x^4 + 10x^3 + 7x^2 + 2x + 1) \free{Fx} \bound{f4}} 
\xtc{} 
\spadpaste{g := fullPartialFraction f \free{f4} \bound{g4}} 
\xtc{} 
This verification takes much longer than the conversion to partial fractions. 
\spadpaste{g :: Fx - f \free{f4 g4 Fx}} 

For more information, see the paper: 
All see \downlink{PartialFraction}{PartialFractionXmpPage} \ignore{PartialFraction} for standard partial fraction decompositions.

Functions in Axiom

In Axiom, a function is an expression in one or more variables. (Think of it as a function of those variables). You can also define a function by rules or use a built-in function. Axiom lets you convert expressions to compiled functions.

- Rational Functions
  - Quotients of polynomials.
- Algebraic Functions
  - Those defined by polynomial equations.
- Elementary Functions
  - The elementary functions of calculus.
- Simplification
  - How to simplify expressions.
- Pattern Matching
  - How to use the pattern matcher.

Additional Topics:
- Operator Algebra
  - The operator algebra facility.

\begin{page}\{FunctionPage\}\{Functions in Axiom\}

% In Axiom, a function is an expression in one or more variables. (Think of it as a function of those variables). You can also define a function by rules or use a built-in function. Axiom lets you convert expressions to compiled functions.
\beginscroll
\beginmenu
Rational Functions

To create a rational function, just compute the quotient of two polynomials:
\spadpaste{f := (x - y) / (x + y)\bound{f}}

Use the functions \spadfun{numer} and \spadfun{denom}:
\spadpaste{numer f\free{f}}
\spadpaste{denom f\free{f}}

Since these are polynomials, you can apply all the polynomial operations to them.
You can substitute values or
other rational functions for the variables using
the function \spadfun{eval}. The syntax for \spadfun{eval} is
similar to the one for polynomials:
\spadpaste{eval(f, x = 1/x)ree{f}}
\spadpaste{eval(f, [x = y, y = x])ree{f}}

Algebraic Functions

Algebraic functions are functions defined by algebraic equations. There are two ways of constructing them: using rational powers, or implicitly. For rational powers, use \spad{**}(or the system functions \spad{sqrt} and \spad{nthRoot} for square and nth roots):

\spad{f := \sqrt{1 + x ** (1/3)}}

To define an algebraic function implicitly use \spad{rootOf}. The following line defines a function \spad{y} of \spad{x} satisfying the equation \spad{y**3 = x*y - y**2 - x**3 + 1}:

\spad{y := rootOf(y**3 + y**2 - x*y + x**3 - 1, y)}

You can manipulate, differentiate or integrate an implicitly defined algebraic function like any other Axiom function:

\spad{differentiate(y, x)}

Higher powers of algebraic functions are automatically reduced during calculations:

\spad{(y + 1) ** 3}

But denominators, are not automatically rationalized:

\spad{g := inv f}

Use \spad{ratDenom} to remove the algebraic quantities from the denominator:

\spad{ratDenom g}

Elementary Functions

--- function.ht ---

Axiom has most of the usual functions from calculus built-in:
\spadpaste{f := x * log y * sin(1/(x+y))\bound{f}}
You can substitute values or another elementary functions for
the variables with the function \spadfun{eval}:
\spadpaste{eval(f, [x = y, y = x])\free{f}}
As you can see, the substitutions are made 'in parallel' as in the
case of polynomials. It's also possible to substitute expressions
for kernels instead of variables:
\spadpaste{eval(f, log y = acosh(x + sqrt y))\free{f}}

--- function.htm ---

\tab{5}\spadcommand{eval(f, log y = acosh(x + sqrt y))}\free{f}
\end{paste}\end{patch}

\begin{page}{FunctionSimplificationPage}{Simplification}
\beginscroll
Simplifying an expression often means different things at different times, so Axiom offers a large number of 'simplification' functions.

The most common one, which performs the usual trigonometric simplifications is \spadfun{simplify}:
\spadpaste{f := cos(x)/sec(x) * log(sin(x)**2/(cos(x)**2+sin(x)**2))}\bound{f}
\spadpaste{g := simplify f}\bound{g}\free{f}

If the result of \spadfun{simplify} is not satisfactory, specific transformations are available.

For example, to rewrite \spad{g} in terms of secants and cosecants instead of sines and cosines, issue:
\%
\spadpaste{h := sin2csc \cos2sec g}\bound{h}\free{g}
\end{scroll}

\end{page}
To apply the logarithm simplification rules to \spad{h}, issue:
\spadpaste{expandLog h\free{h}}
Since the square root of \spad{x**2} is the absolute value of \spad{x} and not \spad{x} itself, algebraic radicals are not automatically simplified, but you can specifically request it by calling \spadfun{rootSimp}:
\spadpaste{f1 := sqrt((x+1)**3)\bound{f1}}
\spadpaste{rootSimp f1\free{f1}}
There are other transformations which are sometimes useful. Use the functions \spadfun{complexElementary} and \spadfun{trigs} to go back and forth between the complex exponential and trigonometric forms of an elementary function:
\spadpaste{g1 := sin(x + cos x)\bound{g1}}
\spadpaste{g2 := complexElementary g1\bound{g2}\free{g1}}
\spadpaste{trigs g2\free{g2}}
Similarly, the functions \spadfun{realElementary} and \spadfun{htrigs} convert hyperbolic functions in and out of their exponential form:
\spadpaste{h1 := sinh(x + cosh x)\bound{h1}}
\spadpaste{h2 := realElementary h1\bound{h2}\free{h1}}
\spadpaste{htrigs h2\free{h2}}
Axiom has other transformations, most of which are in the packages
\spadtype{ElementaryFunctionStructurePackage},
\spadtype{TrigonometricManipulations},
\spadtype{AlgebraicManipulations},
and \spadtype{TranscendentalManipulations}.
If you need to apply a simplification rule not built into the system, you can use Axiom’s \downlink{pattern matcher} {ugUserRulesPage}.

Solving systems of polynomial equations with the Gröbner basis algorithm can often be very time consuming because, in general, the algorithm has exponential run-time. These systems, which often come from concrete applications, frequently have symmetries which are not taken advantage of by the algorithm. However, it often happens in this case that the polynomials which occur during the Gröbner calculations are reducible. Since Axiom has an excellent polynomial factorization algorithm, it is very natural to combine the Groebner and factorization algorithms.

\spadtype{GroebnerFactorizationPkg} exports the \axiomFunFrom{groebnerFactorize}{GroebnerFactorizationPkg} operation which implements a modified Gröbner basis algorithm. In this algorithm, each polynomial that is to be put into the partial list of the basis is first factored. The remaining calculation is split into as many parts as there are irreducible factors. Call these factors \$p_1, \ldots, p_n\$ to \spad{p1, ..., pn}.

In the branches corresponding to \$p_2, \ldots, p_n\$ to \spad{p2, ..., pn} the factor \$p_1\$ to \spad{p1} can be divided out, and so on. This package also contains operations that allow you to specify the polynomials that are not zero on the common roots of the final Gröbner basis.

Here is an example from chemistry. In a theoretical model of the cyclohexan \$\text{C}_6\text{H}_{12}\$ \{C6H12\}, the six carbon atoms each sit in the center of gravity of a tetrahedron that has two hydrogen atoms and two carbon atoms at its corners. We first normalize and set the length of each edge to 1. Hence, the distances of one fixed carbon atom to each of its
immediate neighbours is 1. We will denote the distances to the other three carbon atoms by \(x\), \(y\) and \(z\).

%% reference?

A. Dress developed a theory to decide whether a set of points and distances between them can be realized in an \(n\)-dimensional space. Here, of course, we have \(n = 3\).

For the cyclohexan, the distances have to satisfy this equation.

They also must satisfy the equations given by cyclic shifts of the indeterminates.

The union of the solutions of this list is the solution of our original problem. If we impose positivity conditions, we get two relevant ideals. One ideal is zero-dimensional, namely \(x = y = z = 11/3\), and this determines the ‘‘boat’’ form of the cyclohexan. The other ideal is one-dimensional, which means that we have a solution space given by one parameter. This gives the ‘‘chair’’ form of the cyclohexan. The parameter describes the angle of the ‘‘back of the chair.’’

\(\text{\texttt{axiomFunFrom\{groebnerFactorize\}\{GroebnerFactorizationPkg\}}}\) has an optional \(\text{\texttt{axiomType\{Boolean\}}}\)-valued second argument. When it is \(\text{\texttt{true}}\) partial results are displayed, since it may happen that the calculation does not terminate in a reasonable time. See the source code for \(\text{\texttt{spad\{true\}}}\) in \(\text{\texttt{bf groebf\{spadFileExt\}}}\) for more details about the algorithms used.

— gloss.ht —
(syntax) a separator for items in a tuple.
\spadignore{e.g.} to separate arguments of a function \spad{f(x,{}y)}.
\item newline{em \menuitemstyle{}\em =>}\space{}
(syntax) the expression \spad{a => b} is equivalent to \spad{if a then \spad{exit} \spad{b}}.
1. (syntax) a suffix character for Boolean-valued \spadfun{function} names, \spadignore{e.g.} \spadfun{odd?}. 2. Suffix character for pattern variables. 3. The special type \spad{?} means \{em don’t care\}. For example, the declaration \center{\spad{x : Polynomial ?}}, \{em means that values assigned to \spad{x} must be polynomials over an arbitrary \spad{underlying domain}.
\item newline{em \menuitemstyle{}\em abstract datatype}\space{}
a programming language principle used in Axiom where a datatype is defined in two parts: \{em a public\} part describing a set of \spad{exports}, \{em principally operations that apply to objects of that type\}, and \{em a private\} part describing the implementation of the datatype usually in terms of a \spad{representation} for objects of the type. Programs which create and otherwise manipulate objects of the type may only do so through its exports. The representation and other implementation information is specifically hidden.
\item newline{em \menuitemstyle{}\em abstraction}\space{}
described functionally or conceptually without regard to implementation
\item newline{em \menuitemstyle{}\em accuracy}\space{}
the degree of exactness of an approximation or measurement. In computer algebra systems, computations are typically carried out with complete accuracy using integers or rational numbers of indefinite size. Domain \spadtype{Float} provides a function \spadfunFrom{precision}{Float} to change the precision for floating point computations. Computations using \spadtype{DoubleFloat} have a fixed precision but uncertain accuracy.
\item newline{em \menuitemstyle{}\em add-chain}\space{}
a hierarchy formed by \spad{domain extensions}. If domain \spad{A} extends domain \spad{B} and domain \spad{B} extends domain \spad{C}, then \spad{A} has \{em add-chain\} \spad{B}-\spad{C}.
\item newline{em \menuitemstyle{}\em aggregate}\space{}
a data structure designed to hold multiple values. Examples of aggregates are \spadtype{List}, \spadtype{Set}, \spadtype{Matrix} and \spadtype{Bits}.
\item newline{em \menuitemstyle{}\em AKCL}\space{}
Austin Kyoto Common LISP, \{em a version of \spad{KCL}\} produced by William Schelter, \{em Austin,\} Texas.
\item newline{em \menuitemstyle{}\em algorithm}\space{}
a step-by-step procedure for a solution of a problem; a program
\item newline{em \menuitemstyle{}\em ancestor}\space{}
(of a domain) a category which is a \spad{parent} of the domain, or a \spad{parent} of a \spad{parent}, and so on.
\item newline{em \menuitemstyle{}\em application}\space{}
(\texttt{application}) an expression denoting "application" of a function to a set of \spad{argument} parameters. Applications are written as a \spad{parameterized form}. For example, \{em the form \spad{f(x,{}y)}\} indicates the "application of the function \spad{f} to the tuple of
arguments \spad{x} and \spad{y}”. See also \spadgloss{evaluation} and \spadgloss{invocation}.

See \spadgloss{application}.

1. (actual argument) a value passed to a function at the time of a \spadglossSee{function call}{application}; also called an \spad{actual parameter}. 2. (formal argument) a variable used in the definition of a function to denote the actual argument passed when the function is called.

1. (function) the number of arguments. 2. (operator or operation) corresponds to the arity of a function implementing the operator or operation.

\item \{\em assignment\} \{\em (syntax)\} an expression of the form \spad{x := e}, meaning “assign the value of \spad{e} to \spad{x}”. After \spadgloss{evaluation}, \spad{\{\em assignment\}} the \spadgloss{variable} \spad{x} \spadglossSee{points}{pointer} to an object obtained by evaluating the expression \spad{e}. If \spad{x} has a \spadgloss{type} as a result of a previous \spadgloss{declaration}, \spad{x} must have that type. An interpreter must often \spadglossSee{coerce}{coercion} the value of \spad{e} to make that happen. For example, in the interpreter, \center{\spad{x : Float := 11}} first \spadglossSee{declares}{declaration} \spad{x} to be a float. This declaration causes the interpreter to coerce 11 to 11.0 in order to assign a floating point value to \spad{x}.

\item \{\em attribute\} \{\em (syntax)\} a name or functional form denoting \{\em any\} useful computational property. For example, \{\em \spadatt{commutative}(\spad{"*"})\} asserts that “\spadfun{\ast} is commutative”. Also, \{\em \spadatt{finiteAggregate}\} is used to assert that an aggregate has a finite number of immediate components.

\item \{\em basis\} \spad{S} is a basis of a module \spad{M} over a \spadgloss{ring} if \spad{S} generates \spad{M}, and \spad{S} is linearly independent

\item \{\em benefactor\} (of a given domain) a domain or package that the given domain explicitly references (for example, \{\em \spadgloss{calls}{calls functions from}\} in its implementation \spad{\{\em operation or function with \spadgloss{arity}\} 2 \spadgloss{arity}\} \spad{\{\em binding\}} the association of a variable with properties such as \spadgloss{value} and \spadgloss{type}. The top-level \spadgloss{environment} in the interpreter consists of bindings for all user variables and functions. Every \spadgloss{function} has an associated set of bindings, \spad{\{\em binding\}} one for each formal \spadgloss{argument} and \spadgloss{local variable}. \spad{\{\em block\}} \spad{\{\em (syntax)\} a control structure where expressions are sequentially \spadglossSee{evaluated}{evaluation}. \spad{\{\em body\}} \spad{\{\em boolean\}}
objects denoted by the \spad{true} and \spad{false}; elements of domain \spad{Boolean}. See also \spad{Bits}.

\item a \spad{function} in the standard Axiom library. Contrast \spad{user function}.

\item (noun) a mechanism for immediate retrieval of previously computed data. For example, a function which does a lengthy computation might store its values in a \spad{hash table} using argument as a key. The hash table then serves as a cache for the function (see also \spad{set function cache}). Also, when \spad{recurrence relations} which depend upon \spad{n} previous values are compiled, the previous \spad{n} values are normally cached (use \spad{set functions recurrence} to change this).

\item (verb) to save values in a cache.

\item the part of the \spad{domain constructor} that defines the functions implemented by the constructor.

\item (syntax) an operator used to conditionally evaluate code based on the branch of a \spad{Union}. For example, if value \spad{u} is \spad{Integer}, the conditional expression \spad{if u case Integer then A else B} evaluate \spad{A} if \spad{u} is an integer and \spad{B} otherwise.

\item the distinguished object denoting the type of a category; the class of all categories.

\item second-order types which serve to define useful "classification worlds" for domains, such as algebraic constructs (e.g. groups, rings, fields), and data structures (e.g. homogeneous aggregates, collections, dictionaries). Examples of categories are \spad{Ring} ("the class of all rings") and \spad{Aggregate} ("the class of all aggregates"). The categories of a given world are arranged in a hierarchy (formally, a directed acyclic graph). Each category inherits the properties of all its ancestors. Thus, for example, the category of ordered rings inherits the properties of the category of rings and those of the ordered sets. Categories provide a database of algebraic knowledge and ensure mathematical correctness, that "matrices of polynomials" is correct but "polynomials of hash tables" is not, that the multiply operation for "polynomials of continued fractions" is commutative, but that for "matrices of power series" is not. Optionally provide "default definitions" for operations they export. Categories are defined in Axiom by functions called \spad{category constructors}. Technically, a category designates a class of domains with common operations and attributes but usually with different functions and representations for its constituent objects. Categories are always defined using the Axiom library language.
Glossary

3.49. GLOSS.HT

(see also \spadgloss{category extension}). See also file \catdef.spad for definitions of basic algebraic categories in Axiom.

\item\newline\em category constructor\newline a function that creates categories,{} described by an abstract datatype in the Axiom programming language. For example,{} the category constructor \spad{Module} is a function which takes a domain parameter \spad{R} and creates the category "modules over \spad{R}".

\item\newline\em category extension\newline created by a category definition,{} an expression usually of the form \spad{A == B with ...}. In English,{} this means "category A is a \spad{B} with the new operations and attributes as given by .... See,{} for example,{} file \catdef.spad for a definitions of the algebra categories in Axiom,{} \aggcat.spad for data structure categories.

\item\newline\em category hierarchy\newline hierarchy formed by category extensions. The root category is \spadtype{Object}. A category can be defined as a \spadgloss{Join} of two or more categories so as to have multiple \spadgloss{parents}. Categories may also have parameterized so as to allow conditional inheritance.

\item\newline\em character\newline 1. an element of a character set,{} as represented by a keyboard key. 2. a component of a string. For example,{} the 0th element of the string \spad{"hello there"} is the character \emph{h}.

\item\newline\em client\newline (of a given domain) any domain or package that explicitly calls functions from the given domain

\item\newline\em coercion\newline an automatic transformation of an object of one \spadgloss{type} to an object of a similar or desired target type. In the interpreter,{} coercions and \spadgloss{retractions} are done automatically by the interpreter when a type mismatch occurs. Compare \spadgloss{conversion}.

\item\newline\em comment\newline textual remarks imbedded in code. Comments are preceded by a double dash ((\em --)). For Axiom library code,{} stylized comments for on-line documentation are preceded by a two plus signs ((\em ++)).

\item\newline\em Common LISP\newline A version of \spadgloss{LISP} adopted as an informal standard by major users and suppliers of LISP

\item\newline\em compile-time\newline the time when category or domain constructors are compiled. Contrast \spadgloss{run-time}.

\item\newline\em compiler\newline a program that generates low-level code from a higher-level source language. Axiom has three compilers. A \em graphics compiler\em converts graphical formulas to a compiled subroutine so that points can be rapidly produced for graphics commands. An \em interpreter compiler\em optionally compiles \spadgloss{user functions} when first \spadglossSee{invoked}{invocation} (use \spad{set functions compile} to turn this feature on). A \em library compiler\em compiles all constructors (not available in Release 1)
In Axiom, domains are objects. This term is used to distinguish the objects which are members of domains rather than domains themselves.

- **Conditional**
  - A control structure of the form `if A then B else C`; The evaluation of `A` produces `true` or `false`. If `true`, `B` evaluates to produce a value; otherwise `C` evaluates to produce a value. When the value is not used, `else C` part can be omitted.

- **Constant**
  - (syntax) a reserved word used in signatures in Axiom programming language to signify that an operation always returns the same value. For example, the signature `0: constant -> $` in the source code of `AbelianMonoid` tells the Axiom compiler that `0` is a constant so that suitable optimizations might be performed.

- **Constructor**
  - A function which creates a category, domain, or package.

- **Continuation**
  - When a line of a program is so long that it must be broken into several lines, all but the first line are called continuation lines. If such a line is given interactively, then each incomplete line must end with an underscore.

- **Control Structure**
  - Program structures which can specify a departure from normal sequential execution. Axiom has four kinds of control structures: blocks, case statements, conditionals, and loops.

- **Conversion**
  - The transformation of an object on one type to one of another type. Conversions performed automatically are called coercions. These happen when the interpreter has a type mismatch and a similar or declared target type is needed. In general, the user must use the infix operation `::` to cause this transformation.

- **Copying Semantics**
  - The programming language semantics used in Pascal but not in Axiom. See also pointer semantics for details.

- **Data Structure**
  - A structure for storing data in the computer. Examples are lists and hash tables.

- **Datatype**
  - Equivalent to domain in Axiom.

- **Declaration**
  - (syntax) an expression of the form `x : T` where `T` is some type. A declaration forces all values of the type `T` to be of that type. If a value is of a different type, the interpreter will try to coerce the value to type `T`. Declarations are necessary in case of ambiguity or when a user wants to introduce an unexposed domain.
3.49. GLOSS.HT

a function defined by a `\spadgloss{category}`. Such definitions appear
category definitions of the form `\spad{C: Category == T add I}` in an
optional implementation part `\spad{I}` to the right of the keyword `\spad{add}`.

A optional `\spadgloss{package}` of `\spadgloss{functions}` associated with
a category. Such functions are necessarily defined in terms over other
functions exported by the category.

**default package**
a optional `\spadgloss{package}` of `\spadgloss{functions}` associated with
a category. Such functions are necessarily defined in terms over other
functions exported by the category.

**definition**

- **(syntax)** 1. An expression of the form `\spad{f(a) == b}` defining
  function `\spad{f}` with `\spadgloss{formal arguments}` `\spad{a}` and
  `\spadgloss{body}` `\spad{b}`; equivalent to the statement
  `\spad{f == (a) +-> b}`. 2. An expression of the form `\spad{a == b}`
  where `\spad{a}` is a `\spadgloss{symbol}`, equivalent to `\spad{a() == b}`.
  See also `\spadgloss{macro}` where a similar substitution is done at
  `\spadgloss{parse}` time.

- **delimiter**
a `\spadgloss{character}` which marks the beginning or end of some
  syntactically correct unit in the language, `\spadignore{e.g.}`
  `\spadSyntax{"} for strings, `\spadignore{e.g.}` blanks for identifiers.

**destructive operation**
An operation which changes a component or structure of a value. In
Axiom, all destructive operations have names which end with an
exclamation mark (`\spad{em !}`). For example, domain `\spad{List}` has
two operations to reverse the elements of a list, one named
`\spadfunFrom{reverse}{List}` which returns a copy of the original list with
the elements reversed, one named `\spadfunFrom{reverse!}{List}` which
reverses the elements `\spad{em in place}` thus destructively changing the
original list.

- **documentation**
  1. on-line or hard copy descriptions of Axiom; 2. text in library
  code preceded by `\spad{++}` comments as opposed to general comments
  preceded by `\spad{--}`.

- **domain**
  (basic concept) A domain corresponds to the usual notion of
  abstract datatypes: that of a set of values and a set of "exported
  operations" for the creation and manipulation of these values. Datatypes
  are parameterized, dynamically constructed, and can combine with others
  in any meaningful way, `\spadignore{e.g.}` "lists of floats"
  (`\spadtype{List Float}`), "fractions of polynomials with integer
  coefficients" (`\spadtype{Fraction Polynomial Integer}`), "matrices
  of infinite \spadgloss{streams} of cardinal numbers"
  (`\spadtype{Matrix Stream CardinalNumber}`). The term `\spad{domain}` is
  actually abbreviated `\spad{domain of computation}`. Technically, a
  domain denotes a class of objects, a class of \spadgloss{operations}
  for creating and other manipulating these objects, and a class of
  \spadgloss{attributes} describing computationally useful properties.
  Domains also provide \spadgloss{functions} for each operation often in
terms of some \spadgloss{representation} for the objects. A domain
itself is an \spadgloss{object} created by a \spadgloss{function}
called a \spadgloss{domain constructor}. 

a function that creates domains, described by an abstract datatype in the Axiom programming language. Simple domains like \spad{Integer} and \spad{Boolean} are created by domain constructors with no arguments. Most domain constructors take one or more parameters, one usually denoting an underlying domain. For example, the domain \spad{Matrix(R)} denotes "matrices over \spad{R}". Domains \spad{Mapping}, \spad{Record}, and \spad{Union} are primitive domains. All other domains are written in the Axiom programming language and can be modified by users with access to the library source code.

A domain constructor \spad{A} is said to extend a domain constructor \spad{B} if \spad{A}'s definition has the form \spad{A == B add ...}. This intuitively means "functions not defined by \spad{A} are assumed to come from \spad{B}". Successive domain extensions form \spad{add-chains} affecting the the \spad{search order} for functions not implemented directly by the domain during \spad{dynamic lookup}.

using an infix dot (\spad{.}) for function application. If \spad{u} is the list \spad{[7, 4, -11]} then both \spad{u(2)} and \spad{u.2} return 4. Dot notation nests to left. Thus \spad{f . g . h} is equivalent to \spad{(f . g) . h}.

that which is done at run-time as opposed to \spad{compile-time}. For example, the interpreter will build the domain "matrices over integers" dynamically in response to user input. However, the compilation of all functions for matrices and integers is done during \spad{compile-time}. Constrast \spad{static}.

In Axiom, a \spad{domain} may or may not explicitly provide \spad{function} definitions for all of its exported \spad{operations}. These definitions may instead come from domains in the \spad{add-chain} or from \spad{default packages}. When a \spad{function call} is made for an operation in the domain, up to five steps are carried out. If the domain itself implements a function for the operation, that function is returned. Each of the domains in the \spad{add-chain} are searched for one which implements the function; if found, the function is returned. Each of the \spad{default packages} for the domain are searched in order of the \spad{lineage}. If any of the default packages implements the function, the first one found is returned. Each of the \spad{default packages} for each of the domains in the \spad{add-chain} are searched in the order of their \spad{lineage}. If any of the default packages implements the function, the first one found is returned. If all of the above steps fail, an error message is reported.
the unique value of objects with type \spadtype{Void}.

Glossary:

- **environment**
  - a set of \spadgloss{bindings}.

- **evaluation**
  - a systematic process which transforms an \spadgloss{expression} into an object called the \spadgloss{value} of the expression. Evaluation may produce \spadgloss{side effects}.

- **exit**
  - \{reserved word\} an \spadgloss{operator} which forces an exit from the current block. For example, \{the \spadgloss{block}\} \spad{(a := 1; if i > 0 then exit a; a := 2)} will prematurely exit at the second statement with value 1 if the value of \spad{i} is greater than 0. See \spadgloss{\spad{=>}} for an alternate syntax.

- **explicit export**
  - 1. (of a domain \spad{D}) any \spadgloss{attribute}, \spadgloss{operation}, or \spadgloss{category} explicitly mentioned in the \spadgloss{type} specification part \spad{T} for the domain constructor definition \spad{\spad{D: T == I}} 2. (of a category \spad{C}) any \spadgloss{attribute}, \spadgloss{operation}, \spad{category} explicitly mentioned in the \spadgloss{type} specification part \spad{T} for the domain constructor definition \spad{\spad{C: \spadgloss{Category} == T}}

- **export**
  - \spadgloss{explicit export} or \spadgloss{implicit export} of a domain or category

- **expose**
  - some constructors are \{exposed\}, others \{unexposed\}. Exposed domains and packages are recognized by the interpreter. Use \spadsys{\set expose} to control change what is exposed. To see both exposed and unexposed constructors, \{use \spad{Browse()} with give the system command \spadsyscom{\set hyperdoc browse exposure on}\}. Unexposed constructors will now appear prefixed by star(\spad{*}).

- **expression**
  - 1. any syntactically correct program fragment. 2. an element of domain \spadtype{Expression}

- **extend**
  - see \spadgloss{category extension} or \spadgloss{domain extension}

- **field**
  - \{algebra\} a \spadgloss{domain} which is \spadgloss{ring} where every non-zero element is invertible and where \spad{xy=yx}; a member of category \spadtype{Field}. For a complete list of fields, \{click on \{\spad{Domains}\} under \{\spad{Cross Reference}\} for \spadtype{Field}\}.

- **file**
  - a program or collection of data stored on disk, \{tape or other medium\}

- **float**
  - a floating-point number with user-specified precision; an element of domain \spadtype{Float}. Floats are \spadgloss{literals} which are written two ways: without an exponent (\{\spad{3.1416}\}), \{or with an exponent \spad{3.1416E-12}\}). Use function \spadgloss{precision} to change the precision of the mantissa.
CHAPTER 3. HYPERDOC PAGES

(20 digits by default). See also \spadgloss{small float}.

\item\newline{\em \menuitemstyle{}}{\em formal parameter}\space{}
(of a function) an identifier \spadglossSee{bound}{binding} to the value of an actual \spadgloss{argument} on \spadgloss{invocation}. In the function definition \spad{f(x,\{y\}) == u},\{} for example,\{} \spad{x}
and \spad{y} are the formal parameter.

\item\newline{\em \menuitemstyle{}}{\em frame}\space{}
the basic unit of an interactive session; each frame has its own \spadgloss{step number},\{} \spadgloss{environment},\{} and \spadgloss{history}. In one interactive session,\{} users can create and drop frames,\{} and have several active frames simultaneously.

\item\newline{\em \menuitemstyle{}}{\em free}\space{}
{\em (syntax)} A keyword used in user-defined functions to declare that a variable is a \spadgloss{free variable} of that function. For example,\{} the statement \spad{free x} declares the variable \spad{x} within the body of a function \spad{f} to be a free variable in \spad{f}. Without such a declaration,\{} any variable \spad{x} which appears on the left hand side of an assignment is regarded as a \spadgloss{local variable} of that function. If the intention of the assignment is to give an value to a \spadgloss{global variable} \spad{x},\{} the body of that function must contain the statement \spad{free x}.

\item\newline{\em \menuitemstyle{}}{\em function}\space{}
implementation of \spadgloss{operation}; it takes zero or more \spadgloss{argument} parameters and produces zero or more values. Functions are objects which can be passed as parameters to functions and can be returned as values of functions. Functions can also create other functions (see also \spadgloss{application} and \spadgloss{invocation}). The terms \{\em operation\} and \{\em function\} are distinct notions in Axiom. An operation is an abstraction of a function,\{} described by declaring a \spadgloss{signature}. A function is created by providing an implementation of that operation by some piece of Axiom code. Consider the example of defining a user-function \spad{fact} to compute the \spadfun{factorial} of a nonnegative integer. The Axiom statement \spad{fact: Integer -> Integer} describes the operation,\{} whereas the statement \spad{fact(n) = \text{reduce}(\star,\{1..n\})} defines the functions. See also \spadgloss{generic function}.

\item\newline{\em \menuitemstyle{}}{\em function body}\space{}
the part of a \spadgloss{function}\spad{'}s definition which is evaluated when the function is called at \spadgloss{run-time}; the part of the function definition to the right of the \spadSyntax{\spad{==}}. \spadgloss{garbage collection}\space{}
a system function that automatically recycles memory cells from the \spadgloss{heap}. Axiom is built upon \spadgloss{Common LISP} which provides this facility.
a mechanism for reclaiming storage in the \spadgloss{heap}.
\item a complex-valued expression, \spadignore{e.g.} one with both a real
and imaginary part; a member of a \spadtype{Complex} domain.
\item the use of one function to operate on objects of different types; One
might regard Axiom as supporting generic \spadgloss{operations}
but not generic functions. One operation \spad{+: (D,D) -> D} exists
for adding elements in a ring; each ring however provides its own
type-specific function for implementing this operation.
\item A variable which can be referenced freely by functions. In Axiom,
all top-level user-defined variables defined during an interactive user
session are global variables. Axiom does not allow \spad{fluid variables},
that is, variables \spadgloss{bound} by functions which can be referenced by functions those functions call.
\item \spadgloss{Groebner basis} a special basis for a polynomial ideal that allows a
simple test for membership. It is useful in solving systems of polynomial
equations.
\item \spadgloss{group} a monoid where every element has a multiplicative inverse.
\item A data structure that efficiently maps a given object to another. A hash
table consists of a set of \spad{entries}, each of which associates a
\spad{key} with a \spad{value}. Finding the object stored under a key can
be very fast even if there are a large number of entries since keys are
\spadhashed into numerical codes for fast lookup.
\item an area of storage used by data in programs. For example, Axiom will
use the heap to hold the partial results of symbolic computations. When
cancellations occur, these results remain in the heap until
\spadgloss{garbage collected}
\item a mechanism which records the results for an interactive computation.
Using the history facility, users can save computations, review
previous steps of a computation, and restore a previous interactive
session at some later time. For details, issue the system command
\spad{)history ?} to the interpreter. See also \spadgloss{frame}.
\item \spadgloss{ideal} a subset of a ring that is closed under addition and
multiplication by arbitrary ring elements, \spadignore{i.e.}
it's a module over the ring.
\item \spadgloss{identifier} an Axiom name; a \spad{literal} of type
\spadtype{Symbol}. An identifier begins with an alphabetical character or
\% and may be followed by alphabetic characters, digits, \? or !.
Certain distinguished \spadgloss{reserved words} are not allowed as
identifiers but have special meaning in the Axiom.
\item an \spadtype{immutable}
an object is immutable if it cannot be changed by an operation; not a mutable object. Algebraic objects generally immutable: changing an algebraic expression involves copying parts of the original object. One exception is a matrix object of type Matrix. Examples of mutable objects are data structures such as those of type List. See also pointer semantics.

1. a variable that counts the number of times a loop is repeated. 2. the “address” of an element in a data structure (see also category LinearAggregate).

{\em infix\} an operator placed between two operands; also called a binary operator, e.g. \spad{a + b}. An infix operator may also be used as a prefix, e.g. \spad{+(a,{}b)} is also permissible in the Axiom language. Infix operators have a relative precedence.

a rectangular area on a Hyperdoc screen into which users can enter text. to build a category, domain, or package at run-time a \spad{literal} object of domain \spad{Integer}, the class of integers with an unbounded number of digits. Integer literals consist of one or more consecutive digits (0-9) with no embedded blanks. Underscores can be used to separate digits in long integers if desirable. a system where the user interacts with the computer step-by-step the subsystem of Axiom responsible for handling user input during an interactive session. The following somewhat simplified description of the typical action of the interpreter. The interpreter parses the user’s input expression to create an expression tree then does a bottom-up traversal of the tree. Each subtree encountered which is not a value consists of a root node denoting an operation name and one or more leaf nodes denoting operands. The interpreter resolves type mismatches and uses type-inferencing and a library database to determine appropriate types of the operands and the result, and an operation to be performed. The interpreter then builds a domain to perform the indicated operation, then invokes a function from the domain to compute a value. The subtree is then replaced by that value and the process continues. Once the entire tree has been processed, the value replacing the top node of the tree is displayed back to the user as the value of the expression.
3.49. GLOSS.HT

-of a function) the run-time process involved in
\spadglossSee{evaluating}{evaluation} a a \spadgloss{function}
\spadgloss{application}. This process has two steps. First,{} a
local \spadgloss{environment} is created where \spadgloss{formal arguments}
are locally \spadglossSee{bound}{binding} by \spadgloss{assignment} to
their respective actual \spadgloss{argument}. Second,{} the
\spadgloss{function body} is evaluated in that local environment.
The evaluation of a function is terminated either by completely
evaluating the function body or by the evaluation of a
\spadSyntax{return} expression.

iterated evaluation of an expression or a sequence of expressions.
Iterations use the reserved words \spadSyntax{for},{}
\spadSyntax{while},{} and \spadSyntax{repeat}.
- a primitive Axiom function taking two or more categories as
arguments and producing a category containing all of the operations
and attributes from the respective categories.

Kyoto Common LISP,{} a version of \spadgloss{Common LISP} which
features compilation of the compilation of LISP into the \spad{C}
Programming Language

In Axiom,{} a collection of compiled modules representing
the \spadgloss{category} or \spadgloss{domain} constructor.
the sequence of \spadgloss{default packages} for a given domain to be
searched during \spadgloss{dynamic lookup}. This sequence is computed
first by ordering the category \spadgloss{ancestors} of the domain
according to their \spad{level number},{} an integer equal to to the
minimum distance of the domain from the category. Parents have level
1,{}, parents of parents have level 2,{}, and so on. Among categories
with equal level numbers,{} ones which appear in the left-most branches
of \spad{Join}s in the source code come first. See also
\spadgloss{dynamic lookup}.

acronymn for List Processing Language,{} a language designed for the
manipulation of nonnumerical data. The Axiom library is
translated into LISP then compiled into machine code by an underlying LISP.
an object of a \spadtype{List} domain.
an object with a special syntax in the language. In Axiom,{}
there are five types of literals: \spadgloss{booleans},{}
\spadgloss{integers},{} \spadgloss{floats},{} \spadgloss{strings},{}
and \spadgloss{symbols}.
\spadSyntax{local} A keyword used in user-defined functions to declare that
a variable is a \spadgloss{local variable} of that function. Because of
default assumptions on variables, such a declaration is not necessary but is available to the user for clarity when appropriate.

(of a function) a variable \( \text{bound} \) by that function and such that its binding is invisible to any function that function calls. Also called a \( \text{lexical} \) variable. By default in the

interpreter:

\begin{itemize}
\item 1. any variable \( \text{free} \) which appears on the left hand side of an assignment is regarded a local variable of that function. If the intention of an assignment is to change the value of a \( \text{global} \) variable \( \text{free} \), the body of the function must then contain the statement \( \text{free} \). \item 2. any other variable is regarded as a \( \text{free} \) variable. An optional declaration \( \text{local} \) is available to explicitly declare a variable to be a local variable. All \( \text{formal} \) parameters to the function can be regarded as local variables to the function.
\end{itemize}

\item \( \text{loop} \)

1. an expression containing a \( \text{repeat} \)

2. a collection expression having a \( \text{for} \) or a \( \text{while} \)

\item \( \text{loop body} \)

the part of a loop following the \( \text{repeat} \) that tells what to do each iteration. For example, the body of the loop \( \text{repeat} \) \( \text{for} \) \( \text{in} \) \( \text{S} \)

\item \( \text{macro} \)

1. An expression of the form \( \text{symbol} \) \( \text{==} \) \( \text{expression} \) at parse time. \item 2. An expression of the form \( \text{macro} \) \( \text{==} \) \( \text{expression} \) defining a parameterized macro expansion for a parameterized form \( \text{macro} \) \( \text{==} \) \( \text{expression} \) \( \text{macro} \). This macro causes a form \( \text{expression} \) \( \text{macro} \) \( \text{expression} \) to be textually replaced by the expression \( \text{expression} \) \( \text{macro} \) \( \text{expression} \)

\item \( \text{mode} \)

a type expression containing a question-mark \( \text{?} \). For example, \( \text{the class of all polynomials over an arbitrary ring} \)

\item \( \text{mutable} \)

objects which contain \( \text{pointers} \) to other objects and which have operations defined on them which alter these pointers. Contrast \( \text{immutable} \). Axiom uses \( \text{pointer semantics} \) as does \( \text{LISP} \) in contrast with many other languages such as Pascal which use \( \text{copying semantics} \). See \( \text{pointer semantics} \) for details.

\item \( \text{name} \)

1. a \( \text{symbol} \) denoting a \( \text{variable} \),\( \text{the variable} \)

2. a \( \text{symbol} \) denoting an \( \text{operation} \),\( \text{the operation} \) \n
\( \text{divide: (Integer, Integer) -> Integer} \).
3.49. GLOSS.HT

- **nullary**: a function with no arguments, e.g. \spadfun{characteristic}.
- **nullary**: operation or function with \spadgloss{arity} 0
- **Object**: a category with no operations or attributes, from which most categories in Axiom are \spadglossSee{extensions}{category extension}.
- **object**: a data entity created or manipulated by programs. Elements of domains, and domains themselves are objects. Whereas categories are created by functions, they cannot be dynamically manipulated in the current system and are thus not considered as objects. The most basic objects are \spadgloss{literals}; all other objects must be created \spadgloss{functions}. Objects can refer to other objects using \spadgloss{pointers}. Axiom language uses \spadgloss{pointer semantics} when dealing with \spadgloss{mutable} objects.
- **object code**: code which can be directly executed by hardware; also known as \spadgloss{machine language}.
- **operand**: an argument of an \spadgloss{operator} (regarding an operator as a \spadgloss{function}).
- **operation**: an abstraction of a \spadgloss{function}, described by a \spadgloss{signature}. For example, \spad{fact: NonNegativeInteger -> NonNegativeInteger} describes an operation for "the factorial of a (non-negative) integer".
- **operator**: special reserved words in the language such as \spadop{+} and \spadop{*}; operators can be either \spadgloss{prefix} or \spadgloss{infix} and have a relative \spadgloss{precedence}.
- **overloading**: the use of the same name to denote distinct functions; a function is identified by a \spadgloss{signature} identifying its name, the number and types of its arguments, and its return types. If two functions can have identical signatures, a \spadgloss{package call} must be made to distinguish the two.
- **package**: a domain whose exported operations depend solely on the parameters and other explicit domains, a package for solving systems of equations of polynomials over any field, floats, rational numbers, complex rational functions, or power series. Facilities for integration, differential equations, solution of linear or polynomial equations, and group theory are provided by "packages". Technically, a package is a domain which has no \spadgloss{signature} containing the symbol \$. While domains intuitively provide computational objects you can compute with, packages intuitively provide functions (\spadgloss{polymorphic} functions) which will work over a variety of datatypes.

\em{(syntax)} an expression of the form \spad{e \$ D} where \spad{e} is
an \spadgloss{application} and \spad{D} denotes some \spadgloss{package}
(or \spadgloss{domain}).

\item \em{package call}\space{} 
\em{(syntax)} an expression of the form \spad{f(x,y) \$ D} used to identify
that the function \spad{f} is to be one from \spad{D}.

\item \em{package constructor}\space{} 
same as \spadgloss{domain constructor}.

\item \em{parameter}\space{} 
see \spadgloss{argument}

\item \em{parameterized datatype}\space{} 
a domain that is built on another, for example, polynomials with integer
coefficients.

\item \em{parameterized form}\space{} 
a expression of the form \spad{f(x,y)}, an \spadgloss{application} of a
function.

\item \em{parent}\space{} 
(of a domain) a category which is explicitly declared in the source code
definition for the domain to be an \spadgloss{export} of the domain.

\item \em{parse}\space{} 
1. (verb) to produce an internal representation of a user input string;
the resultant internal representation is then "interpreted" by Axiom
to perform some indicated action.

\item \em{parse}\space{} 
the transformation of a user input string representing a valid Axiom
expression into an internal representation as a tree-structure.

\item \em{partially ordered set}\space{} 
a set with a reflexive, transitive and antisymmetric \spadgloss{binary}
operation.

\item \em{pattern match}\space{} 
1. (on expressions) Given a expression called a "subject" \spad{u},
the attempt to rewrite \spad{u} using a set of "rewrite rules". Each rule has
the form \spad{A == B} where \spad{A} indicates a expression called a
"pattern" and \spad{B} denotes a "replacement". The meaning of this rule
is "replace \spad{A} by \spad{B}\". If a given pattern \spad{A} matches a
subexpression of \spad{u},\{} that subexpression is replaced by \spad{B}.
Once rewritten,\{} pattern matching continues until no further changes occur.
2. (on strings) the attempt to match a string indicating a "pattern" to
another string called a "subject",\{} for example,\{} for the purpose of
identifying a list of names. In \Browse\{},\{} users may enter
\spadgloss{search strings} for the purpose of identifying constructors,\{}
operations,\{} and attributes.

\item \em{pile}\space{} 
alternate syntax for a block,\{} using indentation and column alignment
(see also \spadgloss{block}).

\item \em{pointer}\space{} 
a reference implemented by a link directed from one object to another in
the computer memory. An object is said to \em{refer} to another if it
has a pointer to that other object. Objects can also refer to themselves
(cyclic references are legal). Also more than one object can refer to the
same object. See also \spadgloss{pointer semantics}.

the programming language semantics used in languages such as LISP which allow objects to be \spadgloss{mutable}. Consider the following sequence of Axiom statements:
\begin{items}
  \item \spad{x : Vector Integer := [1,{},4,{},7]}
  \item \spad{y := x}
  \item \spad{swap!(x,{},2,{},3)}
\end{items}

The function \spadfunFrom{swap!}{Vector} is used to interchange the 2nd and 3rd value in the list \spad{x} producing the value \spad{[1,{},7,{},4]}. What value does \spad{y} have after evaluation of the third statement?
The answer is different in Axiom than it is in a language with \spadgloss{copying semantics}. In Axiom, first the vector \spad{[1,{},2,{},3]} is created and the variable \spad{x} set to \spad{V}. Next, the variable \spad{y} is made to point to \spad{V} just as \spad{x} does. Now the third statement interchanges the last 2 elements of \spad{V} (the \{em !\} at the end of the name \spadfunFrom{swap!}{Vector} tells you that this operation is destructive,\{em \} that is,\{em \} it changes the elements \{em in place\}). Both \spad{x} and \spad{y} perceive this change to \spad{V}. Thus both \spad{x} and \spad{y} then have the value \spad{[1,{},7,{},4]}. In Pascal, the second statement causes a copy of \spad{V} to be stored under \spad{y}. Thus the change to \spad{V} made by the third statement does not affect \spad{y}.

a \spadgloss{function} parameterized by one or more \spadgloss{domains}; a \spadgloss{algorithm} defined \spadglossSee{categorically}{category}. Every function defined in a domain or package constructor with a domain-valued parameter is polymorphic. For example,\{em \} the same matrix \spad{matrix}\{em \}* function is used to multiply "matrices over integers" as "matrices over matrices over integers" Likewise,\{em \} various \spad{solve}\{em \} polynomials over any \spadgloss{field}.

an \spadgloss{operator} that follows its single \spadgloss{operand}. Postfix operators are not available in Axiom.

{\em (syntax)} refers to the so-called {\em binding power} of an operator. For example, \spad{\*} has higher binding power than \spad{\+} so that the expression \spad{a + b * c} is equivalent to \spad{a + (b \* c)}.

the number of digits in the specification of a number,\{em \} \spad{\!\!precision\{e.g.\} as set by \spadfunFrom{precision}{Float}.

1. a Boolean valued function,\{em \} \spadignore{e.g.}
\spad{\!\!odd: Integer -> Boolean}. 2. an Boolean valued expression

{\em (syntax)} an \spadgloss{operator} such as \spad{\neg} and \spad{\!\!not}
that is written {\em before} its single \spadgloss{operand}. Every function of one argument can be used as a prefix operator. For example,\{em \}
all of the following have equivalent meaning in Axiom: \spad{f(x)}, \{} and \spad{f\ x}. See also \spadgloss{dot notation}.

the prefix \spadgloss{operator} \spad{'} meaning \{em do not evaluate\}.

(basic domain constructor) a domain constructor used to create a inhomogeneous aggregate composed of pairs of "selectors" and \spadgloss{values}. A Record domain is written in the form \spad{Record(a1:D1,{}...,{}an:Dn)} (\spad{n} > 0) where \spad{a1}, \{}...,\{}\spad{an} are identifiers called the \{\em selectors\} of the record, \{} and \spad{D1}, \{}...,\{}\spad{Dn} are domains indicating the type of the component stored under selector \spad{an}.

A relation which can be expressed as a function \spad{f} with some argument \spad{n} which depends on the value of \spad{f} at \spad{k} previous values. In many cases, \{} Axiom will rewrite a recurrence relation on compilation so as to \spadgloss{cache} its previous \spad{k} values and therefore make the computation significantly more efficient.

use of a self-reference within the body of a function. Indirect recursion is when a function uses a function below it in the call chain.

1. A function that calls itself, \{} either directly or indirectly through another function. 2. self-referential. See also \spadgloss{recursive}.

a special identifier used as \spadgloss{local variable} of a domain constructor body to denote the representation domain for objects of a domain.

a \spadgloss{domain} providing a data structure for elements of a domain; generally denoted by the special identifier \spadgloss{Rep} in the Axiom programming language. As domains are \spadgloss{abstract datatypes}, \{} this representation is not available to users of the domain, \{} only to functions defined in the \spadgloss{function body} for a domain constructor. Any domain can be used as a representation.

a special sequence of non-blank characters with special meaning in the Axiom language. Examples of reserved words are names such as \spad{for}, \{} \spad{if}, \{} and \spad{free}, \{} operator names such as \spad{+} and \spad{mod}, \{} special character strings such as \spad{=} and \spad{:=}.

to move an object in a parameterized domain back to the underlying domain, \{} for example to move the object \spad{7} from a "fraction of integers" (domain \spad{Fraction Integer}) to "the integers" (domain \spad{Integer}).
when leaving a function, the value of the expression following \spadSyntax{return} becomes the value of the function.

\item when leaving a function, the value of the expression following \spadSyntax{return} becomes the value of the function.

\item A set with a commutative addition, associative multiplication, a unit element, and multiplication distributes over addition and subtraction.

\item \spadgloss{rule} (syntax) 1. An expression of the form \spad{rule A == B} indicating a "rewrite rule". 2. An expression of the form \spad{rule (R1;...;Rn)} indicating a set of "rewrite rules" \spad{R1},...,\spad{Rn}. See \spadgloss{pattern matching} for details.

\item \spadgloss{run-time} the time of doing a computation. Contrast \spadgloss{compile-time} rather than prior to it; \spadgloss{dynamic} as opposed to \spadgloss{static}. For example, the decision of the interpreter to build a structure such as "matrices with power series entries" in response to user input is made at run-time.

\item \spadgloss{run-time check} an error-checking which can be done only when the program receives user input; for example, confirming that a value is in the proper range for a computation.

\item \spadgloss{search string} a string entered into an \spadgloss{input area} on a Hyperdoc screen

\item \spadgloss{selector} an identifier used to address a component value of a \spadgloss{Record} datatype.

\item \spadgloss{semantics} the relationships between symbols and their meanings. The rules for obtaining the \spadgloss{meaning} of any syntactically valid expression.

\item \spadgloss{small float} the domain for hardware floating point arithmetic as provided by the computer hardware.

\item \spadgloss{small integer} the domain for hardware integer arithmetic as provided by the computer hardware.

\item \spadgloss{source} the \spadgloss{type} of the argument of a \spadgloss{function}; the type expression before the \spad{->} in a \spadgloss{signature}. For example, the source of \spad{f : (Integer,{}Integer) -> Integer} is \spad{Integer,{}Integer).
data structure whose elements are mostly identical (a sparse matrix is one filled with mostly zeroes).

that computation done before run-time, such as compilation. Contrast \spadgloss{dynamic}.

the number which precedes user input lines in an interactive session; the output of user results is also labeled by this number.

an object of \spadtype{Stream(R)}, a generalization of a \spadgloss{list} to allow an infinite number of elements. Elements of a stream are computed "on demand". Strings are used to implement various forms of power series \ignore{\spad{???}}.

an object of domain \spadtype{String}. Strings are \spadgloss{literals} consisting of an arbitrary sequence of \spadgloss{characters} surrounded by double-quotes \spad{""}, \spadignore{e.g.} \spad{"Look here!"}.

\{\em (basic concept)\} a \spadgloss{subdomain} together with a \spadgloss{predicate} characterizing which members of the domain belong to the subdomain. The exports of a subdomain are usually distinct from the domain itself. A fundamental assumption however is that values in the subdomain are automatically \spadglossSee{coerceable}{coercion} to values in the domain. For example, if \spad{n} and \spad{m} are declared to be members of a subdomain of the integers, then \{\em any\} \spadgloss{binary} operation from \spadtype{Integer} is available on \spad{n} and \spad{m}. On the other hand, if the result of that operation is to be assigned to, say, \spad{k}, also declared to be of that subdomain, a \spadgloss{run-time} check is generally necessary to ensure that the result belongs to the subdomain.

the use of \spad{\mid} followed by an expression to filter an iteration. \spadgloss{suffix} an \spadgloss{operator} which placed after its operand. Suffix operators are not allowed in the Axiom language.

objects denoted by \spadgloss{identifier} \spadgloss{literals}; an element of domain \spadtype{Symbol}. The interpreter defaultly converts a symbol \spad{x} into \spadtype{Variable(x)}.

\spadgloss{rules} of grammar, punctuation etc. for forming correct expressions.\spad{\`}

\spadgloss{top-level Axiom statements that begin with }\spad{\`}. System commands allow users to query the database, \{\em read files,\} \em trace functions,\} and so on.

an identifier used to discriminate a branch of a \spadgloss{Union} type.

\spadgloss{type} of the result of a \spadgloss{function}; the
type expression following the \spad{->} in a \spad{signature}.  
refers to direct user interactions with the Axiom interpreter.  
\spad{a partially ordered set} a partially ordered set where any two elements are 
comparable.  
\item  
use of system function \spad{)trace} to track the arguments passed 
to a function and the values returned.  
\item  
an expression of two or more other expressions separated by commas,{} \spad{f(x,\{\}}{}{}\spad{y))} and in \spad{signatures} \spad{(Integer,\{\}Integer) \rightarrow Integer)}.  A tuple is not a data structure,{} rather a syntax mechanism for grouping expressions.  
\item  
\spad{Category}.  The type of a \spad{domain} is any \spad{category} that domain 
develops to.  The type of any other object is either the (unique) domain 
that object belongs to or any \spad{domain} of that domain.  The 
type of objects is in general not unique.  
\item  
a system function which determines whether the datatype of an object is 
appropriate for a given operation.  
\item  
a \spad{domain constructor} or \spad{category constructor}.  
\item  
when the interpreter chooses the type for an object based on context. 
For example,{} if the user interactively issues the definition  
\spad{f(x) == (x + \%i)**2}} then issues \spad{f(2)},{} the interpreter will infer the type of \spad{f} to be  
\spad{Integer \rightarrow Complex Integer}.  
\item  
operation or function with \spad{arity} 1  
\item  
\spad{domain} that has a single domain-valued parameter,{} the \spad{underlying domain} refers to that parameter.  For example,{} the domain “matrices of integers” \spad{Matrix Integer}) has 
underlying domain \spad{Integer}.  
\item  
(basic domain constructor) a domain constructor used to combine any 
set of domains into a single domain.  A Union domain is written in the 
form \spad{Union(D1,\{\}Dn)} \spad{n} > 0 where  
\spad{D1},{}\ldots{},\spad{Dn} are identifiers called the \spad{tags} of 
the union,{} and \spad{D1},{}\ldots{},\spad{Dn} are domains called the 
\spad{branches} of the union.  The tags \spad{D1} are optional,{} but required when two of the \spad{D1} are equal,{} 
\spad{Union(inches:Integer,\{\}centimeters:Integer))}.  
In the interpreter,{} values of union domains are automatically coerced
to values in the branches and vice-versa as appropriate. See also \spadgloss{case}.
\item an invertible element.
\item a function defined by a user during an interactive session. Contrast \spadgloss{built-in function}.
\item a variable created by the user at top-level during an interactive session
\item 1. the result of \spadgloss{evaluating} an expression.
2. a property associated with a \spadgloss{variable} in a \spadgloss{binding}
in an \spadgloss{environment}.
\item a means of referring to an object but itself \spad{not} an object. A variable has a name and an associated \spadgloss{binding} created by \spadgloss{evaluation} of Axiom expressions such as \spadgloss{declarations}, \spadgloss{assignments}, and \spadgloss{definitions}. In the top-level \spadgloss{environment} of the interpreter, variables are \spadgloss{global variables}. Such variables can be freely referenced in user-defined functions although a \spadgloss{free} declaration is needed to assign values to them. See \spadgloss{local variable} for details.
\item the type given when the \spadgloss{value} and \spadgloss{type} of an expression are not needed. Also used when there is no guarantee at run-time that a value and predictable mode will result.
\item a symbol which matches any substring including the empty string; for example, the search string \spad{*an*} matches an word containing the consecutive letters \spad{a} and \spad{n}
\item an interactive record of the user input and output held in an interactive history file. Each user input and corresponding output expression in the workspace has a corresponding \spadgloss{step number}. The current output expression in the workspace is referred to as \spad{\%}. The output expression associated with step number \spad{n} is referred to by \spad{\%(n)}. The \spad{k}-th previous output expression relative to the current step number \spad{n} is referred to by \spad{\%(n\%(- k))}. Each interactive \spadgloss{frame} has its own workspace.
\endmenu\endscroll
Graphics

Axiom can plot curves and surfaces of various types, as well as lists of points in the plane.

- **Examples** See examples of Axiom graphics
- **2D Graphics** Graphics in the real and complex plane
- **3D Graphics** Plot surfaces, curves, or tubes around curves
- **Viewports** Customize graphics using Viewports

CHAPTER 3. HYPERDOC PAGES

Implicit Curves

— graphics.ht —

Non-singular curves defined by a polynomial equation \( p(x,y) = 0 \) in a rectangular region in the plane.

Pick a particular example or choose 'All' to see all the examples.

A Conic Section (Hyperbola).
\[
\text{\graphpaste{draw(x * y = 1, x, y, range == [-3..3, -3..3])}}
\]

An Elliptic Curve.
\[
\text{\graphpaste{draw(y**2 + y = x**3 - x, x, y, range == [-2..2, -2..1])}}
\]

Cartesian Ovals.
\[
\text{\spadpaste{p := ((x**2 + y**2 + 1) - 8*x)**2 - (8*(x**2 + y**2 + 1) - 4*x - 1)}}
\]
\[
\text{\graphpaste{draw(p = 0, x, y, range == [-1..11, -7..7], title == "Cartesian Ovals")}}
\]

Cassinian Ovals: two loops.
\[
\text{\spadpaste{q := (x**2 + y**2 + 7**2)**2 - (6**4 + 4*7**2*x**2)}}
\]
\[
\text{\graphpaste{draw(q = 0, x, y, range == [-10..10, -4..4], title == "Cassini oval with two loops")}}
\]

Run all examples on this page.

Functions of Two Variables

— graphics.ht —

\begin{page}{TwoVariableGraphicsPage}{Functions of Two Variables}
\beginscroll
This page describes the plotting of surfaces defined by an equation of two variables, \( z = f(x,y) \), for which the ranges of \( x \) and \( y \) are explicitly defined. The basic draw command for this function utilizes either the uncompiled function or compiled function format. The general format for an uncompiled function is:
\indent{5}\newline
\textbf{\em draw}(f(x,y), x = a..b, y = c..d)
\indent{0}\newline
where \texttt{a..b} and \texttt{c..d} are segments defining the intervals \([a,b]\) and \([c,d]\) over which the variables \( x \) and \( y \) span. In this case the function is not compiled until the draw command is executed. Here is an example:
\graphpaste{draw(cos(x*y),x=-3..3,y=-3..3)}
In the case of a compiled function, the function is named and compiled independently. This is useful if you intend to use a function often, or if the function is long and complex. The following line shows a function whose parameters are of the type \texttt{Small Float}. The function is
CHAPTER 3. HYPERDOC PAGES

compiled and stored by Axiom when it is entered.

\indent{5} newline

\em NOTE: It is only necessary to click on the draw command button to
plot this example.

\indent{0} newline

\spadpaste{f(x:SF,y:SF):SF == sin(x)*cos(y) \bound{f}}

\indent{0} newline

Once the function is compiled the draw command only needs the name
of the function to execute. Here is a compiled function example:

\graphpaste{draw(f,-\%pi..\%pi,\%pi..-\%pi) \free{f}}

Note that the parameter ranges do not take the variable names as in the
case of uncompiled functions. The variables are entered in the order in
which they are defined in the function specification. In this case the
first range specifies the x-variable and the second range specifies the
y-variable.

\endscroll

\autobuttons

\end{page}
Parametric Space Curves

This page describes the plotting in three dimensional space of a curve defined by the parametric equations \( x = f(t), y = g(t), z = h(t), \) where \( f, g, \) and \( h \) are functions of the parameter \( t \) which ranges over a specified interval. The basic draw command for this function utilizes either the uncompiled functions or compiled functions format and uses the \spadfun{curve} command to specify the three functions for the \( x, y, \) and \( z \) components of the curve. The general format for uncompiled functions is:

\[ \text{draw(curve}(f(t), g(t), h(t)), t = a..b) \]

where \( a..b \) is the segment defining the interval \([a,b]\) over which the parameter \( t \) ranges. In this case the functions are not compiled until the draw command is executed. Here is an example:

\graphpaste{draw(curve(cos(t),sin(t),t), t=-12..12)}

In the case of compiled functions, the functions are named and compiled independently. This is useful if you intend to use the functions often, or if the functions are long and complex. The following lines show functions whose parameters are of the type Small Float. The functions are compiled and stored by Axiom when entered.

\spadpaste{i1(t:SF):SF == sin(t)*cos(3*t/5) \bound{i1}}
\spadpaste{i2(t:SF):SF == cos(t)*cos(3*t/5) \bound{i2}}
\spadpaste{i3(t:SF):SF == cos(t)*sin(3*t/5) \bound{i3}}

Once the functions are compiled the draw command only needs the names of the functions to execute. Here is a compiled functions example:
\graphpaste{draw(curve(i1,i2,i3),0..15*\pi)} \free{i1 i2 i3}

Note that the parameter range does not take the variable name as in the case of uncompiled functions. It is understood that the indicated range applies to the parameter of the functions, which in this case is $t$.

\end{patch}

\begin{patch}{SpaceCurveGraphicsPageEmpty3}
\begin{paste}{SpaceCurveGraphicsPageEmpty3}{SpaceCurveGraphicsPagePatch3}
\pastebutton{SpaceCurveGraphicsPageEmpty3}{\showpaste}
\tab{5}\spadcommand{i2(t:SF):SF == cos(t)*cos(3*t/5)\bound{i2}}
\end{paste}
\end{patch}
This page describes the plotting in three dimensional space of a tube around a parametric space curve defined by the parametric equations $x = f(t)$, $y = g(t)$, $z = h(t)$, where $f$, $g$, and $h$ are functions of the parameter $t$ which ranges over a specified interval. The basic draw command for this function utilizes either the uncompiled functions or compiled functions format and uses the \spadfun{curve} command to specify the three functions for the $x$, $y$, and $z$ components of the curve. This uses the same format as that for space curves except that it requires a specification for the radius of the tube. If the radius of the tube is 0, then the result is the space curve itself. The
general format for uncompiled functions is:

\[
\text{draw}(\text{curve}(f(t),g(t),h(t)), \ t = a..b, \ \text{tubeRadius} == r)
\]

where \( a..b \) is the segment defining the interval \([a,b]\) over which the parameter \( t \) ranges, and the \( \text{tubeRadius} \) is indicated by the variable \( r \). In this case the functions are not compiled until the \text{draw} \ command is executed. Here is an example:

\[
\text{draw}(\text{curve}(\sin(t)\cdot\cos(3t/5), \ \cos(t)\cdot\cos(3t/5), \ \cos(t)\cdot\sin(3t/5)), \ t=0..15\cdot\pi, \ \text{tubeRadius} == .15)
\]

In the case of compiled functions, the functions are named and compiled independently. This is useful if you intend to use the functions often, or if the functions are long and complex. The following lines show functions whose parameters are of the type Small Float. The functions are compiled and stored by Axiom when entered.

\[
\text{NOTE: It is only necessary to click on the draw command button to plot this example}.
\]

\[
\text{spadpaste}{t1(t:SF):SF == 4/(2-\sin(3t))\cdot\cos(2t) \ \text{bound}\{t1\}}
\]

\[
\text{spadpaste}{t2(t:SF):SF == 4/(2-\sin(3t))\cdot\sin(2t) \ \text{bound}\{t2\}}
\]

\[
\text{spadpaste}{t3(t:SF):SF == 4/(2-\sin(3t))\cdot\cos(3t) \ \text{bound}\{t3\}}
\]

Once the function is compiled the \text{draw} \ command only needs the names of the functions to execute. Here is a compiled functions example of a trefoil knot:

\[
\text{draw}(\text{curve}(t1,t2,t3),0..2\cdot\pi, \ \text{tubeRadius} == .2)
\]

Note that the parameter range does not take the variable name as in the case of uncompiled functions. It is understood that the indicated range applies to the parameter of the functions, which in this case is \( t \). Typically, the radius of the tube should be set between 0 and 1. A radius of less than 0 results in its positive counterpart and a radius of greater than one causes self intersection.

\end{scroll}

3.50. GRAPHICS.HT

\begin{verbatim}

\end{verbatim}
\end{verbatim}
Parametric Surfaces

— graphics.ht —

Graphing a surface defined by \( x = f(u,v), y = g(u,v), z = h(u,v) \).

This page describes the plotting of surfaces defined by the parametric equations of two variables, \( x = f(u,v), y = g(u,v), \) and \( z = h(u,v), \) for which the ranges of \( u \) and \( v \) are explicitly defined. The basic draw command for this function utilizes either the uncompiled function or compiled function format and uses the \spadfun{surface} command to specify the three functions for the \( x, y \) and \( z \) components of the surface. The general format for uncompiled functions is:

\begin{verbatim}
\indent{5}\printem{draw(surface(f(u,v),g(u,v),h(u,v)), u = a..b, v = c..d)}
\end{verbatim}

where \( a..b \) and \( c..d \) are segments defining the intervals \([a,b]\) and \([c,d]\) over which the parameters \( u \) and \( v \) span. In this case the functions are not compiled until the draw command is executed. Here is an example of a surface plotted using the parabolic cylindrical coordinate system option:

\begin{verbatim}
\printgraphpaste{draw(surface(u*cos(v), u*sin(v),v*cos(u)),
u=-4..4,v=0..2*\%pi, coordinates==parabolicCylindrical)}
\end{verbatim}

In the case of compiled functions, the functions are named and compiled independently. This is useful if you intend to use the functions often, or if the functions are long and complex. The following lines show functions whose parameters are of the type Small Float. The functions are compiled and stored by Axiom when entered.

\begin{verbatim}
\indent{5}\printem{NOTE: It is only necessary to click on the draw command button to plot this example.}
\end{verbatim}
3.50. GRAPHICS.HT

\spadpaste{n1(u:SF,v:SF):SF == u*cos(v) \bound{n1}}
\newline
\spadpaste{n2(u:SF,v:SF):SF == u*sin(v) \bound{n2}}
\newline
\spadpaste{n3(u:SF,v:SF):SF == u \bound{n3}}

Once the function is compiled the draw command only needs the names of
the functions to execute. Here is a compiled functions example
plotted using the toroidal coordinate system option:
\graphpaste{draw(surface(n1,n2,n3), 1.0..4.0, 1.0..4*%pi,
coordinates == toroidal(1\$SF)) \free{n1 n2 n3}}

Note that the parameter ranges do not take the variable names as in
the case of uncompiled functions. The variables are entered in the
order in which they are defined in the function specification. In
this case the first range specifies the u-variable and the second
range specifies the v-variable.

\endscroll
\autobuttons
\end{page}
Building 3D Objects

— graphics.ht —
This page describes the Axiom facilities for creating three dimensional objects constructed from geometric primitives. The Axiom operation \spadfun{create3Space()} creates a space to which points, curves, and polygons can be added using the operations from the \spadtype{ThreeSpace} domain. The contents of this space can then be displayed in a viewport using the \spadfun{makeViewport3D()} command. It will be necessary to have these operations exposed in order to use them.

Initially, the space which will hold the objects must be defined and compiled, as in the following example:

```
space := create3Space()
```

Now objects can be sent to this \spad{space} as per the operations allowed by the \spadtype{ThreeSpace} domain. The following examples place curves into \spad{space}.

```
curve(space,[[0,20,20],[0,20,30],[0,30,30],[0,30,100],[0,20,100],[0,20,110],[0,50,110],[0,50,100],[0,40,100],[0,40,30],[0,50,30],[0,50,20],[0,20,20]]) \bound{curveI}
```

```
curve(space,[[0,80,20],[0,70,20],[0,70,110],[0,110,110],[0,120,100],[0,120,70],[0,115,65],[0,120,30],[0,110,20],[0,80,20],[0,80,30],[0,105,30],[0,110,35]]) \bound{curveB1}
```

```
curve(space,[[0,110,35],[0,110,65],[0,105,60],[0,80,60],[0,80,70],[0,105,70],[0,110,75],[0,110,95],[0,105,100],[0,80,100],[0,80,30]]) \bound{curveB2}
```

```
closedCurve(space,[[0,140,20],[0,140,110],[0,150,110],[0,170,50],[0,190,110],[0,200,110],[0,200,20],[0,190,20],[0,190,75],[0,175,35],[0,165,35],[0,150,20]]) \bound{curveM}
```

```
closedCurve(space,[[200,0,20],[200,0,110],[185,0,110],[160,0,45],[160,0,110],[150,0,110],[150,0,20],[165,0,20],[190,0,85],[190,0,20]]) \bound{curveN}
```

```
closedCurve(space,[[140,0,20],[120,0,110],[110,0,110],[90,0,20],[100,0,20],[108,0,50],[123,0,50],[121,0,60],[110,0,60],[115,0,90],[130,0,20]]) \bound{curveA}
```

```
closedCurve(space,[[80,0,30],[80,0,100],[70,0,110],[40,0,110],[30,0,100],[30,0,90],[40,0,90],[40,0,95],[45,0,100],[65,0,100],[70,0,95],[70,0,35],[65,0,30],[45,0,30],[40,0,35],[40,0,60],[50,0,60],[50,0,70],[30,0,70],[30,0,30],[40,0,20],[70,0,20]]) \bound{curveG}
```

Once \spad{space} contains the desired elements a viewport is created and displayed with the following command:

```
makeViewport3D(space,[title("Curves")])
```

The parameters for \spadfun{makeViewport3D()} in this example are \spad{space}, which is the name of the three dimensional space that was
defined, and a string, "curve", which is the title for the viewport. The tailing string \em \spadfun{makeViewport3D} exposes the command \spadtype{ThreeDimensionalViewport} if these commands are unexposed.

Functions of One Variable

⇒ graphics.ht

\begin{page}{OneVariableGraphicsPage}{Functions of One Variable}
\beginscroll
Here we wish to plot a function \( y = f(x) \) on an interval \([a,b]\).
As an example, let's take the function \( y = \sin(\tan(x)) - \tan(\sin(x)) \) on the interval \([0,6]\).
Here is the simplest command that will do this:
\graphpaste{draw(sin(tan(x)) - tan(sin(x)),x = 0..6)}

Notice that Axiom compiled a function before the graph was put on the screen. The expression sin(tan(x)) - tan(sin(x)) was converted to a compiled function so that it's value for various values of x could be computed quickly and efficiently. Let's graph the same function on a different interval and this time we'll give the graph a title. The title is a String, which is an optional argument of the command 'draw'.
\graphpaste{draw(sin(tan(x)) - tan(sin(x)),x = 10..16, title == "y = sin tan x - tan sin x")}

Once again the expression sin(tan(x)) - tan(sin(x)) was converted to a compiled function before any points were computed.

If you want to graph the same function on a number of intervals, it's a good idea to write down a function definition so that the function only has to be compiled once.
Here's an example:
\spadpaste{f(x) == (x-1)*(x-2)*(x-3) \bound{f}}
\newline
\graphpaste{draw(f, 0..2, title == "y = f(x) on \[0,2\]) \free{f}}
\newline
\graphpaste{draw(f, 0..4,title == "y = f(x) on \[0,4\]) \free{f}}

Notice that our titles can be whatever we want, as long as they are enclosed by double quotes. However, a title which is too long to fit within the viewport title window will be clipped.

\end{paste}
\end{patch}
Parametric Curves

One way of producing interesting curves is by using parametric equations. Let \( x = f(t) \) and \( y = g(t) \) for two functions \( f \) and \( g \) as the parameter \( t \) ranges over an interval \([a,b]\).

Here's an example:

\[
\text{draw(curve(sin(t)*sin(2*t)*sin(3*t), sin(4*t)*sin(5*t)*sin(6*t)), t = 0..2\%pi)}
\]

Here \( 0..2\%pi \) represents the interval over which the variable \( t \) ranges.

In the case of parametric curves, Axiom will compile two functions, one for each of the functions \( f \) and \( g \).

You may also put a title on a graph. The title may be an arbitrary string and is an optional argument to the command 'draw'. For example:

\[
\text{draw(curve(cos(t), sin(t)), t = 0..2\%pi, title == "The Unit Circle"}
\]

If you plan on plotting \( x = f(t) \), \( y = g(t) \) as \( t \) ranges over several intervals, you may want to define functions \( f \) and \( g \), so that they need not be recompiled every time you create a new graph. Here's an example:

\[
f(t:SF):SF == sin(3*t/4) \bound{f}
\]
\[
g(t:SF):SF == sin(t) \bound{g}
\]

These examples show how the curve changes as the range of parameter \( t \) varies.

These examples show how the curve changes as the range of parameter \( t \) varies.

Polar Coordinates

--- graphics.ht ---

Graphs in polar coordinates are given by an equation $r = f(\theta)$ as $\theta$ ranges over an interval. This is equivalent to the parametric curve $x = f(\theta) \cdot \cos(\theta)$,
3.50.  GRAPHICS.HT

\[ y = f(\theta) \sin(\theta) \] as \( \theta \) ranges over the same interval.
You may create such curves using the command 'draw', with the optional argument 'coordinates == polar'.
Here are some examples:
\begin{verbatim}
\texttt{draw(1, t = 0..2*\pi, \text{coordinates == polar},
    title == "The Unit Circle")}
\end{verbatim}
\begin{verbatim}
\texttt{draw(sin(17*t), t = 0..2*\pi, \text{coordinates == polar},
    title == "A Petal Curve")}
\end{verbatim}
%When you don't specify an interval, Axiom will assume that you
%mean 0..2*\pi.
You may also define your own functions, when you plan on plotting the
same curve as \( \theta \) varies over several intervals.
\begin{verbatim}
\texttt{f(t) == \cos(4*t/7) \\textit{bound}{f}}
\end{verbatim}
\begin{verbatim}
\texttt{draw(f, 0..2*\pi, \text{coordinates == polar}) \\textit{free}{f}}
\end{verbatim}
\begin{verbatim}
\texttt{draw(f, 0..14*\pi, \text{coordinates == polar}) \\textit{free}{f}}
\end{verbatim}
For information on plotting graphs in other coordinate systems see the
pages for the \spadtype{CoordinateSystems} domain.
\spad{endscroll}
\spad{autobuttons}
\spad{end{page}
Implicit Curves

— graphics.ht —
Axiom has facilities for graphing a non-singular algebraic curve in a rectangular region of the plane. An algebraic curve is a curve defined by a polynomial equation \( p(x,y) = 0 \).

Non-singular means that the curve is "smooth" in that it does not cross itself or come to a point (cusp).

Algebraically, this means that for any point \((a,b)\) on the curve (i.e. a point such that \( p(a,b) = 0 \)), the partial derivatives \( \frac{dp}{dx}(a,b) \) and \( \frac{dp}{dy}(a,b) \) are not both zero.

We require that the polynomial have rational or integral coefficients.

Here is a Cartesian ovals algebraic curve example:

(click on the draw button to execute this example)

\[
\begin{align*}
\text{spadpaste} & \{ p := ((x**2 + y**2 + 1) - 8*x)**2 - (8*(x**2 + y**2 + 1) - 4*x - 1) \} \\
\text{graphpaste} & \{ \text{draw}(p = 0, x, y, \text{range} == [-1..11, -7..7], \\
\text{title} == \text{"Cartesian Ovals"}) \} \\
\{ \text{A range must be declared for each variable specified in the algebraic curve equation}. \}
\end{align*}
\]

Here is a Cartesian ovals algebraic curve example:

\[
\begin{verbatim}
(1) 4 2 2 4 3 2
y + (2x - 16x - 6)y + x - 16x + 58x - 12x - 6
Type: Polynomial Integer
\end{verbatim}
\]

\[
\begin{verbatim}
(1) 4 2 2 4 3 2
y + (2x - 16x - 6)y + x - 16x + 58x - 12x - 6
Type: Polynomial Integer
\end{verbatim}
\]

\[
\begin{verbatim}
(1) 4 2 2 4 3 2
y + (2x - 16x - 6)y + x - 16x + 58x - 12x - 6
Type: Polynomial Integer
\end{verbatim}
\]

\[
\begin{verbatim}
(1) 4 2 2 4 3 2
y + (2x - 16x - 6)y + x - 16x + 58x - 12x - 6
Type: Polynomial Integer
\end{verbatim}
\]

\[
\begin{verbatim}
(1) 4 2 2 4 3 2
y + (2x - 16x - 6)y + x - 16x + 58x - 12x - 6
Type: Polynomial Integer
\end{verbatim}
\]

\[
\begin{verbatim}
(1) 4 2 2 4 3 2
y + (2x - 16x - 6)y + x - 16x + 58x - 12x - 6
Type: Polynomial Integer
\end{verbatim}
\]

\[
\begin{verbatim}
(1) 4 2 2 4 3 2
y + (2x - 16x - 6)y + x - 16x + 58x - 12x - 6
Type: Polynomial Integer
\end{verbatim}
\]
Lists of Points

--- graphics.ht ---

Axiom has the ability to create lists of points in a two dimensional graphics viewport. This is done by utilizing the \spadtype{GraphImage} and \spadtype{TwoDimensionalViewport} domain facilities.

\verb|NOTE: It is only necessary to click on the makeViewport2D command button to plot this curve example.|

In this example, the \spadfun{makeGraphImage} command takes a list of lists of points parameter, a list of colors for each point in the graph, a list of colors for each line in the graph, and a list of numbers which indicate the size of each point in the graph. The following lines create list of lists of points which can be read be made into two dimensional graph images.

\begin{spad}
\begin{verbatim}
%p1 := point [1::SF,1::SF]$(Point SF) \bound{p1}
\end{verbatim}
\end{spad}
These lines set the point color and size, and the line color for all components of the graph.

Now the graph image is created and named according to the component specifications indicated above. The \spadfun{makeViewport2D} command then creates a two dimensional viewport for this graph according to the list of options specified within the brackets.
\begin{verbatim}

Stand-alone Viewport

To get a viewport on a Hyperdoc page, you first need to create one in Axiom and write it out to a file that Hyperdoc can call up.

For example, here we draw a saddle function and assign the result to the variable \( v \):

\[
v := \text{draw}(x^2-y^2,x=-1..1,y=-1..1) \quad \text{bound}(v)
\]

Now that we've created the viewport, we want to write the data out to a file. To do this, we use the \spadfunFrom{write}{ThreeDimensionalViewport} command which takes the following arguments: the viewport to write out, the title of the file to write it out to, and an optional argument telling the write command what type (or types) of data you want to write in addition to the one Axiom will always write out. The optional argument could be a string, like "pixmap", or a list of strings, like ["postscript","pixmap"]. Hyperdoc needs a "pixmap" data type to include a graph in a page so in this case, we write the viewport and tell it to also write a "pixmap" file, as well:

\[
\text{write}(v,"saddle","pixmap") \quad \text{free}(v)
\]

Now we want to put this viewport into a Hyperdoc page. Say you've created a viewport and written it out to a file called "~/tmp/mobius". (Axiom actually tags a ".view" at the end of a viewport data file to make it easier to spot when you're rummaging through your file system, but you needn't worry about that here since Axiom will always automatically add on a "view" for you.)
3.50. GRAPHICS.HT

{f Including Viewports} 

To put a viewport in a Hyperdoc page, include the following line in your Hyperdoc source code:\newline
\space{5}\viewport{/tmp/mobius} \newline
You will get this on your page: \newline
\space{4}\viewport{/tmp/mobius} \newline
\space{4}\spadviewport{mobius} \newline
\centerline{\spadviewport{mobius}} \newline

{f Creating Viewport Buttons} 

To make an active button that would make this viewport come to life, include the following: \newline
\space{5}\viewportbutton{ViewButton}{/tmp/mobius} \newline
this creates this button... \newline
\space{4}\centerline{\viewportbutton{ViewButton}{/tmp/mobius}} \newline
\space{4}\centerline{\spadviewportbutton{ViewButton}{mobius}} \newline

{f Creating Active Viewports} 

To merge the two things described above, namely, getting a picture of a viewport and creating a button to invoke a live viewport, you can do the following: \newline
\space{5}\viewportasbutton{/tmp/mobius} \newline
\centerline{\viewportasbutton{/tmp/mobius}} \newline
This would create a picture of a viewport that is an active button as well. Try it: \newline
\space{5}\viewportasbutton{/tmp/mobius} \newline
\space{5}\spadviewportasbutton{mobius} \newline
\centerline{\spadviewportasbutton{mobius}} \newline

{f Including Viewports Distributed with Axiom} 

All the above commands have counterparts that allow you to access viewports that are already packaged with Axiom. To include those viewports, just add on an “axiom” prefix to the above commands: \newline
\centerline{\axiomviewport{vA} for \viewport{vA}} \newline
\centerline{\axiomviewportbutton{vB} for \viewportbutton{vB}} \newline
\centerline{\axiomviewportasbutton{vC} for \viewportasbutton{vC}} \newline
\newline
All these macros really do is include some path that indicates where Axiom stores the viewports. \newline
\newline

Representations of $A_6$ $A_6$

---

\begin{page}{RepA6Page}{Representations of \texttt{$A_6$}}
In what follows you’ll see how to use Axiom to get all the irreducible representations of the alternating group \(A_6\) over the field with two elements (GF 2). First, we generate \(A_6\) by a three-cycle: \(x = (1,2,3)\) and a 5-cycle: \(y = (2,3,4,5,6)\). Next we have Axiom calculate the permutation representation over the integers and over GF 2:

\begin{spad}
\spad{genA6 : LIST PERM INT := [cycle [1,2,3], cycle [2,3,4,5,6]]}
\spad{pRA6 := permutationRepresentation (genA6, 6)}
\end{spad}

Now we apply Parker’s ‘Meat-Axe’ and split it:

\begin{spad}
\spad{sp0 := meatAxe (pRA6::(LIST MATRIX PF 2))}
\end{spad}

We have found the trivial module as a quotient module and a 5-dimensional sub-module.

Try to split again:

\begin{spad}
\spad{sp1 := meatAxe sp0.1}
\end{spad}

and we find a 4-dimensional sub-module and the trivial one again. Now we can test if this representation is absolutely irreducible:

\begin{spad}
\spad{isAbsolutelyIrreducible? sp1.2}
\end{spad}

and we see that this 4-dimensional representation is absolutely irreducible. So, we have found a second irreducible representation. Now, we construct a representation by reducing an irreducible one of the symmetric group \(S_6\) over the integers mod 2. We take the one labelled by the partition \([2,2,1,1]\) and restrict it to \(A_6\):

\begin{spad}
\spad{d2211 := irreducibleRepresentation ([2,2,1,1], genA6)}
\end{spad}

Now split it:

\begin{spad}
\spad{sp2 := meatAxe d2211:: (LIST MATRIX PF 2)}
\end{spad}

This gave both a five and a four dimensional representation. Now we take the 4-dimensional one and we shall see that it is absolutely irreducible:

\begin{spad}
\spad{is AbsolutelyIrreducible? sp2.1}
\end{spad}

The two 4-dimensional representations are not equivalent:

\begin{spad}
\spad{areEquivalent? (sp1.2, sp2.1)}
\end{spad}

So we have found a third irreducible representation. Now we construct a new representation using the tensor product and try to split it:

\begin{spad}
\spad{dA6d16 := tensorProduct(sp1.2, sp2.1)}
\end{spad}

The representation is irreducible, but it may be not absolutely irreducible.

\begin{spad}
\spad{isAbsolutelyIrreducible? dA6d16}
\end{spad}

So let’s try the same procedure over the field with 4 elements:
Now we find two 8-dimensional representations, \(dA6d8a\) and \(dA6d8b\).
Both are absolutely irreducible...
\spadpaste{isAbsolutelyIrreducible? sp3.1}
\spadpaste{isAbsolutelyIrreducible? sp3.2}
and they are not equivalent:
\spadpaste{areEquivalent? (sp3.1,sp3.2)}
So we have found five absolutely irreducible representations of \(A_6\) in characteristic 2.
General theory now tells us that there are no more irreducible ones.
Here, for future reference are all the absolutely irreducible 2-modular representations of \(A_6\)
\spadpaste{sp0.2 \free{sp0}}
\spadpaste{sp1.2 \free{sp1}}
\spadpaste{sp2.1 \free{sp2}}
\spadpaste{sp3.1 \free{sp3}}
\spadpaste{sp3.2 \free{sp3}}
And here again is the irreducible, but not absolutely irreducible representations of \(A_6\) over GF 2
\spadpaste{dA6d16 \free{dA6d16}}

Representation Theory

— grpthry.ht —
Representation theory for finite groups studies finite groups by embedding them in a general linear group over a field or an integral domain. Hence, we are representing each element of the group by an invertible matrix. Two matrix representations of a given group are equivalent, if, by changing the basis of the underlying space, you can go from one to the other. When you change bases, you transform the matrices that are the images of elements by conjugating them by an invertible matrix.

If we can find a subspace which is fixed under the image of the group, then there exists a ‘base change’ after which all the representing matrices are in upper triangular block form. The block matrices on the main diagonal give a new representation of the group of lower degree. Such a representation is said to be ‘reducible’.

If we can find a subspace which is fixed under the image of the group, then there exists a ‘base change’ after which all the representing matrices are in upper triangular block form. The block matrices on the main diagonal give a new representation of the group of lower degree. Such a representation is said to be ‘reducible’.

Alfred Young's natural form for these representations.

Constructing new representations by symmetric and antisymmetric tensors.

Parker's 'Meat-Axe', working in prime characteristics.

The irreducible representations of the alternating group \(A_6\) over fields of characteristic 2.

Group Theory

— grpthry.ht —
A \it group is a set G together with an associative operation * satisfying the axioms of existence of a unit element and an inverse of every element of the group. The Axiom category \spadtype{Group} represents this setting. Many data structures in Axiom are groups and therefore there is a large variety of examples as fields and polynomials, although the main interest there is not the group structure.

To work with and in groups in a concrete manner some way of representing groups has to be chosen. A group can be given as a list of generators and a set of relations. If there are no relations, then we have a \it free group, realized in the domain \spadtype{FreeMonoid} which won’t be discussed here. We consider \it permutation groups, where a group is realized as a subgroup of the symmetric group of a set, i.e. the group of all bijections of a set, the operation being the composition of maps. Indeed, every group can be realized this way, although this may not be practical.

Furthermore group elements can be given as invertible matrices. The group operation is reflected by matrix multiplication. More precise in representation theory group homomorphisms from a group to general linear groups are constructed. Some algorithms are implemented in Axiom.

Suppose we launched a fund-raising campaign to raise fifty thousand dollars. To record the contributions, we want a table with strings as keys (for the names) and integer entries (for the amount). In a database of cash contributions, unless someone has been explicitly entered, it is reasonable to assume they have made a zero dollar contribution.

This creates a keyed access file with default entry \spad{0}.

\spadpaste{patrons: GeneralSparseTable(String, Integer, KeyedAccessFile(Integer), 0) := table() \free{patrons}}

Now \spad{patrons} can be used just as any other table. Here we record two gifts.

\spadpaste{patrons."Smith" := 10500 \free{patrons}\bound{smith}}

\spadpaste{patrons."Jones" := 22000 \free{smith}\bound{jones}}

Now let us look up the size of the contributions from Jones and Stingy.

\spadpaste{patrons."Jones" \free{jones}}

\spadpaste{patrons."Stingy" \free{jones}}
\xtc{
Have we met our seventy thousand dollar goal?
}\{ 
\spadpaste{reduce(+, entries patrons) \free{jones}} 
\}
\noOutputXtc{
So the project is cancelled and we can delete the database: 
}\{ 
\spadpaste{)system rm -r kaf*.sdata \free{patrons}} 
\}

3.53 heap.ht

Heap

⇒ “notitle” (FlexibleArrayXmpPage) 3.39 on page 472

\beginscroll
The domain \spadtype{Heap(S)} implements a priority queue of objects of type \spad{S} such that the operation \spadfun{extract} removes and returns the maximum element. The implementation represents heaps as flexible arrays (see \downlink{`FlexibleArray'}{FlexibleArrayXmpPage}). The representation and algorithms give complexity of $O(\log(n))$ for insertion and extractions, and $O(n)$ for construction.
\xtc{Create a heap of six elements.}
\spadpaste{\spad{h := heap [-4,9,11,2,7,-7]\bound{h}}}
Use \spadfun{insert} to add an element.
\spadpaste{insert!(3,h)\bound{h1}\free{h}}

The operation \spadfun{extract} removes and returns the maximum element.
\spadpaste{extract! h\bound{h2}\free{h1}}

The internal structure of \spad{h} has been appropriately adjusted.
\spadpaste{h\free{h2}}

Now \spadfun{extract} elements repeatedly until none are left, collecting the elements in a list.
\spadpaste{[extract!(h) while not empty?(h)]\bound{h2}}

Another way to produce the same result is by defining a \userfun{heapsort} function.
\spadpaste{heapsort(x) == (empty? x => []; cons(extract!(x),heapsort x))}\bound{f}

Create another sample heap.
\spadpaste{h1 := heap [17,-4,9,-11,2,7,-7]\bound{h1}}

Apply \spadfun{heapsort} to present elements in order.
\spadpaste{heapsort h1\free{f}}
All rationals have repeating hexadecimal expansions. The operation \texttt{hex} returns these expansions of type \texttt{HexadecimalExpansion}. Operations to access the individual numerals of a hexadecimal expansion can be obtained by converting the value to \texttt{RadixExpansion(16)}. More examples of expansions are available in the \texttt{`DecimalExpansion'}, \texttt{`BinaryExpansion'}, and \texttt{`RadixExpansion'}.

Issue the system command \texttt{)show HexadecimalExpansion} to display the full list of operations defined by \texttt{HexadecimalExpansion}.

This is a hexadecimal expansion of a rational number.

\begin{verbatim}
  r := hex(22/7)
  Arithmetic is exact.
  r + hex(6/7)
  The period of the expansion can be short or long...
  \{hex(1/1) for i in 350..354\}
  or very long!
\end{verbatim}
This is a hexadecimal expansion of a rational number.

\spadpaste{r := hex(22/7) \bound{r}}

Arithmetic is exact.

\spadpaste{r + hex(6/7) \free{r}}

The period of the expansion can be short or long \ldots

\spadpaste{[hex(1/i) for i in 350..354]}

or very long!

\spadpaste{hex(1/1007)}

These numbers are bona fide algebraic objects.

\spadpaste{p := hex(1/4)*x**2 + hex(2/3)*x + hex(4/9) \bound{p}}

\spadpaste{q := D(p, x) \free{p}\bound{q}}

Integer

Axiom provides many operations for manipulating arbitrary precision integers. In this section we will show some of those that come from \texttt{Integer} itself plus some that are implemented in other packages. More examples of using integers are in the following sections: "Numbers" in section 1.5, "IntegerNumberTheoryFunctions", "DecimalExpansion", "BinaryExpansion", "HexadecimalExpansion", and "RadixExpansion".

\begin{itemize}
\item \texttt{9.34.1 Basic Functions}
\item \texttt{9.34.2 Primes and Factorization}
\item \texttt{9.34.3 Some Number Theoretic Functions}
\end{itemize}

\begin{itemize}
\item \texttt{"Integers" (IntegerPage) 3.80 on page 1029}
\item \texttt{"Numbers" (ugIntroNumbersPage) 6 on page 1513}
\end{itemize}

\end{itemize}
Basic Functions

The size of an integer in Axiom is only limited by the amount of computer storage you have available. The usual arithmetic operations are available.

\[ 2^{(5678 - 4856 + 2 \times 17)} \]

There are a number of ways of working with the sign of an integer. Let's use this \texttt{x} as an example.

\[ \texttt{x := -101} \]

First of all, there is the absolute value function.

\[ \texttt{abs(x)} \]

The \texttt{sign} operation returns $-1$ if its argument is negative, 0 if zero and 1 if positive.

\[ \texttt{sign(x)} \]

You can determine if an integer is negative in several other ways.

\[ \texttt{x < 0} \]

\[ \texttt{x <= -1} \]

\[ \texttt{negative?(x)} \]

First of all, there is the absolute value function.
}\{ abs(x) \free{x} \}
\xtc{ The \spadfunFrom{sign}{Integer} operation returns \spad{-1} if its argument is negative, \spad{0} if zero and \spad{1} if positive. }
}\{ sign(x) \free{x} \}
}\%
\xtc{ You can determine if an integer is negative in several other ways. }
}\{ x < 0 \free{x} \}
\xtc{ }
}\{ x <= -1 \free{x} \}
\xtc{ }
}\{ negative?(x) \free{x} \}
}\%
\xtc{ Similarly, you can find out if it is positive. }
}\{ x > 0 \free{x} \}
\xtc{ }
}\{ x >= 1 \free{x} \}
\xtc{ }
}\{ positive?(x) \free{x} \}
\xtc{ }
\beginImportant
Use the \spadfunFrom{zero?}{Integer} operation whenever you are testing any mathematical object for equality with zero. This is usually more efficient that using \spad{=} (think of matrices: it is easier to tell if a matrix is zero by just checking term by term than constructing another ‘‘zero’’ matrix and comparing the two matrices.
term by term) and also avoids the problem that \spadop{=} is usually used for creating equations.
\endImportant

\xtc{
This is the recommended way of determining whether an integer is equal to one.
}
\spadpaste{one?(x) \free{x}}
}

\xtc{
This syntax is used to test equality using \spadFrom{=} \spadtype{Integer}. It says that you want a \spadtype{Boolean} (\spad{true} or \spad{false}) answer rather than an equation.
}
\spadpaste{(x = -101)@Boolean \free{x}}
}

\xtc{
The operations \spadfunFrom{odd?}{Integer} and \spadfunFrom{even?}{Integer} determine whether an integer is odd or even, respectively. They each return a \spadtype{Boolean} object.
}
\spadpaste{odd?(x) \free{x}}

\xtc{
\spadpaste{even?(x) \free{x}}
}

\xtc{
The operation \spadfunFrom{gcd}{Integer} computes the greatest common divisor of two integers.
}
\spadpaste{gcd(56788,43688)}

\xtc{
The operation \spadfunFrom{lcm}{Integer} computes their least common multiple.
}
\spadpaste{lcm(56788,43688)}

\xtc{
To determine the maximum of two integers, use \spadfunFrom{max}{Integer}.
}
\spadpaste{max(678,567)}

\xtc{
To determine the minimum, use \spadfunFrom{min}{Integer}.
}

The \spadfun{reduce} operation is used to extend binary operations to more than two arguments. For example, you can use \spadfun{reduce} to find the maximum integer in a list or compute the least common multiple of all integers in the list.

\spadpaste{reduce(max, [2, 45, -89, 78, 100, -45])}

\spadpaste{reduce(min, [2, 45, -89, 78, 100, -45])}

\spadpaste{reduce(gcd, [2, 45, -89, 78, 100, -45])}

\spadpaste{reduce(lcm, [2, 45, -89, 78, 100, -45])}

The infix operator ``/$$'' is \textit{not} used to compute the quotient of integers. Rather, it is used to create rational numbers as described in \downlink{`Fraction'}{FractionXmpPage}\ignore{Fraction}.

\spadpaste{13 / 4}

The infix operation \spadfunFrom{quo}{Integer} computes the integer quotient.

\spadpaste{13 \, \text{quo} \, 4}

The infix operation \spadfunFrom{rem}{Integer} computes the integer remainder.

\spadpaste{13 \, \text{rem} \, 4}

One integer is evenly divisible by another if the remainder is zero. The operation \spadfunFrom{exquo}{Integer} can also be used. See \downlink{`Unions'}{ugTypesUnionsPage} in Section 2.5\ignore{ugTypesUnions} for an example.

\spadpaste{min(678, 567)}
The operation \spadfunFrom{divide}{Integer} returns a record of the quotient and remainder and thus is more efficient when both are needed.

\spadpaste{d := divide(13,4) \bound{d}}

\spadpaste{d.quotient \free{d}}

\spadpaste{d.remainder \free{d}}

Records are discussed in detail in \downlink{``Records''}{ugTypesRecordsPage} in Section 2.4

Primes and Factorization

Use the operation \texttt{factor} to factor integers. It returns an object of type \texttt{Factored Integer}. See \texttt{"Factored"} for a discussion of the manipulation of factored objects.

\begin{verbatim}
    \texttt{factor 102400}
\end{verbatim}

The operation \texttt{prime?} returns true or false depending on whether its argument is a prime.

\begin{verbatim}
    \texttt{prime? 7}
    \texttt{prime? 8}
\end{verbatim}

The operation \texttt{nextPrime} returns the least prime number greater than its argument.

\begin{verbatim}
    \texttt{nextPrime 100}
\end{verbatim}

The operation \texttt{prevPrime} returns the greatest prime number less than its argument.

\begin{verbatim}
    \texttt{prevPrime 100}
\end{verbatim}

To compute all primes between two integers ( inclusively), use the operation \texttt{primes}.

\begin{verbatim}
    \texttt{primes(100,175)}
\end{verbatim}

You might sometimes want to see the factorization of an integer when it is considered a Gaussian Integer. See \texttt{"Complex"} for more details.

\begin{verbatim}
    \texttt{factor(2 :: Complex Integer)}
\end{verbatim}

Some Number Theoretic Functions

Axiom provides several number theoretic operations for integers. More examples are in

`IntegerNumberTheoryFunctions`

The operation fibonacci computes the Fibonacci numbers. The algorithm has running time $O(\log(n)^2)$ for argument $n$.

```
fibonacci(k) for k in 0..10
```

The operation legendre computes the Legendre symbol for its two integer arguments where the second one is prime. If you know the second argument to be prime, use jacobi instead where no check is made.

```
legendre(i, 11) for i in 0..10
```

The operation jacobi computes the Jacobi symbol for its two integer arguments. By convention, 0 is returned if the greatest common divisor of the numerator and denominator is not 1.

```
jacobi(i, 15) for i in 0..9
```

The operation eulerPhi computes the values of Euler's phi function.
Axiom provides several number theoretic operations for integers. More examples are in \downlink{`IntegerNumberTheoryFunctions'} {IntNumberTheoryFnsXmpPage}.

\begin{page}{ugxIntegerNTPage}{Some Number Theoretic Functions}
\beginscroll

Axiom provides several number theoretic operations for integers. More examples are in \downlink{`IntegerNumberTheoryFunctions'} {IntNumberTheoryFnsXmpPage}.

\begin{itemize}
\item The operation \spadfunFrom{fibonacci}{IntegerNumberTheoryFunctions} computes the Fibonacci numbers. The algorithm has running time $O(\log^3(n))$ for argument \spad{n}.
\end{itemize}

\begin{itemize}
\item The operation \spadfunFrom{legendre}{IntegerNumberTheoryFunctions} computes the Legendre symbol for its two integer arguments where the second one is prime. If you know the second argument to be prime, use \spadfunFrom{jacobi}{IntegerNumberTheoryFunctions} instead where no check is made.
\end{itemize}

\begin{itemize}
\item The operation \spadfunFrom{jacobi}{IntegerNumberTheoryFunctions} computes the Jacobi symbol for its two integer arguments. By convention, \spad{0} is returned if the greatest common divisor of the numerator and denominator is not \spad{1}.
\end{itemize}

\begin{itemize}
\item The operation \spadfunFrom{eulerPhi}{IntegerNumberTheoryFunctions} computes the values of Euler’s \textit{$\phi$}-function where $\phi(n)=\sum_{d|n} \phi(d)$ equals the number of positive integers less than or equal to \spad{n} that are relatively prime to the positive integer \spad{n}.
\end{itemize}

\begin{itemize}
\item The operation \spadfunFrom{moebiusMu}{IntegerNumberTheoryFunctions} computes the \textit{Moebius mu} function.
\end{itemize}
Although they have somewhat limited utility, Axiom provides Roman numerals.

```
spadpaste{a := roman(78) \bound{a}}
spadpaste{b := roman(87) \bound{b}}
spadpaste{a + b \free{a}\free{b}}
spadpaste{a * b \free{a}\free{b}}

IntegerNumberTheoryFunctions

The IntegerNumberTheoryFunctions package contains a variety of operations of interest to number theorists. Many of these operations deal with divisibility properties of integers. (Recall that an integer \(a\) divides an integer \(b\) if there is an integer \(c\) such that \(b = a \times c\).)

The operation \texttt{divisors} returns a list of the divisors of an integer.

\begin{verbatim}
\spadfunFrom{divisors}{IntegerNumberTheoryFunctions} := divisors(144)
\end{verbatim}

You can now compute the number of divisors of 144 and the sum of the divisors of 144 by counting and summing the elements of the list we just created.

\begin{verbatim}
\spad{div144 := divisors(144)}
\end{verbatim}

\xtc{The operation \spadfunFrom{divisors}{IntegerNumberTheoryFunctions} returns a list of the divisors of an integer.}

\begin{verbatim}
\spadpaste{div144 := divisors(144) \bound{div144}}
\end{verbatim}

\xtc{You can now compute the number of divisors of \spad{144} and the sum of}
the divisors of \(\spad{144}\) by counting and summing the elements of the list we just created.
}\{ 
\spadpaste{\#(div144) \free{div144}} 
\}
\xtc{
}\{ 
\spadpaste{reduce(+,div144) \free{div144}} 
\}

Of course, you can compute the number of divisors of an integer \(\spad{n}\), usually denoted \(\spad{d(n)}\), and the sum of the divisors of an integer \(\spad{n}\), usually denoted \(\spad{\sigma(n)}\), without ever listing the divisors of \(\spad{n}\).

\xtc{In Axiom, you can simply call the operations
\spadfunFrom{numberOfDivisors}{IntegerNumberTheoryFunctions} and
\spadfunFrom{sumOfDivisors}{IntegerNumberTheoryFunctions}.
}\{ 
\spadpaste{numberOfDivisors(144)} 
\}
\xtc{\{ 
\spadpaste{sumOfDivisors(144)} 
\}}

The key is that \(\spad{d(n)}\) and \(\spad{\sigma(n)}\) are "multiplicative functions."
This means that when \(\spad{n}\) and \(\spad{m}\) are relatively prime, that is, when \(\spad{n}\) and \(\spad{m}\) have no prime factor in common, then
\(\spad{d(nm) = d(n) d(m)}\) and
\(\spad{\sigma(nm) = \sigma(n) \sigma(m)}\).

Note that these functions are trivial to compute when \(\spad{n}\) is a prime power and are computed for general \(\spad{n}\) from the prime factorization of \(\spad{n}\).
Other examples of multiplicative functions are
\(\spad{\sigma_k(n)}\), the sum of the \(\spad{k}\)-th powers of the divisors of \(\spad{n}\) and
\(\spad{\varphi(n)}\), the number of integers between 1 and \(\spad{n}\) which are prime to \(\spad{n}\).
The corresponding Axiom operations are called
\spadfunFrom{sumOfKthPowerDivisors}{IntegerNumberTheoryFunctions} and
\spadfunFrom{eulerPhi}{IntegerNumberTheoryFunctions}.

An interesting function is \(\spad{\mu(n)}\), the \(\spad{\text{M"{o}bius \mu}}\) function, defined
as follows:
\begin{verbatim}
\spad{\mu(1) = 1, \mu(n) = 0}, when \spad{n} is divisible by a
square, and \spad{\mu(n) = (-1)^k}, when \spad{n}
is the product of \spad{k} distinct primes.
The corresponding Axiom operation is
\spadfunFrom{moebiusMu}{IntegerNumberTheoryFunctions}.
This function occurs in the following theorem:

\indent
{\bf Theorem} (Möbius Inversion Formula): 
\begin{quote}
Let \spad{f(n)} be a function on the positive integers and let \spad{F(n)}
be defined by \spad{F(n) = \sum_{d \mid n} f(n)}, where the sum
is taken over the positive divisors of \spad{n}.
Then the values of \spad{f(n)} can be recovered from the values of
\spad{F(n)}: \spad{f(n) = \sum_{d \mid n} \mu(n) F(n/d)}, where again
the sum is taken over the positive divisors of \spad{n}.
\end{quote}

\begin{verbatim}
When \spad{f(n) = 1}, then \spad{F(n) = d(n)}.
Thus, if you sum \spad{\mu(d) \cdot d(n/d)} over the positive divisors
\spad{d} of \spad{n}, you should always get \spad{1}.
\spad{f1(n) == reduce(+,[moebiusMu(d) * numberOfDivisors(quo(n,d))
for d in divisors(n)])}
\spad{f1(200) \free{f1}}
\spad{f1(846) \free{f1}}

Similarly,
when \spad{f(n) = n}, then \spad{F(n) = \sigma(n)}.
Thus, if you sum \spad{\mu(d) \cdot \sigma(n/d)} over the positive divisors
\spad{d} of \spad{n}, you should always get \spad{n}.
\spad{f2(n) == reduce(+,[moebiusMu(d) * sumOfDivisors(quo(n,d))
for d in divisors(n)])}
\spad{f2(200) \free{f2}}
\spad{f2(846) \free{f2}}
\end{verbatim}
\end{quote}
\end{verbatim}
for d in divisors(n)] \bound{f2}
}
\xtc{
\spadpaste{f2(200) \free{f2}}
}
\xtc{
\spadpaste{f2(846) \free{f2}}
}

The Fibonacci numbers are defined by \pad{F(1) = F(2) = 1} and \pad{F(n) = F(n-1) + F(n-2)} for \pad{n = 3,4, ...}.
\xtc{
The operation \spadfunFrom{fibonacci}{IntegerNumberTheoryFunctions} computes the \eth{\pad{n}} Fibonacci number.
}
\spadpaste{fibonacci(25)}
\xtc{
\spadpaste{[fibonacci(n) for n in 1..15]}\free{fibonacci}
}
\xtc{
Fibonacci numbers can also be expressed as sums of binomial coefficients.
}
\spadpaste{fib(n) == reduce(+,[binomial(n-1-k,k)
for k in 0..quo(n-1,2)]) \bound{fib}}
\xtc{
\spadpaste{fib(25) \free{fib}}
}
\xtc{
\spadpaste{[fib(n) for n in 1..15] \free{fib}}
}

Quadratic symbols can be computed with the operations \spadfunFrom{legendre}{IntegerNumberTheoryFunctions} and \spadfunFrom{jacobi}{IntegerNumberTheoryFunctions}. The Legendre symbol \pad{$(a/p)$} is defined for integers \pad{a} and \pad{p} with \pad{p} an odd prime number. By definition, \pad{$(a/p) = +1$}, when \pad{a} is a square \pad{a (mod p)}, \pad{$(a/p) = -1$}, when \pad{a} is not a square \pad{a (mod p)}, and
\( \left( \frac{a}{p} \right) \) = 0, when \( a \) is divisible by \( p \).

You compute \( \left( \frac{a}{p} \right) \) via the command \( \text{legendre}(a,p) \).

\( \text{legendre}(3,5) \)

\( \text{legendre}(23,691) \)

The Jacobi symbol \( \left( \frac{a}{n} \right) \) is the usual extension of the Legendre symbol, where \( n \) is an arbitrary integer.

The most important property of the Jacobi symbol is the following: if \( K \) is a quadratic field with discriminant \( d \) and quadratic character \( \chi \), then \( \chi(n) = (d/n) \).

Thus, you can use the Jacobi symbol to compute, say, the class numbers of imaginary quadratic fields from a standard class number formula.

This function computes the class number of the imaginary quadratic field with discriminant \( d \).

\( \text{h}(d) \equiv \text{quo}(\text{reduce}(+,[\text{jacobi}(d,k) \text{ for } k \in 1..\text{quo}(-d,2)]),2-\text{jacobi}(d,2)) \)

\( \text{h}(-163) \)

\( \text{h}(-499) \)

\( \text{h}(-1832) \)

This function computes the class number of the imaginary quadratic field with discriminant \( d \).

The domain \spadtype{KeyedAccessFile(S)} provides files which can be used as associative tables. Data values are stored in these files and can be retrieved according to their keys. The keys must be strings so this type behaves very much like the \spadtype{StringTable(S)} domain. The difference is that keyed access files reside in secondary storage while string tables are kept in memory. For more information on table-oriented operations, see the description of \spadtype{Table}.

\begin{description}
\item[Before a keyed access file can be used, it must first be opened.] A new file can be created by opening it for output.
\spadpaste{ey: KeyedAccessFile(Integer) := open("/tmp/editor.year", "output") \bound{ey}}
\item[Just as for vectors, tables or lists, values are saved in a keyed access file by setting elements.]\spadpaste{ey."Char" := 1986 \free{ey} \bound{eya}}
\item[Values are retrieved using application, in any of its syntactic forms.]\spadpaste{ey."Char" \free{eya}}
\end{description}
Attempting to retrieve a non-existent element in this way causes an error. If it is not known whether a key exists, you should use the \spadfunFrom{search}{KeyedAccessFile} operation.

\spadpaste{search("Char", ey) \free{eya,eyb,eyc}\bound{eyaa}}
\xtc{}
\spadpaste{search("Smith", ey) \free{eyaa}}
\xtc{When an entry is no longer needed, it can be removed from the file.}
\spadpaste{remove!("Char", ey) \free{eyaa}\bound{eybb}}
\xtc{The \spadfunFrom{keys}{KeyedAccessFile} operation returns a list of all the keys for a given file.}
\spadpaste{keys ey \free{eybb}}
\xtc{The \spadfunFrom{\#}{KeyedAccessFile} operation gives the number of entries.}
\spadpaste{\#ey \free{eybb}}
\xtc{The table view of keyed access files provides safe operations. That is, if the Axiom program is terminated between file operations, the file is left in a consistent, current state. This means, however, that the operations are somewhat costly. For example, after each update the file is closed.}
\xtc{Here we add several more items to the file, then check its contents.}
\spadpaste{KE := Record(key: String, entry: Integer) \bound{KE}}
\xtc{}
\spadpaste{reopen!(ey, "output") \free{eybb,KE}\bound{eycc}}
\xtc{
If many items are to be added to a file at the same time, then it is more efficient to use the \spadfunFromX{write}{KeyedAccessFile} operation. 

\spadpaste{write!(ey, ["van Hulzen", 1983]\$KE) \bound{eyccA}\free{eycc}}

\xtc{
\spadpaste{write!(ey, ["Calmet", 1982]\$KE) \bound{eyccB}\free{eycc}}
}

\xtc{
\spadpaste{write!(ey, ["Wang", 1981]\$KE) \bound{eyccC}\free{eycc}}
}

\xtc{
\spadpaste{close! ey \free{eyccA,eyccB,eyccC}\bound{eydd}}
}

The \spadfunFromX{read}{KeyedAccessFile} operation is also available from the file view, but it returns elements in a random order. It is generally clearer and more efficient to use the \spadfunFromX{keys}{KeyedAccessFile} operation and to extract elements by key. 

\spadpaste{keys ey \free{eydd}}

\xtc{
\spadpaste{members ey \free{eydd}}
}

\noOutputXtc{
\spadpaste{)system rm -r /tmp/editor.year \free{ey}}
}

3.58. *KERNEL.HT*

Kernel

=> “notitle” (BasicOperatorXmpPage) 3.10 on page 169
=> “notitle” (ExpressionXmpPage) 3.33 on page 436

---

A \textit{kernel} is a symbolic function application (such as
CHAPTER 3. HYPERDOC PAGES

\spad{\sin(x + y)}) or a symbol (such as \spad{x}). More precisely, a non-symbol kernel over a set \{it S\} is an operator applied to a given list of arguments from \{it S\}. The operator has type \axiomType{BasicOperator} (see \downlink{`BasicOperator'}{BasicOperatorXmpPage}\ignore{BasicOperator}) and the kernel object is usually part of an expression object (see \downlink{`Expression'}{ExpressionXmpPage}\ignore{Expression}).

Kernels are created implicitly for you when you create expressions.
\xtc{
\spadpaste{x :: Expression Integer}
}
\xtc{
You can directly create a ‘symbol’ kernel by using the \axiomFunFrom{kernel}{Kernel} operation.
}\{\spadpaste{kernel x}
}
\xtc{
This expression has two different kernels.
}\{\spadpaste{\sin(x) + \cos(x) \bound{sincos}}
}
\xtc{
The operator \axiomFunFrom{kernels}{Expression} returns a list of the kernels in an object of type \axiomType{Expression}.
}\{\spadpaste{kernels \% \free{sincos}}
}\xtc{
This expression also has two different kernels.
}\{\spadpaste{\sin(x)^{**2} + \sin(x) + \cos(x) \bound{sincos2}}
}
\xtc{
The \spad{\sin(x)} kernel is used twice.
}\{\spadpaste{kernels \% \free{sincos2}}
}\xtc{
An expression need not contain any kernels.
}\{\spadpaste{kernels(1 :: Expression Integer)}
\xtc{
If one or more kernels are present, one of them is designated the \{it main\} kernel.
Kernels can be nested. Use `height` to determine the nesting depth.

This has height 2 because the `x` has height 1 and then we apply an operator to that.

Use the `operator` operation to extract the operator component of the kernel. The operator has type `BasicOperator`.

Use the `name` operation to extract the name of the operator component of the kernel. This is really just a shortcut for a two-step process of extracting the operator and then calling `name` on the operator.

Axiom knows about functions such as `sin`, `cos` and so on and can make kernels and then expressions using them. To create a kernel and expression using an arbitrary operator, use `operator{BasicOperator}`.

Now `f` can be used to create symbolic function applications.
Use the \axiomFunFrom{is?}{Kernel} operation to learn if the operator component of a kernel is equal to a given operator.

You can also use a symbol or a string as the second argument to \axiomFunFrom{is?}{Kernel}.

Use the \axiomFunFrom{argument}{Kernel} operation to get a list containing the argument component of a kernel.

Conceptually, an object of type \axiomType{Expression} can be thought of a quotient of multivariate polynomials, where the ‘‘variables’’ are kernels. The arguments of the kernels are again expressions and so the structure recurses.

See \downlink{Expression}{ExpressionXmpPage} for examples of using kernels to take apart expression objects.

The provided text appears to be a code snippet with comments and symbolic expressions, involving operations on expressions and operators. Here is a structured representation of the text:

```plaintext
(15) f
Type: BasicOperator

(16) f(x, y, 10)
Type: Expression Integer

(17) true
Type: Boolean
```

The code snippet includes the definition of operators and expressions, along with their types and values. It seems to be part of a larger context, possibly a documentation or tutorial on symbolic computation, involving mathematical expressions and their evaluation.

3.59 lazm3pk.ht

LazardSetSolvingPackage
The \texttt{LazardSetSolvingPackage} package constructor solves polynomial systems by means of Lazard triangular sets. However one condition is relaxed: Regular triangular sets whose saturated ideals have positive dimension are not necessarily normalized.

The decompositions are computed in two steps. First the algorithm of Moreno Maza (implemented in the \texttt{RegularTriangularSet} domain constructor) is called. Then the resulting decompositions are converted into lists of square-free regular triangular sets and the redundant components are removed. Moreover, zero-dimensional regular triangular sets are normalized.

Note that the way of understanding triangular decompositions is detailed in the example of the \texttt{RegularTriangularSet} constructor.

The \texttt{LazardSetSolvingPackage} constructor takes six arguments. The first one, \texttt{\textbf{R}}, is the coefficient ring of the polynomials; it must belong to the category \texttt{GcdDomain}. The second one, \texttt{\textbf{E}}, is the exponent monoid of the polynomials; it must belong to the category \texttt{OrderedAbelianMonoidSup}. The third one, \texttt{\textbf{V}}, is the ordered set of variables; it must belong to the category \texttt{OrderedSet}. The fourth one is the polynomial ring; it must belong to the category \texttt{RecursivePolynomialCategory(R,E,V)}. The fifth one is a domain of the category \texttt{RegularTriangularSetCategory(R,E,V,P)} and the last one is a domain of the category \texttt{SquareFreeRegularTriangularSetCategory(R,E,V,P)}. The abbreviation for \texttt{LazardSetSolvingPackage} is \texttt{LAZM3PK}.

\textbf{N.B.} For the purpose of solving zero-dimensional algebraic systems, see also \texttt{LexTriangularPackage} and \texttt{ZeroDimensionalSolvePackage}. These packages are easier to call than \texttt{LAZM3PK}. Moreover, the \texttt{ZeroDimensionalSolvePackage} package provides operations to compute either the complex roots or the real roots.

We illustrate now the use of the \texttt{LazardSetSolvingPackage} package constructor with two examples (Butcher and Vermeer).

\begin{verbatim}
\xtc{
Define the coefficient ring.
}

\begin{verbatim}
R := Integer \bound{R}
\}

\xtc{
Define the list of variables,
}\{
\spadpaste{ls : List Symbol := [b1,x,y,z,t,v,u,w] \bound{ls}}
\}
\xtc{
and make it an ordered set;
}\{
\spadpaste{V := OVAR(ls) \free{ls} \bound{V}}
\}
\xtc{
then define the exponent monoid.
}\{
\spadpaste{E := IndexedExponents V \free{V} \bound{E}}
\}
\xtc{
Define the polynomial ring.
}\{
\spadpaste{P := NSMP(R, V) \free{R} \free{V} \bound{P}}
\}
\xtc{
Let the variables be polynomial.
}\{
\spadpaste{b1: P := 'b1 \free{P} \bound{b1}}
\}
\xtc{
}\{
\spadpaste{x: P := 'x \free{P} \bound{x}}
\}
\xtc{
}\{
\spadpaste{y: P := 'y \free{P} \bound{y}}
\}
\xtc{
}\{
\spadpaste{z: P := 'z \free{P} \bound{z}}
\}
\xtc{
}\{
\spadpaste{t: P := 't \free{P} \bound{t}}
\}
\xtc{
\end{verbatim}
\{ 
\texttt{u: P := 'u \free{P} \bound{u}} \}
\texttt{\xtc{}}
\{ 
\texttt{v: P := 'v \free{P} \bound{v}} \}
\texttt{\xtc{}}
\{ 
\texttt{w: P := 'w \free{P} \bound{w}} \}
\texttt{\xtc{}}

Now call the \texttt{RegularTriangularSet} domain constructor.
\{ 
\texttt{T := REGSET(R,E,V,P) \free{R} \free{E} \free{V} \free{P} \bound{T}} \}
\texttt{\xtc{}}

Define a polynomial system (the Butcher example).
\{ 
\texttt{p0 := b1 + y + z - t - w \free{b1} \free{x} \free{y} \free{z} \free{t} \free{u} \free{v} \free{w} \bound{p0}} \}
\texttt{\xtc{}}
\{ 
\texttt{p1 := 2*z*u + 2*y*v + 2*t*w - 2*w**2 - w - 1 \free{b1} \free{x} \free{y} \free{z} \free{t} \free{u} \free{v} \free{w} \bound{p1}} \}
\texttt{\xtc{}}
\{ 
\texttt{p2 := 3*z*w**2 + 3*y*w**2 - 3*t*w**2 + 3*w**3 + 3*w**2 - t + 4*w \free{b1} \free{x} \free{y} \free{z} \free{t} \free{u} \free{v} \free{w} \bound{p2}} \}
\texttt{\xtc{}}
\{ 
\texttt{p3 := 6*x*z*v - 6*t*w**2 + 6*w**3 - 3*t*w + 6*w**2 - t + 4*w \free{b1} \free{x} \free{y} \free{z} \free{t} \free{u} \free{v} \free{w} \bound{p3}} \}
\texttt{\xtc{}}
\{ 
\texttt{p4 := 4*z*w**3+ 4*y*w**3+ 4*t*w**3- 4*w**4 - 6*w**3+ 4*t*w- 10*w**2- w - 1 \free{b1} \free{x} \free{y} \free{z} \free{t} \free{u} \free{v} \free{w} \bound{p4}} \}
\texttt{\xtc{}}
\spadpaste{p5 := 8*x*z*u*v + 8*t*w**3 - 8*w**4 + 4*t*w**2 -
12*w**3 + 4*t*w - 14*w**2 - 3*w - 1 \free{b1} \free{x} \free{y} \free{z} \free{t} \free{u} \free{v} \free{w} \bound{p5}}
\xtc{
}\spadpaste{p6 := 12*x*z*v**2 + 12*t*w**3 - 12*w**4 + 12*t*w**2 -
18*w**3 + 8*t*w - 14*w**2 - w - 1 \free{b1} \free{x} \free{y} \free{z} \free{t} \free{u} \free{v} \free{w} \bound{p6}}
\xtc{
}\spadpaste{p7 := -24*t*w**3 + 24*w**4 - 24*t*w**2 + 36*w**3 -
8*t*w + 26*w**2 + 7*w + 1 \free{b1} \free{x} \free{y} \free{z} \free{t} \free{u} \free{v} \free{w} \bound{p7}}
\xtc{
}\spadpaste{lp := [p0, p1, p2, p3, p4, p5, p6, p7] \free{p0} \free{p1} \free{p2} \free{p3} \free{p4} \free{p5} \free{p6} \free{p7} \bound{lp}}
\xtc{
First of all, let us solve this system in the sense of Lazard
by means of the \spadtype{REGSET} constructor:
}\{\spadpaste{lts := zeroSetSplit(lp, false)$T\free{lp}\free{T}\bound{lts}}\}
\xtc{
We can get the dimensions of each component
of a decomposition as follows.
}\{\spadpaste{[coHeight(ts) for ts in lts] \free{lts}}\}
\xtc{
The first five sets have a simple shape.
However, the last one, which has dimension zero, can be simplified
by using Lazard triangular sets.
}\{\spadpaste{ST := SREGSET(R, E, V, P) \free{R} \free{E} \free{V} \free{P} \bound{ST}}\}
\xtc{
Thus we call the \spadtype{SquareFreeRegularTriangularSet} domain
constructor,
}\{\spadpaste{ST := SREGSET(R, E, V, P) \free{R} \free{E} \free{V} \free{P} \bound{ST}}\}
and set the \spadtype{LAZM3PK} package constructor to our situation.
}\spadpaste{pack := LAZM3PK(R,E,V,P,T,ST) \free{R} \free{E} \free{V} \free{P} \free{T} \free{ST} \bound{pack} }
}
\xtc{
We are ready to solve the system by means of Lazard triangular sets:
}\spadpaste{zeroSetSplit(lp,false)$pack \free{lp} \free{pack}}
}

We see the sixth triangular set is \emph{nicer} now:
each one of its polynomials has a constant initial.

We follow with the Vermeer example. The ordering is the usual one for this system.
\xtc{
Define the polynomial system.
}\spadpaste{f0 := (w - v) ** 2 + (u - t) ** 2 - 1 \free{b1} \free{x} \free{y} \free{z} \free{t} \free{u} \free{v} \free{w} \bound{f0}}
}
\xtc{\}
\spadpaste{f1 := t ** 2 - v ** 3 \free{b1} \free{x} \free{y} \free{z} \free{t} \free{u} \free{v} \free{w} \bound{f1}}
}
\xtc{\}
\spadpaste{f2 := 2 * t * (w - v) + 3 * v ** 2 * (u - t) \free{b1} \free{x} \free{y} \free{z} \free{t} \free{u} \free{v} \free{w} \bound{f2}}
}
\xtc{\}
\spadpaste{f3 := (3 * z * v ** 2 - 1) * (2 * z * t - 1) \free{b1} \free{x} \free{y} \free{z} \free{t} \free{u} \free{v} \free{w} \bound{f3}}
}
\xtc{\}
\spadpaste{lf := \[f0, f1, f2, f3\] \free{f0} \free{f1} \free{f2} \free{f3} \bound{lf}}
}
\xtc{
First of all, let us solve this system in the sense of Kalkbrener by

means of the \spadtype{REGSET} constructor:
}\{
\spadpaste{zeroSetSplit(lf,true)$T \free{lf} \free{T}}
}\}

We have obtained one regular chain (i.e. regular triangular set) with
dimension 1. This set is in fact a characterist set of the (radical
of) of the ideal generated by the input system \texttt{(bf lf)}. Thus we have
only the \texttt{\{em generic points\}} of the variety associated with \texttt{(bf lf)}
(for the elimination ordering given by \texttt{(bf ls)}).

So let us get now a full description of this variety.
\\xtc{Hence, we solve this system in the sense of Lazard by means of the
\spadtype{REGSET} constructor:}
\}\{
\spadpaste{zeroSetSplit(lf,false)$T \free{lf} \free{T}}
\}\}

We retrieve our regular chain of dimension 1 and we get three regular
chains of dimension 0 corresponding to the \texttt{\{em degenerated cases\}}.
We want now to simplify these zero-dimensional regular chains by using
Lazard triangular sets. Moreover, this will allow us to prove that
the above decomposition has no redundant component. \texttt{(bf N.B.)}
Generally, decompositions computed by the \spadtype{REGSET} constructor do not have redundant components. However, to be sure
that no redundant component occurs one needs to use the
\spadtype{SREGSET} or \spadtype{LAZM3PK} constructors.
\\xtc{So let us solve the input system in the sense of Lazard by means of
the \spadtype{LAZM3PK} constructor:}
\}\{
\spadpaste{zeroSetSplit(lf,false)$pack \free{lf} \free{pack}}
\}\}

Due to square-free factorization, we obtained now four
zero-dimensional regular chains. Moreover, each of them is normalized
(the initials are constant). Note that these zero-dimensional
components may be investigated further with the
\spadtype{ZeroDimensionalSolvePackage} package constructor.
\\endscroll

LexTriangularPackage

--- lextraipk.ht ---

This package takes two arguments: the coefficient-ring \(\bf R\) of the polynomials, which must be a \spadtype{GcdDomain} and their set of variables given by \(\bf ls\) a \spadtype{List Symbol}. The type of the input polynomials must be \spadtype{NewSparseMultivariatePolynomial(R,V)} where \(\bf V\) is \spadtype{OrderedVariableList(ls)}. The abbreviation for \spadtype{LexTriangularPackage} is \spadtype{LEXTRIPK}. The main operations are \axiomOpFrom{lexTriangular}{LexTriangularPackage} and \axiomOpFrom{squareFreeLexTriangular}{LexTriangularPackage}. The former provides decompositions by means of square-free regular triangular sets, whereas the latter uses the \spadtype{SREGSET} constructor. Note that these constructors also implement another algorithm for solving algebraic systems by means of regular triangular sets; in that case no computations of Groebner bases are needed and the input system may have any dimension (i.e. it may have an infinite number of solutions).
The implementation of the `{\em lexTriangular}` algorithm provided in the `\spadtype{LexTriangularPackage}` constructor differs from that reported in "Computations of gcd over algebraic towers of simple extensions" by M. Moreno Maza and R. Rioboo (in proceedings of AAECC11, Paris, 1995). Indeed, the `\axiomOpFrom{squareFreeLexTriangular}{LexTriangularPackage}` operation removes all multiplicities of the solutions (i.e. the computed solutions are pairwise different) and the `\axiomOpFrom{lexTriangular}{LexTriangularPackage}` operation may keep some multiplicities; this latter operation runs generally faster than the former.

The interest of the `{\em lexTriangular}` algorithm is due to the following experimental remark. For some examples, a triangular decomposition of a zero-dimensional variety can be computed faster via a lexicographical Groebner basis computation than by using a direct method (like that of `\spadtype{SREGSET}` and `\spadtype{REGSET}`). This happens typically when the total degree of the system relies essentially on its smallest variable (like in the `{\em Katsura}` systems). When this is not the case, the direct method may give better timings (like in the `{\em Rose}` system).

Of course, the direct method can also be applied to a lexicographical Groebner basis. However, the `{\em lexTriangular}` algorithm takes advantage of the structure of this basis and avoids many unnecessary computations which are performed by the direct method.

For this purpose of solving algebraic systems with a finite number of solutions, see also the `\spadtype{ZeroDimensionalSolvePackage}`. It allows to use both strategies (the lexTriangular algorithm and the direct method) for computing either the complex or real roots of a system.

Note that the way of understanding triangular decompositions is detailed in the example of the `\spadtype{RegularTriangularSet}` constructor.

Since the `\spadtype{LEXTRIPK}` package constructor is limited to zero-dimensional systems, it provides a `\axiomOpFrom{zeroDimensional?}{LexTriangularPackage}` operation to check whether this requirement holds. There is also a `\axiomOpFrom{groebner}{LexTriangularPackage}` operation to compute the lexicographical Groebner basis of a set of polynomials with type `\spadtype{NewSparseMultivariatePolynomial(R,V)}`. The elimination ordering is that given by `{\bf ls}` (the greatest variable being the first element of `{\bf ls}`). This basis is computed by the `{\em FLGM}` algorithm (Faugere et al. "Efficient Computation of Zero-Dimensional Groebner Bases by Change of Ordering", J. of Symbol. Comput., 1993) implemented in the `\spadtype{LinGroebnerPackage}` package constructor. Once a lexicographical Groebner basis is computed,
then one can call the operations
\\texttt{\textbackslash axiomOpFrom\{lexTriangular\}\{LexTriangularPackage\}}
and \\texttt{\textbackslash axiomOpFrom\{squareFreeLexTriangular\}\{LexTriangularPackage\}}.

Note that these operations admit an optional argument
to produce normalized triangular sets.

There is also a \texttt{\textbackslash axiomOpFrom\{zeroSetSplit\}\{LexTriangularPackage\}}
operation which does all the job from the input system;
an error is produced if this system is not zero-dimensional.

Let us illustrate the facilities of the \texttt{\textbackslash spadtype\{LEXTRIPK\}} constructor
by a famous example, the \texttt{\textbackslash em cyclic-6 root} system.
\xtc{
Define the coefficient ring.
}{
\spadpaste{R := Integer \bound{R}}
}
\xtc{
Define the list of variables,
}{
\spadpaste{ls : List Symbol := [a,b,c,d,e,f] \bound{ls}}
}
\xtc{
and make it an ordered set.
}{
\spadpaste{V := OVAR(ls) \free{ls} \bound{V}}
}
\xtc{
Define the polynomial ring.
}{
\spadpaste{P := NSMP(R, V) \free{R} \free{V} \bound{P}}
}
\xtc{
Define the polynomials.
}{
\spadpaste{p1: P := a*b*c*d*e*f - 1 \free{P} \bound{p1}}
}
\xtc{
}{
\spadpaste{p2: P := a*b*c*d*e +a*b*c*d*f +a*b*c*e*f +a*b*d*e*f +
a*c*d*e*f +b*c*d*e*f \free{P} \bound{p2}}
}
\xtc{
}{
\spadpaste{p3: P := a*b*c*d + a*b*c*f + a*b*e*f + a*d*e*f +
b*c*d*e + c*d*e*f \free{P} \bound{p3}}
}
\xtc{
}{
\spadpaste{p4: P := a*b*c + a*b*f + a*e*f + b*c*d + c*d*e + d*e*f \free{P} \bound{p4}}
}
Now call \spad{LEXTRIPK}.

\begin{verbatim}
\spadpaste{lextripack := LEXTRIPK(R,ls) \free{R} \free{ls} \bound{lextripack}}
\end{verbatim}

Compute the lexicographical Groebner basis of the system. This may take between 5 minutes and one hour, depending on your machine.

\begin{verbatim}
\spadpaste{lg := groebner(lp)$lextripack \free{lp} \free{lextripack} \bound{lg}}
\end{verbatim}

Apply lexTriangular to compute a decomposition into regular triangular sets. This should not take more than 5 seconds.

\begin{verbatim}
\spadpaste{lexTriangular(lg,false)$lextripack \free{lg} \free{lextripack}}
\end{verbatim}

Note that the first set of the decomposition is normalized (all initials are integer numbers) but not the second one (normalized triangular sets are defined in the description of the \spad{NormalizedTriangularSetCategory} constructor).

So apply now lexTriangular to produce normalized triangular sets.

\begin{verbatim}
\spadpaste{lts := lexTriangular(lg,true)$lextripack \free{lg} \free{lextripack} \bound{lts}}
\end{verbatim}

We check that all initials are constant.

\begin{verbatim}
\spadpaste{[[init(p) for p in (ts :: List(P))] for ts in lts]}
\end{verbatim}
Note that each triangular set in $\{\text{bf lts}\}$ is a lexicographical Groebner basis.
Recall that a point belongs to the variety associated with $\{\text{bf lp}\}$ if and only if it belongs to that associated with one triangular set $\{\text{bf ts}\}$ in $\{\text{bf lts}\}$.

By running the $\text{axiomOpFrom\{squareFreeLexTriangular\}\{LexTriangularPackage\}}$ operation, we retrieve the above decomposition.

\begin{verbatim}
xtc{
\spadpaste{squareFreeLexTriangular(lg,true)$lextripack \text{free\{lg\} \text{free\{lextripack\}}}}
\end{verbatim}

Thus the solutions given by $\{\text{bf lts}\}$ are pairwise different.

\begin{verbatim}
xtc{
\spadpaste{reduce(+,[degree(ts) for ts in lts]) \text{free\{lts\}}}}
\end{verbatim}

We can investigate the triangular decomposition $\{\text{bf lts}\}$ by using the $\text{spadtype\{ZeroDimensionalSolvePackage\}}$.

\begin{verbatim}
xtc{
\spadpaste{ls2 : List Symbol := concat(ls,new()$Symbol) \text{free\{ls\}} \text{bound\{ls2\}}}}
\end{verbatim}

Then we call the package.

\begin{verbatim}
xtc{
\spadpaste{zdpack := ZDSOLVE(R,ls,ls2) \text{free\{R\}} \text{free\{ls\}} \text{free\{ls2\}} \text{bound\{zdpack\}}}}
\end{verbatim}

We compute a univariate representation of the variety associated with the input system as follows.

\begin{verbatim}
xtc{
\spadpaste{concat [univariateSolve(ts)$zdpack for ts in lts] \text{free\{lts\}} \text{free\{zdpack\}}}}
\end{verbatim}

Since the $\text{axiomOpFrom\{univariateSolve\}\{ZeroDimensionalSolvePackage\}}$ operation may
split a regular set, it returns a list. This explains the use of `concat(List)`.

Look at the last item of the result. It consists of two parts. For any complex root of the univariate polynomial in the first part, we get a tuple of univariate polynomials (in `a`, ..., `f` respectively) by replacing `A` by `?` in the second part. Each of these tuples describes a point of the variety associated with `lp` by equaling to zero the polynomials in `t`.

Note that the way of reading these univariate representations is explained also in the example illustrating the `ZeroDimensionalSolvePackage` constructor.

Now, we compute the points of the variety with real coordinates.

\begin{verbatim}
concat [realSolve(ts)$zdpack for ts in lts] \free{lts}$zdpack
\end{verbatim}

We obtain 24 points given by lists of elements in the `RealClosure` of `Fraction` of `R`. In each list, the first value corresponds to the indeterminate `f`, the second to `e` and so on.

See `ZeroDimensionalSolvePackage` to learn more about the `realSolve` operation.

— lib.ht —
The \spadtype{Library} domain provides a simple way to store Axiom values in a file. This domain is similar to \spadtype{KeyedAccessFile} but fewer declarations are needed and items of different types can be saved together in the same file.

To create a library, you supply a file name.

\spadpaste{stuff := library "/tmp/Neat.stuff" \bound{stuff}}

Now values can be saved by key in the file. The keys should be mnemonic, just as the field names are for records. They can be given either as strings or symbols.

\spadpaste{stuff.int := 32**2 \free{stuff}\bound{stuffa}}
\spadpaste{stuff."poly" := x**2 + 1 \free{stuffa}\bound{stuffb}}
\spadpaste{stuff.str := "Hello" \free{stuffb}\bound{stuffc}}

You obtain the set of available keys using the \spadfunFrom{keys}{Library} operation.

\spadpaste{keys stuff \free{stuffa,stuffb,stuffc}\bound{stuffabc}}

You extract values by giving the desired key in this way.

\spadpaste{stuff.poly \free{stuffb}}
\spadpaste{stuff("poly") \free{stuffb}}

When the file is no longer needed, you should remove it from the file system.

\spadpaste{)system rm -rf /tmp/Neat.stuff \free{stuff}\bound{rmstuff}}

CHAPTER 3. HYPERDOC PAGES

1-D quadrature, adaptive, finite interval, strategy due to Plessens and de Doncker, allowing for badly-behaved integrands

1-D quadrature, adaptive, finite interval, method suitable for oscillating functions

1-D quadrature, adaptive, finite interval, allowing for singularities at user specified points

1-D quadrature, adaptive, infinite or semi-finite interval

1-D quadrature, adaptive, finite interval, weight function $\cos(\omega x)$ or $\sin(\omega x)$

1-D quadrature, adaptive, finite interval, weight function with end point singularities of algebraico-logarithmic type

1-D quadrature, adaptive, finite interval, weight function $1/(x-c)$, Cauchy principle value (Hilbert transform)

1-D quadrature, adaptive, semi-infinite interval, weight function $\cos(\omega x)$ or $\sin(\omega x)$

Pre-computed weights and abscissae for Gaussian quadrature rules, restricted choice of rule

Multi-dimensional adaptive quadrature over hyper-rectangle

1-D quadrature, integration of function defined by data values, Gill–Miller method

Multi-dimensional quadrature over hyper-rectangle, Monte Carlo method
D02 Ordinary Differential Equations

A \spadgloss{list} is a finite collection of elements in a specified
order that can contain duplicates.
A list is a convenient structure to work with because it is easy
to add or remove elements and the length need not be constant.
There are many different kinds of lists in Axiom, but the
default types (and those used most often) are created by the
\spadtype{List} constructor.
For example, there are objects of type \spadtype{List Integer},
\spadtype{List Float} and \spadtype{List Polynomial Fraction Integer}.
Indeed, you can even have \spadtype{List List List Boolean}
(that is, lists of lists of lists of Boolean values).
You can have lists of any type of Axiom object.
Creating Lists

\begin{page}{ugxListCreatePage}{Creating Lists}
\beginscroll

The easiest way to create a list with, for example, the elements \spad{2, 4, 5, 6} is to enclose the elements with square brackets and separate the elements with commas.
\xtc{The spaces after the commas are optional, but they do improve the readability.}
\spadpaste{[2, 4, 5, 6]}
\xtc{To create a list with the single element \spad{1}, you can use either \spad{[1]} or the operation \spadfunFrom{list}{List}.}
\spadpaste{[1]}
\xtc{Once created, two lists \spad{k} and \spad{m} can be concatenated by issuing \spad{append(k,m)}. \spadfunFrom{append}{List} does \textit{not} physically join the lists, but rather produces a new list with the elements coming from the two arguments.}
\spadpaste{append([1,2,3],[5,6,7])}
\xtc{Use \spadfunFrom{cons}{List} to append an element onto the front of a list.}
\spadpaste{cons(10,[9,8,7])}

**Accessing List Elements**

--- list.ht ---

To determine whether a list has any elements, use the operation\texttt{empty?\{List\}.}

Alternatively, equality with the list constant \texttt{nil\{List\}} can be tested.
We’ll use this in some of the following examples.
}
\spadpaste{k := [4,3,7,3,8,5,9,2] \bound{k}}
}
\xtc{
Each of the next four expressions extracts the \spadfunFrom{first}{List}
 element of \spad{k}.
}
\spadpaste{first k \free{k}}
}
\xtc{
}\{\{\\}
\spadpaste{k.first \free{k}}
}
\xtc{
}\{\{\\}
\spadpaste{k.1 \free{k}}
}
\xtc{
}\{\{\\}
\spadpaste{k(1) \free{k}}
}
The last two forms generalize to \spad{k.i} and \spad{k(i)},
 respectively, where
\texth{$ 1 \leq i \leq n$}\{\spad{1 <= i <= n}\}
and
\spad{n} equals the length of \spad{k}.
\xtc{
This length is calculated by \spad{opFrom(\#){List}}.
}
\spadpaste{n := \#k \free{k}}
}
Performing an operation such as \spad{k.i} is sometimes
 referred to as {\it indexing into k} or
 {\it elting into k}.
The latter phrase comes about because the name of the operation
 that extracts elements is called \spadfunFrom{elt}{List}.
That is, \spad{k.3} is just alternative syntax for \spad{elt(k,3)}.
It is important to remember that list indices
 begin with 1.
If we issue \spad{k := [1,3,2,9,5]} then \spad{k.4}
 returns \spad{9}.
It is an error to use an index that is not in the range from
\spad{1} to the length of the list.
The last element of a list is extracted by any of the following three expressions.

\{
\spadpaste{last k \free{k}}
\}
\xtc{
\spadpaste{k.last \free{k}}
}\xtc{
This form computes the index of the last element and then extracts the element from the list.
}\{ 
\spadpaste{k.(\#k) \free{k}}
\}
\endscroll
\autobuttons
\end{page}
\begin{verbatim}

Changing List Elements

\begin{page}{ugxListChangePage}{Changing List Elements}
\beginscroll

\labelSpace{4pc}
\xtc{
We’ll use this in some of the following examples.
}{
\spadpaste{k := \{4,3,7,3,8,5,9,2\} \bound{k}}
}
\xtc{
List elements are reset by using the \spad{k.i} form on
the left-hand side of an assignment.
This expression resets the first element of \spad{k} to \spad{999}.
}{
\spadpaste{k.1 := 999 \free{k}\bound{k1}}
}
\xtc{
As with indexing into a list, it is an error to use an index
that is not within the proper bounds.
Here you see that \spad{k} was modified.
}{
\spadpaste{k \free{k1}}
}

The operation that performs the assignment of an element to a particular
position in a list is called \spadfunFrom{setelt}{List}.
This operation is \{it destructive\} in that it changes the list.
In the above example, the assignment returned the value \spad{999} and
\spad{k} was modified.
For this reason, lists are called \spadglos{mutable} objects: it is
possible to change part of a list (mutate it) rather than always returning
a new list reflecting the intended modifications.
\xtc{
Moreover, since lists can share structure, changes to one list can
sometimes affect others.
}{
\spadpaste{k := \{1,2\} \bound{k2}}
}
\xtc{
}{
\spadpaste{m := \spad{cons(0,k)} \free{k2}\bound{m}}
}
\xtc{
Change the second element of \spad{m}.
}{
}
\spadpaste{\texttt{m} := 99 \free{m}\bound{m2}}
\}
\xtc{
See, \spad{m} was altered.
}\{
\spadpaste{m \free{m2}}
\}
\xtc{
But what about \spad{k}? It changed too!
}\{
\spadpaste{k \free{m2 k2}}
\}
\endscroll
\autobuttons
\end{page}

Other Functions

\begin{page}{ugxListOtherPage}{Other Functions}
\beginscroll
\labelSpace{3pc}
\xtc{
An operation that is used frequently in list processing is that which returns all elements in a list after the first element.
}\{
\spadpaste{k := [1,2,3] \bound{k}}
\}
\xtc{
Use the \spadfunFrom{rest}{List} operation to do this.
}\{
\spadpaste{rest k \free{k}}
\}
\xtc{
To remove duplicate elements in a list \spad{k}, use \spadfunFrom{removeDuplicates}{List}.
}\{
\spadpaste{removeDuplicates [4,3,4,3,5,3,4]}
\}
\xtc{
To get a list with elements in the order opposite to those in a list \spad{k}, use \spadfunFrom{reverse}{List}.
}\{
\spadpaste{reverse [1,2,3,4,5,6]}
\}
\xtc{
To test whether an element is in a list, use \spadfunFrom{member?}{List}:
\spad{member?([a,k])} returns \spad{true} or \spad{false} depending on whether \spad{a} is in \spad{k} or not.
}\{
\spadpaste{member?(1/2,[3/4,5/6,1/2])}
\}
\xtc{}
\{
\spadpaste{member?(1/12,[3/4,5/6,1/2])}
\}
\endscroll

As an exercise, the reader should determine how to get a list containing all but the last of the elements in a given non-empty list \spad{k}.\footnote{\spad{reverse(rest(reverse(k)))} works.}

CHAPTER 3. HYPERDOC PAGES

Dot, Dot

| list.ht |

\begin{page}{ugxListDotPage}{Dot, Dot}
\beginscroll

Certain lists are used so often that Axiom provides an easy way of constructing them. If \spad{n} and \spad{m} are integers, then \spad{expand \[n..m\]} creates a list containing \spad{n, n+1, ... m}. If \spad{n > m} then the list is empty. It is actually permissible to leave off the \spad{m} in the dot-dot construction (see below).

\xtc{
The dot-dot notation can be used more than once in a list construction and with specific elements being given. Items separated by dots are called \{it segments.\}
}{
\spadpaste{[1..3,10,20..23]}
}
\xtc{
Segments can be expanded into the range of items between the endpoints by using \spadfunFrom{expand}{Segment}.
}{
\spadpaste{expand \[1..3,10,20..23\]}
}
\xtc{
What happens if we leave off a number on the right-hand side of \spadopFrom{..}{UniversalSegment}?
}{
\spadpaste{expand \[1..\]}
}
What is created in this case is a \spadtype{Stream} which is a generalization of a list. See \downlink{`Stream'}{StreamXmpPage}\ignore{Stream} for more information.

LinearOrdinaryDifferentialOperator1

⇒ “notitle” (ugxLinearOrdinaryDifferentialOperatorOneRatPage) 3.66 on page 895

---

LinearOrdinaryDifferentialOperator1(A) is the domain of linear ordinary differential operators with coefficients in the differential ring \( \text{spad}(A) \).

This includes the cases of operators which are polynomials in \( \text{spad}(D) \) acting upon scalar or vector expressions of a single variable.

The coefficients of the operator polynomials can be integers, rational functions, matrices or elements of other domains.

\showBlurb{LinearOrdinaryDifferentialOperator1}
Differential Operators with Rational Function Coefficients

— lodo1.ht —

We begin by defining \spad{RF} to be the rational functions in \spad{x} with integer coefficients and \spad{Dx} to be the differential operator for \spad{d/dx}.

\spadpaste{RF := Fraction UnivariatePolynomial('x, Integer) \bound{RF0}}
\xtc{\spadpaste{x : RF := 'x \free{RF0}\bound{RF}}}
\xtc{\spadpaste{Dx : LODO1 RF := D()\bound{Dx}\free{RF}}} Operators are created using the usual arithmetic operations.
\spadpaste{b : LODO1 RF := 3*x**2*Dx**2 + 2*Dx + 1/x \free{Dx}\bound{b}}
\spadpaste{a : LODO1 RF := b*(5*x*Dx + 7) \free{b Dx}\bound{a}} Operator multiplication corresponds to functional composition.

Operator multiplication corresponds to functional composition.
Since operator coefficients depend on \spad{x}, the multiplication is not commutative.

When the coefficients of operator polynomials come from a field, as in this case, it is possible to define operator division. Division on the left and division on the right yield different results when the multiplication is non-commutative.

The results of \spadfunFrom{leftDivide}{LinearOrdinaryDifferentialOperator1} and \spadfunFrom{rightDivide}{LinearOrdinaryDifferentialOperator1} are quotient-remainder pairs satisfying:

\spad{leftDivide(a,b) = \[q, r\]} such that \spad{a = b*q + r} \newline
\spad{rightDivide(a,b) = \[q, r\]} such that \spad{a = q*b + r} \newline

In both cases, the \spad{degree} of the remainder, \spad{r}, is less than the degree of \spad{b}.

The operations of left and right division are so-called because the quotient is obtained by dividing \spad{a} on that side by \spad{b}.

Operations \spadfunFrom{rightQuotient}{LinearOrdinaryDifferentialOperator1} and \spadfunFrom{rightRemainder}{LinearOrdinaryDifferentialOperator1} are available if only one of the quotient or remainder are of
This is the quotient from right division.
}\spad{\texttt{rightQuotient(a,b) \free{a b}}}
}\xtc{
This is the remainder from right division.
The corresponding ‘left’ functions
\spad{\texttt{leftQuotient(a,b)} \free{a b}} and
\spad{\texttt{leftRemainder(a,b)} \free{a b}}
are also available.
}\spad{\texttt{rightRemainder(a,b) \free{a b}}}
}\xtc{
For exact division, the operations
\spad{\texttt{leftExactQuotient(a,b)}} and
\spad{\texttt{rightExactQuotient(a,b)}}
are supplied. These return the quotient but only if the remainder is zero.
The call \spad{\texttt{rightExactQuotient(a,b)}} would yield an error.
}\spad{\texttt{leftExactQuotient(a,b) \free{a b}}}
}\xtc{
The division operations allow the computation of left and right
Greatest common divisors (\spad{\texttt{leftGcd(a,b) \free{a b}}}) and
\spad{\texttt{rightGcd(a,b) \free{a b}}}) via
remainder sequences, and consequently the computation of left and
right least common multiples (\spad{\texttt{rightLcm(a,b) \free{a b}}}) and
\spad{\texttt{leftLcm(a,b) \free{a b}}}).
}\spad{e := \texttt{leftGcd(a,b) \bound{e} \free{a b}}}
}\xtc{
Note that a greatest common divisor doesn’t necessarily divide \spad{a} and
\spad{b} on both sides. Here the left greatest common divisor does not divide \spad{a} on the right.
}\spad{\texttt{leftRemainder(a, e) \free{a e}}}
}\xtc{
}\spad{\texttt{rightRemainder(a, e) \free{a e}}}

Similarly, a least common multiple is not necessarily divisible from both sides.

Differential Operators with Matrix Coefficients Operating on Vectors

— lodo2.ht —

Differential Operators with Matrix Coefficients Operating on Vectors

This is another example of linear ordinary differential operators with non-commutative multiplication.
Unlike the rational function case, the differential ring of
square matrices (of a given dimension) with univariate polynomial entries does not form a field. Thus the number of operations available is more limited.

\begin{verbatim}
\labelSpace{1pc}
\xtc{In this section, the operators have three by three matrix coefficients with polynomial entries.}
\spadpaste{PZ := UnivariatePolynomial(x,Integer)}
\xtc{\}
\spadpaste{x:PZ := 'x}
\xtc{
\spadpaste{Mat := SquareMatrix(3,PZ)}
\xtc{\}
\spadpaste{Vect := DPMM(3, PZ, Mat, PZ)}
\xtc{\}
\spadpaste{Modo := LODO2(Mat, Vect)}
\xtc{\}
\spadpaste{m:Mat := matrix \[x^{**2},1,0\],\[1,x^{**4},0\],\[0,0,4*x^{**2}\]} \free{Mat} \bound{m}
\xtc{\}
\spadpaste{p:Vect := directProduct \[3*x^{**2}+1,2*x,7*x^{**3}+2*x\]} \free{Vect} \bound{p}
\xtc{\}
\spadpaste{q: Vect := m * p} \free{m p Vect} \bound{q}
\xtc{\}
\spadpaste{Dx : Modo := D()} \bound{Dx} \free{Modo}
\end{verbatim}

Now form a few operators.
These operators can be applied to vector values.

\spad{a : Modo := Dx + m}
\spad{b : Modo := m*Dx + 1}
\spad{c := a*b}

These operators can be applied to vector values.

\spad{a p}
\spad{b p}
\spad{(a + b + c) (p + q)}

\begin{spad}{UnivariatePolynomial(x,Integer)}

There are lisp functions which exist behind certain pages and the page information is created dynamically by calling the function.

This is a list of the macros which use lisp functions:

- `oPage` axiomFun
- `oPageFrom` axiomFunFrom
- `htGloss` gloss

Domain Mapping(T,S,...)

⇒ “Description” (LispFunctions) 3.71 on page 952
⇒ “Operations” (LispFunctions) 3.71 on page 952

— mapping.ht —

\begin{page}{DomainMapping}{Domain \textit{Mapping(T,S,...)}}
\beginscroll
\item \textit{Mapping} takes any number of arguments of the form:
\indentrel{2}
\newline \texttt{spad(T)}, a domain of category \texttt{SetCategory}
\newline \texttt{spad(S)}, a domain of category \texttt{SetCategory}
\indentrel{-2}
This constructor is a primitive in Axiom.
\end{scroll}
\end{page}
Domain Constructor Mapping

---

Function are objects of type \texttt{Mapping}. In this section we demonstrate some library operations from the
packages \spadtype{MappingPackage1}, \spadtype{MappingPackage2}, and \spadtype{MappingPackage3} that manipulate and create functions. Some terminology: a \textit{nullary} function takes no arguments, a \textit{unary} function takes one argument, and a \textit{binary} function takes two arguments.

\xtc{We begin by creating an example function that raises a rational number to an integer exponent.}
\spadpaste{power(q: FRAC INT, n: INT): FRAC INT == q**n \bound{power}}
\xtc{}
\spadpaste{power(2, 3) \free{power}}
\xtc{The \spadfunFrom{twist}{MappingPackage3} operation transposes the arguments of a binary function. Here \spad{rewop(a, b)} is \spad{power(b, a)}.}
\spadpaste{rewop := twist power \free{power} \bound{rewop}}
\xtc{This is \texttt{$2^3.$} \spad{2**3.}}
\spadpaste{rewop(3, 2) \free{rewop}}
\xtc{Now we define \texttt{square} in terms of \texttt{power}.}
\spadpaste{square: FRAC INT -> FRAC INT \bound{squaredec}}
\xtc{The \spadfunFrom{curryRight}{MappingPackage3} operation creates a unary function from a binary one by providing a constant argument on the right.}
\spadpaste{square:= curryRight(power, 2) \free{squaredec power} \bound{square}}
\xtc{Likewise, the \spadfunFrom{curryLeft}{MappingPackage3} operation provides a constant argument on the left.}
\spadpaste{square 4 \free{square}}
\xtc{The \spadfunFrom{constantRight}{MappingPackage3} operation creates
(in a trivial way) a binary function from a unary one:
\spad{constantRight(f)} is the function \spad{g} such that
\spad{g(a,b)= f(a).}
\spadpaste{squirrel:= constantRight(square)$MAPPKG3(FRAC INT,
FRAC INT,FRAC INT) \free{square}\bound{squirrel}}
\xtc{
Likewise,\spad{constantLeft(f)} is the function \spad{g} such that
\spad{g(a,b)= f(b).}
}\spadpaste{squirrel(1/2, 1/3) \free{squirrel}}
\xtc{
The \spadfunFrom{curry}{MappingPackage2} operation makes a
unary function nullary.
}\spadpaste{sixteen := curry(square, 4/1) \free{square}\bound{sixteen}}
\xtc{
}\spadpaste{sixteen() \free{sixteen}}
\xtc{
The \spadopFrom{*}{MappingPackage3} operation
constructs composed functions.
}\spadpaste{square2:=square*square \free{square}\bound{square2}}
\xtc{
}\spadpaste{square2 3 \free{square2}}
\xtc{
Use the \spadopFrom{**}{MappingPackage1} operation to create
functions that are \spad{n}-fold iterations of other functions.
}\spadpaste{sc(x: FRAC INT): FRAC INT == x + 1 \bound{sc}}
\xtc{
This is a list of \pspadtype{Mapping} objects.
}\spadpaste{incfns := [sc**i for i in 0..10] \free{sc}\bound{incfns}}
\xtc{
This is a list of applications of those functions.
}\spadpaste{[f 4 for f in incfns] \free{incfns}}
Use the \spadfunFrom{recur}{MappingPackage1} operation for recursion:
\spad{g := recur f} means \spad{g(n,x) == f(n,f(n-1,\ldots f(1,x))).}

\spadpaste{times(n:NNI, i:INT):INT == n*i}

This is a factorial function.
\spadpaste{fact := curryRight(r, 1)

fact 4

Constructed functions can be used within other functions.
\begin{spadsrc}
\free{square}
\bound{mto2ton}
mto2ton(m, n) ==
  raiser := square**n
  raiser m
\end{spadsrc}

This is \texttt{3^{2^3}.}
\spadpaste{mto2ton(3, 3)}

Here \userfun{shiftfib} is a unary function that modifies its argument.
\begin{spadsrc}
\free{shiftfib}
shiftfib(r: List INT) : INT ==
  t := r.1
  r.1 := r.2
  r.2 := r.2 + t
  t
\end{spadsrc}

By currying over the argument we get a function with private state.
\spadpaste{fibinit: List INT := [0, 1]}
\xtc{
  }
\spadpaste{fibs := curry(shiftfib, fibinit)
  \free{shiftfib fibinit}\bound{fibs}}
\xtc{
  }
\spadpaste{[fibs() for i in 0..30] \free{fibs}}
\endscroll

3.74 mset.ht

MultiSet

--- mset.ht ---

Create a multiset of integers.

\begin{spadpaste}
\spadpaste{s := multiset \{1,2,3,4,5,4,3,2,3,4,5,6,7,4,10\}}
\end{spadpaste}

The operation \spadfunX{insert} adds an element to a multiset.

\begin{spadpaste}
\spadpaste{insert!(3,s)}
\end{spadpaste}

Use \spadfunX{remove} to remove an element. If a third argument is present, it specifies how many instances to remove. Otherwise all instances of the element are removed. Display the resulting multiset.

\begin{spadpaste}
\spadpaste{remove!(3,s,1)}
\end{spadpaste}
The operation `count` returns the number of copies of a given value.

```spad
\spadpaste{count(5,s)\free{s2}}
```

A second multiset.

```spad
\spadpaste{t := multiset [2,2,2,-9]\bound{t}}
```

The \spad{union} of two multisets is additive.

```spad
\spadpaste{U := union(s,t)\bound{U}}
```

The \spad{intersect} operation gives the elements that are in common, with additive multiplicity.

```spad
\spadpaste{I := intersect(s,t)\bound{I}}
```

The \spad{difference} of \spad{s} and \spad{t} consists of the elements that \spad{s} has but \spad{t} does not. Elements are regarded as indistinguishable, so that if \spad{s} and \spad{t} have any element in common, the \spad{difference} does not contain that element.

```spad
\spadpaste{difference(s,t)\free{s t}}
```

The \spad{symmetricDifference} is the \spad{union} of \spad{difference(s,t)} and \spad{difference(t,s)}.

```spad
\spadpaste{S := symmetricDifference(s,t)\bound{S}\free{s t}}
```

Check that the \spad{union} of the \spad{symmetricDifference} and the \spad{intersect} equals the \spad{union} of the elements.

```spad
\spadpaste{(U = union(S,I))@Boolean\free{S I U}}
```

Check some inclusion relations.

```spad
\spadpaste{t1 := multiset [1,2,2,3]; [t1 < t, t1 < s, t < s, t1 <= s] \free{t s2}}
```
\begin{paste}{MultiSetXmpPageFull1}{MultiSetXmpPageEmpty1}

3.75 matrix.ht

Matrix

\begin{page}{MatrixXmpPage}{Matrix}
\beginscroll
The \spadtype{Matrix} domain provides arithmetic operations on matrices
and standard functions from linear algebra.
This domain is similar to the \spadtype{TwoDimensionalArray} domain, except
that the entries for \spadtype{Matrix} must belong to a \spadtype{Ring}.
\end{scroll}
\autobuttons
\end{page}

Creating Matrices

\begin{page}{ugxMatrixCreatePage}{Creating Matrices}
\beginscroll
There are many ways to create a matrix from a collection of
values or from existing matrices.

\xtc{
If the matrix has almost all items equal to the same value,
use \spadfunFrom{new}{Matrix} to create a matrix filled with that
value and then reset the entries that are different.
}\}
\spadpaste{m : Matrix(Integer) := new(3,3,0) \bound{m}}
\xtc{
To change the entry in the second row, third column to \spad{5}, use
}
\spadfunFrom{setelt}{Matrix}.
{\spadpaste{setelt(m,2,3,5) \free{m}\bound{m1}}}
\xtc{An alternative syntax is to use assignment.}
{\spadpaste{m(1,2) := 10 \free{m1}\bound{m2}}}
\xtc{The matrix was \textit{destructively modified}.}
{\spadpaste{m \free{m2}}}
\xtc{If you already have the matrix entries as a list of lists, use \spadfunFrom{matrix}{Matrix}.
{\spadpaste{matrix [[1,2,3,4],[0,9,8,7]]}}}
\xtc{If the matrix is diagonal, use}
\spadfunFrom{diagonalMatrix}{Matrix}.
{\spadpaste{dm := diagonalMatrix [1,x**2,x**3,x**4,x**5] \bound{dm}}}
\xtc{Use \spadfunFromX{setRow}{Matrix} and \spadfunFromX{setColumn}{Matrix} to change a row or column of a matrix.}
{\spadpaste{setRow!(dm,5,vector [1,1,1,1,1]) \free{dm}\bound{dm1}}} 
\xtc{ }
{\spadpaste{setColumn!(dm,2,vector [y,y,y,y,y]) \free{dm1}\bound{dm2}}} 
% 
\xtc{Use \spadfunFrom{copy}{Matrix} to make a copy of a matrix.}
{\spadpaste{cdm := copy(dm) \free{dm2}\bound{cdm}}} 
\xtc{This is useful if you intend to modify a matrix destructively but want a copy of the original.}
{\spadpaste{setelt(dm,4,1,1-x**7) \free{dm2}\bound{setdm}}}
Use \spadfunFrom{subMatrix}{Matrix} to extract part of an existing matrix. The syntax is \spad{subMatrix({\it m, firstrow, lastrow, firstcol, lastcol})}.

\spadpaste{subMatrix(dm,2,3,2,4) \free{setdm}}

To change a submatrix, use \spadfunFromX{setsubMatrix}{Matrix}. If \spad{e} is too big to fit where you specify, an error message is displayed. Use \spadfunFrom{subMatrix}{Matrix} to extract part of \spad{e}, if necessary.

\spadpaste{d := diagonalMatrix [1.2,-1.3,1.4,-1.5] \bound{d}}

\spadpaste{e := matrix [[6.7,9.11],[-31.33,67.19]] \bound{e}}

\spadpaste{setsubMatrix!(d,1,2,e) \free{setdm}}

Matrices can be joined either horizontally or vertically to make new matrices.

\spadpaste{a := matrix [[1/2,1/3,1/4],[1/5,1/6,1/7]] \bound{a}}
3.75. MATRIX.HT

\spadpaste{b := matrix \[[3/5,3/7,3/11],[3/13,3/17,3/19]\] \bound{b}}
}\xtc{
Use \spadfunFrom{horizConcat}{Matrix} to append them side to side.
The two matrices must have the same number of rows.
}\spadpaste{horizConcat(a,b) \free{a b}}
}\xtc{
Use \spadfunFrom{vertConcat}{Matrix} to stack one upon the other.
The two matrices must have the same number of columns.
}\spadpaste{vab := vertConcat(a,b) \free{a b}\bound{vab}}
}

% \xtc{
The operation \spadfunFrom{transpose}{Matrix} is used to create a new matrix by
reflection across the main diagonal.
}\spadpaste{transpose vab \free{vab}}
}

\endscroll
autoscroll

Operations on Matrices

Axiom provides both left and right scalar multiplication.

\begin{spad}{m := matrix \([1,2],[3,4]\)} \end{spad}

You can add, subtract, and multiply matrices provided, of course, that the matrices have compatible dimensions. If not, an error message is displayed.

\begin{spad}{n := matrix([[1,0,-2],[-3,5,1]])} \end{spad}

This following product is defined but \spad{n \times m} is not.

\begin{spad}{m \times n} \end{spad}

The operations \spadfunFrom{nrows}{Matrix} and \spadfunFrom{ncols}{Matrix} return the number of rows and columns of a matrix.

You can extract a row or a column of a matrix using the operations \spadfunFrom{row}{Matrix} and \spadfunFrom{column}{Matrix}.

The object returned is a \spadtype{Vector}.

Here is the third column of the matrix \spad{n}.

\begin{spad}{vec := column(n,3)} \end{spad}
You can multiply a matrix on the left by a "row vector" and on the right by a "column vector."

\spadpaste{vec * m \free{vec m}}
\xtc{
Of course, the dimensions of the vector and the matrix must be compatible or an error message is returned.
}\spadpaste{m * vec \free{vec m}}

The operation \spadfunFrom{inverse}{Matrix} computes the inverse of a matrix if the matrix is invertible, and returns \spad{"failed"} if not.

\xtc{This Hilbert matrix is invertible.}
\spadpaste{hilb := matrix([[1/(i + j) for i in 1..3] for j in 1..3]) \bound{hilb}}
\xtc{inverse(hilb) \free{hilb}}

\xtc{This matrix is not invertible.}
\spadpaste{mm := matrix([[1,2,3,4], [5,6,7,8], [9,10,11,12], [13,14,15,16]]) \bound{mm}}
\xtc{inverse(mm) \free{mm}}

The operation \spadfunFrom{determinant}{Matrix} computes the determinant of a matrix provided that the entries of the matrix belong to a \spadtype{CommutativeRing}.

\xtc{The above matrix \spad{mm} is not invertible and, hence, must have determinant \spad{0}.}
\spadpaste{determinant(mm) \free{mm}}

The operation
\spadfunFrom{trace}{SquareMatrix} computes the trace of a square matrix.

\spadpaste{trace(mm) \free{mm}}

\xtc{
The operation \spadfunFrom{rank}{Matrix} computes the rank of a matrix: the maximal number of linearly independent rows or columns.
\spadpaste{rank(mm) \free{mm}}
}

\xtc{
The operation \spadfunFrom{nullity}{Matrix} computes the nullity of a matrix: the dimension of its null space.
\spadpaste{nullity(mm) \free{mm}}
}

\xtc{
The operation \spadfunFrom{nullSpace}{Matrix} returns a list containing a basis for the null space of a matrix. Note that the nullity is the number of elements in a basis for the null space.
\spadpaste{nullSpace(mm) \free{mm}}
}

\xtc{
The operation \spadfunFrom{rowEchelon}{Matrix} returns the row echelon form of a matrix. It is easy to see that the rank of this matrix is two and that its nullity is also two.
\spadpaste{rowEchelon(mm) \free{mm}}
}

MakeFunction

⇒ “notitle” (ugUserMakePage) 10 on page 1889

\begin{page}{MakeFunctionXmpPage}{MakeFunction}
\beginscroll
It is sometimes useful to be able to define a function given by the result of a calculation.
\%
\xtc{
Suppose that you have obtained the following expression after several computations and that you now want to tabulate the numerical values of \spad{f} for \spad{x} between \spad{-1} and \spad{+1} with increment \spad{0.1}.
}
\spadpaste{expr := (x - \exp x + 1)**2 * (\sin(x**2) * x + 1)**3
\bound{expr}}
\%
You could, of course, use the function \spadfunFrom{eval}{Expression} within a loop and evaluate \spad{expr} twenty-one times, but this would be quite slow. A better way is to create a numerical function \spad{f} such that \spad{f(x)} is defined by the expression \spad{expr} above, but without retyping \spad{expr}!! The package \spadtype{MakeFunction} provides the operation
\spadfunFrom{function}{MakeFunction} which does exactly this.
%
\xtc{
Issue this to create the function \spad{f(x)} given by \spad{expr}.
}\{
\spad{function(expr, f, x) \bound{f}\free{expr}}
\}
\xtc{
To tabulate \spad{expr}, we can now quickly evaluate \spad{f} 21 times.
}\{
\spad{tbl := [f(0.1 * i - 1) for i in 0..20]; \free{f}\bound{tbl}}
\}
%
%
\xtc{
Use the list \spad{[x1,...,xn]} as the
third argument to \spadfunFrom{function}{MakeFunction}
to create a multivariate function \spad{f(x1,...,xn)}.
}\{
\spad{e := (x - y + 1)**2 * (x**2 * y + 1)**2 \bound{e}}
\}
\xtc{
}\{
\spad{function(e, g, [x, y]) \free{e}}
\}
%
%
\xtc{
In the case of just two
variables, they can be given as arguments without making them into a list.
}\{
\spad{function(e, h, x, y) \free{e}\bound{h}}
\}
%
%
\xtc{
Note that the functions created by \spadfunFrom{function}{MakeFunction}
are not limited to floating point numbers, but can be applied to any type
for which they are defined.
}\{
\spad{m1 := squareMatrix [[1, 2], [3, 4]] \bound{m1}}
\}
\xtc{
}\{
\spad{m2 := squareMatrix [[1, 0], [-1, 1]] \bound{m2}}
\}
\xtc{
}\{
\spad{h(m1, m2) \free{h m1 m2}}
\}

MultivariatePolynomial

\Rightarrow “notitle” (PolynomialXmpPage) 3.88 on page 1110
\Rightarrow “notitle” (UnivariatePolyXmpPage) 3.112 on page 1327
\Rightarrow “notitle” (DistributedMultivariatePolyXmpPage) 3.24 on page 375

---

The domain constructor \spadtype{MultivariatePolynomial} is similar to
\spadtype{Polynomial} except that it specifies the variables to be used. \spadtype{Polynomial} are available for \spadtype{MultivariatePolynomial}. The abbreviation for \spadtype{MultivariatePolynomial} is \spadtype{MPOLY}. The type expressions
\centerline{{\spadtype{MultivariatePolynomial([x,y],Integer)}}}
and
\centerline{{\spadtype{MPOLY([x,y],INT)}}}
refer to the domain of multivariate polynomials in the variables \spad{x} and \spad{y} where the coefficients are restricted to be integers. The first variable specified is the main variable and the display of the polynomial reflects this.
\xtc{
This polynomial appears with terms in descending powers of the variable \spad{x}.
}{
\spadpaste{m : MPOLY([x,y],INT) := (x**2 - x*y**3 +3*y)**2 \bound{m}}
}
\xtc{
It is easy to see a different variable ordering by doing a conversion.
}{
\spadpaste{m :: MPOLY([y,x],INT) \free{m}}
}
\xtc{
You can use other, unspecified variables, by using \spadtype{Polynomial} in the coefficient type of \spadtype{MPOLY}.
}{
\spadpaste{p : MPOLY([x,y],POLY INT) \bound{pdec}}
}
\xtc{
Conversions can be used to re-express such polynomials in terms of the other variables. For example, you can first push all the variables into a polynomial with integer coefficients.
}{
\spadpaste{p :: POLY INT \free{p}\bound{prev}}
}
\xtc{
Now pull out the variables of interest.
}{
\spadpaste{\% :: MPOLY([a,b],POLY INT) \free{prev}}
}

\beginImportant
\noindent {\bf Restriction:}
\texht{
\begin{quotation}
\noindent{5}
\end{quotation}}
\endImportant
Axiom does not allow you to create types where \(\texttt{MultivariatePolynomial}\) is contained in the coefficient type of \(\texttt{Polynomial}\). Therefore, \(\texttt{MPOLY([x,y],\text{POLY INT})}\) is legal but \(\texttt{POLY MPOLY([x,y],\text{INT})}\) is not.

Multivariate polynomials may be combined with univariate polynomials to create types with special structures.

\[
q : \text{UP}(x, \text{FRAC MPOLY([y,z],\text{INT})}) \text{ free}\{qdec\}
\]

This is a polynomial in \(x\) whose coefficients are quotients of polynomials in \(y\) and \(z\).

\[
q := (x^2 - x*(z+1)/y +2)**2 \text{ free}\{qdec\}\text{ bound}\{q\}
\]

Use conversions for structural rearrangements. \(z\) does not appear in a denominator and so it can be made the main variable.

\[
q : \text{UP}(z, \text{FRAC MPOLY([x,y],\text{INT})}) \text{ free}\{q\}
\]

Or you can make a multivariate polynomial in \(x\) and \(z\) whose coefficients are fractions in polynomials in \(y\).

\[
q : \text{MPOLY([x,z], FRAC UP(y,\text{INT})}) \text{ free}\{q\}
\]

A conversion like \(\texttt{q :: MPOLY([x,y], FRAC UP(z,\text{INT})})\) is not possible in this example because \(\texttt{y}\) appears in the denominator of a fraction. As you can see, Axiom provides extraordinary flexibility in the manipulation and display of expressions via its conversion facility.

For more information on related topics, see \(\text{Polynomial}\), \(\text{UnivariatePolynomial}\), and \(\text{DistributedMultivariatePoly}\).

The `None` domain is not very useful for interactive work but it is provided nevertheless for completeness of the Axiom type system.

Probably the only place you will ever see it is if you enter an empty list with no type information.

```spad
[]
```

Such an empty list can be converted into an empty list of any other type.

```spad
[] :: List Float
```

If you wish to produce an empty list of a particular type directly, such as `List NonNegativeInteger`, do it this way.

```spad
[]$List(NonNegativeInteger)
```

```
(1) []
Type: List None
```

```spad
[]
```

```spad
[]
```

```spad
[]
```

Axiom Number Types

The following types of numbers are among those available in Axiom.

- **Integers**: Arithmetic with arbitrarily large integers.
- **Rational Numbers**: Rational numbers and general fractions.
- **Machine Floats**: Fixed precision machine floating-point.
- **Real Numbers**: Arbitrary precision decimal arithmetic.
- **Complex Numbers**: Complex numbers in general.
- **Finite Fields**: Arithmetic in characteristic $p$.

Additional Topics

- **Numeric Functions**
- **Cardinal Numbers**
- **Machine-sized Integers**
- **Roman Numerals**
- **Continued Fractions**
- **Partial Fractions**
- **Quaternions**
- **Octonions**
- **Repeating Decimals**
- **Repeating Binary Expansions**
- **Repeating Hexadecimal Expansions**
- **Expansions in other Bases**

Fraction

Axiom handles fractions in many different contexts and will automatically simplify fractions whenever possible. Here are some examples:

\begin{verbatim}
1/4 - 1/5
f := (x**2 + 1)/(x - 1)
g := (x**2 - 3*x + 2)/(x + 2)
f * g
\end{verbatim}

**Rational Number**

--- numbers.ht ---

Like integers, rational numbers can be arbitrarily large. For example:
\[
61657 ** 10 / 999983 ** 12
\]
Rational numbers will not be converted to decimals unless you explicitly ask Axiom to do so. To convert a rational number to a decimal, use the function \spadfun{numeric}. Here’s an example:
\[
x := 104348/33215 \quad \text{bound}(x)
\]
You can find the numerator and denominator of rational numbers using the functions \spadfun{numer} and \spadfun{denom}, respectively.

\spadpaste{numer(x) \free{x}}
\spadpaste{denom(x) \free{x}}

To factor the numerator and denominator of a fraction, use the following command:
\spadpaste{factor(numer x) / factor(denom x) \free{x}}

\begin{patch}{RationalNumberPagePatch1}
\begin{paste}{RationalNumberPageFull1}{RationalNumberPageEmpty1}
\pastebutton{RationalNumberPageFull1}{\hidepaste}

\texttt{factor(numer \ \textit{x}) / factor(denom \ \textit{x})}\ \textit{free}\{\ \textit{x}\ \}

\begin{verbatim}
2
2 19 1373
(6)
5 7 13 73
\end{verbatim}

Type: Fraction Factored Integer
In Axiom, integers can be as large as you like. Try the following examples:

\begin{spad}
\begin{verbatim}
x := factorial(200)
y := 2**90 - 1
\end{verbatim}
\end{spad}

Of course, you can now do arithmetic as usual on these (very) large integers:

\begin{spad}
\begin{verbatim}
x + y
x - y
x*y
\end{verbatim}
\end{spad}

Axiom can factor integers, but numbers with small prime factors
\begin{spad}
\begin{verbatim}
factor(x)
factor(y)
\end{verbatim}
\end{spad}
will factor more rapidly than numbers with large prime factors.
Axiom can factor integers, but numbers with small prime factors
\spadpaste{\texttt{factor(x) \free{x}}}
will factor more rapidly than numbers with large prime factors.
\spadpaste{\texttt{factor(y) \free{y}}}

Type: Factored Integer
Integer Examples

One can show that if an integer of the form $2^k + 1$ is prime, then $k$ must be a power of 2. **Proof**

Pierre Fermat conjectured that every integer of the form $2^{2^{2^n}} + 1$ is prime. Let’s look for a counterexample. First define a function:

```plaintext
f: NNI -> INT
f(n) == 2**(2**n) + 1
```

Now try commands like:

```plaintext
factor f(1)
factor f(2)
```

until you find an integer of this form which is composite. You can also try the following command:

```plaintext
for n in 1..6 repeat output factor f(n)
```

Obviously, Fermat didn’t have access to Axiom.

---

Proposition. If $2^k + 1$ is prime, then $k$ is a power of 2.

Proof. Suppose that $k = m \times n$ with $m > 1$ odd. Then

Therefore, $2^k + 1$ is divisible by $2^n + 1$. Now $1 < 2^n + 1$ and since $m > 1$, $2^n + 1 < 2^{n \cdot m} + 1$. Hence, $2^k + 1$ has a non-trivial factor.

Integer Problem Proof

---

Solution to Problem #1

---
This gets tedious after a while, so let’s use Axiom’s stream facility. (A stream is essentially an infinite sequence.)

First, we create a stream consisting of the positive integers:
\spad{ints := [n for n in 1..] \bound{ints}}

Now, we create a stream consisting of the primes:
\spad{primes := [x for x in ints | prime? x] \bound{primes} \free{ints}}

Here’s the 25th prime:
\spad{primes.25 \free{primes}}

Next, create the stream of numbers of the form \(2^{**}p - 1\) with \(p\) prime:
\spad{numbers := [f(n) for n in primes] \bound{numbers} \free{primes f}}

Finally, form the stream of factorizations of the elements of \spad{numbers}:
\spad{factors := [factor n for n in numbers] \bound{factors} \free{numbers}}

You can see that the fifth number in the stream (2047 = 23*89) is the first one that has a non-trivial factorization.

Since \(2^{**}11 = 2048\), the solution to the problem is 11.

Here’s another way to see that 2047 is the first number in the stream that is composite:
\spad{nums := [x for x in numbers | not prime? x] \bound{nums} \free{numbers}}

You can see that the fifth number in the stream (2047 = 23*89) is the first one that has a non-trivial factorization.

Since \(2^{**}11 = 2048\), the solution to the problem is 11.

Solution to Problem #2

numbers.txt

Problem #2: Find the smallest positive integer \( n \) such that \( n^2 - n + 41 \) is not prime.

When \( n = 41 \), \( n^2 - n + 41 = 41^2 \), which certainly isn't prime. Let's see if any smaller integer works.

Here are the first 40 values:

\[
\text{numbers := [n**2 - n + 41 for n in 0..40] \bound{numbers}}
\]

Now have Axiom factor the numbers on this list:

\[
\text{[factor n for n in numbers] \free{numbers}}
\]

You can see that 41 is the smallest positive integer \( n \) such that \( n^2n - n + 41 \) is not prime.

\end{verbatim}}
\end{spadcommand}
The Octonions, also called the Cayley-Dixon algebra, defined over a commutative ring are an eight-dimensional non-associative algebra. Their construction from quaternions is similar to the construction of quaternions from complex numbers (see `Quaternion`). As Octonion creates an eight-dimensional algebra, you have to give eight components to construct an octonion.

\begin{verbatim}
oci1 := octon(1,2,3,4,5,6,7,8)
oci2 := octon(7,2,3,-4,5,6,-7,0)
\end{verbatim}

Or you can use two quaternions to create an octonion.

\begin{verbatim}
oci3 := octon(quatern(-7,-12,3,-10), quatern(5,6,9,0))
\end{verbatim}

You can easily demonstrate the non-associativity of multiplication.

\begin{verbatim}
(oci1 * oci2) * oci3 - oci1 * (oci2 * oci3)
\end{verbatim}

As with the quaternions, we have a real part, the imaginary parts i, j, k, and four additional imaginary parts E, I, J and K. These parts correspond to the canonical basis.
Or you can use two quaternions to create an octonion.
\begin{verbatim}
oci3 := octon(quatern(-7,-12,3,-10), quatern(5,6,9,0))
\end{verbatim}
You can easily demonstrate the non-associativity of multiplication.
\begin{verbatim}
(oci1 * oci2) * oci3 - oci1 * (oci2 * oci3)
\end{verbatim}
As with the quaternions, we have a real part, the imaginary parts \spad{i}, \spad{j}, \spad{k}, and four additional imaginary parts \spad{E}, \spad{I}, \spad{J} and \spad{K}. These parts correspond to the canonical basis \spad{(1,i,j,k,E,I,J,K)}.
For each basis element there is a component operation to extract the coefficient of the basis element for a given octonion.
\begin{verbatim}
\spadfunFrom{real}{Octonion}, \spadfunFrom{imagi}{Octonion}, \spadfunFrom{imagj}{Octonion}, \spad{imagk}{Octonion}, \spadfunFrom{imagE}{Octonion}, \spadfunFrom{imagI}{Octonion}, \spadfunFrom{imagJ}{Octonion}, \spadfunFrom{imagK}{Octonion}.
\end{verbatim}
A basis with respect to the quaternions is given by \spad{(1,E)}. However, you might ask, what then are the commuting rules? To answer this, we create some generic elements.
\begin{verbatim}
q : Quaternion Polynomial Integer := quatern(q1, qi, qj, qk)
\end{verbatim}
Note that quaternions are automatically converted to octonions in the obvious way.

\spadpaste{q * E free(q E)}
\spadpaste{E * q free(E q)}
\spadpaste{q * 1\$(Octonion Polynomial Integer) free(q)}
\spadpaste{1\$(Octonion Polynomial Integer) * q free(q)}

Finally, we check that the \spadfunFrom{norm}{Octonion}, defined as the sum of the squares of the coefficients, is a multiplicative map.

\spadpaste{o : Octonion Polynomial Integer := octon(o1, oi, oj, ok, oE, oI, oJ, oK) bound(o)}
\spadpaste{norm o free(o)}
\spadpaste{p : Octonion Polynomial Integer := octon(p1, pi, pj, pk, pE, pI, pJ, pK) bound(p)}
\spadpaste{norm(o*p)-norm(p)*norm(p) free(o p) }

Since the result is \spad{0}, the norm is multiplicative.

**OrderlyDifferentialPolynomial**

— **odpol.ht** —

\begin{page}{OrderlyDifferentialPolynomialXmpPage}
{OrderlyDifferentialPolynomial}
\begin{scroll}

\end{scroll}
Many systems of differential equations may be transformed to equivalent systems of ordinary differential equations where the equations are expressed polynomially in terms of the unknown functions. In Axiom, the domain constructors \spadtype{OrderlyDifferentialPolynomial} (abbreviated \spadtype{ODPOL}) and \spadtype{SequentialDifferentialPolynomial} (abbreviation \spadtype{SDPOL}) implement two domains of ordinary differential polynomials over any differential ring. In the simplest case, this differential ring is usually either the ring of integers, or the field of rational numbers. However, Axiom can handle ordinary differential polynomials over a field of rational functions in a single indeterminate.

The two domains \spadtype{ODPOL} and \spadtype{SDPOL} are almost identical, the only difference being the choice of a different ranking, which is an ordering of the derivatives of the indeterminates. The first domain uses an orderly ranking, that is, derivatives of higher order are ranked higher, and derivatives of the same order are ranked alphabetically. The second domain uses a sequential ranking, where derivatives are ordered first alphabetically by the differential indeterminates, and then by order. A more general domain constructor, \spadtype{DifferentialSparseMultivariatePolynomial} (abbreviation \spadtype{DSMP}) allows both a user-provided list of differential indeterminates as well as a user-defined ranking. We shall illustrate \spadtype{ODPOL(FRAC INT)}, which constructs a domain of ordinary differential polynomials in an arbitrary number of differential indeterminates with rational numbers as coefficients. 

A differential indeterminate \spad{w} may be viewed as an infinite sequence of algebraic indeterminates, which are the derivatives of \spad{w}.

To facilitate referencing these, Axiom provides the operation \spadfunFrom{makeVariable}{OrderlyDifferentialPolynomial} to convert an element of type \spadtype{Symbol} to a map from the natural numbers to the differential polynomial ring.

The fifth derivative of \spad{w} can be obtained by applying the map \spad{w} to the number \spad{5.} Note that the order of differentiation is given as a subscript (except when the order is 0).
The first five derivatives of \( z \) can be generated by a list.
\[
[z.i \text{ for } i \text{ in } 1..5]
\]
The usual arithmetic can be used to form a differential polynomial from the derivatives.
\[
f := w.4 - w.1 \times w.1 \times z.3
\]
The operation \( \text{DifferentialPolynomial} \) computes the derivative of any differential polynomial.
\[
D(f)
\]
The same operation can compute higher derivatives, like the fourth derivative.
\[
D(f,4)
\]
The operation \( \text{makeVariable} \) creates a map to facilitate referencing the derivatives of \( f \), similar to the map \( w \).
\[
df := \text{makeVariable}(f)\text{dpol}
\]
The fourth derivative of \( f \) may be referenced easily.
\[
df.4
\]
The operation \( \text{order} \) returns the order of a differential polynomial, or the order in a specified differential indeterminate.
The operation \spadfunFrom{differentialVariables}{OrderlyDifferentialPolynomial} returns a list of differential indeterminates occurring in a differential polynomial.

\spadpaste{differentialVariables(g) \free{g}}

The operation \spadfunFrom{degree}{OrderlyDifferentialPolynomial} returns the degree, or the degree in the differential indeterminate specified.

\spadpaste{degree(g) \free{g}}

\spadpaste{degree(g, 'w) \free{g}}

The operation \spadfunFrom{weights}{OrderlyDifferentialPolynomial} returns a list of weights of differential monomials appearing in differential polynomial, or a list of weights in a specified differential indeterminate.

\spadpaste{weights(g) \free{g}}

\spadpaste{weights(g,'w) \free{g}}

The operation \spadfunFrom{weight}{OrderlyDifferentialPolynomial} returns the maximum weight of all differential monomials appearing in the differential polynomial.

\spadpaste{weight(g) \free{g}}

A differential polynomial is \textit{isobaric} if the weights of all differential monomials appearing in it are equal.

\spadpaste{isobaric?(g) \free{g}}
To substitute \emph{differentially}, use \spadfunFrom{eval}{OrderlyDifferentialPolynomial}. Note that we must coerce \spad{'w} to \spadtype{Symbol}, since in \spadtype{ODPOL}, differential indeterminates belong to the domain \spadtype{Symbol}. Compare this result to the next, which substitutes \emph{algebraically} (no substitution is done since \spad{w.0} does not appear in \spad{g}).

\spadpaste{eval(g,['w::Symbol],[f]) \free{f}\free{g}}

\spadpaste{eval(g,variables(w.0),[f]) \free{f}\free{g}}

Since \spadtype{OrderlyDifferentialPolynomial} belongs to \spadtype{PolynomialCategory}, all the operations defined in the latter category, or in packages for the latter category, are available.

\spadpaste{monomials(g) \free{g}}

\spadpaste{variables(g) \free{g}}

\spadpaste{gcd(f,g) \free{f}\free{g}}

\spadpaste{groebner([f,g]) \free{f}\free{g}}

The next three operations are essential for elimination procedures in differential polynomial rings. The operation \spadfunFrom{leader}{OrderlyDifferentialPolynomial} returns the leader of a differential polynomial, which is the highest ranked derivative of the differential indeterminates that occurs.

\spadpaste{lg:=leader(g) \free{g}\bound{lg}}

The operation \spadfunFrom{separant}{OrderlyDifferentialPolynomial} returns the separant of a differential polynomial, which is the partial derivative with respect to the leader.

\spadpaste{sg:=separant(g) \free{g}\bound{sg}}

The operation \spadfunFrom{initial}{OrderlyDifferentialPolynomial} returns the initial, which is the leading coefficient when the given differential polynomial is expressed as a polynomial in the leader.

```spad
ing := initial(g) \free{g}\bound{ig}()
```

Using these three operations, it is possible to reduce \spad{f} modulo the differential ideal generated by \spad{g}. The general scheme is to first reduce the order, then reduce the degree in the leader. First, eliminate \spad{z.3} using the derivative of \spad{g}.

```spad
g1 := D g \free{g}\bound{g1}()
```

Find its leader.

```spad
lg1 := leader g1 \free{g1}\bound{lg1}()
```

Differentiate \spad{f} partially with respect to this leader.

```spad
pdf := D(f, lg1) \free{f}\free{lg1}\bound{pdf}()
```

Compute the partial remainder of \spad{f} with respect to \spad{g}.

```spad
prf := sg * f - pdf * g1 \free{sg}\free{pdf} \free{g1}\bound{prf}()
```

Note that high powers of \spad{lg} still appear in \spad{prf}. Compute the leading coefficient of \spad{prf} as a polynomial in the leader of \spad{g}.

```spad
lcf := leadingCoefficient univariate(prf, lg) \free{prf}\free{lg}\bound{lcf}()
```

Finally, continue eliminating the high powers of \spad{lg} appearing in \spad{prf} to obtain the (pseudo) remainder of \spad{f} modulo \spad{g} and its derivatives.

```spad
ig * prf - lcf * g * lg \free{ig}\free{prf} \free{lcf}\free{lg}()
```

3.83. `op.ht`

Operator

--- `op.ht` ---

Given any ring `\spad{R}`, the ring of the `\spadtype{Integer}`-linear operators over `\spad{R}` is called `\spadtype{Operator(\spad{R})}`. To create an operator over `\spad{R}`, first create a basic operator using the operation `\spadfun{operator}{\spad{R}}`, and then convert it to `\spadtype{Operator(\spad{R})}` for the `\spad{R}` you want.

%
We choose \texttt{R} to be the two by two matrices over the integers.

\begin{verbatim}
\spad{R := SQMATRIX(2, INT)}
\end{verbatim}

Create the operator \texttt{tilde} on \texttt{R}.

\begin{verbatim}
\spad{t := operator("tilde") :: OP(R)}
\end{verbatim}

Since \texttt{Operator} is unexposed we must either package-call operations from it, or expose it explicitly. For convenience we will do the latter.

\begin{verbatim}
\set expose add constructor Operator
\end{verbatim}

To attach an evaluation function (from \texttt{R} to \texttt{R}) to an operator over \texttt{R}, use \texttt{evaluate(op, f)} where \texttt{op} is an operator over \texttt{R} and \texttt{f} is a function \texttt{R -> R}.

This needs to be done only once when the operator is defined.

Note that \texttt{f} must be \texttt{Integer}-linear (that is, \texttt{f(ax+y) = a f(x) + f(y)} for any integer \texttt{a}, and any \texttt{x} and \texttt{y} in \texttt{R}).

We now attach the transpose map to the above operator \texttt{t}.

\begin{verbatim}
\spad{evaluate(t, m +-> transpose m)}
\end{verbatim}

Operators can be manipulated formally as in any ring: \texttt{op(+)} is the pointwise addition and \texttt{op(*)} is composition.

Any element \texttt{x} of \texttt{R} can be converted to an operator \texttt{x} over \texttt{R}, and the evaluation function of \texttt{x} is left-multiplication by \texttt{x}.

Multiplying on the left by this matrix swaps the two rows.

\begin{verbatim}
\spad{s : R := matrix [[0, 1], [1, 0]]}
\end{verbatim}
Can you guess what is the action of the following operator?

\[
\rho := t \ast s
\]

Hint: applying \(\rho\) four times gives the identity, so
\(\rho^{**4} - 1\) should return 0 when applied to any two by two matrix.

\[
\z := \rho^{**4} - 1
\]

Now check with this matrix.

\[
\m:R := \begin{bmatrix} 1, 2 \\ 3, 4 \end{bmatrix}
\]

As you have probably guessed by now, \(\rho\) acts on matrices by rotating the elements clockwise.

\[
\rho \m
\]

Do the swapping of rows and transposition commute? We can check by computing their bracket.

\[
b := t \ast s - s \ast t
\]
Now apply it to \spad{m}.
}\spadpaste{b m \free{b m}}

Next we demonstrate how to define a differential operator on a polynomial ring.
\xtc{This is the recursive definition of the \spad{n}-th Legendre polynomial.}
{\begin{spadsrc}
L n ==
  n = 0 => 1
  n = 1 => x
  \frac{(2n-1)n}{n} \times L(n-1) - \frac{(n-1)n}{n} \times L(n-2)
\end{spadsrc}}
\xtc{Create the differential operator \texht{$d \over {dx}$} on polynomials in \spad{x} over the rational numbers.}
{\spadpaste{dx := operator("D") :: OP(POLY FRAC INT) \free{dx} \bound{dx}}}
\xtc{Now attach the map to it.}
{\spadpaste{evaluate(dx, p +-> D(p, 'x)) \free{dx} \bound{edx}}}
\xtc{This is the differential equation satisfied by the \spad{n}-th Legendre polynomial.}
{\spadpaste{E n == (1 - x**2) * dx**2 - 2 * x * dx + n*(n+1) \free{edx} \bound{E}}}
\xtc{Now we verify this for \spad{n = 15}. Here is the polynomial.}
{\spadpaste{L 15 \free{L}}}
\xtc{Here is the operator.}
{\spadpaste{E 15 \free{E}}}
\xtc{Here is the evaluation.

Permanent

--- perman.ht ---

\begin{spadexample}
\begin{verbatim}
kn n ==
  r : MATRIX INT := new(n,n,1)
  for i in 1..n repeat
    r.i.i := 0
  r
\end{verbatim}
\end{spadexample}

The package \texttt{Permanent} provides the function \texttt{permanent\{Permanent\}} for square matrices. The \texttt{permanent\{Permanent\}} of a square matrix can be computed in the same way as the determinant by expansion of minors except that for the permanent the sign for each element is \texttt{1}, rather than being \texttt{1} if the row plus column indices is positive and \texttt{-1} otherwise. This function is much more difficult to compute efficiently than the \texttt{determinant\{Matrix\}}.

An example of the use of \texttt{permanent\{Permanent\}} is the calculation of the \texttt{\textbackslash \texttt{eth\{spad\(n\)}} derangement number, defined to be the number of different possibilities for \texttt{spad\(n\)} couples to dance but never with their own spouse.

\begin{spadexample}
\begin{verbatim}
Consider an \texttt{spad\(n\)} by \texttt{spad\(n\)} matrix with entries \texttt{spad\(0\)} on the diagonal and \texttt{spad\(1\)} elsewhere. Think of the rows as one-half of each couple (for example, the males) and the columns the other half. The permanent of such a matrix gives the desired derangement number.
\end{verbatim}
\end{spadexample}

\begin{spadexample}
\begin{verbatim}
\texttt{kn n ==

3.80 pfr.ht

PartialFraction

A partial fraction is a decomposition of a quotient into a sum of quotients where the denominators of the summands are powers of primes. (Most people first encounter partial fractions when they are learning integral calculus. For a technical discussion of partial fractions, see, for example, Lang’s *Algebra.* ) For example, the rational number $1/6$ is decomposed into $1/2-1/3$. You can compute partial fractions of quotients of objects from domains belonging to the category *EuclideanDomain.* For example, *Integer, Complex Integer,* and *UnivariatePolynomial(x, Fraction Integer)* all belong to *EuclideanDomain.* In the examples following, we demonstrate how to decompose quotients of each of these kinds of object into partial fractions. Issue the system command `)show PartialFraction` to display the full list of operations defined by *PartialFraction.*

It is necessary that we know how to factor the denominator when we want to compute a partial fraction. Although the
It is necessary that we know how to factor the denominator when we want to compute a partial fraction. Although the interpreter can often do this automatically, it may be necessary for you to include a call to \texttt{factor}. In these examples, it is not necessary to factor the denominators explicitly.

The main operation for computing partial fractions is called \texttt{partialFraction} and we use this to compute a decomposition of \texttt{1 / 10!}.

The first argument to \texttt{partialFraction} is the numerator of the quotient and the second argument is the factored denominator.

\begin{verbatim}
partialFraction(1, factorial 10) \bound{prev1}
\end{verbatim}

Since the denominators are powers of primes, it may be possible to expand the numerators further with respect to those primes. Use the operation \texttt{padicFraction} to do this.

\begin{verbatim}
f := padicFraction(\%) \free{prev1}\bound{f}
\end{verbatim}

The operation \texttt{compactFraction} returns an expanded fraction into the usual form. The compacted version is used internally for computational efficiency.

\begin{verbatim}
compactFraction(f) \free{f}
\end{verbatim}

You can add, subtract, multiply and divide partial fractions. In addition, you can extract the parts of the decomposition. \texttt{numberOfFractionalTerms} computes the number of terms in the fractional part. This does not include the whole part of the fraction, which you get by calling \texttt{wholePart}. In this example, the whole part is just \texttt{0}.

\begin{verbatim}
numberOfFractionalTerms(f) \free{f}
\end{verbatim}

The operation \texttt{nthFractionalTerm} returns the individual terms in the decomposition. Notice that the object returned is a partial fraction itself.

\begin{verbatim}
\end{verbatim}
\spadfunFrom{firstDenom}{PartialFraction} extract the numerator and
denominator of the first term of the fraction.
\begin{verbatim}
\spadpaste{nthFractionalTerm(f,3) \free{f}}
\end{verbatim}

\xtc{
Given two gaussian integers (see\downlink{`Complex'}{ComplexXmpPage}\ignore{Complex}), you can
decompose their quotient into a partial fraction.
\begin{verbatim}
\spadpaste{partialFraction(1,- 13 + 14 * \%i) \bound{prev2}}
\end{verbatim}
\xtc{
To convert back to a quotient, simply use a conversion.
\begin{verbatim}
\spadpaste{\% :: Fraction Complex Integer \free{prev2}}
\end{verbatim}
\xtc{
To conclude this section, we compute the decomposition of
\begin{verbatim}
\narrowDisplay{1 \over {{(x + 1)}{(x + 2)}^2{(x + 3)}^3{(x + 4)}^4}}
\end{verbatim}
\begin{verbatim}
\verbatim{1
-----------------------------------
 2 3 4
 (x + 1)(x + 2) (x + 3) (x + 4)
\end{verbatim}
\xtc{
The polynomials in this object have type\spadtype{UnivariatePolynomial(x, Fraction Integer)}.
\xtc{
We use the \spadfunFrom{primeFactor}{Factored} operation (see\downlink{`Factored'}{FactoredXmpPage}\ignore{Factored}) to create the denominator in factored form directly.
\begin{verbatim}
\spadpaste{u : FR UP(x, FRAC INT) := reduce(*,[primeFactor(x+i,i)\for i in 1..4]) \bound{u}}
\end{verbatim}
\xtc{
These are the compact and expanded partial fractions for the quotient.
\begin{verbatim}
\spadpaste{partialFraction(1,u) \free{u}\bound{prev3}}
\end{verbatim}
\xtc{
All see `FullPartialFracExpansion' for examples of factor-free conversion of quotients to full partial fractions.

The Specific Polynomial Types

The general type.

One variable polynomials.

Multiple variable polynomials, recursive structure.
Multiple variable polynomials, non-recursive structure.

Skew or Ore polynomials

Basic Operations On Polynomials

You create polynomials using the usual operations of \begin{spad}{+}{Polynomial}, \begin{spad}{-}{Polynomial}, \begin{spad}{*}{Polynomial} (for multiplication), and \begin{spad}{**}{Polynomial} (for exponentiation). Here are two examples:

\begin{spad}{p := a*x**2 + b*x*y + c*y**2\free{p}}\end{spad}
\begin{spad}{q := 13*x**2 + 3*z\free{q}}\end{spad}

These operations can also be used to combine polynomials. Try the following:

\begin{spad}{p + q \free{p q}}\end{spad}
\begin{spad}{p - 3*q \free{p q}}\end{spad}
\begin{spad}{p**2 + p*q \free{p q}}\end{spad}
\begin{spad}{r := (p + q)**2 \free{p q}}\end{spad}

As you can see from the above examples, the variables are ordered by defaults \begin{spad}{z > y > x > c > b > a},\end{spad} that is, \begin{spad}{z} is the main variable, then \begin{spad}{y} and so on in reverse alphabetical order.

You can redefine this ordering (for display purposes only) with the \begin{spadfun}{setVariableOrder} command.

For example, the following makes \begin{spad}{a} the main variable, then \begin{spad}{b}, and so on:
\begin{spad}{setVariableOrder \[a,b,c,x,y,z\] \free{vord}}\end{spad}

Now compare the way polynomials are displayed:

\begin{spad}{p \free{p vord}}\end{spad}
\begin{spad}{q \free{q vord}}\end{spad}
\begin{spad}{r \free{r vord}}\end{spad}

To return to the system's default ordering,
use \spadfun{resetVariableOrder}.
\spadpaste{resetVariableOrder() \bound{rvord}}
\spadpaste{p \free{p rvord}}
Polynomial coefficients can be pulled out using the function \spadfun{coefficient}.
For example:
\spadpaste{coefficient(q,x,2) \free{q}}
will give you the coefficient of \spad{x**2} in the polynomial \spad{q}.

Try these commands:
\spadpaste{coefficient(r,x,3) \free{r}}
\spadpaste{c := coefficient(r,z,1) \free{r} \bound{c}}
\spadpaste{coefficient(c,x,2) \free{c}}
Coefficients of monomials can be obtained as follows:
\spadpaste{coefficient(q**2, [x,z], [2,1]) \free{q}}
This will return the coefficient of \spad{x**2 * z} in the polynomial \spad{q**2}.
Also,
\spadpaste{coefficient(r, [x,y], [2,2]) \free{r}}
will return the coefficient of \spad{x**2 * y**2} in the polynomial \spad{r(x,y)}.

Polynomial Evaluation and Substitution

poly.ht
The function \texttt{eval} is used to substitute values into polynomials. Here’s an example of how to use it:
\texttt{p := x**2 + y**2 \bound{p}}
\texttt{eval(p, x=5) \free{p}}

This example would give you the value of the polynomial \texttt{p} at 5. You can also substitute into polynomials with several variables. First, specify the polynomial, then give a list of bindings of the form \texttt{variable = value}. For example:
\texttt{eval(p, \{x = a + b, y = c + d\}) \free{p}}
Here \texttt{p(x)} was replaced by \texttt{p(a + b)}, and \texttt{p(y)} was replaced by \texttt{p(c + d)}.

Here’s another example:
\texttt{q := x**3 + 5*x - y**4 \bound{q}}
\texttt{eval(q, \{x=y, y=x\}) \free{q}}
Substitution is done ‘‘in parallel.’’ That is, Axiom takes \texttt{q(x,y)} and returns \texttt{q(y,x)}.

You can also substitute numerical values for some or all of the variables:
\texttt{px := eval(p, y = \text{sin}(2.0)) \bound{px}}
\texttt{eval(px, x = \text{cos}(2.0)) \free{px}}
\indentrel{3}\begin{verbatim}
2
(2) y + 25

\( \text{Type: Polynomial Float} \)

\( \text{Type: Polynomial Float} \)
Greatest Common Divisors, Resultants, and Discriminants

\begin{page}{PolynomialGCDPage}
\{Greatest Common Divisors, Resultants, and Discriminants\}
\beginscroll
You can compute the greatest common divisor of two polynomials using the function \spadfun{gcd}. Here’s an example:
\spadpaste{p := 3*x**8 + 2*x**7 + 6*x**2 + 7*x + 2 \bound{p}}
\spadpaste{q := 2*x**13 + 9*x**7 + 2*x**6 + 10*x + 5 \bound{q}}
\spadpaste{gcd(p,q) \free{p q}}
You could also see that \spad{p} and \spad{q} have a factor in common by using the function \spadfun{resultant}:
\spadpaste{resultant(p,q,x) \free{p q}}
The resultant of two polynomials vanishes precisely when they have a factor in common.
(In the example above we specified the variable with which we wanted to compute the resultant because the polynomials could have involved variables other than x.)

\begin{page}{PolynomialXmpPage}{Polynomial}
\beginscroll
The domain constructor \spadtype{Polynomial}
(abbreviation: \spadtype{POLY})
provides polynomials with an arbitrary number of unspecified variables.

\xtc{
  It is used to create the default polynomial domains in Axiom.
  Here the coefficients are integers.
}{
  \spadpaste{x + 1}
}\xtc{
  Here the coefficients have type \spadtype{Float}.
}{
  \spadpaste{z - 2.3}
}\xtc{
  And here we have a polynomial in two variables with coefficients which have type \spadtype{Fraction Integer}.
}{
  \spadpaste{y**2 - z + 3/4}
}

The representation of objects of domains created by \spadtype{Polynomial} is that of recursive univariate polynomials. The term \spad{univariate} means ‘‘one variable.’’ \spad{multivariate} means ‘‘possibly more than one variable.’’
\xtc{
  This recursive structure is sometimes obvious from the display of a polynomial.
}{
  \spadpaste{y **2 + x*y + y \bound{prev}}
}\xtc{
  In this example, you see that the polynomial is stored as a polynomial in \spad{y} with coefficients that are polynomials in \spad{x} with integer coefficients.
  In fact, you really don’t need to worry about the representation unless you are working on an advanced application where it is critical.
  The polynomial types created from \spadtype{DistributedMultivariatePoly} and \spadtype{NewDistributedMultivariatePoly} (discussed in \downlink{'DistributedMultivariatePoly'}) \ignore{DistributedMultivariatePolyXmpPage} are stored and displayed in a non-recursive manner.
}{
  You see a ‘‘flat’’ display of the above polynomial by converting to one of those types.
}{
  \spadpaste{\% :: DMP([y,x],INT) \free{prev}}
}
We will demonstrate many of the polynomial facilities by using two polynomials with integer coefficients.

By default, the interpreter expands polynomial expressions, even if they are written in a factored format.

```
\spadpaste{p := (y-1)**2 * x * z \bound{p}}
```

See \downlink{`Factored'}{FactoredXmpPage} to see how to create objects in factored form directly.

```
\spadpaste{q := (y-1) * x * (z+5) \bound{q}}
```

The fully factored form can be recovered by using \spadfunFrom{factor}{Polynomial}.

```
\spadpaste{factor(q) \free{q}}
```

This is the same name used for the operation to factor integers. Such reuse of names is called \spadglos{overloading} and makes it much easier to think of solving problems in general ways. Axiom facilities for factoring polynomials created with \spadtype{Polynomial} are currently restricted to the integer and rational number coefficient cases. There are more complete facilities for factoring univariate polynomials: see \downlink{``Polynomial Factorization''}{ugProblemFactorPage} in Section 8.2\ignore{ugProblemFactor}.

The standard arithmetic operations are available for polynomials.

```
\spadpaste{p - q**2 \free{p q}}
```

The operation \spadfunFrom{gcd}{Polynomial} is used to compute the greatest common divisor of two polynomials.

```
\spadpaste{gcd(p,q) \free{p q}\bound{prev4}}
```

In the case of \spad{p} and \spad{q}, the gcd is obvious from their definitions.

We factor the gcd to show this relationship better.

```
\spadpaste{factor \% \free{prev4}}
```
The least common multiple is computed by using \spadfunFrom{lcm}{Polynomial}.
\spadpaste{lcm(p,q) \free{p q}}

Use \spadfunFrom{content}{Polynomial} to compute the greatest common divisor of the coefficients of the polynomial.
\spadpaste{content p \free{p}}

Many of the operations on polynomials require you to specify a variable. For example, \spadfunFrom{resultant}{Polynomial} requires you to give the variable in which the polynomials should be expressed.
\spadpaste{resultant(p,q,z) \free{p q}}

This computes the resultant of the values of \spad{p} and \spad{q}, considering them as polynomials in the variable \spad{z}. They do not share a root when thought of as polynomials in \spad{z}.
\spadpaste{resultant(p,q,x) \free{p q}}

This value is \spad{0} because as polynomials in \spad{x} the polynomials have a common root.
\spadpaste{resultant(p,q,x) \free{p} \free{q}}

The data type used for the variables created by \spadtype{Polynomial} is \spadtype{Symbol}.
As mentioned above, the representation used by \spadtype{Polynomial} is recursive and so there is a main variable for nonconstant polynomials.
\spadpaste{mainVariable p \free{p}}

The latter branch of the union is be used if the polynomial has no variables, that is, is a constant.
\spadpaste{mainVariable(1 :: POLY INT)}

You can also use the predicate \spadfunFrom{ground?}{Polynomial} to test whether a polynomial is in fact a member of its ground ring.
The complete list of variables actually used in a particular polynomial is returned by \spadfunFrom{variables}{Polynomial}. For constant polynomials, this list is empty.

The \spadfunFrom{degree}{Polynomial} operation returns the degree of a polynomial in a specific variable.

If you give a list of variables for the second argument, a list of the degrees in those variables is returned.

The minimum degree of a variable in a polynomial is computed using \spadfunFrom{minimumDegree}{Polynomial}.

The total degree of a polynomial is returned by \spadfunFrom{totalDegree}{Polynomial}.

It is often convenient to think of a polynomial as a leading monomial
plus the remaining terms.
}{
\spadpaste{leadingMonomial p \free{p}}
}
\xtc{The \spadfun{reductum}{Polynomial} operation returns a polynomial consisting of the sum of the monomials after the first.}
}{
\spadpaste{reductum p \free{p}}
}
\xtc{These have the obvious relationship that the original polynomial is equal to the leading monomial plus the reductum.}
}{
\spadpaste{p - leadingMonomial p - reductum p \free{p}}
}
\xtc{The value returned by \spadfun{leadingCoefficient}{Polynomial} includes the coefficient of that term. This is extracted by using \spadfun{leadingCoefficient}{Polynomial} on the original polynomial.}
}{
\spadpaste{leadingCoefficient p \free{p}}
}
\xtc{The operation \spadfun{eval}{Polynomial} is used to substitute a value for a variable in a polynomial.}
}{
\spadpaste{p \free{p}}
}
\xtc{This value may be another variable, a constant or a polynomial.}
}{
\spadpaste{eval(p,x,w) \free{p}}
}
\xtc{}
\spadpaste{eval(p,x,1) \free{p}}
\xtc{Actually, all the things being substituted are just polynomials, some more trivial than others.}
}{
\spadpaste{eval(p,x,y**2 - 1) \free{p}}
}
\xtc{Derivatives are computed using the \spadfun{D}{Polynomial} operation.}
}{

\spadpaste{D(p,x) \free{p}}
}
\xtc{The first argument is the polynomial and the second is the variable.}
}\{\spadpaste{D(p,y) \free{p}}
}
\xtc{Even if the polynomial has only one variable, you must specify it.}
}\{\spadpaste{D(p,z) \free{p}}
}

Integration of polynomials is similar and the \spadfunFrom{integrate}{Polynomial} operation is used.
\xtc{Integration requires that the coefficients support division. Consequently, Axiom converts polynomials over the integers to polynomials over the rational numbers before integrating them.}
}\{\spadpaste{integrate(p,y) \free{p}}
}

It is not possible, in general, to divide two polynomials. In our example using polynomials over the integers, the operation \spadfunFrom{monicDivide}{Polynomial} divides a polynomial by a monic polynomial (that is, a polynomial with leading coefficient equal to 1). The result is a record of the quotient and remainder of the division.
\xtc{You must specify the variable in which to express the polynomial.}
}\{\spadpaste{qr := monicDivide(p,x+1,x) \free{p}\bound{qr}}
}
\xtc{The selectors of the components of the record are \spad{quotient} and \spad{remainder}. Issue this to extract the remainder.}
}\{\spadpaste{qr.remainder \free{qr}}
}
\xtc{Now that we can extract the components, we can demonstrate the relationship among them and the arguments to our original expression \spad{qr := monicDivide(p,x+1,x)}.}
}\{\spadpaste{p - ((x+1) * qr.quotient + qr.remainder) \free{p}\free{qr}}
}
If the `\spadop{\text{Fraction}}` operator is used with polynomials, a fraction object is created. In this example, the result is an object of type `\spadtype{\text{Fraction Polynomial Integer}}`.
\spadpaste{\frac{p}{q} \free{p}\free{q}}

If you use rational numbers as polynomial coefficients, the resulting object is of type `\spadtype{\text{Polynomial Fraction Integer}}`.
\spadpaste{\left(\frac{2}{3}\right) \times x^2 - y + \frac{4}{5} \\begin{eqnarray*} \text{prev1} \end{eqnarray*}}

This can be converted to a fraction of polynomials and back again, if required.
\spadpaste{\% :: \text{FRAC POLY INT} \\text{prev1} \\text{bound{prev2}}} \begin{eqnarray*} \text{prev1} \end{eqnarray*}
\spadpaste{\% :: \text{POLY FRAC INT} \\text{prev2} \\text{bound{prev3}}} \begin{eqnarray*} \text{prev2} \end{eqnarray*}

To convert the coefficients to floating point, map the `\spadfun{\text{numeric}}` operation on the coefficients of the polynomial.
\spadpaste{\text{map(numeric,\%)} \free{prev3}}

For more information on related topics, see `UnivariatePolynomial`{\UnivariatePolyXmpPage}, `MultivariatePolynomial`{\MultivariatePolyXmpPage}, and `DistributedMultivariatePoly`{\DistributedMultivariatePolyXmpPage}. You can also issue the system command 
\spadcmd{\text{)show Polynomial}} to display the full list of operations defined by `\spadtype{\text{Polynomial}}`.

3.89 quat.ht

Quaternion

The domain constructor \texttt{Quaternion} implements quaternions over commutative rings. For information on related topics, see \texttt{Complex} and \texttt{Octonion}. You can also issue the system command \texttt{)show Quaternion} to display the full list of operations defined by \texttt{Quaternion}.

The basic operation for creating quaternions is \texttt{quatern}. This is a quaternion over the rational numbers.
\begin{verbatim}
\begin{axiom}
q := quatern(2/11,-8,3/4,1)
\end{axiom}
\end{verbatim}

The four arguments are the real part, the i imaginary part, the j imaginary part, and the k imaginary part, respectively.
\begin{verbatim}
\begin{axiom}
[real q, imagI q, imagJ q, imagK q]
\end{axiom}
\end{verbatim}

Because \(q\) is over the rationals (and nonzero), you can invert it.
\begin{verbatim}
\begin{axiom}
inv q
\end{axiom}
\end{verbatim}

The usual arithmetic (ring) operations are available
\begin{verbatim}
\begin{axiom}
q**6
r := quatern(-2,3,23/9,-89); q + r
\end{axiom}
\end{verbatim}
The four arguments are the real part, the \spad{i} imaginary part, the \spad{j} imaginary part, and the \spad{k} imaginary part, respectively.
\spadpaste{[real q, imagI q, imagJ q, imagK q] \free{q}}
Because \spad{q} is over the rationals (and nonzero), you can invert it.
\spadpaste{inv q \free{q}}
The usual arithmetic (ring) operations are available
\spadpaste{q**6 \free{q}}
\spadpaste{r := quatern(-2,3,23/9,-89); q + r \bound{r}\free{q}}
In general, multiplication is not commutative.
\spadpaste{q * r - r * q\free{q r}}
There are no predefined constants for the imaginary \spad{i, j}, and \spad{k} parts, but you can easily define them.
\spadpaste{i:=quatern(0,1,0,0); j:=quatern(0,0,1,0); k:=quatern(0,0,0,1) \bound{i j k}}
These satisfy the normal identities.
\spadpaste{[i*i, j*j, k*k, i*j, j*k, k*i, q*i] \free{i j k q}}
The norm is the quaternion times its conjugate.
\spadpaste{norm q \free{q}}

It is possible to expand numbers in general bases. Here we expand 111 in base 5. This means $10*2+10*1+10*0 = 4*5*2+2*5*1+5*0$.

| radix.ht |

It is possible to expand numbers in general bases. Here we expand 111 in base 5. This means $10*2+10*1+10*0 = 4*5*2+2*5*1+5*0$.

\begin{scroll}
It is possible to expand numbers in general bases. Here we expand 111 in base 5. This means $10*2+10*1+10*0 = 4*5*2+2*5*1+5*0$.
\end{scroll}

For bases from 11 to 36 the letters A through Z are used.

For bases greater than 36, the rags are separated by blanks.

The \texttt{RadixExpansion} type provides operations to obtain the individual rags. Here is a rational number in base 8.
Here we expand \spad{111} in base \spad{5}.
This means
\[
10^2+10^1+10^0 = 4 \cdot 5^2 + 2 \cdot 5^1 + 5^0.
\]
\spad{10**2+10**1+10**0 = 4*5**2+2*5**1+5**0.}
\spadpaste{111::RadixExpansion(5)}

You can expand fractions to form repeating expansions.
\spadpaste{(5/24)::RadixExpansion(2)}
\spadpaste{(5/24)::RadixExpansion(3)}
\spadpaste{(5/24)::RadixExpansion(8)}
\spadpaste{(5/24)::RadixExpansion(10)}

For bases from 11 to 36 the letters A through Z are used.
\spadpaste{(5/24)::RadixExpansion(12)}
\spadpaste{(5/24)::RadixExpansion(16)}
\spadpaste{(5/24)::RadixExpansion(36)}

For bases greater than 36, the ragits are separated by blanks.
\spadpaste{(5/24)::RadixExpansion(38)}

The \spadtype{RadixExpansion} type provides operations to obtain the individual ragits.
Here is a rational number in base \spad{8}.
\spadpaste{a := (76543/210)::RadixExpansion(8) \bound{a}}
The operation \spadfunFrom{wholeRagits}{RadixExpansion} returns a list of the ragits for the integral part of the number.

\spadpaste{w := wholeRagits a \free{a}\bound{w}}

The operations \spadfunFrom{prefixRagits}{RadixExpansion} and \spadfunFrom{cycleRagits}{RadixExpansion} return lists of the initial and repeating ragits in the fractional part of the number.

\spadpaste{f0 := prefixRagits a \free{a}\bound{f0}}

\spadpaste{f1 := cycleRagits a \free{a}\bound{f1}}

You can construct any radix expansion by giving the whole, prefix and cycle parts. The declaration is necessary to let Axiom know the base of the ragits.

\spadpaste{u:RadixExpansion(8):=wholeRadix(w)+fractRadix(f0,f1) \free{w f0 f1}\bound{u}}

If there is no repeating part, then the list \spad{[0]} should be used.

\spadpaste{v: RadixExpansion(12) := fractRadix([1,2,3,11], [0]) \bound{v}}

If you are not interested in the repeating nature of the expansion, an infinite stream of ragits can be obtained using \spadfunFrom{fractRagits}{RadixExpansion}.

\spadpaste{fractRagits(u) \free{u}}

Of course, it's possible to recover the fraction representation:

\spadpaste{a :: Fraction(Integer) \free{a}}

\showBlurb{RadixExpansion}

RealClosure

--- reclos.ht ---

\begin{page}{RealClosureXmpPage}{RealClosure}
\beginscroll

The Real Closure 1.0 package provided by Renaud Rioboo (Renaud.Rioboo@lip6.fr) consists of different packages, categories and domains:

\begin{items}
\item The package \texttt{RealPolynomialUtilitiesPackage} which needs a \texttt{Field} \texttt{F} and a \texttt{UnivariatePolynomialCategory} domain with coefficients in \texttt{F}. It computes some simple functions such as Sturm and Sylvester sequences (\texttt{sturmSequence}\{RealPolynomialUtilitiesPackage\}, \texttt{sylvesterSequence}\{RealPolynomialUtilitiesPackage\}).

\item The category \texttt{RealRootCharacterizationCategory} provides abstract functions to work with "real roots" of univariate polynomials. These resemble variables with some functionality needed to compute important operations.

\item The category \texttt{RealClosedField} provides common operations available over real closed fields. These include finding all the roots of a univariate polynomial, taking square (and higher) roots, ...

\item The domain \texttt{RightOpenIntervalRootCharacterization} is the main code that provides the functionality of \texttt{RealRootCharacterizationCategory} for the case of archimedean fields. Abstract roots are encoded with a left closed right open interval containing the root together with a defining polynomial for the root.

\item The \texttt{RealClosure} domain is the end-user code. It provides usual arithmetic with real algebraic numbers, along with the functionality of a real closed field. It also provides functions to approximate a real algebraic number by an element of the base field. This approximation may either be absolute (\texttt{approximate}\{RealClosure\}) or relative (\texttt{relativeApprox}\{RealClosure\}).
\end{items}
\endscroll\end{page}
Since real algebraic expressions are stored as depending on "real roots" which are managed like variables, there is an ordering on these. This ordering is dynamical in the sense that any new algebraic takes precedence over older ones. In particular every creation function raises a new "real root". This has the effect that when you type something like \( \texttt{sqrt(2) + sqrt(2)} \) you have two new variables which happen to be equal. To avoid this name the expression such as in \( \texttt{s2 := sqrt(2) ; s2 + s2} \)

Also note that computing times depend strongly on the ordering you implicitly provide. Please provide algebraics in the order which seems most natural to you.

This packages uses algorithms which are published in [1] and [2] which are based on field arithmetics, in particular for polynomial gcd related algorithms. This can be quite slow for high degree polynomials and subresultants methods usually work best. Beta versions of the package try to use these techniques in a better way and work significantly faster. These are mostly based on unpublished algorithms and cannot be distributed. Please contact the author if you have a particular problem to solve or want to use these versions.

Be aware that approximations behave as post-processing and that all computations are done exactly. They can thus be quite time consuming when depending on several "real roots".

   In Mathematics and Computers in Simulation Volume 42, Issue 4-6, November 1996.

We shall work with the real closure of the ordered field of rational numbers.

\( \texttt{Ran := RECLOS(FRAC INT)} \)
Some simple signs for square roots, these correspond to an extension of degree 16 of the rational numbers. Examples provided by J. Abbot.

\spadpaste{\texttt{fourSquares(a:Ran,b:Ran,c:Ran,d:Ran):Ran == sqrt(a)+sqrt(b) - sqrt(c)-sqrt(d) \free{Ran} \bound{fs}}} 

These produce values very close to zero.

\spadpaste{\texttt{squareDiff1 := fourSquares(73,548,60,586) \free{fs} \bound{sd1}}} 

\spadpaste{\texttt{recip(squareDiff1)\free{sd1}}} 

\spadpaste{\texttt{sign(squareDiff1)\free{sd1}}} 

\spadpaste{\texttt{squareDiff2 := fourSquares(165,778,86,990) \free{fs} \bound{sd2}}} 

\spadpaste{\texttt{recip(squareDiff2)\free{sd2}}} 

\spadpaste{\texttt{sign(squareDiff2)\free{sd2}}} 

\spadpaste{\texttt{squareDiff3 := fourSquares(217,708,226,692) \free{fs} \bound{sd3}}} 

\spadpaste{\texttt{recip(squareDiff3)\free{sd3}}} 

\spadpaste{\texttt{sign(squareDiff3)\free{sd3}}}
\spadpaste{squareDiff4 := fourSquares(155,836,162,820)
\free{fs}\bound{sd4}}
}\xtc{}
}\spadpaste{recip(squareDiff4)\free{sd4}}
}\xtc{}
}\spadpaste{sign(squareDiff4)\free{sd4}}
}\xtc{}
}\spadpaste{squareDiff5 := fourSquares(591,772,552,818)
\free{fs}\bound{sd5}}
}\xtc{}
}\spadpaste{recip(squareDiff5)\free{sd5}}
}\xtc{}
}\spadpaste{sign(squareDiff5)\free{sd5}}
}\xtc{}
}\spadpaste{squareDiff6 := fourSquares(434,1053,412,1088)
\free{fs}\bound{sd6}}
}\xtc{}
}\spadpaste{recip(squareDiff6)\free{sd6}}
}\xtc{}
}\spadpaste{sign(squareDiff6)\free{sd6}}
}\xtc{}
]\spadpaste{squareDiff7 := fourSquares(514,1049,446,1152)
\free{fs}\bound{sd7}}
}\xtc{}
}\spadpaste{recip(squareDiff7)\free{sd7}}
}\xtc{}
]\spadpaste{sign(squareDiff7)\free{sd7}}
\texttt{\{squareDiff8 := fourSquares(190,1751,208,1698)\}}
\texttt{\{\}}
\texttt{\{recip(squareDiff8)\}}
\texttt{\{\}}
\texttt{\{sign(squareDiff8)\}}
\texttt{\{\}}
\texttt{\{This should give three digits of precision\}}
\texttt{\{relativeApprox(squareDiff8,10**(-3)):Float\}}
\texttt{\{\}}
\texttt{\{The sum of these 4 roots is 0\}}
\texttt{\{\}}
\texttt{\{allRootsOf((x**2-2)**2-2)\}}
\texttt{\{\}}
\texttt{\{removeDuplicates map(mainDefiningPolynomial,l)\}}
\texttt{\{\}}
\texttt{\{map(mainCharacterization,l)\}}
\texttt{\{\}}
\texttt{\{[reduce(+,l),reduce(*,l)-2]\}}
\texttt{\{\}}
\texttt{\{\}}
\texttt{\{(s2, s5, s10) := (sqrt(2)$Ran, sqrt(5)$Ran, sqrt(10)$Ran)\}}
\texttt{\{\}}
\texttt{\{eq1:=sqrt(s10+3)*sqrt(s5+2) - sqrt(s10-3)*sqrt(s5-2) = sqrt(10*s2+10)\}}
\[eq1::\text{Boolean}\]
\(eq2:=\sqrt{s5+2}\cdot\sqrt{s2+1} - \sqrt{s5-2}\cdot\sqrt{s2-1} = \sqrt{2s10+2}\)
\(eq2::\text{Boolean}\)

Some more examples from J. M. Arnaudies

\(s3 := \sqrt{3}\)
\(s7 := \sqrt{7}\)
\(e1 := \sqrt{2s7-3s3}\)
\(e2 := \sqrt{2s7+3s3}\)
\(e2-e1-s3\)

A quartic polynomial

\(\text{pol} := x^4 + \frac{7}{3}x^2 + 30x - \frac{100}{3}\)

Add some cubic roots

\(r1 := \sqrt{7633}\)
\(\alpha := \sqrt{5r1-436}/3\)
A quintic polynomial
\[
qol : \text{UP}(x, \text{Ran}) := x^5 + 10x^3 + 20x + 22 \quad \text{\free{Ran}} \text{\bound{qol}}
\]
Add some cubic roots
\[
r2 := \sqrt{153} \quad \text{\free{Ran}} \text{\bound{r2}}
\]
\[
alpha2 := \sqrt{r2 - 11.5} \quad \text{\free{r2}} \text{\bound{alpha2}}
\]
\[
beta2 := -\sqrt{r2 + 11.5} \quad \text{\free{r2}} \text{\bound{beta2}}
\]
Finally, some examples from the book Computer Algebra by Davenport, Siret and Tournier (page 77).
The last one is due to Ramanujan.
\[
dst1 := \sqrt{9 + 4s2} = 1 + 2s2 \quad \text{\free{s2}} \text{\bound{dst1}}
\]
\{s29: \text{Ran} := \sqrt{29} \} \\
\{dst4 := \sqrt{(112+70s29)+(46+34s29)s5} = (5+4s2)+(3+s2)s5 \} \\
\{dst6 := \sqrt{(f32-f27,3)} = f25*(1+f3-f3**2) \}

RegularTriangularSet

beginscroll
The \spadtype{RegularTriangularSet} domain constructor implements regular triangular sets. These particular triangular sets were introduced by M. Kalkbrener (1991) in his PhD Thesis under the name regular chains. Regular chains and their related concepts are presented in the paper "On the Theories of Triangular sets" by P. Aubry, D. Lazard and M. Moreno Maza (to appear in the Journal of Symbolic Computation). The \spadtype{RegularTriangularSet} constructor also provides a new method (by the third author) for solving polynomial system by means of regular chains. This method has two ways of solving. One has the same specifications as Kalkbrener's algorithm (1991) and the other is closer to Lazard's method (Discr. App. Math, 1991). Moreover, this new method removes redundant component from the decompositions when this is not too expensive. This is always the case with square-free regular chains. So if you want to obtain decompositions without redundant components just use the \spadtype{SquareFreeRegularTriangularSet} domain constructor or the \spadtype{LazardSetSolvingPackage} package constructor. See also the \spadtype{LexTriangularPackage} and \spadtype{ZeroDimensionalSolvePackage} for the case of algebraic systems with a finite number of (complex) solutions.

One of the main features of regular triangular sets is that they naturally define towers of simple extensions of a field. This allows to perform with multivariate polynomials the same kind of operations as one can do in an \spadtype{EuclideanDomain}.

The \spadtype{RegularTriangularSet} constructor takes four arguments. The first one, \spad{R}, is the coefficient ring of the polynomials; it must belong to the category \spadtype{GcdDomain}. The second one, \spad{E}, is the exponent monoid of the polynomials; it must belong to the category \spadtype{OrderedAbelianMonoidSup}. The third one, \spad{V}, is the ordered set of variables; it must belong to the category \spadtype{OrderedSet}. The last one is the polynomial ring; it must belong to the category \spadtype{RecursivePolynomialCategory(R,E,V)}. The abbreviation for \spadtype{RegularTriangularSet} is \spadtype{REGSET}. See also the constructor \spadtype{RegularChain} which only takes two arguments, the coefficient ring and the ordered set of variables; in that case, polynomials are necessarily built with the \spadtype{NewSparseMultivariatePolynomial} domain constructor.
We shall explain now how to use the constructor \spadtype{REGSET} and how to read the decomposition of a polynomial system by means of regular sets.

Let us give some examples. We start with an easy one (Donati-Traverso) in order to understand the two ways of solving polynomial systems provided by the \spadtype{REGSET} constructor.

\xtc{Define the coefficient ring.}
\spad{R := Integer \bound{R}}
\xtc{Define the list of variables.}
\spad{ls : List Symbol := [x,y,z,t] \bound{ls}}
\xtc{and make it an ordered set.}
\spad{V := OVAR(ls) \free{ls} \bound{V}}
\xtc{then define the exponent monoid.}
\spad{E := IndexedExponents V \free{V} \bound{E}}
\xtc{Define the polynomial ring.}
\spad{P := NSMP(R, V) \free{R} \free{V} \bound{P}}
\xtc{Let the variables be polynomial.}
\spad{x: P := 'x \free{P} \bound{x}}
\spad{y: P := 'y \free{P} \bound{y}}
\spad{z: P := 'z \free{P} \bound{z}}
\spad{t: P := 't \free{P} \bound{t}}
Now call the \texttt{RegularTriangularSet} domain constructor.}
\spadpaste{T := REGSET(R,E,V,P) \free{R} \free{E} \free{V} \free{P} \bound{T} }
\xtc{Define a polynomial system.}
\spadpaste{p1 := x ** 31 - x ** 6 - x - y \free{x} \free{y} \bound{p1}}
\xtc{p2 := x ** 8 - z \free{x} \free{z} \bound{p2}}
\xtc{p3 := x ** 10 - t \free{x} \free{t} \bound{p3}}
\xtc{lp := \[p1, p2, p3\] \free{p1} \free{p2} \free{p3} \bound{lp}}
\xtc{First of all, let us solve this system in the sense of Kalkbrener.}
\spadpaste{zeroSetSplit(lp)$T \free{lp} \free{T} \bound{lts}}
\xtc{And now in the sense of Lazard (or Wu and other authors).}
\spadpaste{lts := zeroSetSplit(lp,false)$T \free{lp} \free{T} \bound{lts}}
\xtc{We can see that the first decomposition is a subset of the second. So how can both be correct ?}
\xtc{Recall first that polynomials from a domain of the category \texttt{RecursivePolynomialCategory} are regarded as univariate polynomials in their main variable. For instance the second polynomial in the first set of each decomposition has main variable \texttt{y} and its initial (i.e. its leading coefficient w.r.t. its main variable) is \texttt{t z}.}
\xtc{Now let us explain how to read the second decomposition. Note that the non-constant initials of the first set are \texttt{t^4-t} and \texttt{t z}. Then the solutions described by this first set are the common zeros of its polynomials that do not cancel the polynomials \texttt{t^4-t} and \texttt{t z}. Now the solutions of the input system \texttt{lp}.
satisfying these equations are described by the second and the third sets of the decomposition. Thus, in some sense, they can be considered as degenerated solutions. The solutions given by the first set are called the generic points of the system; they give the general form of the solutions. The first decomposition only provides these generic points. This latter decomposition is useful when they are many degenerated solutions (which is sometimes hard to compute) and when one is only interested in general informations, like the dimension of the input system.

\xtc{
We can get the dimensions of each component of a decomposition as follows.
}

\spadpaste{{\text{coHeight}(ts) \text{ for ts in lts}} \setminus \text{free(lts)}}

Thus the first set has dimension one. Indeed \textbf{t} can take any value, except \textbf{0} or any third root of \textbf{1}, whereas \textbf{z} is completely determined from \textbf{t}, \textbf{y} is given by \textbf{z} and \textbf{t}, and finally \textbf{x} is given by the other three variables.

In the second and the third sets of the second decomposition the four variables are completely determined and thus these sets have dimension zero.

We give now the precise specifications of each decomposition. This assume some mathematical knowledge. However, for the non-expert user, the above explanations will be sufficient to understand the other features of the \spadtype{RSEGSET} constructor.

The input system \textbf{lp} is decomposed in the sense of Kalkbrener as finitely many regular sets \{\textbf{T1},\ldots,\textbf{Ts}\} such that the radical ideal generated by \textbf{lp} is the intersection of the radicals of the saturated ideals of \{\textbf{T1},\ldots,\textbf{Ts}\}. In other words, the affine variety associated with \textbf{lp} is the union of the closures (w.r.t. Zarisky topology) of the regular-zeros sets of \{\textbf{T1},\ldots,\textbf{Ts}\}.

\textbf{N. B.} The prime ideals associated with the radical of the saturated ideal of a regular triangular set have all the same dimension; moreover these prime ideals can be given by characteristic sets with the same main variables. Thus a decomposition in the sense of Kalkbrener is unmixed dimensional. Then it can be viewed as a \textit{lazy}
decomposition into prime ideals (some of these prime ideals being merged into unmixed dimensional ideals).

Now we explain the other way of solving by means of regular triangular sets. The input system $\{\textbf{lp}\}$ is decomposed in the sense of Lazard as finitely many regular triangular sets $\{\textbf{T1}, \ldots, \textbf{Ts}\}$ such that the affine variety associated with $\{\textbf{lp}\}$ is the union of the regular-zeros sets of $\{\textbf{T1}, \ldots, \textbf{Ts}\}$. Thus a decomposition in the sense of Lazard is also a decomposition in the sense of Kalkbrener; the converse is false as we have seen before.

When the input system has a finite number of solutions, both ways of solving provide similar decompositions as we shall see with this second example (Caprasse).

\begin{verbatim}
\xtc{Define a polynomial system.}
\spadpaste{f1 := y**2*z+2*x*y*t-2*x-z \free{z} \free{x} \free{y} \free{t} \bound{f1}}
\xtc{}
\spadpaste{f2 := -x**3*z+ 4*x*y**2*z+ 4*x**2*y*t+ 2*y**3*t+ 4*x**2- 10*y**2+ 4*x*z- 10*y*t+ 2 \free{z} \free{x} \free{y} \free{t} \bound{f2}}
\xtc{}
\spadpaste{f3 := 2*y*z*t+x*t**2-x-2*z \free{z} \free{x} \free{y} \free{t} \bound{f3}}
\xtc{}
\spadpaste{f4 := -x*z**3+ 4*y*z**2*t+ 4*x*z*t**2+ 2*y*t**3+ 4*x**2+ 4*z**2-10*y*t- 10*t**2+2 \free{z} \free{x} \free{y} \free{t} \bound{f4}}
\xtc{}
\spadpaste{lf := [f1, f2, f3, f4] \free{f1} \free{f2} \free{f3} \free{f4} \bound{lf}}
\xtc{First of all, let us solve this system in the sense of Kalkbrener.}
\end{verbatim}
\spadpaste{zeroSetSplit(\sf{lf}) \free{lf} \free{T}}}
}\xtc{And now in the sense of Lazard (or Wu and other authors).}
\{\spadpaste{lts2 := zeroSetSplit(\sf{lf},false) \free{lf} \free{T} \bound{lts2}}}
\}

Up to the ordering of the components, both decompositions are identical.

\xtc{Let us check that each component has a finite number of solutions.}
\{\spadpaste{[\sf{coHeight}(\sf{ts})\ \text{for} \ \sf{ts} \ \text{in} \ \sf{lts2}] \free{lts2}}}
\}
\xtc{Let us count the degrees of each component,}

We study now the options of the \spadfun{zeroSetSplit} operation. As we have seen yet, there is an optional second argument which is a boolean value. If this value is true (this is the default) then the decomposition is computed in the sense of Kalkbrener, otherwise it is computed in the sense of Lazard.

There is a second boolean optional argument that can be used (in that case the first optional argument must be present). This second option allows you to get some information during the computations.

Therefore, we need to understand a little what is going on during the computations. An important feature of the algorithm is that the intermediate computations are managed in some sense like the processes of a Unix system. Indeed, each intermediate computation may generate other intermediate computations and the management of all these computations is a crucial task for the efficiency. Thus any intermediate computation may be suspended, killed or resumed, depending on algebraic considerations that determine priorities for
these processes. The goal is of course to go as fast as possible towards the final decomposition which means to avoid as much as possible unnecessary computations.

To follow the computations, one needs to set to \spad{true} the second argument. Then a lot of numbers and letters are displayed. Between a \spad{} and a \spad{} one has the state of the processes at a given time. Just after \spad{} one can see the number of processes. Then each process is represented by two numbers between \spad{} and \spad{}. A process consists of a list of polynomial \spad{} and a triangular set \spad{}; its goal is to compute the common zeros of \spad{} that belong to the regular-zeros set of \spad{}. After the processes, the number between pipes gives the total number of polynomials in all the sets \spad{}. Finally, the number between braces gives the number of components of a decomposition that are already computed. This number may decrease.

Let us take a third example (Czapor-Geddes-Wang) to see how these informations are displayed.

\begin{verbatim}
\xtc{
Define a polynomial system.
}{
\spadpaste{u : R := 2 \free{R} \bound{u}}
}
\xtc{
}{
\spadpaste{q1 := 2*(u-1)**2+ 2*(x-z*x+z**2)+ y**2*(x-1)**2-2*u*x+ 2*y*t*(1-x)*(x-z)+ 2*u*z*t*(t-y)+ u**2*t**2*(1-2*z)+2*u*t**2*(z-x)+ 2*u*t*y*(z-1)+ 2*u*z*x*(y+1)+ (u**2-2*u)*z**2*t**2+ 2*u**2*z**2+ 4*u*(1-u)*z+ t**2*(z-x)**2 \free{z} \free{x} \free{y} \free{t} \free{u} \bound{q1}}
}
\xtc{
}{
\spadpaste{q2 := t*(2*z+1)*(x-z)+ y*(z+2)*(1-x)+ u*(u-2)*t+ u*(1-2*u)*z*t+ u*y*(x+u-z*x-1)+ u*(u+1)*z**2*t \free{x} \free{y} \free{t} \free{u} \bound{q2}}
}
\xtc{
}{
\spadpaste{q3 := -u**2*(z-1)**2+ 2*z*(z-x)-2*(x-1) \free{z} \free{x} \free{y} \free{t} \free{u} \bound{q3}}
}
\xtc{
}{
\spadpaste{q4 := u**2+4*(z-x**2)+3*y**2*(x-1)**2- 3*t**2*(z-x)**2 +3*u**2*t**2*(z-1)**2+u**2*z*(z-2)+ 6*u*t*y*(x+u-z*x-1) \free{z} \free{x} \free{y} \free{t} \free{u} \bound{q4}}
}
\end{verbatim}
Let us try the information option.
N.B. The timing should be between 1 and 10 minutes, depending on your machine.

\spad{\textbf{zeroSetSplit}(lq,\text{true},\text{true})}\ T \ \text{\\textbf{free}(lq)} \ \text{\\textbf{free}(T)}

Between a sequence of processes, thus between a \spad{[]} and a \spad{[]} you can see capital letters \spad{W, G, I} and lower case letters \spad{i, w}. Each time a capital letter appears a non-trivial computation has been performed and its result is put in a hash-table. Each time a lower case letter appears a needed result has been found in an hash-table. The use of these hash-tables generally speed up the computations. However, on very large systems, it may happen that these hash-tables become too big to be handle by your Axiom configuration. Then in these exceptional cases, you may prefer getting a result (even if it takes a long time) than getting nothing. Hence you need to know how to prevent the \spad{\textbf{RSEGSET}} constructor from using these hash-tables. In that case you will be using the \spad{\textbf{zeroSetSplit}} with five arguments. The first one is the input system \spad{bf lq} as above. The second one is a boolean value \spad{\textbf{hash?}} which is \spad{\text{false}} iff you want to use hash-tables. The third one is boolean value \spad{\textbf{clos?}} which is \spad{\text{true}} iff you want to solve your system in the sense of Kalkbrener, the other way remaining that of Lazard. The fourth argument is boolean value \spad{\textbf{info?}} which is \spad{\text{true}} iff you want to display information during the computations. The last one is boolean value \spad{\textbf{prep?}} which is \spad{\text{true}} iff you want to use some heuristics that are performed on the input system before starting the real algorithm. The value of this flag is \spad{\text{false}} when you are using \spad{\textbf{zeroSetSplit}} with less than five arguments. Note that there is no available signature for \spad{\textbf{zeroSetSplit}} with four arguments.

We finish this section by some remarks about both ways of solving, in the sense of Kalkbrener or in the sense of Lazard. For problems with a finite number of solutions, there are theoretically equivalent and the resulting decompositions are identical, up to the ordering of the components. However, when solving in the sense of Lazard, the algorithm behaves differently. In that case, it becomes more incremental than in the sense of Kalkbrener. That means the polynomials of the input system are considered one after another whereas in the sense of Kalkbrener the input system is treated more
globally.

This makes an important difference in positive dimension. Indeed when solving in the sense of Kalkbrener, the \emph{Primeidealkettensatz} of Krull is used. That means any regular triangular containing more polynomials than the input system can be deleted. This is not possible when solving in the sense of Lazard. This explains why Kalkbrener’s decompositions usually contain less components than those of Lazard. However, it may happen with some examples that the incremental process (that cannot be used when solving in the sense of Kalkbrener) provide a more efficient way of solving than the global one even if the \emph{Primeidealkettensatz} is used. Thus just try both, with the various options, before concluding that you cannot solve your favorite system with \spadfun{zeroSetSplit}. There exist more options at the development level that are not currently available in this public version. So you are welcome to contact \emph{marc@nag.co.uk} for more information and help.

\end{paste}\end{patch}
The Roman numeral package was added to Axiom in MCMLXXXVI for use in denoting higher order derivatives.

For example, let \( f \) be a symbolic operator.

\[
\text{\begin{code}\begin{axiom}
f := \text{operator 'f}
\end{axiom}\end{code}}
\]

This is the seventh derivative of \( f \) with respect to \( x \).

\[
\text{\begin{code}\begin{axiom}
D(f \times x, 7)
\end{axiom}\end{code}}
\]

You can have integers printed as Roman numerals by declaring variables to be of type \spadtype{RomanNumeral} (abbreviation \spadtype{ROMAN}).

\[
\text{\begin{code}\begin{axiom}
a := \text{roman(1978 - 1965)}
\end{axiom}\end{code}}
\]

This package now has a small but devoted group of followers that claim this domain has shown its efficacy in many other contexts. They claim that Roman numerals are every bit as useful as ordinary integers. In a sense, they are correct, because Roman numerals form a ring and you can therefore construct polynomials with Roman numeral coefficients, matrices over Roman numerals, etc..

\[
\text{\begin{code}\begin{axiom}
x : \text{UTIS(ROMAN, 'x, 0)} := x
\end{axiom}\end{code}}
\]
This package now has a small but devoted group of followers that claim this domain has shown its efficacy in many other contexts. They claim that Roman numerals are every bit as useful as ordinary integers.

\xtc{In a sense, they are correct, because Roman numerals form a ring and you can therefore construct polynomials with Roman numeral coefficients, matrices over Roman numerals, etc..}
\{\spadpaste{x : UTS(ROMAN,'x,0) := x \bound{x}}\}
\xtc{Was Fibonacci Italian or ROMAN?}
\{\spadpaste{recip(1 - x - x**2) \free{x}}\}
\xtc{You can also construct fractions with Roman numeral numerators and denominators, as this matrix Hilberticus illustrates.}
\{\spadpaste{m : MATRIX FRAC ROMAN \bound{m}}\}
\xtc{Note that the inverse of the matrix has integral \spadtype{ROMAN} entries.}
\{\spadpaste{inverse m \free{m1}}\}
\xtc{Unfortunately, the spoil-sports say that the fun stops when the numbers get big---mostly because the Romans didn’t establish conventions about representing very large numbers.}
\{\spadpaste{y := factorial 10 \bound{y}}\}
\xtc{You work it out!}
\{\spadpaste{roman y \free{y}}\}

Issue the system command
\spadcmd{)show RomanNumeral}
to display the full list of operations defined by 
\spadtype{RomanNumeral}.

The \spadtype{Segment} domain provides a generalized interval type.

\begin{page}{SegmentXmpPage}{Segment}
\beginscroll

Segments are created using the \spad{..} construct by indicating the (included) end points.
\begin{spadblock}
\spad{s := 3..10 \bound{s}}
\end{spadblock}

The first end point is called the \spadfunFrom{lo}{Segment} and the second is called \spadfunFrom{hi}{Segment}.
\begin{spadblock}
\spad{lo s \free{s}}
\end{spadblock}

These names are used even though the end points might belong to an unordered set.
\begin{spadblock}
\spad{hi s \free{s}}
\end{spadblock}

In addition to the end points, each segment has an integer "increment." An increment can be specified using the "\spad{by}" construct.
\begin{spadblock}
\spad{t := 10..3 by -2 \bound{t}}
\end{spadblock}

This part can be obtained using the \spadfunFrom{incr}{Segment} function.
\begin{spadblock}
\spad{incr s \free{s}}
\end{spadblock}

Unless otherwise specified, the increment is \spad{1}.
\begin{spadblock}
\spad{incr t \free{t}}
\end{spadblock}

A single value can be converted to a segment with equal end points. This happens if segments and single values are mixed in a list.
\spadpaste{l := \[1..3, 5, 9, 15..11 by -1\] \bound{l}}
}

\xtc{If the underlying type is an ordered ring, it is possible to perform additional operations. The \spadfunFrom{expand}{Segment} operation creates a list of points in a segment. }
}\spadpaste{expand s \free{s}}

\xtc{If \spad{k > 0}, then \spad{expand(l..h by k)} creates the list \spad{\[l, l+k, \ldots, lN\]} where \spad{1N <= h < lN+k}. If \spad{k < 0}, then \spad{lN >= h > lN+k}.}
}\spadpaste{expand t \free{t}}

\xtc{It is also possible to expand a list of segments. This is equivalent to appending lists obtained by expanding each segment individually.}
}\spadpaste{expand l \free{l}}

For more information on related topics, see \downlink{`SegmentBinding'}{SegmentBindingXmpPage}\ignore{SegmentBinding} and \downlink{`UniversalSegment'}{UniversalSegmentXmpPage}\ignore{UniversalSegment}.

\begin{verbatim}
(10) \[1,2,3,5,9,15,14,13,12,11\]  
Type: List Integer
\end{verbatim}
The `SegmentBinding` type is used to indicate a range for a named symbol.

First give the symbol, then an `=` and finally a segment of values.

\begin{spadpaste}
\spad{x = a..b}
\end{spadpaste}

This is used to provide a convenient syntax for arguments to certain operations.

\begin{spadpaste}
\spad{\sum(i**2, i = 0..n)}
\end{spadpaste}

\begin{graphpaste}
\texttt{draw(x**2, x = -2..2)}
\end{graphpaste}

The left-hand side must be of type `Symbol` but the right-hand side can be a segment over any type.

\begin{spadpaste}
\spad{sb := y = 1/2..3/2 \bound{sb}}
\end{spadpaste}

The left- and right-hand sides can be obtained using the `variable` and `segment` operations.

\begin{spadpaste}
\spad{\text{variable(sb) free(sb)}}
\end{spadpaste}

\begin{spadpaste}
\spad{\text{segment(sb) free(sb)}}
\end{spadpaste}

For more information on related topics, see
Segment and UniversalSegment.

3.97. set.ht

Set

⇒ “notitle” (ListXmpPage) 3.64 on page 866

— set.ht —

The \texttt{Set} domain allows one to represent explicit finite sets of values. These are similar to lists, but duplicate elements are not allowed.

Sets can be created by giving a fixed set of values \ldots

\spadcommand{s := \text{set} [x^2-1, y^2-1, z^2-1] \free{s}}

or by using a collect form, just as for lists. In either case, the set is formed from a finite collection of values.

\spadcommand{t := \text{set} [x^i - i+1 \text{ for } i \text{ in } 2..10 \text{ | prime? } i] \free{t}}

The basic operations on sets are \spadfunFrom{intersect}{Set}, \spadfunFrom{union}{Set}, \spadfunFrom{difference}{Set}, and \spadfunFrom{symmetricDifference}{Set}.

\spadcommand{i := \text{intersect}(s, t) \free{s t}\bound{i}}
\spadpaste{u := union(s,t) \free{s t}\bound{u}}
\)
\xtc{
The set \spad{difference(s,t)} contains those members of \spad{s} which are not in \spad{t}.
}\{
\spadpaste{difference(s,t) \free{s t}}
\)
\xtc{
The set \spad{symmetricDifference(s,t)} contains those elements which are in \spad{s} or \spad{t} but not in both.
}\{
\spadpaste{symmetricDifference(s,t) \free{s t}}
\)
\xtc{
Set membership is tested using the \spadfunFrom{member?}{Set} operation.
}\{
\spadpaste{member?(y, s) \free{s}}
\)
\xtc{
}\{
\spadpaste{member?((y+1)*(y-1), s) \free{s}}
\)
\xtc{
The \spadfunFrom{subset?}{Set} function determines whether one set is a subset of another.
}\{
\spadpaste{subset?(i, s) \free{i s}}
\)
\xtc{
}\{
\spadpaste{subset?(u, s) \free{u s}}
\)
\xtc{
When the base type is finite, the absolute complement of a set is defined.
This finds the set of all multiplicative generators of \spadtype{PrimeField 11}---the integers mod \spad{11}.
}\{
\spadpaste{gs := set [g for i in 1..11 | primitive?(g := i::PF 11)] \bound{gs}}
\)
\xtc{
The following values are not generators.
}\{
\spadpaste{complement gs \free{gs}}
\)
Often the members of a set are computed individually; in addition, values can be inserted or removed from a set over the course of a computation.

There are two ways to do this:

One is to view a set as a data structure and to apply updating operations.

The other way is to view a set as a mathematical entity and to create new sets from old.

For more information about lists, see \downlink{'List'}{ListXmpPage}\ignore{List}.

Type: Set PositiveInteger
\end{verbatim}
The `SingleInteger` domain is intended to provide support in Axiom for machine integer arithmetic. It is generally much faster than (bignum) `Integer` arithmetic but suffers from a limited range of values. Since Axiom can be implemented on top of various dialects of Lisp, the actual representation of small integers may not correspond exactly to the host machines integer representation.

In the CCL implementation of Axiom (Release 2.1 onwards) the underlying representation of `SingleInteger` is the same as `Integer`. The underlying Lisp primitives treat machine-word sized computations specially.

You can discover the minimum and maximum values in your implementation by using `min` and `max`

\begin{verbatim}
min($)SingleInteger
max($)SingleInteger
\end{verbatim}

To avoid confusion with `Integer`, which is the default type for integers, you usually need to work with declared variables (``Declarations`` in Section 2.3) ...

\begin{page}{SingleIntegerXmpPage}{SingleInteger}
\beginscroll
\end{page}
You can discover the minimum and maximum values in your implementation by using \spadfunFrom{min}{SingleInteger} and \spadfunFrom{max}{SingleInteger}.

\spadpaste{min()$\text{SingleInteger}$}
\xspace
\spadpaste{max()$\text{SingleInteger}$}
\xspace

To avoid confusion with \axiomType{Integer}, which is the default type for integers, you usually need to work with declared variables (\downlink{``Declarations''}{ugTypesDeclarePage} in Section 2.3)\ldots

\spadpaste{a := 1234 :: SingleInteger \bound{a}}

or use package calling (\downlink{``Package Calling and Target Types''}{ugTypesPkgCallPage} in Section 2.9).

\spadpaste{b := 124$\text{SingleInteger}$ \bound{b}}

You can add, multiply and subtract \axiomType{SingleInteger} objects, and ask for the greatest common divisor (\spad{gcd}).

\spadpaste{gcd(a,b) \free{a}\free{b}}

The least common multiple (\spad{ lcm}) is also available.

\spadpaste{lcm(a,b) \free{a}\free{b}}

Operations \spadfunFrom{mulmod}{SingleInteger}, \spadfunFrom{addmod}{SingleInteger}, \spadfunFrom{submod}{SingleInteger}, and \spadfunFrom{invmod}{SingleInteger} are similar---they provide arithmetic modulo a given small integer. Here is \spad{5 * 6 \ttmod 13}.

\spadpaste{mulmod(5,6,13)$\text{SingleInteger}$}

To reduce a small integer modulo a prime, use \spadfunFrom{positiveRemainder}{SingleInteger}. 

Operations \spadfunFrom{And}{SingleInteger}, \spadfunFrom{Or}{SingleInteger}, \spadfunFrom{xor}{SingleInteger}, and \spadfunFrom{Not}{SingleInteger} provide bit level operations on small integers.

\begin{verbatim}
\spad{And(3,4)$\spad{\text{SingleInteger}}}
\end{verbatim}

Use \spad{shift(int,numToShift)} to shift bits, where \spad{i} is shifted left if \spad{numToShift} is positive, right if negative.

\begin{verbatim}
\spad{shift(1,4)$\spad{\text{SingleInteger}}}
\end{verbatim}

\begin{verbatim}
\spad{shift(31,-1)$\spad{\text{SingleInteger}}}
\end{verbatim}

Many other operations are available for small integers, including many of those provided for \axiomType{Integer}. To see the other operations, use the Browse Hyperdoc facility (\downlink{``Browse''}{ugBrowsePage} in Section 14\ignore{ugBrowse}).

3.99 sqmatrix.ht

SquareMatrix

\Rightarrow “notitle” (MatrixXmpPage) 3.75 on page 984
\Rightarrow “notitle” (ugTypesWritingModesPage) 7 on page 1637
\Rightarrow “notitle” (ugTypesExposePage) 7 on page 1699

The top level matrix type in Axiom is \spadtype{Matrix} (see \downlink{`Matrix'}{MatrixXmpPage}\ignore{Matrix}), which provides basic arithmetic and linear algebra functions. However, since the matrices can be of any size it is not true that any pair can be added or multiplied. Thus \spadtype{Matrix} has little algebraic structure.

Sometimes you want to use matrices as coefficients for polynomials or in other algebraic contexts. In this case, \spadtype{SquareMatrix} should be used. The domain \spadtype{SquareMatrix(n,R)} gives the ring of \spad{n} by \spad{n} square matrices over \spad{R}.

\xtc{Since \spadtype{SquareMatrix} is not normally exposed at the top level, you must expose it before it can be used.}
\spadpaste{)set expose add constructor SquareMatrix \bound{SQ}}

\xtc{Once \spad{SQMATRIX} has been exposed, values can be created using the \spadfunFrom{squareMatrix}{SquareMatrix}
function.
}\{m := squareMatrix [[1, -\%i], [\%i, 4]] \bound{m}\free{SQ}}
\xtc{}
The usual arithmetic operations are available.
}\{m*m - m \free{m}}
\xtc{}
Square matrices can be used where ring elements are required.
For example, here is a matrix with matrix entries.
}\{mm := squareMatrix [[m, 1], [1-m, m**2]] \free{m}\bound{mm}}
\xtc{}
Or you can construct a polynomial with square matrix coefficients.
}\{p := (x + m)**2 \free{m}\bound{p}}
\xtc{}
This value can be converted to a square matrix with polynomial coefficients.
}\{p::SquareMatrix(2, ?) \free{p}}
\}

3.100 sregset.ht

SquareFreeRegularTriangularSet

The \spadtype{SquareFreeRegularTriangularSet} domain constructor implements square-free regular triangular sets. See the \spadtype{RegularTriangularSet} domain constructor for general regular triangular sets. Let \{t1, \ldots, tm\} be a regular triangular set consisting of polynomials \{t1, \ldots, tm\} ordered by increasing main variables. The regular triangular set \{t1, \ldots, tm\} is square-free if \{t1, \ldots, tm\} is empty or if \{t1, \ldots, tm-1\} is square-free and if the polynomial \{tm\} is square-free as a univariate polynomial with coefficients in the tower of simple extensions associated with \{t1, \ldots, tm-1\}.

The main interest of square-free regular triangular sets is that their associated towers of simple extensions are product of fields. Consequently, the saturated ideal of a square-free regular triangular set is radical. This property simplifies some of the operations related to regular triangular sets. However, building square-free regular triangular sets is generally more expensive than building general regular triangular sets.

As the \spadtype{RegularTriangularSet} domain constructor, the \spadtype{SquareFreeRegularTriangularSet} domain constructor also implements a method for solving polynomial systems by means of regular triangular sets. This is in fact the same method with some adaptations to take into account the fact that the computed regular chains are square-free. Note that it is also possible to pass from a decomposition into general regular triangular sets to a decomposition into square-free regular triangular sets. This conversion is used internally by the \spadtype{LazardSetSolvingPackage} package constructor.

\bf{N.B.} When solving polynomial systems with the \spadtype{SquareFreeRegularTriangularSet} domain constructor or the \spadtype{LazardSetSolvingPackage} package constructor, decompositions have no redundant components. See also \spadtype{LexTriangularPackage} and \spadtype{ZeroDimensionalSolvePackage} for the case of algebraic systems with a finite number of (complex) solutions.

We shall explain now how to use the constructor
This constructor takes four arguments. The first one, \texttt{R}, is the coefficient ring of the polynomials; it must belong to the category \spadtype{GcdDomain}. The second one, \texttt{E}, is the exponent monoid of the polynomials; it must belong to the category \spadtype{OrderedAbelianMonoidSup}. The third one, \texttt{V}, is the ordered set of variables; it must belong to the category \spadtype{OrderedSet}. The last one is the polynomial ring; it must belong to the category \spadtype{RecursivePolynomialCategory(R,E,V)}. The abbreviation for \spadtype{SquareFreeRegularTriangularSet} is \spadtype{SREGSET}.

Note that the way of understanding triangular decompositions is detailed in the example of the \spadtype{RegularTriangularSet} constructor.

\xtc{Let us illustrate the use of this constructor with one example (Donati-Traverso). Define the coefficient ring.}
\spadpaste{R := Integer \bound{R}}
\xtc{Define the list of variables,}
\spadpaste{ls : List Symbol := [x,y,z,t] \bound{ls}}
\xtc{and make it an ordered set;}
\spadpaste{V := OVAR(ls) \free{ls} \bound{V}}
\xtc{then define the exponent monoid.}
\spadpaste{E := IndexedExponents V \free{V} \bound{E}}
\xtc{Define the polynomial ring.}
\spadpaste{P := NSMP(R, V) \free{R} \free{V} \bound{P}}
\xtc{Let the variables be polynomial.}
\spadpaste{x: P := 'x \free{P} \bound{x}}
Now call the \spadtype{SquareFreeRegularTriangularSet} domain constructor.
}\{ 
\spadpaste{ST := SREGSET(R,E,V,P) \free{R} \free{E} \free{V} \free{P} \bound{ST} } 
\}
\xtc{ Define a polynomial system. }
}\{ 
\spadpaste{p1 := x ** 31 - x ** 6 - x - y \free{x} \free{y} \bound{p1}} 
\}
\xtc{ }
\spadpaste{p2 := x ** 8 - z \free{x} \free{z} \bound{p2}} 
\}
\xtc{ }
\spadpaste{p3 := x ** 10 - t \free{x} \free{t} \bound{p3}} 
\}
\xtc{ }
\spadpaste{lp := [p1, p2, p3] \free{p1} \free{p2} \free{p3} \bound{lp}} 
\}
\xtc{ First of all, let us solve this system in the sense of Kalkbrener. }
}\{ 
\spadpaste{zeroSetSplit(lp)$ST \free{lp} \free{ST}} 
\}
\xtc{ And now in the sense of Lazard (or Wu and other authors). }
}\{ 
\spadpaste{zeroSetSplit(lp,false)$ST \free{lp} \free{ST} \bound{lts}} 
\}
Now to see the difference with the \spadtype{RegularTriangularSet} domain constructor,
\xtc{
we define:
}
\spadpaste{T := REGSET(R,E,V,P) \free{R} \free{E} \free{V} \free{P} \bound{T} }
}
\xtc{
and compute:
}
\spadpaste{lts := zeroSetSplit(lp,false)$T \free{lp} \free{T} \bound{lts}}
}

If you look at the second set in both decompositions in the sense of Lazard, you will see that the polynomial with main variable \textbf{y} is not the same.

Let us understand what has happened.
\xtc{
We define:
}
\spadpaste{ts := lts.2 \free{lts} \bound{ts}}
}
\xtc{
}
\spadpaste{pol := select(ts,'y)$T \free{ts} \free{y} \free{T} \bound{pol}}
}
\xtc{
}
\spadpaste{tower := collectUnder(ts,'y)$T \free{ts} \free{y} \free{T} \bound{tower}}
}
\xtc{
}
\spadpaste{pack := RegularTriangularSetGcdPackage(R,E,V,P,T) \free{R} \free{E} \free{V} \free{P} \free{T} \bound{pack}}
}
\xtc{
Then we compute:
}
\spadpaste{toseSquareFreePart(pol,tower)$pack \free{pol} \free{pack}}
}
\endscroll

\end{page}

\begin{patch}{SqFreeRegTriangSetXmpPagePatch1}
\begin{verbatim}
R := Integer
(1) Integer
Type: Domain
\end{verbatim}

\begin{verbatim}
ls := [x,y,z,t]
(2) [x,y,z,t]
Type: List Symbol
\end{verbatim}

\begin{verbatim}
V := OVAR(ls)
(3) OrderedVariableList [x,y,z,t]
Type: Domain
\end{verbatim}
The document contains code examples from a programming language, specifically using the `spadcommand` and `verbatim` blocks to display code and its output. Here is the content in a natural text representation:

```
\tab{5}\spadcommand{E := IndexedExponents V\free{V}\bound{E}}
\indentrel{3}\begin{verbatim}(4) IndexedExponents OrderedVariableList [x,y,z,t]
    Type: Domain\end{verbatim}
\end{verbatim}
\end{verbatim}

\begin{verbatim}(5)
NewSparseMultivariatePolynomial(Integer,OrderedVariableList [x,y,z,t])
    Type: Domain\end{verbatim}
\end{verbatim}
\end{verbatim}

\begin{verbatim}(6) x
    Type: NewSparseMultivariatePolynomial(Integer,OrderedVariableList [x,y,z,t])\end{verbatim}
\end{verbatim}
```

The code examples illustrate the creation of an indexed exponents list and a new sparse multivariate polynomial, with each step showing the type of the resulting object. The output is presented in a natural text format, highlighting the code and its results.

SparseTable

⇒ “notitle” (TableXmpPage) 3.106 on page 1298
⇒ “notitle” (GeneralSparseTableXmpPage) 3.52 on page 687

\begin{verbatim}
\spad{t: SparseTable(Integer, String, "Try again!") := table()
\bound{t}}
\end{verbatim}

\begin{verbatim}
\spad{t.3 := "Number three" \free{t}\bound{t1}}
\end{verbatim}

% The \spadtype{SparseTable} domain provides a general purpose
table type with default entries.
\begin{verbatim}
\spad{t: SparseTable(Integer, String, "Try again!") := table()
\bound{t}}
\end{verbatim}

Entries can be stored in the table.
\begin{verbatim}
\spad{t.3 := "Number three" \free{t}\bound{t1}}
\end{verbatim}
These values can be retrieved as usual, but if a look up fails the default entry will be returned.

To see which values are explicitly stored, the functions can be used.

If a specific table representation is required, the constructor should be used. The domain $\text{SparseTable}(K, E, \text{dflt})$ is equivalent to $\text{GeneralSparseTable}(K,E, \text{Table}(K,E), \text{dflt})$.

For more information, see \downlink{`Table'}{TableXmpPage} and \downlink{`GeneralSparseTable'}{GeneralSparseTableXmpPage}.

3.102 stream.ht

Stream

A \spadtype{Stream} object is represented as a list whose last element contains the wherewithal to create the next element, should it ever be required.

\begin{verbatim}
\spad{ints := \[i for i in 0..\] \bound{ints}}
\end{verbatim}

By default, ten stream elements are calculated. This number may be changed to something else by the system command \spadcmd{)set streams calculate}. For the display purposes of this book, we have chosen a smaller value.

More generally, you can construct a stream by specifying its initial value and a function which, when given an element, creates the next element.

\begin{verbatim}
\spad{f : List \text{INT} -> List \text{INT} \bound{fdec}}
\end{verbatim}

\begin{verbatim}
\spad{f \ x == \[x.1 + x.2, x.1\] \bound{f}\free{fdec}}
\end{verbatim}

\begin{verbatim}
\spad{fibs := \[i.2 for i in \[generate(f,\[1,1\)]\]] \bound{fibs}\free{f}}
\end{verbatim}

You can create the stream of odd non-negative integers by either filtering them from the integers, or by evaluating an expression for each integer.

\begin{verbatim}
\spad{\[i for i in ints \ where odd? i\] \free{ints}}
\end{verbatim}
You can accumulate the initial segments of a stream using the \spadfunFrom{scan}{StreamFunctions2} operation.
}\)
\xtc{
The corresponding elements of
two or more streams can be combined in this way.
}\)
\xtc{
Many operations similar to those applicable to lists are available for streams.
}\)
\xtc{
The packages \spadtype{StreamFunctions1},
\spadtype{StreamFunctions2} and
\spadtype{StreamFunctions3} export some useful stream manipulation operations.

String

⇒ “notitle” (CharacterXmpPage) 3.15 on page 228
⇒ “notitle” (CharacterClassXmpPage) 3.14 on page 221

\begin{page}{StringXmpPage}{String}
\beginscroll

The type \spadtype{String} provides character strings. Character strings provide all the operations for a one-dimensional array of characters, plus additional operations for manipulating text. For more information on related topics, see \downlink{`Character'}{CharacterXmpPage}\ignore{Character} and \downlink{`CharacterClass'}{CharacterClassXmpPage}\ignore{CharacterClass}. You can also issue the system command \spadcmd{)show String} to display the full list of operations defined by \spadtype{String}.

\xtc{
String values can be created using double quotes.
}
\spadpaste{hello := "Hello, I'm Axiom!" \bound{hello}}
\xtc{
Note, however, that double quotes and underscores must be preceded by an extra underscore.
}
\spadpaste{said := "Jane said, _"Look!_"" \bound{said}}
\xtc{
It is also possible to use \spadfunFrom{new}{String} to create a string of any size filled with a given character. Since there are many \spadfun{new} functions it is necessary to indicate the desired type.
}
\spadpaste{gasp: String := new(32, char "x") \bound{gasp}}
\xtc{
The length of a string is given by \spadopFrom{#}{List}.
}
\spadpaste{\#gasp \free{gasp}}
\endscroll
\end{page}

Indexing operations allow characters to be extracted or replaced in strings. For any string $s$, indices lie in the range $1..\#s$.

\spadpaste{hello.2 \free{hello}}

Indexing is really just the application of a string to a subscript, so any application syntax works.

\spadpaste{hello 2 \free{hello}}

\spadpaste{hello(2) \free{hello}}

If it is important not to modify a given string, it should be copied before any updating operations are used.

\spadpaste{hullo := copy hello \free{hello}\bound{hullo0}}

\spadpaste{hullo.2 := char "u"; [hello, hullo] \free{hullo0 hello} \bound{hullo}}

Operations are provided to split and join strings. The $\texttt{concat(String)}$ operation allows several strings to be joined together.

\spadpaste{saidsaw := concat ["alpha","---","omega"] \bound{saidsaw}}

There is a version of $\texttt{concat(String)}$ that works with two strings.

\spadpaste{concat("hello ","goodbye")}

Juxtaposition can also be used to concatenate strings.

\spadpaste{"This " "is " "several " "strings " "concatenated."}

Substrings are obtained by giving an index range.
3.103. STRING.HT
\spadpaste{hello(1..5) \free{hello}}
}
\xtc{
}{
\spadpaste{hello(8..) \free{hello}}
}
\xtc{
A string can be split into several substrings by giving a
separation character or character class.
}{
\spadpaste{split(hello, char " ")
\free{hello}}
}
\xtc{
}{
\spadpaste{other := complement alphanumeric(); \bound{other}}
}
\xtc{
}{
\spadpaste{split(saidsaw, other)
\free{saidsaw other}}
}
\xtc{
Unwanted characters can be trimmed from the beginning or end of a
string using the operations \spadfunFrom{trim}{String},
\spadfunFrom{leftTrim}{String} and \spadfunFrom{rightTrim}{String}.
}{
\spadpaste{trim
("\#\# ++ relax ++ \#\#", char "\#")}
}
\xtc{
Each of these functions takes a string and a second argument to specify
the characters to be discarded.
}{
\spadpaste{trim
("\#\# ++ relax ++ \#\#", other) \free{other}}
}
\xtc{
The second argument can be given
either as a single character or as a character class.
}{
\spadpaste{leftTrim ("\#\# ++ relax ++ \#\#", other) \free{other}}
}
\xtc{
}{
\spadpaste{rightTrim("\#\# ++ relax ++ \#\#", other) \free{other}}
}
\xtc{
Strings can be changed to upper case or lower case using the operations
\spadfunFrom{upperCase}{String}, \spadfunFromX{upperCase}{String},
\spadfunFrom{lowerCase}{String} and
\spadfunFromX{lowerCase}{String}.
}{

CHAPTER 3. HYPERDOC PAGES

\spadpaste{upperCase hello \free{hello}}
}
\xtc{
The versions with the exclamation mark
change the original string, while the others produce a copy.
}{
\spadpaste{lowerCase hello \free{hello}}
}
\xtc{
Some basic string matching is provided.
The function \spadfunFrom{prefix?}{String}
tests whether one string is an initial prefix of another.
}{
\spadpaste{prefix?("He", "Hello")}
}
\xtc{
}{
\spadpaste{prefix?("Her", "Hello")}
}
\xtc{
A similar function, \spadfunFrom{suffix?}{String}, tests for suffixes.
}{
\spadpaste{suffix?("", "Hello")}
}
\xtc{
}{
\spadpaste{suffix?("LO", "Hello")}
}
\xtc{
The function \spadfunFrom{substring?}{String} tests for a substring
given a starting
position.
}{
\spadpaste{substring?("ll", "Hello", 3)}
}
\xtc{
}{
\spadpaste{substring?("ll", "Hello", 4)}
}
\xtc{
A number of \spadfunFrom{position}{String} functions locate things in
strings. If the first argument to position is a string, then
\spad{position(s,t,i)} finds the location of \spad{s} as a substring
of \spad{t} starting the search at position \spad{i}.
}{
\spadpaste{n := position("nd", "underground",
1) \bound{n}}
}
\xtc{


If \spad{s} is not found, then \spad{0} is returned (\spad{minIndex(s)-1} in \spad{minIndex} in \spadtype{IndexedString}).

To search for a specific character or a member of a character class, a different first argument is used.

StringTable

⇒ “notitle” (TableXmpPage) 3.106 on page 1298

— strtbl.ht —

This domain provides a table type in which the keys are known to
be strings so special techniques can be used.
Other than performance, the type \spadtype{StringTable(S)} should
behave exactly the same way as \spadtype{Table(String,S)}.
See \downlink{'Table'}{TableXmpPage}\ignore{Table}
for general information about tables.
\showBlurb{StringTable}

\xtc{This creates a new table whose keys are strings.}
{\spadpaste{t: StringTable(Integer) := table() \bound{t}}}

3.105 symbol.ht
Symbol

— symbol.ht —
\begin{page}{SymbolXmpPage}{Symbol}
Symbols are one of the basic types manipulated by Axiom. The \spadtype{Symbol} domain provides ways to create symbols of many varieties.

\begin{verbatim}
xtc{\showBlurb{Symbol}}
  The simplest way to create a symbol is to `'single quote'` an identifier.
  }
  \spadpaste{X: Symbol := 'x \bound{X}}
  }
  xtnc{This gives the symbol even if \spad{x} has been assigned a value. If \spad{x} has not been assigned a value, then it is possible to omit the quote.}
  }
  \spadpaste{XX: Symbol := x}
  }
  xtnc{Declarations must be used when working with symbols, because otherwise the interpreter tries to place values in a more specialized type \spadtype{Variable}.}
  }
  \spadpaste{A := 'a}
  }
  xtnc{\spadpaste{B := b}
  }
  xtnc{The normal way of entering polynomials uses this fact.}
  }
  \spadpaste{x**2 + 1}
  }
  xtnc{Another convenient way to create symbols is to convert a string. This is useful when the name is to be constructed by a program.}
  }
  \spadpaste{"Hello"::Symbol}
  }
  xtnc{Sometimes it is necessary to generate new unique symbols, for example, to name constants of integration. The expression \spad{new()} generates a symbol starting with \spad{\%}.}
  }
  \spadpaste{new()\$Symbol}
  }
\end{verbatim}
Successive calls to \spadfunFrom{new}{Symbol} produce different symbols.
\spadpaste{new()}\$Symbol
A symbol can be adorned in various ways. The most basic thing is applying a symbol to a list of subscripts.
\spadpaste{X[i,j] \free{X}}

Somewhat less pretty is to attach subscripts, superscripts or arguments.
\spadpaste{U := subscript(u, [1,2,1,2]) \bound{U}}
\spadpaste{V := superscript(v, [n]) \bound{V}}
\spadpaste{P := argscript(p, [t]) \bound{P}}

It is possible to test whether a symbol has scripts using the \spadfunFrom{scripted?}{Symbol} test.
\spadpaste{scripted? U \free{U}}
\spadpaste{scripted? X \free{X}}

If a symbol is not scripted, then it may be converted to a string.
\spadpaste{string X \free{X}}
The basic parts can always be extracted using the \spadfunFrom{name}{Symbol} and \spadfunFrom{scripts}{Symbol} operations.
The most general form is obtained using the \spadfunFrom{script}{Symbol} operation. This operation takes an argument which is a list containing, in this order, lists of subscripts, superscripts, presuperscripts, presubscripts and arguments to a symbol.

\spadpaste{M := script(Mammoth, \[[i,j],[k,l],[0,1],[2],[u,v,w]\]) \bound{M}}

If trailing lists of scripts are omitted, they are assumed to be empty.

\spadpaste{N := script(Nut, \[[i,j],[k,l],[0,1]\]) \bound{N}}

Table

The \spadtype{Table} constructor provides a general structure for associative storage. This type provides hash tables in which data objects can be saved according to keys of any type. For a given table, specific types must be chosen for the keys and entries.

\xtc{
In this example the keys to the table are polynomials with integer coefficients. The entries in the table are strings.
}{
\spadpaste{t: Table(Polynomial Integer, String) := table() \bound{t}}
}
\xtc{
To save an entry in the table, the \spadfun{setelt}{Table} operation is used. This can be called directly, giving the table a key and an entry.
}{
\spadpaste{setelt(t, x**2 - 1, "Easy to factor") \bound{p1}\free{t}}
}
\xtc{
Alternatively, you can use assignment syntax.
}{
\spadpaste{t(x**3 + 1) := "Harder to factor" \bound{p2}\free{p1}}
}
\xtc{
}{
\spadpaste{t(x) := "The easiest to factor" \bound{p3}\free{p2}}
}
\xtc{
Entries are retrieved from the table by calling the \spadfun{elt}{Table} operation.
}{
\spadpaste{elt(t, x) \free{p3}}
}
This operation is called when a table is `'applied'` to a key using this or the following syntax.

\spadpaste{t.x \free{p3}}

Parentheses are used only for grouping. They are needed if the key is an infixed expression.

\spadpaste{t.(x**2 - 1) \free{p3}}

Note that the \spadfun{elt}{Table} operation is used only when the key is known to be in the table---otherwise an error is generated.

\spadpaste{t (x**3 + 1) \free{p3}}

You can get a list of all the keys to a table using the \spadfun{keys}{Table} operation.

\spadpaste{keys t \free{p3}}

If you wish to test whether a key is in a table, the \spadfun{search}{Table} operation is used. This operation returns either an entry or \spad{"failed"}.

\spadpaste{search(x, t) \free{p3}}

The return type is a union so the success of the search can be tested using \spad{case}.

\spadkey{case}

\spadpaste{search(x**2, t) case "failed" \free{p3}}

The \spadfun{remove}{Table} operation is used to delete values from a table.
If an entry exists under the key, then it is returned. Otherwise, \spadfunFromX{remove}{Table} returns \spad{“failed”}.

The number of key-entry pairs can be found using the \spadfunFrom{\#}{Table} operation.

Just as \spadfunFrom{keys}{Table} returns a list of keys to the table, a list of all the entries can be obtained using the \spadfunFrom{members}{Table} operation.

A number of useful operations take functions and map them on to the table to compute the result. Here we count the entries which have \spad{“Hard”} as a prefix.

Other table types are provided to support various needs.

\begin{itemize}
\item The \spadtype{AssociationList} gives a list with a table view. This allows new entries to be appended onto the front of the list to cover up old entries. This is useful when table entries need to be stacked or when frequent list traversals are required. See \downlink{`AssociationList'}{AssociationListXmpPage}\ignore{AssociationList} for more information.
\item The \spadtype{EqTable} gives tables in which keys are considered equal only when they are in fact the same instance of a structure. See \downlink{'EqTable'}{EqTableXmpPage}\ignore{EqTable} for more information.
\item The \spadtype{StringTable} should be used when the keys are known to be strings. See \downlink{'StringTable'}{StringTableXmpPage}\ignore{StringTable} for more information.
\end{itemize}
\item \spadtype{SparseTable} provides tables with default entries, so lookup never fails. The \spadtype{GeneralSparseTable} constructor can be used to make any table type behave this way. See \downlink{`SparseTable'}{SparseTableXmpPage} for more information.

\item \spadtype{KeyedAccessFile} allows values to be saved in a file, accessed as a table. See \downlink{`KeyedAccessFile'}{KeyedAccessFileXmpPage} for more information.

The domain \spadtype{TextFile} allows Axiom to read and write character data and exchange text with other programs. This type behaves in Axiom much like a \spadtype{File} of strings, with additional operations to cause new lines. We give an example of how to produce an upper case copy of a file.

\begin{verbatim}
This is the file from which we read the text.
}\[
\spadpaste{f1: TextFile := open("/etc/group", "input") \bound{f1}}
\]
\xtc{This is the file to which we read the text.}
}\[
\spadpaste{f2: TextFile := open("/tmp/MOTD", "output") \bound{f2}}
\]
\xtc{Entire lines are handled using the \spadfunFromX{readLine}{TextFile} and \spadfunFromX{writeLine}{TextFile} operations.}
\[
\spadpaste{l := readLine! f1 \free{f1}\bound{l}}
\]
\end{verbatim}
Use the \spadfunFrom{endOfFile?}{TextFile} operation to check if you have reached the end of the file.

\begin{spadsrc}
while not endOfFile? f1 repeat
  s := readLine! f1
  writeLine!(f2, upperCase s)
\end{spadsrc}

The file \spad{f1} is exhausted and should be closed.

\spadpaste{close! f1}  

It is sometimes useful to write lines a bit at a time. The \spadfunFromX{write}{TextFile} operation allows this.

\spadpaste{write!(f2, "-The-" )}

This ends the line. This is done in a machine-dependent manner.

\spadpaste{writeLine! f2}  

Finally, clean up.

\spadpaste{)system rm /tmp/MOTD}

Solving Equations

Axiom lets you solve equations of various types:

- **Solution of Systems of Linear Equations**
  Solve systems of linear equations.

- **Solution of a Single Polynomial Equation**
  Find roots of polynomials.

- **Solution of Systems of Polynomial Equations**
  Solve systems of polynomial equations.

- **Solution of Differential Equations**
  Closed form and series solutions of differential equations.
Linear Algebra

Introduction
Create and manipulate matrices. Work with the entries of a
matrix. Perform matrix arithmetic.

Creating Matrices
Create matrices from scratch and from other matrices.

Operations on Matrices
Algebraic manipulations with matrices. Compute the inverse,
determinant and trace of a matrix. Find the rank, nullspace
and row echelon form of a matrix.

Eigenvalues and Eigenvectors
How to compute eigenvalues and eigenvectors.

Additional Topics:
- Example: Determinant of a Hilbert Matrix
- Computing the Permanent
- Working with Vectors
- Working with Square Matrices
- Working with One-Dimensional Arrays
- Working with Two-Dimensional Arrays
- Conversion (Polynomials of Matrices)

Category Type

\begin{page}{CategoryType}{Category \textit{Type}}
\beginscroll
\textit{Type} is a primitive category in Axiom, one which is an ancestor of all Axiom categories.

\textit{Type} is the root of Axiom’s category hierarchy, a category with no properties (exported operations and attributes) of which all other categories are descendants.

Two important children of \textit{Type} are \texttt{SetCategory}, the category of all algebraic domains, and \texttt{Aggregate}, the category of all data structures.
\endscroll

\end{page}

Domain \texttt{Union(a:A,...,b:B)}

⇒ “Description” (LispFunctions) 3.71 on page 952
⇒ “Operations” (LispFunctions) 3.71 on page 952
⇒ “Exports” (LispFunctions) 3.71 on page 952

\begin{page}{DomainUnion}{Domain \textit{Union(a:A,...,b:B)}}
\beginscroll
\textit{Union} takes any number of "tag"-domain pairs of arguments:
Domain Constructor Union

— union.ht —
\{\text{Union}(a:A,b:B)\} denotes the class of objects which are either members of domain \{\text{A}\} or of domain \{\text{B}\}. The symbols \{\text{a}\} and \{\text{b}\} are called "tags" and are used to identify the two "branches" of the union. The \{\text{Union}\} constructor can take any number of arguments and has an alternate form without \{\text{em tags}\}. This tagged \{\text{Union}\} type is necessary, for example, to disambiguate two branches of a union where \{\text{A}\} and \{\text{B}\} denote the same type. \{\text{Union}\} is a primitive domain of Axiom which cannot be defined in the Axiom language.

\newline\tab{-2}\{\em B\}, a domain of category \spadtype{SetCategory}
\indent{0}\begin{tab}{2}\em{Returns:}\indent{17}\tab{-2}
the "union of \{\em A\} and \{\em B\}" as described below.
\indent{0}\begin{tab}{2}\em{Description:}\indent{15}\tab{0}
\{\em Union(A,B)\} denotes the class of objects which are
which are either members of domain \{\em A\} or of domain \{\em B\}.
The \{\em Union\} constructor can take any number of arguments and
has an alternate form using \{\em tags\}.
\{\em Union\} is a primitive domain of Axiom which cannot be
defined in the Axiom language.

Values of type \texttt{Segment} are automatically converted to type \texttt{UniversalSegment} when appropriate.

The operation \texttt{hasHi\{UniversalSegment\}} is used to test whether a segment has a \texttt{hi} end point.

All operations available on type \texttt{Segment} apply to \texttt{UniversalSegment}, with the proviso that expansions produce streams rather than lists. This is to accommodate infinite expansions.

For more information on related topics, see \texttt{Segment}, \texttt{SegmentBinding}, \texttt{List}, and \texttt{Stream}.

The domain constructor \texttt{UnivariatePolynomial} (abbreviated \texttt{UP}) creates domains of univariate polynomials in a specified variable. For example, the domain \texttt{UP(a1,POLY FRAC INT)} provides polynomials in the single variable \texttt{a1} whose coefficients are general polynomials with rational number coefficients.

\beginImportant
Axiom does not allow you to create types where \texttt{UnivariatePolynomial} is contained in the coefficient type of \texttt{Polynomial}. Therefore, \texttt{UP(x,POLY INT)} is legal but \texttt{POLY UP(x,INT)} is not.
\endImportant

\begin{verbatim}
\spad{p} := (3*x-1)**2 * (2*x + 8) \free{p}
\spad{q} := (1 - 6*x + 9*x**2)**2 \free{q}
\end{verbatim}
The usual arithmetic operations are available for univariate polynomials.

\begin{spad}{p**2 + p*q \free{p q}}
\end{spad}

\begin{xtc}{
The operation \spadfunFrom{leadingCoefficient}{UnivariatePolynomial} extracts the coefficient of the term of highest degree.
}
\begin{spad}{leadingCoefficient p \free{p}}
\end{spad}
\begin{xtc}{
The operation \spadfunFrom{degree}{UnivariatePolynomial} returns the degree of the polynomial. Since the polynomial has only one variable, the variable is not supplied to operations like \spadfunFrom{degree}{UnivariatePolynomial}.
}
\begin{spad}{degree p \free{p}}
\end{spad}
\begin{xtc}{
The reductum of the polynomial, the polynomial obtained by subtracting the term of highest order, is returned by \spadfunFrom{reductum}{UnivariatePolynomial}.
}
\begin{spad}{reductum p \free{p}}
\end{spad}
\begin{xtc}{
The operation \spadfunFrom{gcd}{UnivariatePolynomial} computes the greatest common divisor of two polynomials.
}
\begin{spad}{gcd(p,q) \free{p q}}
\end{spad}
\begin{xtc}{
The operation \spadfunFrom{lcm}{UnivariatePolynomial} computes the least common multiple.
}
\begin{spad}{lcm(p,q) \free{p q}}
\end{spad}
\begin{xtc}{
The operation \spadfunFrom{resultant}{UnivariatePolynomial} computes the resultant of two univariate polynomials. In the case of \spad{p} and \spad{q}, the resultant is \spad{0} because they share a common root.
}
\begin{spad}{resultant(p,q) \free{p q}}
\end{spad}
\begin{xtc}{
To compute the derivative of a univariate polynomial with respect to its variable, use \spadfunFrom{D}{UnivariatePolynomial}.
}
\begin{spad}{D(p) \free{p}}
\end{spad}
Univariate polynomials can also be used as if they were functions. To evaluate a univariate polynomial at some point, apply the polynomial to the point.

\spadpaste{p(2) \free{p}}

The same syntax is used for composing two univariate polynomials, i.e. substituting one polynomial for the variable in another. This substitutes \spad{q} for the variable in \spad{p}.

\spadpaste{p(q) \free{p \ q}}

This substitutes \spad{p} for the variable in \spad{q}.

\spadpaste{q(p) \free{p \ q}}

To obtain a list of coefficients of the polynomial, use \spadfunFrom{coefficients}{UnivariatePolynomial}.

\spadpaste{l := coefficients p \free{p}\bound{l}}

From this you can use \spadfunFrom{gcd}{UnivariatePolynomial} and \spadfunFrom{reduce}{List} to compute the content of the polynomial.

\spadpaste{reduce(gcd,l) \free{l}}

Alternatively (and more easily), you can just call \spadfunFrom{content}{UnivariatePolynomial}.

\spadpaste{content p \free{p}}

Note that the operation \spadfunFrom{coefficients}{UnivariatePolynomial} omits the zero coefficients from the list. Sometimes it is useful to convert a univariate polynomial to a vector whose \eth{\spad{i}} position contains the degree \spad{i-1} coefficient of the polynomial.

\spadpaste{ux := (x**4+2*x+3)::UP(x,INT) \bound{ux}}
To get a complete vector of coefficients, use the operation \spadfunFrom{vectorise}{UnivariatePolynomial}, which takes a univariate polynomial and an integer denoting the length of the desired vector.

\spadpaste{vectorise(ux,5) \free{ux}}

It is common to want to do something to every term of a polynomial, creating a new polynomial in the process.

This is a function for iterating across the terms of a polynomial, squaring each term.

\begin{spadsrc}
\texttt{\textbf{squareTerms}}(p) == \\
\texttt{reduce(\texttt{+},[t**2 for t in monomials p])}
\end{spadsrc}

Recall what \spad{p} looked like.

\spadpaste{p \free{p}}

We can demonstrate \userfun{squareTerms} on \spad{p}.

\spadpaste{\texttt{\textbf{squareTerms} p \free{p}\free{\textbf{\texttt{\textbf{\textbf{\textbf{\textbf{squareTerms}}}}}}}}}

When the coefficients of the univariate polynomial belong to a field, it is possible to compute quotients and remainders.

\spadpaste{(r,s) : \texttt{UP(a1,FRAC INT)} \bound{rdec}\bound{sdec}}
\spadpaste{r := a1**2 - 2/3 \free{rdec}\bound{r}}
\spadpaste{s := a1 + 4 \free{sdec}\bound{s}}
When the coefficients are rational numbers or rational expressions, the operation \( \text{quo}(\text{UnivariatePolynomial}) \) computes the quotient of two polynomials.
\[
\text{r \quad \text{quo} \quad s \quad \text{free}(\text{r \quad s})}
\]
The operation \( \text{rem}(\text{UnivariatePolynomial}) \) computes the remainder.
\[
\text{r \quad \text{rem} \quad s \quad \text{free}(\text{r \quad s})}
\]
The operation \( \text{divide}(\text{UnivariatePolynomial}) \) can be used to return a record of both components.
\[
\text{d := divide(r, s) \quad \text{free}(\text{r \quad s})\text{\quad bound(d)}}
\]
Now we check the arithmetic!
\[
\text{r \quad - \quad (d.quotient \times s \quad + \quad d.remainder) \quad \text{free}(\text{r \quad s \quad d})}
\]
It is also possible to integrate univariate polynomials when the coefficients belong to a field.
\[
\text{integrate \quad r \quad \text{free}(r)}
\]
\[
\text{integrate \quad s \quad \text{free}(s)}
\]
One application of univariate polynomials is to see expressions in terms of a specific variable.
\%
We start with a polynomial in \( \text{a1} \) whose coefficients are quotients of polynomials in \( \text{b1} \) and \( \text{b2} \).
\[
\text{t := a1**2 \quad - \quad a1/b2 \quad + \quad (b1**2-b1)/(b2+3) \quad \text{free}(\text{dec})\text{\quad bound(t)}}
\]
Since in this case we are not talking about using multivariate polynomials in only two variables, we use \( \text{spadtype(Polynomial)} \). We also use \( \text{spadtype(Fraction)} \) because we want fractions.
\[
\text{t := a1**2 \quad - \quad a1/b2 \quad + \quad (b1**2-b1)/(b2+3) \quad \text{free}(\text{dec})\text{\quad bound(t)}}
\]
We push all the variables into a single quotient of polynomials.

\spadpaste{u : FRAC POLY INT := t \bound{u}\free{t}}

Alternatively, we can view this as a polynomial in the variable $u$.

This is a \textit{mode-directed} conversion: you indicate as much of the structure as you care about and let Axiom decide on the full type and how to do the transformation.

\spadpaste{u :: UP(b1,?) \free{u}}

See \link{``Polynomial Factorization''}{ugProblemFactorPage} in Section 8.2 for a discussion of the factorization facilities in Axiom for univariate polynomials. For more information on related topics, see \link{``Polynomials''}{ugIntroVariablesPage}, \link{``Conversion''}{ugTypesConvertPage}, \link{`Polynomial'}{PolynomialXmpPage}, \link{`MultivariatePolynomial'}{MultivariatePolyXmpPage}, and \link{`DistributedMultivariatePoly'}{DistributedMultivariatePolyXmpPage}.

\indentrel{-3}\end{paste}\end{patch}
Skew or Ore polynomial rings provide a unified framework to compute with differential and difference equations.

In the following, let $A$ be an integral domain, equipped with two endomorphisms $\sigma$ and $\delta$ where:

- $\sigma: A \to A$ is an injective ring endomorphism
- $\delta: A \to A$, the pseudo-derivation with respect to $\sigma$, is an additive endomorphism with
  - $\delta(ab) = \sigma(a)\delta(b) + \delta(a)b$

for all $a, b$ in $A$

The skew polynomial ring $[\Delta; \sigma, \delta]$ is the ring of polynomials in $\delta$ with coefficients in $A$, with the usual addition, while the product is given by

$\delta a = \sigma(a)\delta + \delta(a)$ for $a$ in $A$

The two most important examples of skew polynomial rings are:

- $K(x)[D, 1, \delta]$ where $1$ is the identity on $K$ and $\delta$ is the usual derivative, is the ring of differential polynomials
- $\text{subscriptIt}(K)[n] [E, n, n \to n+1, 0]$ is the ring of linear recurrence operators with polynomial coefficients

The UnivariateSkewPolynomialCategory (OREPCAT) provides a unified framework for polynomial rings in a non-central indeterminate over some coefficient ring $R$. The commutation relations between the indeterminate $x$ and the coefficient $t$ is given by
where $\sigma$ is a ring endomorphism of $R$ and $\delta$ is a $\sigma$-derivation of $R$ which is an additive map from $R$ to $R$ such that

$$
\delta(rs) = \sigma(r) \delta(s) + \delta(r) s
$$

In case $\sigma$ is the identity map on $R$, a $\sigma$-derivation of $R$ is just called a derivation.

We start with a linear ordinary differential operator. First, we define the coefficient ring to be expressions in one variable $x$ with fractional coefficients:

$$
F := \text{EXPR}(\text{FRAC}(\text{INT}))
$$

Define $Dx$ to be a derivative $d/dx$:

Define a skew polynomial ring over $F$ with identity endomorphism as $\sigma$ and derivation $d/dx$ as $\delta$:

\begin{verbatim}
D0 := \text{OREUP}('d,F,1,Dx)
\end{verbatim}

\begin{verbatim}
u:D0 := (\text{operator} 'u)(x)
\end{verbatim}

\begin{verbatim}
d:D0 := 'd
\end{verbatim}

\begin{verbatim}
a:D0:=u^3*d^3+u^2*d^2+u*d+1
\end{verbatim}

\begin{verbatim}
3 3 2 2
u(x) d + u(x) d + u(x)d + 1
\end{verbatim}

\begin{verbatim}
b:D0:=(u+1)*d^2+2*d
\end{verbatim}

\begin{verbatim}
2
(u(x) + 1)d + 2d
\end{verbatim}

\begin{verbatim}
r:=\text{rightDivide}(a,b)
\end{verbatim}

\begin{verbatim}
3 , 3 2
3 - u(x) u (x) - u(x) + u(x)
\end{verbatim}
As a second example, we consider the so-called Weyl algebra.

Define the coefficient ring to be an ordinary polynomial over integers in one variable $t$

Define a skew polynomial ring over $R$ with identity map as $\sigma$ and derivation $d/dt$ as $\delta$. 

```plaintext
3 , 3 2
u(x) u(x) - u(x) + u(x)
d + -----------------------------
u(x) + 1 2 u(x) + 2u(x) + 1

r.quotient

3 , 3 2
u(x) 2u(x) u(x) + 3u(x) + u(x)
d + -----------------------------
u(x) + 2u(x) + 1

r.remainder

2
u(x) + 2u(x) + 1
```
The resulting algebra is then called a Weyl algebra:
\begin{verbatim}
W := OREUP('x,R,1,D)

t:W := 't

x:W := 'x
\end{verbatim}

Let
\begin{verbatim}
a:W:=(t-1)*x^4+(t^3+3*t+1)*x^2+2*t*x+t^3

(t - 1)x + (t + 3t + 1)x + 2t x + t
\end{verbatim}

\begin{verbatim}
b:W:=(6*t^4+2*t^2)*x^3+3*t^2*x^2

(6t + 2t )x + 3t x
\end{verbatim}

Then
\begin{verbatim}
a*b
(6t - 6t + 2t - 2t )x + (96t - 93t + 13t - 16t)x
+ 
(6t + 20t + 6t + 438t - 406t - 24)x
+ 
(48t + 15t + 152t + 61t + 603t - 532t - 36)x
+ 
(6t + 74t + 60t + 226t + 116t + 168t - 140)x
+ 
(3t + 6t + 12t + 18t + 6)x
\end{verbatim}

\begin{verbatim}
a^3
(t - 3t + 3t - 1)x + (3t - 6t + 12t - 15t + 3t + 3)x
+ 
(6t - 12t + 6t)x + (3t - 3t + 21t - 18t + 24t - 9t - 15t - 3)x
+ 
(3t - 3t - 3t + 2t - 18t - 24t - 9t - 15t - 3)x
\end{verbatim}
As a third example, we construct a difference operator algebra over
the ring of EXPR(INT) by using an automorphism $S$ defined by a
"shift" operation $S:EXPR(INT) \rightarrow EXPR(INT)$

\begin{verbatim}
s(e)(n) = e(n+1)
\end{verbatim}

and an $S$-derivation defined by $DF:EXPR(INT) \rightarrow EXPR(INT)$ as

\begin{verbatim}
DF(e)(n) = e(n+1)-e(n)
\end{verbatim}

Define $S$ to be a "shift" operator, which acts on expressions with
the discrete variable $n$:

\begin{verbatim}
S:EXPR(INT)->EXPR(INT):=e++->eval(e,[n],[n+1])
\end{verbatim}

Define $DF$ to be a "difference" operator, which acts on expressions
with a discrete variable $n$:

\begin{verbatim}
DF:EXPR(INT)->EXPR(INT):=e++->eval(e,[n],[n+1])-e
\end{verbatim}

Then define the difference operator algebra $D_0$:

\begin{verbatim}
D0:=OREUP('D,EXPR(INT),morphism S,DF)
\end{verbatim}
As a fourth example, we construct a skew polynomial ring by using an inner derivation \( \delta \) induced by a fixed \( y \) in \( R \):

First we should expose the constructor `SquareMatrix` so it is visible in the interpreter:

Define \( R \) to be the square matrix with integer entries:

Define \( \delta \) as the inner derivative:

Define \( S \) to be a skew polynomial determined by \( \sigma = 1 \) and \( \delta \) as an inner derivative:

--- vector.ht ---

\begin{page}{VectorXmpPage}{Vector}
\beginscroll

The \spadtype{Vector} domain is used for storing data in a one-dimensional indexed data structure. A vector is a homogeneous data structure in that all the components of the vector must belong to the same Axiom domain. Each vector has a fixed length specified by the user; vectors are not extensible. This domain is similar to the \spadtype{OneDimensionalArray} domain, except that when the components of a \spadtype{Vector} belong to a \spadtype{Ring}, arithmetic operations are provided. For more examples of operations that are defined for both \spadtype{Vector} and \spadtype{OneDimensionalArray}, see \downlink{"OneDimensionalArray"}{OneDimensionalArrayXmpPage}
\ignore{OneDimensionalArray}.

As with the \spadtype{OneDimensionalArray} domain, a \spadtype{Vector} can be created by calling the operation \spadfunFrom{new}{Vector}, its
components can be accessed by calling the operations \spadfun{elt}{Vector} and \spadfun{qelt}{Vector}, and its components can be reset by calling the operations \spadfun{setelt}{Vector} and \spadfun{qsetelt}{Vector}.

\xtc{ This creates a vector of integers of length \spad{5} all of whose components are \spad{12}. }{ \spadpaste{u : VECTOR INT := new(5,12) \bound{u}} } \xtc{ This is how you create a vector from a list of its components. }{ \spadpaste{v : VECTOR INT := vector([1,2,3,4,5]) \bound{v}} }

\xtc{ Indexing for vectors begins at \spad{1}. The last element has index equal to the length of the vector, which is computed by \spadop{\#}{Vector}. }{ \spadpaste{\#(v) \free{v}}} \xtc{ This is the standard way to use \spadfun{elt}{Vector} to extract an element. Functionally, it is the same as if you had typed \spad{elt(v,2)}. }{ \spadpaste{v.2 \free{v}}} \xtc{ This is the standard way to use \spadfun{setelt}{Vector} to change an element. It is the same as if you had typed \spad{setelt(v,3,99)}. }{ \spadpaste{v.3 := 99 \free{v}\bound{vdelta}}} \xtc{ Now look at \spad{v} to see the change. You can use \spadfun{qelt}{Vector} and \spadfun{qsetelt}{Vector} (instead of \spadfun{elt}{Vector} and \spadfun{setelt}{Vector}, respectively) but \{it only\} when you know that the index is within the valid range. }{ \spadpaste{v \free{vdelta}}} \xtc{ When the components belong to a \spadtype{Ring}, Axiom provides arithmetic operations for \spadtype{Vector}. These include left and right scalar multiplication. }{ \spadpaste{5 * v \free{vdelta}}} \xtc{ }{ }
VECTOR HT

\spadpaste{v * 7 \free{v\text{delta}}} \\
\xtc{} \\
\spadpaste{w : VECTOR INT := vector([2,3,4,5,6]) \bound{w}} \\
\xtc{}

Addition and subtraction are also available.

\spadpaste{v + w \free{v\text{delta } w}} \\
\xtc{}

Of course, when adding or subtracting, the two vectors must have the same length or an error message is displayed.

\spadpaste{v - w \free{v\text{delta } w}} \\
\xtc{}

For more information about other aggregate domains, see the following:
\downlink{`List'}{ListXmpPage}\ignore{List}, \downlink{`Matrix'}{MatrixXmpPage}\ignore{Matrix}, \downlink{`OneDimensionalArray'}{OneDimensionalArrayXmpPage}\ignore{OneDimensionalArray}, \downlink{`Set'}{SetXmpPage}\ignore{Set}, \downlink{`Table'}{TableXmpPage}\ignore{Table}, and \downlink{`TwoDimensionalArray'}{TwoDimensionalArrayXmpPage}\ignore{TwoDimensionalArray}.

Issue the system command \spadcmd{)show Vector} to display the full list of operations defined by \spadtype{Vector}.

WuWenTsunTriangularSet

— wutset.ht —

The \spadtype{WuWenTsunTriangularSet} domain constructor implements the characteristic set method of Wu Wen Tsun. This algorithm computes a list of triangular sets from a list of polynomials such that the algebraic variety defined by the given list of polynomials decomposes into the union of the regular-zero sets of the computed triangular sets. The constructor takes four arguments. The first one, \{\bf R\}, is the coefficient ring of the polynomials; it must belong to the category \spadtype{IntegralDomain}. The second one, \{\bf E\}, is the exponent monoid of the polynomials; it must belong to the category \spadtype{OrderedAbelianMonoidSup}. The third one, \{\bf V\}, is the ordered set of variables; it must belong to the category \spadtype{OrderedSet}. The last one is the polynomial ring; it must belong to the category \spadtype{RecursivePolynomialCategory(R,E,V)}. The abbreviation for \spadtype{WuWenTsunTriangularSet} is \spadtype{WUTSET}.

Let us illustrate the facilities by an example.

\xtc{
  Define the coefficient ring.
}
\spadpaste{R := Integer \bound{R}}
Define the list of variables,
}\{\spad{ls : List Symbol := [x,y,z,t] \bound{ls}}
\}
\xtc{and make it an ordered set;}
}\{\spad{V := OVAR(ls) \free{ls} \bound{V}}
\}
\xtc{then define the exponent monoid.}
}\{\spad{E := IndexedExponents V \free{V} \bound{E}}
\}
\xtc{Define the polynomial ring.}
}\{\spad{P := NSMP(R, V) \free{R} \free{V} \bound{P}}
\}
\xtc{Let the variables be polynomial.}
}\{\spad{x: P := 'x \free{P} \bound{x}}
\}
\xtc{y: P := 'y \free{P} \bound{y}}
\}
\xtc{z: P := 'z \free{P} \bound{z}}
\}
\xtc{t: P := 't \free{P} \bound{t}}
\}
\xtc{Now call the \spad{WuWenTsunTriangularSet} domain constructor.}
}\{\spad{T := WUTSET(R,E,V,P) \free{R} \free{E} \free{V} \free{P} \bound{T}}
\}
\xtc{Define a polynomial system.}
}\{\spad{p1 := x ** 31 - x ** 6 - x - y \free{x} \free{y} \bound{p1}}
\}
\xtc{p2 := x ** 8 - z \free{x} \free{z} \bound{p2}}
CHAPTER 3. HYPERDOC PAGES

\spadpaste{p3 := x ** 10 - t \free{x} \free{t} \bound{p3}}

\spadpaste{lp := [p1, p2, p3] \free{p1} \free{p2} \free{p3} \bound{lp}}

Compute a characteristic set of the system.

\spadpaste{characteristicSet(lp)$T \free{lp} \free{T}}

Solve the system.

\spadpaste{zeroSetSplit(lp)$T \free{lp} \free{T}}

The \spadtype{RegularTriangularSet} and \spadtype{SquareFreeRegularTriangularSet} domain constructors, and the \spadtype{LazardSetSolvingPackage}, \spadtype{SquareFreeRegularTriangularSet} and \spadtype{ZeroDimensionalSolvePackage} package constructors also provide operations to compute triangular decompositions of algebraic varieties. These five constructor use a special kind of characteristic sets, called regular triangular sets. These special characteristic sets have better properties than the general ones. Regular triangular sets and their related concepts are presented in the paper "On the Theories of Triangular sets" By P. Aubry, D. Lazard and M. Moreno Maza (to appear in the Journal of Symbolic Computation). The decomposition algorithm (due to the third author) available in the four above constructors provide generally better timings than the characteristic set method. In fact, the \spadtype{WUTSET} constructor remains interesting for the purpose of manipulating characteristic sets whereas the other constructors are more convenient for solving polynomial systems.

Note that the way of understanding triangular decompositions is detailed in the example of the \spadtype{RegularTriangularSet} constructor.

**XPolynomial**

— **xpoly.ht** —

The \spadtype{XPolynomial} domain constructor implements multivariate polynomials whose set of variables is \spadtype{Symbol}. These variables do not commute. The only parameter of this constructor is the coefficient ring which may be non-commutative. However, coefficients and variables commute. The representation of the polynomials is recursive. The abbreviation for \spadtype{XPolynomial} is \spadtype{XPOLY}.

Other constructors like \spadtype{XPolynomialRing}, \spadtype{XRecursivePolynomial}, \spadtype{XDistributedPolynomial}, \spadtype{LiePolynomial} and \spadtype{XPBWPolynomial} implement multivariate polynomials in non-commutative variables.

We illustrate now some of the facilities of the \spadtype{XPOLY} domain constructor.

\xtc{
Define a polynomial ring over the integers.}

Type: XPolynomial Integer
The \spadtype{XPolynomialRing} domain constructor implements generalized polynomials with coefficients from an arbitrary \spadtype{Ring} (not necessarily commutative) and whose exponents are words from an arbitrary \spadtype{OrderedMonoid} (not necessarily commutative too).
Thus these polynomials are (finite) linear combinations of words.

This constructor takes two arguments. The first one is a \texttt{Ring} and the second is an \texttt{OrderedMonoid}. The abbreviation for \texttt{XPolynomialRing} is \texttt{XPR}.

Other constructors like \texttt{XPolynomial}, \texttt{XRecursivePolynomial}, \texttt{XDistributedPolynomial}, \texttt{LiePolynomial} and \texttt{XPBWPolynomial} implement multivariate polynomials in non-commutative variables.

We illustrate now some of the facilities of the \texttt{XPR} domain constructor.

\begin{verbatim}
xtc{Define the free ordered monoid generated by the symbols.}
\{\spad{Word := OrderedFreeMonoid(Symbol) \bound{Word}}\}

xtc{Define the linear combinations of these words with integer coefficients.}
\{\spad{poly := XPR(Integer,Word) \free{Word} \bound{poly}}\}

xtc{Then we define a first element from \texttt{poly}.}
\{\spad{p:poly := 2 * x - 3 * y + 1 \free{poly} \bound{p}}\}

xtc{And a second one.}
\{\spad{q:poly := 2 * x + 1 \free{poly} \bound{q}}\}

xtc{We compute their sum,}
\{\spad{p + q \free{p}\free{q} }\}
\end{verbatim}
their product,
}
\spadpaste{p \times q \free{p}\free{q} \}

and see that variables do not commute.
}
\spadpaste{(p + q)^2 - p^2 - q^2 - 2p \times q \free{p}\free{q} \}

Now we define a ring of square matrices,
}
\spadpaste{M := \text{SquareMatrix}(2,\text{Fraction Integer}) \ \text{bound}(M)\}

and the linear combinations of words with these matrices as coefficients.
}
\spadpaste{\text{poly1} := \text{XPR}(M,\text{Word}) \free{\text{Word}} \free{M} \ \text{bound}(\text{poly1})\}

Define a first matrix,
}
\spadpaste{m_1 := \text{matrix} \[[i \times j^2 \text{ for } i \text{ in } 1..2] \text{ for } j \in 1..2\]
\free{M} \ \text{bound}(m_1)\}

a second one,
}
\spadpaste{m_2 := m_1 - 5/4 \free{M} \free{m_1} \ \text{bound}(m_2)\}

and a third one.
}
\spadpaste{m_3 := m_2^2 \free{M} \free{m_2} \ \text{bound}(m_3)\}

Define a polynomial,
}
\spadpaste{pm := m_1 \times x + m_2 \times y + m_3 \times z - 2/3 \free{\text{poly1}}\}
\free{m1} \free{m2} \free{m3} \bound{pm}

\xtc{
a second one,
}
\spadpaste{qm:poly1 := pm - m1*x \free{m1} \free{pm} \bound{qm}}

\xtc{
and the following power.
}
\spadpaste{qm**3 \bound{qm}}

ZeroDimensionalSolvePackage

--- zdsolve.ht ---

\begin{page}{ZeroDimSolvePkgXmpPage}{ZeroDimensionalSolvePackage}
\beginscroll
The \spadtype{ZeroDimensionalSolvePackage} package constructor provides operations for computing symbolically the complex or real roots of zero-dimensional algebraic systems.

The package provides \bf{no} multiplicity information (i.e. some returned roots may be double or higher) but only distinct roots are returned.

Complex roots are given by means of univariate representations of irreducible regular chains. These representations are computed by the \axiomOpFrom{univariateSolve}{ZeroDimensionalSolvePackage} operation (by calling the \spadtype{InternalRationalUnivariateRepresentationPackage} package constructor which does the job).

Real roots are given by means of tuples of coordinates lying in the \spadtype{RealClosure} of the coefficient ring. They are computed by the \axiomOpFrom{realSolve}{ZeroDimensionalSolvePackage} and \axiomOpFrom{positiveSolve}{ZeroDimensionalSolvePackage} operations. The former computes all the solutions of the input system with real coordinates whereas the later concentrate on the solutions with (strictly) positive coordinates. In both cases, the computations are performed by the \spadtype{RealClosure} constructor.

Both computations of complex roots and real roots rely on triangular decompositions. These decompositions can be computed in two different ways. First, by applying the \axiomOpFrom{zeroSetSplit}{RegularTriangularSet} operation from the \spadtype{REGSET} domain constructor. In that case, no Groebner bases are computed. This strategy is used by default. Secondly, by applying the \axiomOpFrom{zeroSetSplit}{LexTriangularPackage} from \spadtype{LEXTRIPK}. To use this later strategy with the operations \axiomOpFrom{univariateSolve}{ZeroDimensionalSolvePackage}, \axiomOpFrom{realSolve}{ZeroDimensionalSolvePackage} and \axiomOpFrom{positiveSolve}{ZeroDimensionalSolvePackage} one just needs to use an extra boolean argument.

Note that the way of understanding triangular decompositions is detailed in the example of the \spadtype{RegularTriangularSet} constructor.
The \spadtype{ZeroDimensionalSolvePackage} constructor takes three arguments. The first one \{\bf R\} is the coefficient ring; it must belong to the categories \spadtype{OrderedRing}, \spadtype{EuclideanDomain}, \spadtype{CharacteristicZero} and \spadtype{RealConstant}. This means essentially that \{\bf R\} is \spadtype{Integer} or \spadtype{Fraction(Integer)}. The second argument \{\bf ls\} is the list of variables involved in the systems to solve. The third one MUST BE \{\bf concat(ls,s)\} where \{\bf s\} is an additional symbol used for the univariate representations. The abbreviation for \spadtype{ZeroDimensionalSolvePackage} is \spadtype{ZDSOLVE}.

We illustrate now how to use the constructor \spadtype{ZDSOLVE} by two examples: the \{\em Arnborg and Lazard\} system and the \{\em L-3\} system (Aubry and Moreno Maza). Note that the use of this package is also demonstrated in the example of the \spadtype{LexTriangularPackage} constructor.

\xtc{Define the coefficient ring.}{
\spadpaste{R := Integer \bound{R}}
}

\xtc{Define the lists of variables:}{
\spadpaste{ls : List Symbol := \[x,y,z,t\] \bound{ls}}
}

\xtc{and:}{
\spadpaste{ls2 : List Symbol := \[x,y,z,t,new()$Symbol\] \bound{ls2}}
}

\xtc{Call the package:}{
\spadpaste{pack := ZDSOLVE(R,ls,ls2) \free{ls} \free{ls2} \free{R} \bound{pack}}
}

\xtc{Define a polynomial system (Arnborg-Lazard)}{\}
\spadpaste{p1 := x**2*y*z + x*y**2*z + x*y*z**2 + x*y*z + x*y + x*z + y*z \bound{p1}}
CHAPTER 3. HYPERDOC PAGES

\begin{verbatim}
p2 := x**2*y**2*z + x*y**2*z**2 + x**2*y*z + x*y*z + y*z + x + z \bound{p2}

p3 := x**2*y**2*z**2 + x**2*y**2*z + x*y**2*z + x*y*z + x*z + z + 1 \bound{p3}

lp := [p1, p2, p3] \free{p1} \free{p2} \free{p3} \bound{lp}
\end{verbatim}

Note that these polynomials do not involve the variable $t$; we will use it in the second example.

First compute a decomposition into regular chains (i.e. regular triangular sets).

\begin{verbatim}
triangSolve(lp)$pack \free{lp} \free{pack}
\end{verbatim}

We can see easily from this decomposition (consisting of a single regular chain) that the input system has 20 complex roots.

Then we compute a univariate representation of this regular chain.

\begin{verbatim}
univariateSolve(lp)$pack \free{lp} \free{pack}
\end{verbatim}

We see that the zeros of our regular chain are split into three components. This is due to the use of univariate polynomial factorization.

Each of these components consist of two parts. The first one is an irreducible univariate polynomial $p(\%A)$ which defines a simple algebraic extension of the field of fractions of $R$. The second one consists of multivariate polynomials $\{\text{pol1}(x,\%A)\}$, $\{\text{pol2}(y,\%A)\}$ and $\{\text{pol3}(z,\%A)\}$. Each of these polynomials involve two variables: one is an indeterminate $x$, $y$ or $z$ of the input system $lp$ and the other is $\%A$ which represents any root of $p(\%A)$. Recall that this $\%A$ is the last element of the third parameter of \spadtype{ZDSOLVE}. Thus any complex root $\%A$ of $p(\%A)$ leads to a solution of the input system $lp$ by replacing $\%A$ by this $\%A$ in $\{\text{pol1}(x,\%A)\}$, $\{\text{pol2}(y,\%A)\}$ and $\{\text{pol3}(z,\%A)\}$. Note that the polynomials $\{\text{pol1}(x,\%A)\}$, $\{\text{pol2}(y,\%A)\}$ and $\{\text{pol3}(z,\%A)\}$
have degree one w.r.t. \textit{bf x}, \textit{bf y} or \textit{bf z} respectively. This is always the case for all univariate representations. Hence the operation \textit{bf univariateSolve} replaces a system of multivariate polynomials by a list of univariate polynomials, what justifies its name. Another example of univariate representations illustrates the \spadtype{LexTriangularPackage} package constructor.

\xtc{
We now compute the solutions with real coordinates:
}\{
\spadpaste{lr := realSolve(lp)$pack \free{lp} \free{pack} \bound{lr}}
}

\xtc{
The number of real solutions for the input system is:
}\{
\spadpaste{\# lr \free{lr}}
}

Each of these real solutions is given by a list of elements in \spadtype{RealClosure(R)}. In these 8 lists, the first element is a value of \textit{bf z}, the second of \textit{bf y} and the last of \textit{bf x}. This is logical since by setting the list of variables of the package to \{x,y,z,t\} we mean that the elimination ordering on the variables is \{bf t < z < y < x \}. Note that each system treated by the \spadtype{ZDSOLVE} package constructor needs only to be zero-dimensional w.r.t. the variables involved in the system it self and not necessarily w.r.t. all the variables used to define the package.

\xtc{
We can approximate these real numbers as follows. This computation takes between 30 sec. and 5 min, depending on your machine.
}\{
\spadpaste{[[approximate(r,1/1000000) for r in point] for point in lr] \free{lr}}
}

\xtc{
We can also concentrate on the solutions with real (strictly) positive coordinates:
}\{
\spadpaste{lpr := positiveSolve(lp)$pack \free{lp} \free{pack} \bound{lpr}}
}

Thus we have checked that the input system has no solution with strictly positive coordinates.
Let us define another polynomial system (L-3).
\[ f_0 := x^{3} + y + z + t - 1 \]
\[ f_1 := x + y^{3} + z + t - 1 \]
\[ f_2 := x + y + z^{3} + t - 1 \]
\[ f_3 := x + y + z + t^{3} - 1 \]
\[ \textit{lf} := [f_0, f_1, f_2, f_3] \]

First compute a decomposition into regular chains (i.e. regular triangular sets).
\[ \textit{lts} := \text{triangSolve}(\textit{lf}) \]

Then we compute a univariate representation.
\[ \text{univariateSolve}(\textit{lf}) \]

Note that this computation is made from the input system \( \text{lf} \). However it is possible to reuse a pre-computed regular chain as follows:
\[ \textit{ts} := \text{triangSolve}(\textit{lf}) \]

\[ \text{univariateSolve}(\textit{ts}) \]
We compute now the full set of points with real coordinates:
\spadpaste{realSolve(ts)$pack \free{ts} \free{pack}}
\xtc{We compute now the full set of points with real coordinates:}{\spadpaste{lr2 := realSolve(lf)$pack \free{lf} \free{pack} \bound{lr2}}}
\xtc{The number of real solutions for the input system is:}{\spadpaste{\#lr2 \free{lr2}}}
Another example of computation of real solutions illustrates the \spadtype{LexTriangularPackage} package constructor.
\spadpaste{R := Integer \bound{R}}
\spad{R := Integer}
\begin{verbatim}
(1) Integer
Type: Domain
\end{verbatim}
\begin{verbatim}
(1) Integer
Type: Domain
\end{verbatim}
\xtc{We concentrate now on the solutions with real (strictly) positive coordinates:}{\spadpaste{lpr2 := positiveSolve(lf)$pack \free{lf} \free{pack} \bound{lpr2}}}
\xtc{Finally, we approximate the coordinates of this point with 20 exact digits:}{\spadpaste{[approximate(r,1/10**21)::Float for r in lpr2.1] \free{lpr2}}}

\end{verbatim}
\indentrel{-3}\end{paste}\end{patch}
The elements \( v_1, \ldots, v_n \) of a module \( M \) over a ring \( R \) are said to be \( \text{it linearly dependent over } R \) if there exist \( c_1, \ldots, c_n \) in \( R \), not all \( 0 \), such that \( c_1 v_1 + \ldots c_n v_n = 0 \). If such \( c_i \)'s exist, they form what is called a \( \text{it linear dependence relation over } R \) for the \( v_i \)'s.

The package \spadtype{IntegerLinearDependence} provides functions for testing whether some elements of a module over the integers are linearly dependent over the integers, and to find the linear dependence relations, if any.

\begin{verbatim}
\end{verbatim}

\begin{verbatim}
\end{verbatim}

Consider the domain of two by two square matrices with integer entries.

\begin{verbatim}
\end{verbatim}

Now create three such matrices.
\spadpaste{m1: M := squareMatrix matrix \[
[1, 2],
[0, -1]
\]
\free(M)\bound{m1}}}

\xtc{
}\spadpaste{m2: M := squareMatrix matrix \[
[2, 3],
[1, -2]
\]
\free(M)\bound{m2}}}

\xtc{
}\spadpaste{m3: M := squareMatrix matrix \[
[3, 4],
[2, -3]
\]
\free(M)\bound{m3}}}

This tells you whether \spad{m1}, \spad{m2} and \spad{m3} are linearly dependent over the integers.

\spadpaste{linearlyDependentOverZ? vector \[m1, m2, m3\] \free{m1 m2 m3}}}

Since they are linearly dependent, you can ask for the dependence relation.

\spadpaste{c := linearDependenceOverZ vector \[m1, m2, m3\] \free{m1 m2 m3}\bound{c}}}

This means that the following linear combination should be \spad{0}.

\spadpaste{c.1 * m1 + c.2 * m2 + c.3 * m3 \free{c m1 m2 m3}}}

When a given set of elements are linearly dependent over \spad{R}, this also means that at least one of them can be rewritten as a linear combination of the others with coefficients in the quotient field of \spad{R}.

To express a given element in terms of other elements, use the operation \spadfunFrom{solveLinearlyOverQ}{IntegerLinearDependence}.

\spadpaste{solveLinearlyOverQ(vector \[m1, m3\], m2) \free{m1 m2 m3}}}

New polynomial domains and algorithms

Univariate polynomial factorisation over the integers has been enhanced by updates to the \spadtype{GaloisGroupFactorizer} type and friends from Frederic Lehobey (Frederic.Lehobey@lifl.fr, University of Lille I, France).

The package constructor \spadtype{PseudoRemainderSequence} provides efficient algorithms by Lionel Ducos (Lionel.Ducos@mathlabo.univ-poitiers.fr, University of Poitiers, France) for computing sub-resultants. This leads to a speed up in many places in Axiom where sub-resultants are computed (polynomial system solving, algebraic factorization, integration).

Based on this package, the domain constructor \spadtype{NewSparseUnivariatePolynomial} extends the constructor \spadtype{SparseUnivariatePolynomial}. In a similar way, the \spadtype{NewSparseMultivariatePolynomial} extends the constructor \spadtype{SparseUnivariatePolynomial}; it also provides some additional operations related to polynomial system solving by means of triangular sets.

Several domain constructors implement regular triangular sets (or regular chains). Among them \spadtype{RegularTriangularSet} and \spadtype{SquareFreeRegularTriangularSet}. They also implement an algorithm by Marc Moreno Maza (marc@nag.co.uk, NAG) for computing triangular decompositions of polynomial systems. This method is refined in the package \spadtype{LazardSetSolvingPackage} in order to produce decompositions by means of Lazard triangular sets. For the case of polynomial systems with finitely many solutions, these decompositions can also be computed by the package \spadtype{LexTriangularPackage}.

The domain constructor \spadtype{RealClosure} by Renaud Rioboo (Renaud.Rioboo@lip6.fr, University of Paris 6, France) provides the real closure of an ordered field. The implementation is based on interval arithmetic. Moreover, the design of this constructor and its related packages allows an easy use of other codings for real algebraic numbers.

Based on triangular decompositions and the \spadtype{RealClosure} constructor, the package \spadtype{ZeroDimensionalSolvePackage} provides operations for computing symbolically the real or complex
roots of polynomial systems with finitely many solutions.

Polynomial arithmetic with non-commutative variables has been improved too by a contribution of Michel Petitot (Michel.Petitot@lifl.fr, University of Lille I, France). The domain constructors \spadtype{XRecursivePolynomial} and \spadtype{XDistributedPolynomial} provide recursive and distributed representations for these polynomials. They are the non-commutative equivalents for the \spadtype{SparseMultivariatePolynomial} and \spadtype{DistributedMultivariatePoly} constructors. The constructor \spadtype{LiePolynomial} implement Lie polynomials in the Lyndon basis. The constructor \spadtype{XPBWPolynomial} manage polynomials with non-commutative variables in the \texttt{Poincar'e}-Birkhoff-Witt basis from the Lyndon basis. This allows to compute in the Lie Group associated with a free nilpotent Lie algebra by using the \spadtype{LieExponentials} domain constructor.

Chapter 6

Users Guide Chapter 1
(ug01.ht)

An Overview of Axiom

Welcome to the Axiom environment for interactive computation and problem solving. Consider this chapter a brief, whirlwind tour of the
Axiom world. We introduce you to Axiom's graphics and the Axiom language. Then we give a sampling of the large variety of facilities in the Axiom system, ranging from the various kinds of numbers, to data types (like lists, arrays, and sets) and mathematical objects (like matrices, integrals, and differential equations). We conclude with the discussion of system commands and an interactive ‘undo.’

Before embarking on the tour, we need to brief those readers working interactively with Axiom on some details. Others can skip right immediately to \downlink{‘Typographic Conventions’}{ugIntroTypoPage} in Section 1.2\ignore{ugIntroTypo}.

— ug01.ht —

\begin{page}{ugIntroStartPage}{1.1. Starting Up and Winding Down}
You need to know how to start the Axiom system and how to stop it. We assume that Axiom has been correctly installed on your machine (as described in another Axiom document).

To begin using Axiom, issue the command {\bf axiom} to the operating system shell. There is a brief pause, some start-up messages, and then one or more windows appear.

If you are not running Axiom under the X Window System, there is only one window (the console). At the lower left of the screen there is a prompt that looks like

\verbatim
(1) ->
@endverbatim

When you want to enter input to Axiom, you do so on the same line after the prompt. The ‘‘1’’ in ‘‘(1)’’ is the computation step number and is incremented after you enter Axiom statements. Note, however, that a system command such as \spad{)clear all} may change the step number in other ways. We talk about step numbers more when we discuss system commands and the workspace history facility.

If you are running Axiom under the X Window System, there may be two windows: the console window (as just described) and the Hyperdoc main menu. Hyperdoc is a multiple-window hypertext system that lets you view Axiom documentation and examples on-line, execute Axiom expressions, and generate graphics. If you are in a graphical windowing environment, it is usually started automatically when Axiom begins. If it is not running, issue \spad{)hd} to start it. We discuss the basics of Hyperdoc in \downlink{``Using Hyperdoc''}{ugHyperPage} in Chapter 3\ignore{ugHyper}.

To interrupt an Axiom computation, hold down the \texttt{\{\bf Ctrl\}\{\bf Ctrl\}} (control) key and press \texttt{\{\bf c\}}. This brings you back to the Axiom prompt.

\beginImportant
To exit from Axiom, move to the console window, type \spad{)quit} at the input prompt and press the \texttt{\{\bf Enter\}} key. You will probably be prompted with the following message: \centerline{Please enter \{\bf y\} or \{\bf yes\} if you really want to leave the \}} \centerline{interactive environment and return to the operating system} You should respond \{\bf yes\}, for example, to exit Axiom.
@endImportant

We are purposely vague in describing exactly what your screen looks
like or what messages Axiom displays. Axiom runs on a number of
different machines, operating systems and window environments, and
these differences all affect the physical look of the system. You can
also change the way that Axiom behaves via \spadgloss{system commands}
described later in this chapter and in
\downlink{"Axiom System Commands"}{ugSysCmdPage} in Appendix B
\ignore{ugSysCmd}. System commands are special
commands, like \spadcmd{\()set\)}, that begin with a closing parenthesis
and are used to change your environment. For example, you can set a
system variable so that you are not prompted for confirmation when you
want to leave Axiom.

\beginmenu
  \menu{\ref{1.1.1. Clef{}}}{ugAvailCLEFPage}
\endmenu
\endscroll
\autobuttons
\endpage

Clef

If you are using Axiom under the X Window System, the Clef command line editor is probably available and installed. With this editor you can recall previous lines with the up and down arrow keys. To move forward and backward on a line, use the right and left arrows. You can use the Insert key to toggle insert mode on or off. When you are in insert mode, the cursor appears as a large block and if you type anything, the characters are inserted into the line without deleting the previous ones.

If you press the Home key, the cursor moves to the beginning of the line and if you press the End key, the cursor moves to the end of the line. Pressing Ctrl-End deletes all the text from the cursor to the end of the line.

Clef also provides Axiom operation name completion for a limited set of operations. If you enter a few letters and then press the Tab key, Clef tries to use those letters as the prefix of an Axiom operation name. If a name appears and it is not what you want, press Tab again to see another name.

You are ready to begin your journey into the world of Axiom. Proceed to the first step.
\begin{scroll}{ugIntroIntroPage}{3. Typographic Conventions}

In this book we have followed these typographical conventions:
\begin{itemize}
\item Categories, domains and packages are displayed in a sans-serif typeface:
\begin{itemize}
\item \texttt{Ring}, \texttt{Integer}, \texttt{DiophantineSolutionPackage}.
\end{itemize}
\item Prefix operators, infix operators, and punctuation symbols in the Axiom language are displayed in the text like this:
\begin{itemize}
\item \texttt{+}, \texttt{\$}, \texttt{+->}.
\end{itemize}
\item Axiom expressions or expression fragments are displayed in a monospace typeface:
\begin{itemize}
\item \texttt{inc(x) == x + 1}.
\end{itemize}
\item For clarity of presentation, \TeX{} is often used to format expressions:
\begin{itemize}
\item $g(x) = x^2 + 1$.
\end{itemize}
\end{itemize}
\end{scroll}

1.3. The Axiom Language

The Axiom language is a rich language for performing interactive computations and for building components of the Axiom library. Here we present only some basic aspects of the language that you need to know for the rest of this chapter. Our discussion here is intentionally informal, with details unveiled on an 'as needed'
Arithmetic Expressions

For arithmetic expressions, use the \spadop{+} and \spadop{-} \spadgloss{operators} as in mathematics. Use \spadop{*} for multiplication, and \spadop{**} for exponentiation. To create a fraction, use \spadop{/}. When an expression contains several operators, those of highest \spadgloss{precedence} are evaluated first. For arithmetic operators, \spadop{**} has highest precedence, \spadop{*} and \spadop{/} have the next highest precedence, and \spadop{+} and \spadop{-} have the lowest precedence.

\xtc{Axiom puts implicit parentheses around operations of higher precedence, and groups those of equal precedence from left to right.}
\spadpaste{1 + 2 - 3 / 4 * 3 ** 2 - 1}
\xtc{The above expression is equivalent to this.}
\spadpaste{1 + 2 - 3 / 4 * 3 ** 2 - 1}
If an expression contains subexpressions enclosed in parentheses, the parenthesized subexpressions are evaluated first (from left to right, from inside out).

```

Everything in Axiom has a type. The type determines what operations you can perform on an object and how the object can be used.

An entire chapter of this book (in Chapter 2) is dedicated to the interactive use of types. Several of the final chapters discuss how types are built and how they are organized in the Axiom library.
Positive integers are given type \texttt{PositiveInteger}.

\begin{verbatim}
(1) 8
Type: PositiveInteger
\end{verbatim}

Negative ones are given type \texttt{Integer}.
This fine distinction is helpful to the Axiom interpreter.

\begin{verbatim}
(2) -8
\end{verbatim}

Here a positive integer exponent gives a polynomial result.

\begin{verbatim}
(3) x**8
\end{verbatim}

Here a negative integer exponent produces a fraction.

Symbols, Variables, Assignments, and Declarations

A symbol is a literal used for the input of things like the "variables" in polynomials and power series.

We use the three symbols \axiom{x}, \axiom{y}, and \axiom{z} in entering this polynomial.

\spadpaste{(x - y*z)**2}

A symbol has a name beginning with an uppercase or lowercase alphabetic character, \axiom{\%}, or \axiom{!}. Successive characters (if any) can be any of the above, digits, or \axiom{?}. Case is distinguished: the symbol \axiom{points} is different from the symbol \axiom{Points}.

A symbol can also be used in Axiom as a variable. A variable refers to a value. To assign a value to a variable, the operator \axiom{:=} is used. Axiom actually has two forms of assignment: immediate assignment, as discussed here, and delayed assignment. See Immediate and Delayed Assignments in Section 5.1 for details.

A variable initially has no restrictions on the kinds of values to which it can refer.

\spadpaste{x := 4}

\spadpaste{x := z + 3/5}

To restrict the types of objects that can be assigned to a variable,
use a \spadgloss{declaration}

\spadpaste{y : Integer \boundary{y}}

\xtc{
After a variable is declared to be of some type, only values
of that type can be assigned to that variable.
}
\spadpaste{y := 89 \boundary{y1} \free{y}}

\xtc{
The declaration for \axiom{y} forces values assigned to \axiom{y} to
be converted to integer values.
}
\spadpaste{y := \sin \\pi}

\xtc{
If no such conversion is possible, Axiom refuses to assign a value to \axiom{y}.
}
\spadpaste{y := 2/3}

\xtc{
A type declaration can also be given together with an assignment. The declaration can assist Axiom in choosing the correct
operations to apply.
}
\spadpaste{f : Float := 2/3}

Any number of expressions can be given on input line. Just separate them by semicolons. Only the result of evaluating the last expression is displayed.

\xtc{
These two expressions have the same effect as the previous single expression.
}
\spadpaste{f : Float; f := 2/3 \boundary{f}}

The type of a symbol is either \axiomType{Symbol} or \axiomType{Variable({\it name})} where \{\it name\} is the name of the symbol.

\xtc{
By default, the interpreter gives this symbol the type \axiomType{Variable(q)}.
}
\spadpaste{q}
When multiple symbols are involved, \axiomType{Symbol} is used.

{\spadpaste{[q, r]}}

What happens when you try to use a symbol that is the name of a variable?

{\spadpaste{f \free{fff}}}

Use a single quote (\axiomSyntax{'}) before the name to get the symbol.

{\spadpaste{'f}}

Quoting a name creates a symbol by preventing evaluation of the name as a variable. Experience will teach you when you are most likely going to need to use a quote. We try to point out the location of such trouble spots.

{(x - y*z)**2}

Conversion

⇒ “notitle” (ugTypesConvertPage) 7 on page 1671
Objects of one type can usually be "converted" to objects of several other types. To use the `::` infix operator. Conversion is discussed in detail in Section 2.7. For example, to display an object, it is necessary to convert the object to type `OutputForm`.

This produces a polynomial with rational number coefficients.

Create a quotient of polynomials with integer coefficients by using `::`.

Some conversions can be performed automatically when Axiom tries to evaluate your input. Others conversions must be explicitly requested.
Calling Functions

— ug01.ht —

As we saw earlier, when you want to add or subtract two values, you place the arithmetic operator $\spadop{+}$ or $\spadop{-}$ between the two $\spadglossSee{arguments}{argument}$ denoting the values. To use most other Axiom operations, however, you use another syntax: write the name of the operation first, then an open parenthesis, then each of the arguments separated by commas, and, finally, a closing parenthesis. If the operation takes only one argument and the argument is a number or a symbol, you can omit the parentheses.

This calls the operation \axiomFun{factor} with the single integer argument \axiom{120}.

This is a call to \axiomFun{divide} with the two integer arguments
An operation that returns a \spadtype{Boolean} value (that is, \spad{true} or \spad{false}) frequently has a name suffixed with a question mark (``?''). For example, the \spadfun{even?} operation returns \spad{true} if its integer argument is an even number, \spad{false} otherwise.

An operation that can be destructive on one or more arguments usually has a name ending in an exclamation point (``!''). This actually means that it is \{it allowed\} to update its arguments but it is not \{it required\} to do so. For example, the underlying representation of a collection type may not allow the very last element to be removed and so an empty object may be returned instead. Therefore, it is important that you use the object returned by the operation and not rely on a physical change having occurred within the object. Usually, destructive operations are provided for efficiency reasons.
\begin{verbatim}
(2) [quotient= 17, remainder= 6]
  Type: Record(quotient: Integer, remainder: Integer)
\end{verbatim}

\begin{verbatim}
(3) 3.4 + 5.6 \text{i} + 2.9 \text{j} + 0.1 \text{k}
  Type: Quaternion Float
\end{verbatim}

\begin{verbatim}
(4) 3628800
  Type: PositiveInteger
\end{verbatim}
Some Predefined Macros

⇒ “notitle” (ugUserMacrosPage) 10 on page 1827
— ug01.ht —

Axiom provides several \spadglossSee{macros}{macro} for your convenience.\footnote{See \downlink{``Macros''}{ugUserMacrosPage} in Section 6.2\ignore{ugUserMacros} for a discussion on how to write your own macros.} Macros are names (or forms) that expand to larger expressions for commonly used values.

\begin{tabular}{ll}
\spadgloss{\%i} & The square root of \(-1\). \\
\spadgloss{\%e} & The base of the natural logarithm. \\
\spadgloss{\%pi} & \(\pi\). \\
\spadgloss{\%infinity} & \(\infty\). \\
\spadgloss{\%plusInfinity} & \(+\infty\). \\
\spadgloss{\%minusInfinity} & \(-\infty\).
\end{tabular}

%To display all the macros (along with anything you have %defined in the workspace), issue the system command \spadsys{display all}.

\end{page}
Long Lines

When you enter Axiom expressions from your keyboard, there will be times when they are too long to fit on one line. Axiom does not care how long your lines are, so you can let them continue from the right margin to the left side of the next line.

Alternatively, you may want to enter several shorter lines and have Axiom glue them together. To get this glue, put an underscore (_) at the end of each line you wish to continue.

\begin{verbatim}
  2_
  +_
  3
\end{verbatim}
is the same as if you had entered

\begin{verbatim}
  2+3
\end{verbatim}

If you are putting your Axiom statements in an input file (see \downlink{``Input Files''}{ugInOutInPage} in Section 4.1\ignore{ugInOutIn}), you can use indentation to indicate the structure of your program. (see \downlink{``Blocks''}{ugLangBlocksPage} in Section 5.2\ignore{ugLangBlocks}).
Comments

\begin{page}{ugIntroCommentsPage}{1.3.9. Comments}
\beginscroll
Comment statements begin with two consecutive hyphens or two consecutive plus signs and continue until the end of the line.

\xtc{
The comment beginning with \tt{--} is ignored by Axiom.
}\{
\spadpaste{2 + 3 -- this is rather simple, no?}
\}

There is no way to write long multi-line comments other than starting each line with \spad{--} or \spad{++}.

---

Graphics

⇒ \textit{“notitle” (ugProblemNumericPage) 12 on page 2079}
Axiom has a two- and three-dimensional drawing and rendering package that allows you to draw, shade, color, rotate, translate, map, clip, scale and combine graphic output of Axiom computations. The graphics interface is capable of plotting functions of one or more variables and plotting parametric surfaces. Once the graphics figure appears in a window, move your mouse to the window and click. A control panel appears immediately and allows you to interactively transform the object.

This is an example of Axiom's two-dimensional plotting. From the 2D Control Panel you can rescale the plot, turn axes and units on and off and save the image, among other things. This PostScript image was produced by clicking on the 2D Control Panel button.

This is an example of Axiom's three-dimensional plotting. It is a monochrome graph of the complex arctangent function. The image displayed was rotated and had the 'shade' and 'outline' display options set from the 3D Control Panel. The PostScript output was produced by clicking on the 3D Control Panel button and then clicking on the PostScript button. See "Numeric Functions" for more details and examples of Axiom's numeric and graphics capabilities.

An exhibit of is given in the center section of this book. For a description of the commands and programs that produced these figures, see
PostScript output is available so that Axiom images can be printed. See Chapter 7 for more examples and details about using Axiom's graphics facilities.
Numbers

Axiom distinguishes very carefully between different kinds of numbers, how they are represented and what their properties are. Here are a sampling of some of these kinds of numbers and some things you can do with them.

Integer arithmetic is always exact.

\begin{spadpaste}
11**13 * 13**11 * 17**7 - 19**5 * 23**3
\end{spadpaste}

Integers can be represented in factored form.

Factor

\begin{spadpaste}
643238070748569023720594412551704344145570763243
\end{spadpaste}

Results stay factored when you do arithmetic. Note that the 12 is automatically factored for you.

\begin{spadpaste}
11 * 12
\end{spadpaste}

Integers can also be displayed to bases other than 10. This is an integer in base 11.

\begin{spadpaste}
radix(25937424601, 11)
\end{spadpaste}

Roman numerals are also available for those special occasions.

\begin{spadpaste}
roman(1992)
\end{spadpaste}
Integers can be represented in factored form.
{
\spadpaste{factor 643238070748569023720594412551704344145570763243
\bound{ex1}}
}
\xtc{
Results stay factored when you do arithmetic.
Note that the \axiom{12} is automatically factored for you.
}{
\spadpaste{\% * 12 \free{ex1}}
}
\xtc{
Integers can also be displayed to bases other than 10.
This is an integer in base 11.
}{
\spadpaste{radix(25937424601,11)}
}
\xtc{
Roman numerals are also available for those special occasions.
}{
\spadpaste{roman(1992)}
}
\xtc{
Rational number arithmetic is also exact.
}{
\spadpaste{r := 10 + 9/2 + 8/3 + 7/4 + 6/5 + 5/6 + 4/7 + 3/8 + 2/9
\bound{r}}
}
\xtc{
To factor fractions, you have to
map \axiomFun{factor} onto the numerator and denominator.
}{
\spadpaste{map(factor,r) \free{r}}
}
\xtc{
Type \spadtype{SingleInteger} refers to machine word-length
integers.
In English, this expression means ‘‘\axiom{11} as a small
integer’’.
}{
\spadpaste{110\@SingleInteger}
}
\xtc{
Machine double-precision floating-point numbers are also
available for numeric and graphical
applications.
}{
\spadpaste{123.210\@DoubleFloat}
The normal floating-point type in Axiom, \spadtype{Float}, is a software implementation of floating-point numbers in which the exponent and the mantissa may have any number of digits. See \downlink{'Float'}{FloatXmpPage} and \downlink{'DoubleFloat'}{DoubleFloatXmpPage} for additional information on floating-point types.) The types \spadtype{Complex(Float)} and \spadtype{Complex(DoubleFloat)} are the corresponding software implementations of complex floating-point numbers.

This is a floating-point approximation to about twenty digits. The \axiomSyntax{::} is used here to change from one kind of object (here, a rational number) to another (a floating-point number).

\spadpaste{r :: Float \free{r}}

Use \spadfunFrom{digits}{Float} to change the number of digits in the representation. This operation returns the previous value so you can reset it later.

\spadpaste{digits(22) \bound{fewerdigits}}

To \axiom{22} digits of precision, the number \texttt{exp(\%pi * sqrt 163.0)} appears to be an integer.

\spadpaste{exp(\%pi * sqrt 163.0) \free{fewerdigits}}

Increase the precision to forty digits and try again.

\spadpaste{digits(40); exp(\%pi * sqrt 163.0) \free{moredigits}}

Here are complex numbers with rational numbers as real and imaginary parts.

\spadpaste{(2/3 + \%i)**3 \bound{gaussint}}

The standard operations on complex numbers are available.

\spadpaste{conjugate \% \free{gaussint}}
You can factor complex integers.
\spadpaste{factor(89 - 23 * __('i'))}

Complex numbers with floating point parts are also available.
\spadpaste{exp(__('pi/4.0') * __('i'))}

Every rational number has an exact representation as a repeating decimal expansion (see \downlink{'DecimalExpansion'}{DecimalExpansionXmpPage}).
\spadpaste{decimal(1/352)}

A rational number can also be expressed as a continued fraction (see \downlink{'ContinuedFraction'}{ContinuedFractionXmpPage}).
\spadpaste{continuedFraction(6543/210)}

Also, partial fractions can be used and can be displayed in a compact format or expanded format (see \downlink{'PartialFraction'}{PartialFractionXmpPage}).
\spadpaste{padicFraction(__('') \free{partfrac}}

Like integers, bases (radices) other than ten can be used for rational numbers (see \downlink{'RadixExpansion'}{RadixExpansionXmpPage}).
Here we use base eight.
\spadpaste{radix(4/7, 8) \bound{rad}}

Of course, there are complex versions of these as well.
Axiom decides to make the result a complex rational number.
}\{
\spadpaste{\% + 2/3*\%i\free{rad}}
\}
\xtc{You can also use Axiom to manipulate fractional powers.}
}\{
\spadpaste{(5 + sqrt 63 + sqrt 847)**(1/3)}
\}
\xtc{You can also compute with integers modulo a prime.}
}\{
\spadpaste{x : PrimeField 7 := 5 \bound{x}}
\}
\xtc{Arithmetic is then done modulo \mathOrSpad{7}.}
}\{
\spadpaste{x**3 \free{x}}
\}
\xtc{Since \mathOrSpad{7} is prime, you can invert nonzero values.}
}\{
\spadpaste{1/x \free{x}}
\}
\xtc{You can also compute modulo an integer that is not a prime.}
}\{
\spadpaste{y : IntegerMod 6 := 5 \bound{y}}
\}
\xtc{All of the usual arithmetic operations are available.}
}\{
\spadpaste{y**3 \free{y}}
\}
\xtc{Inversion is not available if the modulus is not a prime number. Modular arithmetic and prime fields are discussed in \downlink{``Modular Arithmetic and Prime Fields''}{ugxProblemFinitePrimePage} in Section 8.11.1\ignore{ugxProblemFinitePrime}.}
}\{
\spadpaste{1/y \free{y}}
\}
\xtc{This defines \axiom{a} to be an algebraic number, that is, a root of a polynomial equation.}
}\{
\spadpaste{a := rootOf(a**5 + a**3 + a**2 + 3,a) \bound{a}}
}
 Computations with \axiom{a} are reduced according to the polynomial equation.
\spadpaste{(a + 1)**10} \free{a}

Define \axiom{b} to be an algebraic number involving \axiom{a}.
\spadpaste{b := rootOf(b**4 + a, b)} \bound{b} \free{a}

Do some arithmetic.
\spadpaste{2/(b - 1}} \free{b} \bound{check}

To expand and simplify this, call \axiomFun{ratDenom} to rationalize the denominator.
\spadpaste{ratDenom(\%) \free{check}} \bound{check1}

If we do this, we should get \axiom{b}.
\spadpaste{2/\%+1 \free{check1}} \bound{check2}

But we need to rationalize the denominator again.
\spadpaste{ratDenom(\%)} \free{check2}

Types \spadtype{Quaternion} and \spadtype{Octonion} are also available. Multiplication of quaternions is non-commutative, as expected.
\spadpaste{q:=quatern(1,2,3,4)*quatern(5,6,7,8) - quatern(5,6,7,8)*quatern(1,2,3,4)}

\end{verbatim}
Axiom has a large variety of data structures available. Many data structures are particularly useful for interactive computation and others are useful for building applications. The data structures of Axiom are organized into \spadglossSee{category hierarchies}{hierarchy} as shown on the inside back cover.

A \spadgloss{list} is the most commonly used data structure in Axiom for holding objects all of the same type. Lists are discussed in...
The name \it list is short for `linked-list of nodes.' Each node consists of a value (\spadfun{first}{List}) and a link (\spadfun{rest}{List}) that \spadglossSee{points}{pointer} to the next node, or to a distinguished value denoting the empty list.

To get to, say, the third element, Axiom starts at the front of the list, then traverses across two links to the third node.

\spadpaste{u := [1,-7,11] \free{u}}

This is the value at the third node. Alternatively, you can say \axiom{u.3}.

Many operations are defined on lists, such as: \axiomFun{empty?}, to test that a list has no elements; \axiomFun{cons}\axiom{(x,l)}, to create a new list with \axiomFun{first} element \axiom{x} and \axiomFun{rest} \axiom{l}; \axiomFun{reverse}, to create a new list with elements in reverse order; and \axiomFun{sort}, to arrange elements in order.

An important point about lists is that they are `mutable': their constituent elements and links can be changed `in place.' To do this, use any of the operations whose names end with the character \axiomSyntax{!}.

\spadpaste{concat!(u,[9,1,3,-4]); u\free{u}\bound{u1}}

A \it cyclic list is a list with a `cycle': a link pointing back to an earlier node of the list. To create a cycle, first get a node somewhere down the list.
\spadpaste{lastnode := rest(u,3)\free{u1}\bound{u2}}
\xtc{
Use \spadfunFromX{setrest}{List} to change the link emanating from that node to point back to an earlier part of the list.}
\spadpaste{setrest!(lastnode,rest(u,2)); u\free{u2}}

A \spadgloss{stream} is a structure that (potentially) has an infinite number of distinct elements. Streams are discussed in \dlink{`Stream'}{StreamXmpPage}\ignore{Stream} and in \dlink{``Creating Lists and Streams with Iterators''}{ugLangItsPage} in Section 5.5\ignore{ugLangIts}. Think of a stream as an ‘‘infinite list’’ where elements are computed successively.

Create an infinite stream of factored integers. Only a certain number of initial elements are computed and displayed.
\spadpaste{[factor(i) for i in 2.. by 2] \bound{stream1}}
\xtc{
Axiom represents streams by a collection of already-computed elements together with a function to compute the next element ‘‘on demand.’’ Asking for the \eth{\axiom{n}} element causes elements \axiom{1} through \axiom{n} to be evaluated.}
\spadpaste{\%.36 \free{stream1}}

Streams can also be finite or cyclic. They are implemented by a linked list structure similar to lists and have many of the same operations. For example, \axiomFun{first} and \axiomFun{rest} are used to access elements and successive nodes of a stream.

A \spadgloss{one-dimensional array} is another data structure used to hold objects of the same type. See \dlink{`OneDimensionalArray'}{OneDimensionalArrayXmpPage}\ignore{OneDimensionalArray} for
Unlike lists, one-dimensional arrays are inflexible—they are implemented using a fixed block of storage. Their advantage is that they give quick and equal access time to any element.

A simple way to create a one-dimensional array is to apply the operation \(\text{oneDimensionalArray}\) to a list of elements.

\begin{verbatim}
\spadpaste{a := oneDimensionalArray [1, -7, 3, 3/2]\bound{a}}
\end{verbatim}

One-dimensional arrays are also mutable: you can change their constituent elements "in place."

\begin{verbatim}
\spadpaste{a.3 := 11; a\bound{a1}\free{a}}
\end{verbatim}

However, one-dimensional arrays are not flexible structures. You cannot destructively \(\text{concat}\) them together.

\begin{verbatim}
\spadpaste{concat!(a,oneDimensionalArray [1,-2])\free{a1}}
\end{verbatim}

Examples of datatypes similar to \(\text{OneDimensionalArray}\) are: \(\text{Vector}\) (vectors are mathematical structures implemented by one-dimensional arrays), \(\text{String}\) (arrays of "characters," represented by byte vectors), and \(\text{Bits}\) (represented by "bit vectors").

A vector of 32 bits, each representing the \(\text{Boolean}\) value \(\text{true}\).

\begin{verbatim}
\spadpaste{bits(32,true)}
\end{verbatim}

A \(\text{flexible array}\) is a cross between a list and a one-dimensional array. Like a one-dimensional array, a flexible array occupies a fixed block of storage. Its block of storage, however, has room to expand! When it gets full, it grows (a new, larger block of storage is allocated); when it has too much room, it contracts.

Create a flexible array of three elements.
Flexible arrays are used to implement 'heaps.' A
\spadgloss{heap} is an example of a data structure called a
\spadgloss{priority queue}, where elements are ordered with respect to one another.\footnote{See \downlink{`Heap'}{HeapXmpPage}\ignore{Heap} for more details. Heaps are also examples of data structures called
\spadglossSee{bags}{bag}. Other bag data structures are \spadtype{Stack}, \spadtype{Queue}, and \spadtype{Dequeue}.}

A heap is organized so as to optimize insertion and extraction of maximum elements. The \spadfunX{extract} operation returns the maximum element of the heap, after destructively removing that element and reorganizing the heap so that the next maximum element is ready to be delivered.

A \spadgloss{binary tree} is a 'tree' with at most two branches per node: it is either empty, or else is a node consisting of a value, and a left and right subtree (again, binary trees).\footnote{Example of binary tree types are \spadtype{BinarySearchTree} (see \downlink{`BinarySearchTree'}{BinarySearchTreeXmpPage}\ignore{BinarySearchTree}, \spadtype{PendantTree}, \spadtype{TournamentTree}, and \spadtype{BalancedBinaryTree} (see \downlink{`BalancedBinaryTree'}{BalancedBinaryTreeXmpPage}\ignore{BalancedBinaryTree}).}
A binary search tree is a binary tree such that, for each node, the value of the node is greater than all values (if any) in the left subtree, and less than or equal all values (if any) in the right subtree.

\spadpaste{binarySearchTree [5,3,2,9,4,7,11]}

A balanced binary tree is useful for doing modular computations. Given a list \axiom{lm} of moduli, \axiomFun{modTree}\axiom{(a,lm)} produces a balanced binary tree with the values \Texht{$a \mod m$}\{a \ttt mod m\} at its leaves.

\spadpaste{modTree(8,[2,3,5,7])}

A set is a collection of elements where duplication and order is irrelevant.\footnote{See \downlink{'Set'}{SetXmpPage}\ignore{Set} for more details.} Sets are always finite and have no corresponding structure like streams for infinite collections.

\spadpaste{fs := set [1/3,4/5,-1/3,4/5] \bound{fs}}

A multiset is a set that keeps track of the number of duplicate values.\footnote{See \downlink{'MultiSet'}{MultiSetXmpPage}\ignore{MultiSet} for details.}

\spadpaste{multiset \[x \rem 5 \text{ for } x \text{ in primes(2,1000)}\]}

A table is conceptually a set of ‘key--value’ pairs and is a generalization of a multiset.\footnote{For examples of tables, see \spadtype{AssociationList} (\downlink{'AssociationList'}{AssociationListXmpPage}\ignore{AssociationList})}
The domain \spadtype{Table(Key, Entry)} provides a general-purpose type for tables with \textit{values} of type \axiom{Entry} indexed by \textit{keys} of type \axiom{Key}.

\begin{verbatim}
Compute the above distribution of primes using tables. First, let \axiom{t} denote an empty table of keys and values, each of type \spadtype{Integer}.
\spadpaste{t : Table(Integer,Integer) := empty() \bound{t}}

We define a function \userfun{howMany} to return the number of values of a given modulus \axiom{k} seen so far. It calls \axiomFun{search}\axiom{(k,t)} which returns the number of values stored under the key \axiom{k} in table \axiom{t}, or \axiom{"failed"} if no such value is yet stored in \axiom{t} under \axiom{k}.
\spadpaste{ howMany(k) == (n:=search(k,t); n case "failed" => 1; n+1) \bound{how}}

We define a function \userfun{howMany} to return the number of values of a given modulus \axiom{k} seen so far. It calls \axiomFun{search}\axiom{(k,t)} which returns the number of values stored under the key \axiom{k} in table \axiom{t}, or \axiom{"failed"} if no such value is yet stored in \axiom{t} under \axiom{k}.

\spadpaste{for p in primes(2,1000) repeat (m:= p rem 5; t.m:= howMany(m)); t\free{how t}}
\end{verbatim}

A \{\textit{it record}\} is an example of an inhomogeneous collection.
of objects.\footnote{See} in Section 2.4\ignore{ugTypesRecords} for details.) A record consists of a set of named \{it selectors\} that can be used to access its components.

\xtc{ Declare that \axiom{daniel} can only be assigned a record with two prescribed fields. }
\spadpaste{daniel : Record(age : Integer, salary : Float) \bound{danieldec}}

\xtc{ Give \axiom{daniel} a value, using square brackets to enclose the values of the fields. }
\spadpaste{daniel := [28, 32005.12] \free{danieldec}\bound{daniel}}

\xtc{ Give \axiom{daniel} a raise. }
\spadpaste{daniel.salary := 35000; daniel \free{daniel}}

A \{\it union\} is a data structure used when objects have multiple types.\footnote{See in Section 2.5\ignore{ugTypesUnions} for details.}

\xtc{ Let \axiom{dog} be either an integer or a string value. }
\spadpaste{dog: Union(licenseNumber: Integer, name: String)\bound{xint}}

\xtc{ Give \axiom{dog} a name. }
\spadpaste{dog := "Whisper"\free{xint}}

All told, there are over forty different data structures in Axiom. Using the domain constructors described in Chapter 13\ignore{ugDomains}, you can add your own data structure or extend an existing one. Choosing the right data structure for your application may be the key to obtaining good performance.

Expanding to Higher Dimensions

⇒ “notitle” (TwoDimensionalArrayXmpPage) 3.5 on page 143
⇒ “notitle” (MatrixXmpPage) 3.75 on page 984
⇒ “notitle” (PermanentXmpPage) 3.85 on page 1085
To get higher dimensional aggregates, you can create one-dimensional aggregates with elements that are themselves aggregates, for example, lists of lists, one-dimensional arrays of lists of multisets, and so on. For applications requiring two-dimensional homogeneous aggregates, you will likely find \textit{two-dimensional arrays} and \textit{matrices} most useful.

The entries in \texttt{TwoDimensionalArray} and \texttt{Matrix} objects are all the same type, except that those for \texttt{Matrix} must belong to a \texttt{Ring}. You create and access elements in roughly the same way. Since matrices have an understood algebraic structure, certain algebraic operations are available for matrices but not for arrays. Because of this, we limit our discussion here to \texttt{Matrix}, that can be regarded as an extension of \texttt{TwoDimensionalArray}. For more information about Axiom’s linear algebra facilities, see \texttt{Matrix}\xmpPage, \texttt{Permanent}\xmpPage, \texttt{SquareMatrix}\xmpPage, \texttt{Vector}\xmpPage, \texttt{Computation of Eigenvalues and Eigenvectors}\xmpPage in Section 8.4, and \texttt{Solution of Linear and Polynomial Equations}\xmpPage in Section 8.5.

You can create a matrix from a list of lists, where each of the inner lists represents a row of the matrix.

\spad{m := matrix([[1,2], [3,4]])}
The "collections" construct (see Section 5.5) is useful for creating matrices whose entries are given by formulas.

\begin{verbatim}
1/(i + j - x) for i in 1..4 for j in 1..4
\end{verbatim}

Let \texttt{vm} denote the three by three Vandermonde matrix.

\begin{verbatim}
[1,1,1, [x,y,z], [x*x,y*y,z*z]]
\end{verbatim}

Use this syntax to extract an entry in the matrix.

\begin{verbatim}
vm(3,3)
\end{verbatim}

You can also pull out a \texttt{row} or a \texttt{column}.

\begin{verbatim}
column(vm,2)
\end{verbatim}

You can do arithmetic.

\begin{verbatim}
vm * vm
\end{verbatim}

You can perform operations such as \texttt{transpose}, \texttt{trace}, and \texttt{determinant}.

\begin{verbatim}
factor determinant vm
\end{verbatim}

\begin{verbatim}
m := matrix([[1,2], [3,4]])
\end{verbatim}

Type: Matrix Integer
\begin{verbatim}
1 1 1 1

2 & 2 & 2 & 2 & 2 & 2 & 3 & 2 & 4 & 2 & 2 \\
x z + x y + x & y z + y + x & z + y z + x \\
\end{array}
\]

Type: Matrix Polynomial Integer

\begin{verbatim}
(7) \( (y - x)(z - y)(z - x) \)
Type: Factored Polynomial Integer
\end{verbatim}

Writing Your Own Functions
Axiom provides you with a very large library of predefined operations and objects to compute with. You can use the Axiom library of constructors to create new objects dynamically of quite arbitrary complexity. For example, you can make lists of matrices of fractions of polynomials with complex floating point numbers as coefficients. Moreover, the library provides a wealth of operations that allow you to create and manipulate these objects.

For many applications, you need to interact with the interpreter and write some Axiom programs to tackle your application. Axiom allows you to write functions interactively, thereby effectively extending the system library. Here we give a few simple examples, leaving the details to \downlink{`User-Defined Functions, Macros and Rules'}` {ugUserPage} in Chapter 6\ignore{ugUser}.

We begin by looking at several ways that you can define the ‘factorial’ function in Axiom. The first way is to give a piece-wise definition of the function. This method is best for a general recurrence relation since the pieces are gathered together and compiled into an efficient iterative function. Furthermore, enough previously computed values are automatically saved so that a subsequent call to the function can pick up from where it left off.

\xtc{Define the value of \userfun{fact} at \axiom{0}.}{\spadpaste{fact(0) == 1 \bound{fact}}}  
\xtc{Define the value of \axiom{fact(n)} for general \axiom{n}.}{\spadpaste{fact(n) == n*fact(n-1) \bound{facta}\free{fact}}}  
\xtc{Ask for the value at \axiom{50}.}{\spadpaste{fact(50) \free{facta}}}  
\xtc{A second definition uses an \axiom{if-then-else} and recursion.}{\spadpaste{fac(n) == if n < 3 then n else n * fac(n - 1) \bound{fac}}}  
\xtc{This function is less efficient than the previous version since each iteration involves a recursive function call.}{\spadpaste{fac(50) \free{fac}}}

A third version directly uses iteration.

\spadpaste{fa(n) == (a := 1; for i in 2..n repeat a := a*i; a) \bound{fa}}

This is the least space-consuming version.

\spadpaste{fa(50) \free{fa}}

A final version appears to construct a large list and then reduces over it with multiplication.

\spadpaste{f(n) == reduce(*,[i for i in 2..n]) \bound{f}}

In fact, the resulting computation is optimized into an efficient iteration loop equivalent to that of the third version.

\spadpaste{f(50) \free{f}}

The library version uses an algorithm that is different from the four above because it highly optimizes the recurrence relation definition of \axiomFun{factorial}.

\spadpaste{factorial(50) \free{factorial}}

You are not limited to one-line functions in Axiom. If you place your function definitions in \axiom{.input} files (see \downlink{``Input Files''}{ugInOutInPage} in Section 4.1\ignore{ugInOutIn}), you can have multi-line functions that use indentation for grouping.

Given \axiom{n} elements, \axiomFun{diagonalMatrix} creates an \axiom{n} by \axiom{n} matrix with those elements down the diagonal. This function uses a permutation matrix that interchanges the \axiom{i}th and \axiom{j}th rows of a matrix by which it is right-multiplied.

This function definition shows a style of definition that can be used in \axiom{.input} files. Indentation is used to create \spadglossSee{blocks}{block}: sequences of expressions that are evaluated in sequence except as modified by control statements such as \axiom{if-then-else} and \axiom{return}.\{
\begin{spadsrc}
\texttt{permMat(n, i, j) ==}
\begin{spadlit}
m := \text{diagonalMatrix}
\quad ((\text{if } i = k \text{ or } j = k \text{ then } 0 \text{ else } 1)
\quad \text{for } k \text{ in } 1..n)
\quad m(i,j) := 1
\quad m(j,i) := 1
\quad m
\end{spadlit}
\end{spadsrc}

This creates a four by four matrix that interchanges the second and third rows.

\begin{spadpaste}
\texttt{p := permMat(4,2,3) \free{permMat} \bound{p}}
\end{spadpaste}

Create an example matrix to permute.

\begin{spadpaste}
\texttt{m := \text{matrix} \quad \texttt{[[4*i + j for j in 1..4] for i in 0..3]} \bound{m}}
\end{spadpaste}

Interchange the second and third rows of m.

\begin{spadpaste}
\texttt{permMat(4,2,3) * m \free{p m}}
\end{spadpaste}

A function can also be passed as an argument to another function, which then applies the function or passes it off to some other function that does.

You often have to declare the type of a function that has functional arguments.

\begin{spadpaste}
\texttt{t : (Float \to Float, Float) \to Float \free{tdecl}}
\end{spadpaste}

This declares \userfun{t} to be a two-argument function that returns a \spadtype{Float}.

The first argument is a function that takes one \spadtype{Float} argument and returns a \spadtype{Float}.

\begin{spadpaste}
\texttt{t(fun, x) == fun(x)**2 + \sin(x)**2 \free{tdecl}}
\end{spadpaste}

This is the definition of \userfun{t}.

\begin{spadpaste}
\texttt{t(fun, x) == fun(x)**2 + \sin(x)**2 \free{tdecl} \bound{t}}
\end{spadpaste}

We have not defined a \axiomFun{cos} in the workspace. The one from the Axiom library will do.

Here we define our own (user-defined) function.

\spadpaste{cosinv(y) == cos(1/y) \bound{cosinv}}

Pass this function as an argument to \userfun{t}.

\spadpaste{t(cosinv, 5.2058) \free{t}\free{cosinv}}

Axiom also has pattern matching capabilities for simplification of expressions and for defining new functions by rules. For example, suppose that you want to apply regularly a transformation that groups together products of radicals:
\[
\sqrt{a} \cdot \sqrt{b} \mapsto \sqrt{ab}, \quad (\forall a)(\forall b)
\]
\[
\text{for any } \text{axiom}(a) \text{ and } \text{axiom}(b)
\]
Note that such a transformation is not generally correct. Axiom never uses it automatically.

\spadpaste{groupSqrt := rule(sqrt(a) * sqrt(b) == sqrt(a*b)) \bound{g}}

\spadpaste{a := (sqrt(x) + sqrt(y) + sqrt(z))**4 \bound{sxy}}

\spadpaste{groupSqrt a \free{sxy} \free{g}}

Polynomials

--- ug01.ht ---

Polynomials are the commonly used algebraic types in symbolic computation. Interactive users of Axiom generally only see one type of polynomial: `\spadtype{Polynomial(R)}`. This type represents polynomials in any number of unspecified variables over a particular coefficient domain `\axiom{R}`. This type represents its coefficients `\spadglossSee{sparsely}{sparse}`: only terms with non-zero coefficients are represented.

In building applications, many other kinds of polynomial representations are useful. Polynomials may have one variable or multiple variables, the variables can be named or unnamed, the coefficients can be stored sparsely or densely. So-called ‘distributed multivariate polynomials’ store polynomials as coefficients paired with vectors of exponents. This type is particularly efficient for use in algorithms for solving systems of non-linear polynomial equations.

\xtc{
The polynomial constructor most familiar to the interactive user is `\spadtype{Polynomial}`.
}{
\spadpaste{(x**2 - x*y**3 +3*y)**2}
}
\xtc{
If you wish to restrict the variables used, `\spadtype{UnivariatePolynomial}` provides polynomials in one variable.
}{
\spadpaste{p: UP(x,INT) := (3*x-1)**2 * (2*x + 8)}
}
\xtc{
The constructor `\spadtype{MultivariatePolynomial}` provides polynomials in one or more specified variables.
}{
\spadpaste{m: MPOLY([x,y],INT) := (x**2-x*y**3*3*y)**2 \bound{m}}
}
You can change the way the polynomial appears by modifying the variable ordering in the explicit list.
}
\spadpaste{m :: MPOLY([y,x],INT) \free{m}}
} 
\xtc{
The constructor
\spadtype{DistributedMultivariatePoly} provides polynomials in one or more specified variables with the monomials ordered lexicographically.
}
\spadpaste{m :: DMP([y,x],INT) \free{m}}
} 
\xtc{
The constructor
\spadtype{HomogeneousDistributedMultivariatePoly} is similar except that the monomials are ordered by total order refined by reverse lexicographic order.
}
\spadpaste{m :: HDMP([y,x],INT) \free{m}}
} 
\xtc{
More generally, the domain constructor
\spadtype{GeneralDistributedMultivariatePoly} allows the user to provide an arbitrary predicate to define his own term ordering. These last three constructors are typically used in \texht{Gr"{o}bner} basis applications and when a flat (that is, non-recursive) display is wanted and the term ordering is critical for controlling the computation.

% Limits

⇒ “notitle” (ugProblemLimitsPage) 12 on page 2145
— ug01.ht —

\begin{page}{ugIntroCalcLimitsPage}{1.10. Limits}
\beginscroll

\end{scroll}
\end{page}
Axiom's \axiomFun{limit} function is usually used to evaluate limits of quotients where the numerator and denominator both tend to zero or both tend to infinity.

To find the limit of an expression \axiom{f} as a real variable \axiom{x} tends to a limit value \axiom{a}, enter \axiom{limit(f, x=a)}.

Use \axiomFun{complexLimit} if the variable is complex.

Additional information and examples of limits are in \downlink{``Limits''}{ugProblemLimitsPage} in Section 8.6\ignore{ugProblemLimits}.

\xtc{You can take limits of functions with parameters.}{
\spadpaste{g := \csc(a*x) / \csch(b*x) \bound{g}}
}
\xtc{As you can see, the limit is expressed in terms of the parameters.}{
\spadpaste{limit(g,x=0) \free{g}}
}
\%
\xtc{A variable may also approach plus or minus infinity:}{
\spadpaste{h := (1 + k/x)**x \bound{h}}
}
\xtc{Use \axiom{\%plusInfinity} and \axiom{\%minusInfinity} to denote $\infty$ and $-\infty$.}{
\spadpaste{limit(h,x=\%plusInfinity) \free{h}}
}
\xtc{A function can be defined on both sides of a particular value, but may tend to different limits as its variable approaches that value from the left and from the right.}{
\spadpaste{limit(sqrt(y**2)/y,y = 0)}
}
\xtc{As \axiom{x} approaches \axiom{0} along the real axis, \axiom{exp(-1/x**2)} tends to \axiom{0}.}{
\spadpaste{limit(exp(-1/x**2),x = 0)}
}
\xtc{However, if \axiom{x} is allowed to approach \axiom{0} along any path in the complex plane, the limiting value of \axiom{exp(-1/x**2)} depends on the path taken because the function has an essential singularity at \axiom{x=0}. This is reflected in the error message

}
returned by the function.

Type: Expression Integer
Series

⇒ "notitle" (ugProblemSeriesPage) 12 on page 2164 — ug01.ht —

Axiom also provides power series. By default, Axiom tries to compute and display the first ten elements of a series. Use \texttt{\textbackslash spad\textbackslash s(\textbackslash set\textbackslash streams\textbackslash calculate\textbackslash \textbackslash)} to change the default value to something else.

For the purposes of this book, we have used this system command to display fewer than ten terms.

For more information about working with series, see
You can convert a functional expression to a power series by using the operation \axiomFun{series}.
In this example, \axiom{\sin(a*x)} is expanded in powers of \axiom{(x - 0)},
that is, in powers of \axiom{x}.
\spad{\text{series}(\sin(a*x),x = 0)}
\xtc{This expression expands
\axiom{\sin(a*x)} in powers of \axiom{(x - \%pi/4)}.}
\spad{\text{series}(\sin(a*x),x = \%pi/4)}
\xtc{Axiom provides
\textit{Puiseux series:} series with rational number exponents.
The first argument to \axiomFun{series} is an in-place function that
computes the \(n\) coefficient.
(Recall that
the \axiomSyntax{+->} is an infix operator meaning ‘maps to.’)
\spad{\text{series}(\text{n} +-> (-1)**((3*\text{n} - 4)/6)/factorial(\text{n} - 1/3),x = 0,4/3..,2)}
\xtc{Once you have created a power series, you can perform arithmetic operations
on that series.
We compute the Taylor expansion of \axiom{1/(1-x)}.}
\spad{\text{series}(1/(1-x),x = 0)}
\xtc{Compute the square of the series.}
\spad{\text{series}(1/(1-x),x = 0) ** 2}
\xtc{The usual elementary functions
(\axiomFun{log}, \axiomFun{exp}, trigonometric functions, and so on)
are defined for power series.}
\spad{\text{series}(1/(1-x),x = 0) ** 2}
Here is a way to obtain numerical approximations of \texttt{e} from the Taylor series expansion of \texttt{exp(x)}. First create the desired Taylor expansion.

\begin{verbatim}
\spadcommand{f := taylor(exp(x))}
\end{verbatim}

Evaluate the series at the value \texttt{1.0}. As you see, you get a sequence of partial sums.

\begin{verbatim}
\spadcommand{eval(f,1.0)}
\end{verbatim}

\begin{verbatim}
\spadcommand{series(sin(a*x),x = 0)}

\begin{page}{ugIntroIntegratePage}{1.13. Integration}
\beginscroll
\%Axiom has extensive library facilities for integration.
\xxtc{We use a factorization-free algorithm.}{\spadpaste{integrate((x**2+2*x+1)/((x+1)**6+1),x)}}
\end{scroll}
\end{page}
When real parameters are present, the form of the integral can depend on the signs of some expressions.

Rather than query the user or make sign assumptions, Axiom returns all possible answers.

\spadpaste{integrate(1/(x**2 + a),x)}

The \axiomFun{integrate} operation generally assumes that all parameters are real.
The only exception is when the integrand has complex valued quantities.

If the parameter is complex instead of real, then the notion of sign is undefined and there is a unique answer. You can request this answer by ‘prepending’ the word ‘complex’ to the command name:

\spadpaste{complexIntegrate(1/(x**2 + a),x)}

The following two examples illustrate the limitations of table-based approaches. The two integrands are very similar, but the answer to one of them requires the addition of two new algebraic numbers.

This one is the easy one.
The next one looks very similar but the answer is much more complicated.

\spadpaste{integrate(x**3 / (a+b*x)**(1/3),x)}

Only an algorithmic approach is guaranteed to find what new constants must be added in order to find a solution.

\spadpaste{integrate(1 / (x**3 * (a+b*x)**(1/3)),x)}

Some computer algebra systems use heuristics or table-driven approaches to integration. When these systems cannot determine the answer to an integration problem, they reply ‘‘I don’t know.’’ Axiom uses an algorithm for integration that conclusively proves that an integral cannot be expressed in terms of elementary functions.
When Axiom returns an integral sign, it has proved that no answer exists as an elementary function.

Axiom can handle complicated mixed functions much beyond what you can find in tables.

Whenever possible, Axiom tries to express the answer using the functions present in the integrand.

A strong structure-checking algorithm in Axiom finds hidden algebraic relationships between functions.

The discovery of this algebraic relationship is necessary for correct integration of this function.

Here are the details:

If \( x = \tan t \) and \( g = \tan \left( \frac{t}{3} \right) \) then the following algebraic relation is true:

\[
 g^3 - 3xg^2 - 3g + x = 0
\]

Integrate \( g \) using this algebraic relation; this produces:

\[
 \frac{(24g^2 - 8)\log(3g^2 - 2) + (81x^2 + 24)g^2 + 72gx - 27x^2 - 16}{54g^2 - 18}
\]

Rationalize the denominator, producing:

\[
 \frac{8\log(3g^2 - 1) - 3g^2 + 18gx + 16}{18}
\]

Replace \( g \) by the initial definition to produce the final result.
This is an example of a mixed function where the algebraic layer is over the transcendental one.

\( \text{integrate}\left(\frac{x + 1}{x(x + \log x)^{3/2}}, x\right) \)

While incomplete for non-elementary functions, Axiom can handle some of them.

\( \text{integrate}\left(\frac{\exp(-x^2) \cdot \text{erf}(x)}{(\text{erf}(x)^3 - \text{erf}(x)^2 - \text{erf}(x) + 1)}, x\right) \)

More examples of Axiom's integration capabilities are discussed in the link to "Integration" in Section 8.8.

Differential Equations

\begin{page}{ugIntroDiffEqnsPage}{1.14. Differential Equations}
\beginscroll
%
The general approach used in integration also carries over to the
solution of linear differential equations.

\labelSpace{2pc}
\xtc{Let’s solve some differential equations.}
\labelSpace{2pc}
\xtc{\begin{verbatim}
Let \axiom{y} be the unknown function in terms of \axiom{x}.
\end{verbatim}}
\xtc{\spadpaste{y := operator 'y \bound{y}} }
\xtc{\xtc{Here we solve a third order equation with polynomial coefficients.}
\xtc{\begin{verbatim}
\spadpaste{deq := x**3 * D(y x, x, 3) + x**2 * D(y x, x, 2) - 2 * x * D(y x, x) + 2 * y x = 2 * x**4 \bound{e3}\free{y}}
\end{verbatim}}
}\xtc{\spadpaste{solve(deq, y, x) \free{e3}\free{y}}}
\xtc{\xtc{Here we find all the algebraic function solutions of the equation.}
\xtc{\begin{verbatim}
deq := (x**2 + 1) * D(y x, x, 2) + 3 * x * D(y x, x) + y x = 0 \bound{e5}\free{y}}
\end{verbatim}}
\xtc{\spadpaste{solve(deq, y, x) \free{e5}\free{y}}}
\xtc{Coefficients of differential equations can come from arbitrary
constant fields.
For example, coefficients can contain algebraic numbers.}
\xtc{\xtc{}}}
\endscroll
This example has solutions whose logarithmic derivative is an algebraic function of degree two.

\[
\text{eq := } 2x^3 \cdot \frac{D(y(x),x,2)}{D(y(x),x)} + 3x^2 \cdot \frac{D(y(x),x)}{D(y(x),x)} - 2 \cdot y(x)
\]

Here’s another differential equation to solve.

\[
deq := \frac{D(y(x),x)}{y(x)} = \frac{y(x)}{x + y(x) \cdot \log y(x)}
\]

Rather than attempting to get a closed form solution of a differential equation, you instead might want to find an approximate solution in the form of a series.

Let’s solve a system of nonlinear first order equations and get a solution in power series. Tell Axiom that \texttt{x} is also an operator.

Here are the two equations forming our system.

\[
eq 1 := \frac{D(x(t),t)}{1 + x(t)^2}
\]

\[
eq 2 := \frac{D(y(t),t)}{y(t)} - x(t) \cdot y(t)
\]

We can solve the system around \texttt{x(t = 0)} with the initial conditions \texttt{x(0) = 0} and \texttt{y(0) = 1}. Notice that since we give the unknowns in the order \texttt{|x, y|}, the answer is a list of two series in the order \texttt{|series for x(t), series for y(t)|}.
\spadpaste{seriesSolve([eq2, eq1], [x, y], t = 0, [y(0) = 1, x(0) = 0])\free{x}\free{y}\free{eq1}\free{eq2}}

Solution of Equations

--- ug01.ht ---

Axiom also has state-of-the-art algorithms for the solution of systems of polynomial equations. When the number of equations and unknowns is the same, and you have no symbolic coefficients, you can use \spadfun{solve} for real roots and \spadfun{complexSolve} for complex roots. In each case, you tell Axiom how accurate you want your result to be. All operations in the \spadfun{solve} family return answers in the form of a list of solution sets, where each solution set is a list of equations.

A system of two equations involving a symbolic parameter \axiom{t}.

\spad{S(t) == \[x**2-2*y**2 - t,x*y-y-5*x + 5\]} \free{S1}

Find the real roots of \spad{S(19)} with rational arithmetic, correct to within \spad{1/10**20}.

\spad{solve(S(19),1/10**20)} \free{S1}

Find the complex roots of \spad{S(19)} with floating point coefficients to \spad{20} digits accuracy in the mantissa.
If a system of equations has symbolic coefficients and you want a solution in radicals, try \spadfun{radicalSolve}.

For systems of equations with symbolic coefficients, you can apply \spadfun{solve}, listing the variables that you want Axiom to solve for. For polynomial equations, a solution cannot usually be expressed solely in terms of the other variables. Instead, the solution is presented as a ‘‘triangular’’ system of equations, where each polynomial has coefficients involving only the succeeding variables. This is analogous to converting a linear system of equations to ‘‘triangular form’’.

A system of three equations in five variables.

\spad{eqns := [x**2 - y + z, x**2*z + x**4 - b*y, y**2 z - a - b*x]}

Solve the system for unknowns \smath{[x,y,z]}, reducing the solution to triangular form.

\spad{solve(eqns,[x,y,z])}

System Commands

⇒ "notitle" (ugSysCmdPage) 19 on page 2538
— ug01.ht —

We conclude our tour of Axiom with a brief discussion of
\spadgloss{system commands}. System commands are special statements
that start with a closing parenthesis (\axiomSyntax{)}. They are used
to control or display your Axiom environment, start the Hyperdoc
system, issue operating system commands and leave Axiom. For example,
\spadsys{system} is used to issue commands to the operating system
from Axiom. Here is a brief description of some of these commands.
For more information on specific commands, see
\downlink{"Axiom System Commands'’}{ugSysCmdPage} in Appendix B
\ignore{ugSysCmd}.

Perhaps the most important user command is the \spadsys{clear all}
command that initializes your environment. Every section and
subsection in this book has an invisible \spadsys{clear all} that is
read prior to the examples given in the section. \spadsys{clear all}
gives you a fresh, empty environment with no user variables defined
and the step number reset to axiom{1}. The \spad{clear} command can also be used to selectively clear values and properties of system variables.

Another useful system command is \spad{read}. A preferred way to develop an application in Axiom is to put your interactive commands into a file, say \{\bf my.input\} file. To get Axiom to read this file, you use the system command \spad{read my.input}. If you need to make changes to your approach or definitions, go into your favorite editor, change \{\bf my.input\}, then \spad{read my.input} again.

Other system commands include: \spad{history}, to display previous input and/or output lines; \spad{display}, to display properties and values of workspace variables; and \spad{what}.

\xtc{Issue \spad{what} to get a list of Axiom objects that contain a given substring in their name.}
\spadpaste{\spad{what operations integrate}}

\section{Undo}

A useful system command is \spad{undo}. Sometimes while computing interactively with Axiom, you make a mistake and enter an incorrect definition or assignment. Or perhaps you need to try one of several alternative approaches, one after another, to find the best way to approach an application. For this, you will find the \spad{undo} facility of Axiom helpful.

System command \spad{undo n} means ‘undo back to step axiom{n}’; it restores the values of user variables to those that existed immediately after input expression axiom{n} was evaluated. Similarly, \spad{undo -n} undoes changes caused by the last axiom{n} input expressions. Once you have done an \spad{undo}, you can continue on from there, or make a change and \{\bf redo\} all your input expressions from the point of the \spad{undo} forward. The \spad{undo} is completely general: it changes the environment like any user expression. Thus you can \spad{undo} any previous undo.

Here is a sample dialogue between user and Axiom.
\xtc{‘Let me define two mutually dependent functions axiom{f} and axiom{g} piece-wise.’}
\spadpaste{f(0) == 1; g(0) == 1\spad{undo}}
''Here is the general term for \texttt{f}.''
\spadpaste{f(n) == e/2*f(n-1) - x*g(n-1)}

''And here is the general term for \texttt{g}.''
\spadpaste{g(n) == -x*f(n-1) + d/3*g(n-1)}

''What is value of \texttt{f(3)}?''
\spadpaste{f(3)}

Hmm, I think I want to define \texttt{f} differently.
Undo to the environment right after I defined \texttt{f}.''
\spadpaste{)undo 2}

''Here is how I think I want \texttt{f} to be defined instead.''
\spadpaste{f(n) == d/3*f(n-1) - x*g(n-1)}

Redo the computation from expression \texttt{3} forward.
\spadpaste{)undo )redo}

''I want my old definition of \texttt{f} after all. Undo the undo and restore
the environment to that immediately after \texttt{(4)}.''
\spadpaste{)undo 4}

''Check that the value of \texttt{f(3)} is restored.''
\spadpaste{f(3)}

After you have gone off on several tangents, then backtracked to
previous points in your conversation using \texttt{undo}, you might
want to save all the ‘‘correct’’ input commands you issued,
disregarding those undone. The system command \texttt{history}
\texttt{write mynew.input} writes a clean straight-line program onto the file
mynew.input on your disk.

This concludes your tour of Axiom.
To disembark, issue the system command \spads{)quit} to leave Axiom and return to the operating system.

In this chapter we look at the key notion of \spadgloss{type} and its generalization \spadgloss{mode}. We show that every Axiom object has a type that determines what you can do with the object. In particular, we explain how to use types to call specific functions from particular parts of the library and how types and modes can be used to create new objects from old. We also look at \pspadtype{Record} and \pspadtype{Union} types and the special type \axiomType{Any}. Finally, we give you an idea of how Axiom
manipulates types and modes internally to resolve ambiguities.

---

The Basic Idea

The Axiom world deals with many kinds of objects. There are mathematical objects such as numbers and polynomials, data structure objects such as lists and arrays, and graphics objects such as points and graphic images. Functions are objects too.

Axiom organizes objects using the notion of \textit{domain of computation}, or simply \textit{domain}. Each domain denotes a class of objects. The class of objects it denotes is usually given by the name of the domain: \texttt{Integer} for the integers, \texttt{Float} for floating-point numbers, and so on. The convention is that the first letter of a domain name is capitalized. Similarly, the domain \texttt{Polynomial(Integer)} denotes "polynomials with integer coefficients." Also, \texttt{Matrix(Float)} denotes "matrices with floating-point entries."

Every basic Axiom object belongs to a unique domain. The integer $3$ belongs to the domain \texttt{Integer} and the polynomial $x + 3$
The Axiom world deals with many kinds of objects. There are mathematical objects such as numbers and polynomials, data structure objects such as lists and arrays, and graphics objects such as points and graphic images. Functions are objects too.

Axiom organizes objects using the notion of \textit{domain of computation}, or simply \textit{domain}. Each domain denotes a class of objects. The class of objects it denotes is usually given by the name of the domain: \texttt{Integer} for the integers, \texttt{Float} for floating-point numbers, and so on. The convention is that the first letter of a domain name is capitalized. Similarly, the domain \texttt{Polynomial(Integer)} denotes ''polynomials with integer coefficients.''' Also, \texttt{Matrix(Float)} denotes ''matrices with floating-point entries.'''

Every basic Axiom object belongs to a unique domain. The integer \texttt{3} belongs to the domain \texttt{Integer} and the polynomial \texttt{x + 3} belongs to the domain \texttt{Polynomial(Integer)}. The domain of an object is also called its \textit{type}. Thus we speak of ''the type \texttt{Integer}'' and ''the type \texttt{Polynomial(Integer)}.''

\texttt{After an Axiom computation, the type is displayed toward the right-hand side of the page (or screen).}{\spadpaste{-3}}

\texttt{Here we create a rational number but it looks like the last result. The type however tells you it is different. You cannot identify the type of an object by how Axiom displays the object.}{\spadpaste{-3/1}}

\texttt{When a computation produces a result of a simpler type, Axiom leaves the type unsimplified. Thus no information is lost.}
This seldom matters since Axiom retracts the answer to the simpler type if it is necessary.

When you issue a positive number, the type \texttt{PositiveInteger} is printed. Surely, \texttt{3} also has type \texttt{Integer}! The curious reader may now have two questions. First, is the type of an object not unique? Second, how is \texttt{PositiveInteger} related to \texttt{Integer}? Read on!

Any domain can be refined to a subdomain by a membership predicate. For example, the domain \texttt{Integer} can be refined to the subdomain \texttt{PositiveInteger}, the set of integers \texttt{x} such that \texttt{x > 0}, by giving the Axiom predicate \texttt{x \rightarrow x > 0}. Similarly, Axiom can define subdomains such as ‘the subdomain of diagonal matrices,’ ‘the subdomain of lists of length two,’ ‘the subdomain of monic irreducible polynomials in \texttt{x},’ and so on. Trivially, any domain is a subdomain of itself.

While an object belongs to a unique domain, it can belong to any number of subdomains. Any subdomain of the domain of an object can be used as the \texttt{type} of that object. The type of \texttt{3} is indeed both \texttt{Integer} and \texttt{PositiveInteger} as well as any other subdomain of integer whose predicate is satisfied, such as ‘the prime integers,’ ‘the odd positive integers between 3 and 17,’ and so on.
(1) \(-3\)

\end{verbatim}
\begin{verbatim}
3
\end{verbatim}

\begin{verbatim}
(5) 3
Type: PositiveInteger
\end{verbatim}
In Axiom, domains are objects. You can create them, pass them to functions, and, as we'll see later, test them for certain properties.

In Axiom, you ask for a value of a function by applying its name to a set of arguments.

To ask for "the factorial of 7" you enter this expression to Axiom. This applies the function factorial to the value 7 to compute the result.

```
factorial(7)
```

Enter the type `Polynomial (Integer)` as an expression to Axiom. This looks much like a function call as well. It is! The result is appropriately stated to be of type `Domain`, which according to our usual convention, denotes the class of all domains.

```
Polynomial (Integer)
```

The most basic operation involving domains is that of building a new domain from a given one. To create the domain of "polynomials over the integers," Axiom applies the function
according to our usual convention, denotes the class of all domains.

\texttt{Polynomial(Integer)}

The most basic operation involving domains is that of building a new domain from a given one. To create the domain of ‘‘polynomials over the integers,’’ Axiom applies the function \texttt{Polynomial} to the domain \texttt{Integer}. A function like \texttt{Polynomial} is called a \texttt{domain constructor} or, more simply, a \texttt{constructor}. A domain constructor is a function that creates a domain. An argument to a domain constructor can be another domain or, in general, an arbitrary kind of object. \texttt{Polynomial} takes a single domain argument while \texttt{SquareMatrix} takes a positive integer as an argument to give its dimension and a domain argument to give the type of its components.

What kinds of domains can you use as the argument to \texttt{Polynomial} or \texttt{SquareMatrix} or \texttt{List}? Well, the first two are mathematical in nature. You want to be able to perform algebraic operations like \texttt{+} and \texttt{*} on polynomials and square matrices, and operations such as \texttt{determinant} on square matrices. So you want to allow polynomials of integers \{it and\} polynomials of square matrices with complex number coefficients and, in general, anything that ‘‘makes sense.’’ At the same time, you don’t want Axiom to be able to build nonsense domains such as ‘‘polynomials of strings!’’

In contrast to algebraic structures, data structures can hold any kind of object. Operations on lists such as \texttt{insert\{}List, \texttt{delete\{}List, and \texttt{concat\{}List\} just manipulate the list itself without changing or operating on its elements. Thus you can build \texttt{List} over almost any datatype, including itself.

\texttt{Create a complicated algebraic domain.}

\texttt{List (List (Matrix (Polynomial (Complex (Fraction (Integer))))))}

\texttt{Create a meaningless domain.}

\texttt{Polynomial(String)}

Evidently from our last example, Axiom has some mechanism that tells what a constructor can use as an argument. This brings us to the notion of \texttt{category}. As domains are objects, they too have a domain.
The domain of a domain is a category.
A category is simply a type whose members are domains.

A common algebraic category is \(\text{\texttt{Ring}}\), the class of all domains that are "rings." A ring is an algebraic structure with constants \(\text{\texttt{0}}\) \(\text{\texttt{1}}\) and operations \(\text{\texttt{+}}\), \(\text{\texttt{-}}\), and \(\text{\texttt{*}}\). These operations are assumed "closed" with respect to the domain, meaning that they take two objects of the domain and produce a result object also in the domain. The operations are understood to satisfy certain "axioms," certain mathematical principles providing the algebraic foundation for rings. For example, the "additive inverse axiom" for rings states: "Every element \(\text{\texttt{x}}\) has an additive inverse \(\text{\texttt{y}}\) such that \(\text{\texttt{x + y = 0}}\)." The prototypical example of a domain that is a ring is the integers. Keep them in mind whenever we mention \(\text{\texttt{Ring}}\).

Many algebraic domain constructors such as \(\text{\texttt{Complex}}, \text{\texttt{Polynomial}}, \text{\texttt{Fraction}}\), take rings as arguments and return rings as values. You can use the infix operator "\(\text{\texttt{has}}\)" \(\text{\texttt{has}}\) to ask a domain if it belongs to a particular category.

\(\text{\texttt{Polynomial(Integer) has Ring}}\)
Use \texttt{SquareMatrix(n,R)} instead. For any positive integer \texttt{n}, it builds \(^{\prime\prime}\text{the ring of }\texttt{n}\text{ by }\texttt{n}\text{ matrices over }\texttt{R}^{\prime\prime}\).

\begin{verbatim}
\spadpaste{Polynomial(SquareMatrix(7,Complex(Integer)))}
\end{verbatim}

Another common category is \texttt{Field}, the class of all fields. A field is a ring with additional operations. For example, a field has commutative multiplication and a closed operation \texttt{Field} for the division of two elements. \texttt{Field} is not a field since, for example, \texttt{3/2} does not have an integer result. The prototypical example of a field is the rational numbers, that is, the domain \texttt{Fraction(Integer)}. In general, the constructor \texttt{Field} takes a ring as an argument and returns a field.\footnote{Actually, the argument domain must have some additional properties so as to belong to category \texttt{IntegralDomain}.} Other domain constructors, such as \texttt{Complex}, build fields only if their argument domain is a field.

\begin{verbatim}
\spadpaste{Complex(Integer) has Field}
\end{verbatim}

But fractions of complex integers do.

\begin{verbatim}
\spadpaste{Fraction(Complex(Integer)) has Field}
\end{verbatim}

\begin{verbatim}
\spadpaste{Complex(Fraction(Integer)) has Field}
\end{verbatim}

The algebraically equivalent domain of complex rational numbers is a field since domain constructor \texttt{Complex} produces a field whenever its argument is a field.

The most basic category is \texttt{Type}. It denotes the class of all domains and subdomains.\footnote{\texttt{Type} does not denote the class of all types. The type of all categories is \texttt{Category}. The type of \texttt{Type} itself is undefined.} Domain constructor \texttt{List} is able to build \(^{\prime\prime}\text{lists of elements from domain }\texttt{D}^{\prime\prime}\) for arbitrary \texttt{D} simply by requiring that \texttt{D} belong to category \texttt{Type}.\footnote{\texttt{List} is a member of \texttt{Category}.}
Now, you may ask, what exactly is a category?
Like domains, categories can be defined in the Axiom language.
A category is defined by three components:

1. a name (for example, `axiomType{Ring}`), used to refer to the class of domains that the category represents;
2. a set of operations, used to refer to the operations that the domains of this class support (for example, `axiomOp{+}`, `axiomOp{-}`, and `axiomOp{*}` for rings); and
3. an optional list of other categories that this category extends.

This last component is a new idea. And it is key to the design of Axiom! Because categories can extend one another, they form hierarchies. Detailed charts showing the category hierarchies in Axiom are displayed in the endpages of this book. There you see that all categories are extensions of `axiomType{Type}` and that `axiomType{Field}` is an extension of `axiomType{Ring}`.

The operations supported by the domains of a category are called the exports of that category because these are the operations made available for system-wide use. The exports of a domain of a given category are not only the ones explicitly mentioned by the category. Since a category extends other categories, the operations of these other categories---and all categories these other categories extend---are also exported by the domains.

For example, polynomial domains belong to `axiomType{PolynomialCategory}`. This category explicitly mentions some twenty-nine operations on polynomials, but it extends eleven other categories (including `axiomType{Ring}`). As a result, the current system has over one hundred operations on polynomials.

If a domain belongs to a category that extends, say, `axiomType{Ring}`, it is convenient to say that the domain exports `axiomType{Ring}`. The name of the category thus provides a convenient shorthand for the list of operations exported by the category. Rather than listing operations such as `axiomOpFrom{+}{Ring}` and `axiomOpFrom{*}{Ring}` of `axiomType{Ring}` each time they are needed, the definition of a type simply asserts that it exports category `axiomType{Ring}`.

The category name, however, is more than a shorthand. The name `axiomType{Ring}`, in fact, implies that the operations exported by rings are required to satisfy a set of ‘‘axioms’’ associated with the name `axiomType{Ring}`.

This subtle but important feature distinguishes Axiom from
other abstract datatype designs.}

Why is it not correct to assume that some type is a ring if it exports all of the operations of \axiomType{Ring}? Here is why. Some languages such as \textit{bf APL} denote the \axiomType{Boolean} constants \axiom{true} and \axiom{false} by the integers \axiom{1} and \axiom{0} respectively, then use \axiomOp{+} and \axiomOp{*} to denote the logical operators \axiomOp{or} and \axiomOp{and}. But with these definitions \axiomType{Boolean} is not a ring since the additive inverse axiom is violated.\footnote{There is no inverse element \axiom{a} such that \axiom{1 + a = 0}, or, in the usual terms:
\axiom{true or a = false}.} This alternative definition of \axiomType{Boolean} can be easily and correctly implemented in Axiom, since \axiomType{Boolean} simply does not assert that it is of category \axiomType{Ring}. This prevents the system from building meaningless domains such as \axiomType{Polynomial(Boolean)} and then wrongfully applying algorithms that presume that the ring axioms hold.

Enough on categories. To learn more about them, see \downlink{``Categories''}{ugCategoriesPage} in Chapter 12\ignore{ugCategories}. We now return to our discussion of domains.

Domains \spadgloss{export} a set of operations to make them available for system-wide use. \axiomType{Integer}, for example, exports the operations \axiomOp{+}{Integer} and \axiomOp{=}{Integer} given by the \spadglossSee{signatures}{signature} \axiomOp{+}{Integer}: \spadsig{(Integer,Integer)}{Integer} and \axiomOp{=}{Integer}: \spadsig{(Integer,Integer)}{Boolean}, respectively. Each of these operations takes two \axiomType{Integer} arguments. The \axiomOp{+}{Integer} operation also returns an \axiomType{Integer} but \axiomOp{=}{Integer} returns a \axiomType{Boolean}: \axiom{true} or \axiom{false}. The operations exported by a domain usually manipulate objects of the domain---but not always.

The operations of a domain may actually take as arguments, and return as values, objects from any domain. For example, \axiomType{Fraction (Integer)} exports the operations \axiomOp{+}{Fraction}:
\spadsig{(Integer,Integer)}{Fraction} and \axiomFun{characteristic}{Fraction}:
\spadsig{NonNegativeInteger}.

Suppose all operations of a domain take as arguments and return as values, only objects from \textit{it other} domains. This kind of domain is what Axiom calls a \spadgloss{package}.

A package does not designate a class of objects at all. Rather, a package is just a collection of operations. Actually the bulk of the Axiom library of algorithms consists of packages. The facilities for
factorization; integration; solution of linear, polynomial, and
differential equations; computation of limits; and so on, are all
defined in packages. Domains needed by algorithms can be passed to a
package as arguments or used by name if they are not "variable."
Packages are useful for defining operations that convert objects of
one type to another, particularly when these types have different
parameterizations. As an example, the package
\axiomType{PolynomialFunction2(R,S)} defines operations that convert
polynomials over a domain \axiom{R} to polynomials over \axiom{S}. To
convert an object from \axiomType{Polynomial(Integer)} to
\axiomType{Polynomial(Float)}, Axiom builds the package
\axiomType{PolynomialFunctions2(Integer,Float)} in order to create the
required conversion function. (This happens "behind the scenes" for
you: see \downlink{"Conversion"}{ugTypesConvertPage} in
Section 2.7\ignore{ugTypesConvert} for details on
how to convert objects.)

Axiom categories, domains and packages and all their contained
functions are written in the Axiom programming language and have
been compiled into machine code.
This is what comprises the Axiom \spadgloss{library}.
In the rest of this book we show you how to use these domains and
their functions and how to write your own functions.

We have already seen in the last section several examples of types. Most of these examples had either no arguments (for example, \texttt{axiomType(Integer)}) or one argument (for example, \texttt{axiomType(Polynomial (Integer))}). In this section we give details about writing arbitrary types. We then define \texttt{spadglossSee{modes}{mode}} and discuss how to write them. We conclude the section with a discussion on constructor abbreviations.
When might you need to write a type or mode?
You need to do so when you declare variables.

Types with No Arguments

— ug02.ht —

A constructor with no arguments can be written either with or without trailing opening and closing parentheses (\texttt{()}).

\begin{verbatim}
| \texttt{Boolean()} is the same as \texttt{Boolean} | \quad |
| \texttt{Integer()} is the same as \texttt{Integer} |
| \texttt{String()} is the same as \texttt{String} | \quad |
| \texttt{Void()} is the same as \texttt{Void} |
\end{verbatim}
Types with One Argument

A constructor with one argument can frequently be written with no parentheses. Types nest from right to left so that \texttt{Complex Fraction Polynomial Integer} is the same as \texttt{Complex (Fraction (Polynomial (Integer)))}. You need to use parentheses to force the application of a constructor to the correct argument, but you need not use any more than is necessary to remove ambiguities.

Here are some guidelines for using parentheses (they are possibly slightly more restrictive than they need to be).

\begin{itemize}
  \item If the argument is an expression like \texttt{2 + 3} then you must enclose the argument in parentheses.
  \end{itemize}

\begin{itemize}
  \item If the type is to be used with package calling then you must enclose the argument in parentheses.
  \end{itemize}
Alternatively, you can write the type without parentheses then enclose the whole type expression with parentheses.
\spadpaste{content(2)\$(Polynomial Complex Fraction Integer)}

If you supply computation target type information (\downlink{‘Package Calling and Target Types’}{ugTypesPkgCallPage} in Section 2.9\ignore{ugTypesPkgCall}) then you should enclose the argument in parentheses.
\spadpaste{(2/3)@Fraction(Polynomial(Integer))}

If the type itself has parentheses around it and we are not in the case of the first example above, then the parentheses can usually be omitted.
\spadpaste{(2/3)@Fraction(Polynomial Integer)}

If the type is used in a declaration and the argument is a single-word type, integer or symbol, then the parentheses can usually be omitted.
\spadpaste{(d,f,g) : Complex Polynomial Integer}

\begin{verbatim}
e : PrimeField(2 + 3)
\end{verbatim}

Type: Void
\begin{verbatim}
content(2)$\text{Polynomial(Integer)}$
\end{verbatim}

Type: Integer

\begin{verbatim}
content(2)$\text{Polynomial(Integer)}$
\end{verbatim}

Type: Complex Fraction Integer

\begin{verbatim}
(2/3)$\text{Fraction(Polynomial(Integer))}$
\end{verbatim}

Type: Fraction Polynomial Integer
Types with More Than One Argument

If a constructor has more than one argument, you must use parentheses.
Some examples are
\begin{verbatim}
\centerline{{\axiomType{UnivariatePolynomial(x, Float)}}}
\centerline{{\axiomType{MultivariatePolynomial([z,w,r], Complex Float)}}}
\centerline{{\axiomType{SquareMatrix(3, Integer)}}}
\centerline{{\axiomType{FactoredFunctions2(Integer, Fraction Integer)}}}
\end{verbatim}

\section*{Modes}

\begin{itemize}
\item “notitle” (ugTypesDeclarePage) on page 1641
\item “notitle” (ugTypesConvertPage) on page 1671
\end{itemize}

\begin{verbatim}
\begin{page}{ugTypesWritingModesPage}{2.2.4. Modes}
\beginscroll
A \spadgloss{mode} is a type that possibly is a question mark \axiomSyntax{?} or contains one in an argument position. For example, the following are all modes.
\begin{verbatim}
\centerline{{\begin{tabular}{ccc}}}
\centerline{{\axiomType{?} & \quad &}}
\centerline{{\axiomType{Polynomial ?} & \quad &}}
\centerline{{\axiomType{Matrix Polynomial ?} & \quad &}}
\centerline{{\axiomType{SquareMatrix(3, ?)} & \quad &}}
\centerline{{\axiomType{Integer} & \quad &}}
\centerline{{\axiomType{OneDimensionalArray(Float)}}}
\centerline{{\axiomType{?} & \quad &}}
\centerline{{\axiomType{Polynomial ?} & \quad &}}
\centerline{{\axiomType{Matrix Polynomial ?} & \quad &}}
\centerline{{\axiomType{SquareMatrix(3, ?)} & \quad &}}
\centerline{{\axiomType{Integer} & \quad &}}
\centerline{{\axiomType{OneDimensionalArray(Float)}}}
\end{tabular}}
\end{verbatim}
As is evident from these examples, a mode is a type with a part that is not specified (indicated by a question mark). Only one \axiomSyntax{?} is allowed per mode and it must appear in the most
\end{verbatim}
\end{scroll}
\end{page}
\end{verbatim}
deeply nested argument that is a type. Thus
\nonLibAxiomType{?(Integer)}, \nonLibAxiomType{Matrix(?
(Polynomial))}, \nonLibAxiomType{SquareMatrix(?, Integer)} and
\nonLibAxiomType{SquareMatrix(?, ?)} are all invalid. The question
mark must take the place of a domain, not data (for example, the
integer that is the dimension of a square matrix). This rules out,
for example, the two \axiomType{SquareMatrix} expressions.

Modes can be used for declarations
\downlink{‘Declarations’}{ugTypesDeclarePage} in Section 2.3\ignore{ugTypesDeclare} and conversions
\downlink{‘Conversion’}{ugTypesConvertPage} in Section 2.7\ignore{ugTypesConvert}.
However, you cannot use a mode for package calling or giving target
type information.

Abbreviations

⇒ “notitle” (ugSysCmdwhatPage) 19 on page 2586
— ug02.ht —

\begin{page}{ugTypesWritingAbbrPage}{2.2.5. Abbreviations}
\beginscroll

Every constructor has an abbreviation that you can freely substitute
for the constructor name. In some cases, the abbreviation is nothing
more than the capitalized version of the constructor name.

\beginImportant
Aside from allowing types to be written more concisely,
abbreviations are used by Axiom to name various system
files for constructors (such as library filenames, test input
files and example files).
Here are some common abbreviations.
\texht{}\{table{
  \{\axiomType{COMPLEX} abbreviates \axiomType{Complex} \}
  \{\axiomType{DFLOAT} abbreviates \axiomType{DoubleFloat} \}
  \{\axiomType{EXPR} abbreviates \axiomType{Expression} \}
  \{\axiomType{FLOAT} abbreviates \axiomType{Float} \}
  \{\axiomType{FRAC} abbreviates \axiomType{Fraction} \}
  \{\axiomType{INT} abbreviates \axiomType{Integer} \}
\}
You can combine both full constructor names and abbreviations in a type expression.

Here are some types using abbreviations.

\begin{center}
\verb|POLY INT| is the same as \verb|Polynomial(INT)|
\end{center}

\begin{center}
\verb|POLY(Integer)| is the same as \verb|Polynomial(Integer)|
\end{center}

\begin{center}
\verb|POLY(Integer)| is the same as \verb|Polynomial(INT)|
\end{center}

\begin{center}
\verb|FRAC(COMPLEX(INT))| is the same as \verb|Fraction Complex Integer|
\end{center}

\begin{center}
\verb|FRAC(COMPLEX(INT))| is the same as \verb|FRAC(Complex Integer)|
\end{center}

There are several ways of finding the names of constructors and their abbreviations. For a specific constructor, use \verb|)abbreviation query|. You can also use the \verb|)what| system command to see the names and abbreviations of constructors. For more information about \verb|)what|, see \url{ugSysCmdwhatPage} in Section B.28.

\begin{xtc}
\verb|)abbreviation query| can be abbreviated (no pun intended) to \verb|)abb q|.
\end{xtc}

\begin{verbatim}
\verb|)abb q Integer|
\end{verbatim}

\begin{xtc}
The \verb|)abbreviation query| command lists the constructor name if you give the abbreviation. Issue \verb|)abb q| if you want to see the names and abbreviations of all Axiom constructors.
\end{xtc}

\begin{verbatim}
\verb|)abb q DMP|
\end{verbatim}

\begin{xtc}
Issue this to see all packages whose names contain the string ‘ode’.
\end{xtc}

\begin{verbatim}
\verb|)what packages ode|

A \spadgloss{declaration} is an expression used to restrict the type of values that can be assigned to variables. A colon (\axiomSyntax{:}) is always used after a variable or list of variables to be declared.

You can always combine a declaration with an assignment. When you do, it is equivalent to first giving a declaration statement, then giving an assignment.

To see how to declare your own functions, see  
\downlink{``Declaring the Type of Functions''}{ugUserDeclarePage} in Section 6.4\ignore{ugUserDeclare}.

Records

| ug02.ht |

\begin{page}{ugTypesRecordsPage}{2.4. Records}
\beginscroll
A \emph{Record} is an object composed of one or more other objects, each of which is referenced with a \spadgloss{selector}. Components can all belong to the same type or each can have a different
The syntax for writing a Record type is
\begin{center}
\texttt{Record(\_selector\_1:\_type\_1, \\
\_selector\_2:\_type\_2, \ldots, \\
\_selector\_N:\_type\_N))}
\end{center}
You must be careful if a selector has the same name as a variable in the workspace. If this occurs, precede the selector name by a single quote.

Record components are implicitly ordered. All the components of a record can be set at once by assigning the record a bracketed tuple of values of the proper length (for example, \axiom{r : Record(a: Integer, b: String) := [1, "two"]}). To access a component of a record \axiom{r}, write the name \axiom{r}, followed by a period, followed by a selector.

\begin{xref}
The object returned by this computation is a record with two components: a quotient part and a remainder part.
\end{xref}
\axiom{u := divide(5,2) \bound{u}}
\begin{xref}
This is the quotient part.
\end{xref}
\axiom{u.quotient \free{u}}
\begin{xref}
This is the remainder part.
\end{xref}
\axiom{u.remainder \free{u}}
\begin{xref}
You can use selector expressions on the left-hand side of an assignment to change destructively the components of a record.
\end{xref}
\axiom{u.quotient := 8978 \free{u}\bound{u1}}
\begin{xref}
The selected component \axiom{quotient} has the value \axiom{8978}, which is what is returned by the assignment.
Check that the value of \axiom{u} was modified.
\end{xref}
\axiom{u \free{u}\free{u1}}
Selectors are evaluated. Thus you can use variables that evaluate to selectors instead of the selectors themselves.

\[
\spadpaste{s := 'quotient \bound{s}}
\]

Be careful! A selector could have the same name as a variable in the workspace. If this occurs, precede the selector name by a single quote, as in \axiom{u.'quotient}.

\[
\spadpaste{\text{divide}(5,2).s \free{s}}
\]

Here we declare that the value of \axiom{bd} has two components: a string, to be accessed via \axiom{name}, and an integer, to be accessed via \axiom{birthdayMonth}.

\[
\spadpaste{\text{bd : Record(name : String, birthdayMonth : Integer)}}
\]

You must initially set the value of the entire \spadtype{Record} at once.

\[
\spadpaste{\text{bd := ["Judith", 3] \free{bddec}}} \bound{bd}
\]

Once set, you can change any of the individual components.

\[
\spadpaste{\text{bd.name := "Katie" \free{bd}}} \bound{bd}
\]

Records may be nested and the selector names can be shared at different levels.

\[
\spadpaste{\text{r : Record(a : Record(b: Integer, c: Integer), b: Integer)}} \bound{rdec}
\]

The record \axiom{r} has a \axiom{b} selector at two different levels. Here is an initial value for \axiom{r}.

\[
\spadpaste{\text{r := [[1,2],3] \bound{r} \free{rdec}}} \bound{r}
\]
This extracts the $\text{axiom}\{b\}$ component from the $\text{axiom}\{a\}$ component of $\text{axiom}\{r\}$.
\spad{r.a.b \free{r}}
\xtc{

Unions

⇒ “notitle” (ugTypesUnionsWOSelPage) 7 on page 1657
⇒ “notitle” (ugTypesUnionsWSelPage) 7 on page 1664

---

Type \texttt{Union} is used for objects that can be of any of a specific finite set of types. Two versions of unions are available, one with selectors (like records) and one without.
Unions Without Selectors

---

The declaration \texttt{x : Union(Integer, String, Float)} states that \texttt{x} can have values that are integers, strings or ‘big’ floats.

If, for example, the \texttt{Union} object is an integer, the object is said to belong to the \texttt{Integer} \texttt{it} branch of the \texttt{Union}.

Note that we are being a bit careless with the language here. Technically, the type of \texttt{x} is always \texttt{Union(Integer, String, Float)}.

If it belongs to the \texttt{Integer} branch, \texttt{x} may be converted to an object of type \texttt{Integer}.

It is possible to create unions like \texttt{Union(Integer, PositiveInteger)} but they are difficult to work with because of the overlap in the branch types.

See below for the rules Axiom uses for converting something into a union object.

The \texttt{case} infix \texttt{case} operator returns a \texttt{Boolean} and can be used to determine the branch in which an object lies.

This function displays a message stating in which branch of the \texttt{Union} the object (defined as \texttt{x} above) lies.

\xtc{
\begin{spadsrc}
sayBranch(x : Union(Integer,String,Float)) : Void ==
   output
   x case Integer  => "Integer branch"
   x case String   => "String branch"
   "Float branch"
\end{spadsrc}

This tries \userfun{sayBranch} with an integer.
\spadpaste{sayBranch 1 \free{sayBranch}}

This tries \userfun{sayBranch} with a string.
\spadpaste{sayBranch "hello" \free{sayBranch}}

This tries \userfun{sayBranch} with a floating-point number.
\spadpaste{sayBranch 2.718281828 \free{sayBranch}}

There are two things of interest about this particular example to which we would like to draw your attention.
\begin{itemize}
\item[1.] Axiom normally converts a result to the target value before passing it to the function. If we left the declaration information out of this function definition then the \axiom{sayBranch} call would have been attempted with an \axiomType{Integer} rather than a \pspadtype{Union}, and an error would have resulted.
\item[2.] The types in a \pspadtype{Union} are searched in the order given. So if the type were given as
\begin{spad}{small}
\axiom{sayBranch(x: Union(String,Integer,Float,Any)): Void}}
\end{spad}
then the result would have been "String branch" because there is a conversion from \axiomType{Integer} to \axiomType{String}.
\end{itemize}
Sometimes \pspadtype{Union} types can have extremely
long names.
Axiom therefore abbreviates the names of unions by printing
the type of the branch first within the \texttt{Union} and then
eliding the remaining types with an ellipsis (\texttt{...}).

\begin{verbatim}
Here the \texttt{Union(Integer,String)} branch is displayed first.
Use \texttt{::} to create a \texttt{Union} object from an object.
\}\{ \spadpaste{78 :: Union(Integer,String)} \}
\begin{verbatim}
Here the \texttt{Union(String)} branch is displayed first.
\}\{ \spadpaste{s := "string" :: Union(Integer,String) \bound{s}} \}
\end{verbatim}
Use \texttt{\textbf{typeOf}} to see the full and actual \texttt{Union} type.
\}\{ \spadpaste{\textbf{typeOf s}} \}
\begin{verbatim}
A common operation that returns a union is \texttt{exquo} which returns the ‘‘exact quotient’’ if the quotient is exact,...
\}\{ \spadpaste{three := exquo(6,2) \bound{three}} \}
\begin{verbatim}
and \texttt{"failed"} if the quotient is not exact.
\}\{ \spadpaste{exquo(5,2)} \}
\end{verbatim}
A union with a \texttt{"failed"} is frequently used to indicate the failure
or lack of applicability of an object.
As another example, assign an integer a variable \texttt{r} declared to be a
rational number.
\}\{ \spadpaste{r: FRAC INT := 3 \bound{r}\bound{rdec}} \}
\begin{verbatim}
The operation \texttt{retractIfCan} tries to retract the
fraction to the underlying domain \texttt{Integer}.
It produces a union object.
Here it succeeds.
\}\{ \spadpaste{retractIfCan(r) \free{r}} \}
\end{verbatim}
\end{verbatim}
Assign it a rational number.

\spadpaste{r := 3/2 \bound{r1}\free{rdec}}
\xtc{Here the retraction fails.}
\spadpaste{retractIfCan(r) \free{r1}}

Type: Fraction Integer
Like records ( \downlink{``Records''}{ugTypesRecordsPage} in Section 2.4\ignore{ugTypesRecords}), you can write \pspadtype{Union} types

Unions With Selectors
with selectors.

Important
The syntax for writing a \texttt{Union} type with selectors is

\begin{verbatim}
Union(selector{1}:type{1}, selector{2}:type{2}, \ldots, selector{N}:type{N})
\end{verbatim}

You must be careful if a selector has the same name as a variable in the
workspace. If this occurs, precede the selector name by a single
quote. It is an error to use a selector that does not correspond to
the branch of the \texttt{Union} in which the element actually lies.

Important

Be sure to understand the difference between records and unions with
selectors. Records can have more than one component and the selectors
are used to refer to the components. Unions always have one component
but the type of that one component can vary. An object of type
\texttt{Record(a: Integer, b: Float, c: String)} contains an
integer \textit{and} a float \textit{and} a string. An object of type
\texttt{Union(a: Integer, b: Float, c: String)} contains an integer
\textit{or} a float \textit{or} a string.

Here is a version of the \texttt{sayBranch} function (cf.
\downlink{``Unions Without Selectors''}{ugTypesUnionsWOSelPage}
in Section 2.5.1) that works with a union with selectors.
It displays a message stating in which branch of the \texttt{Union} the
object lies.

\begin{verbatim}
sayBranch(x:Union(i:Integer,s:String,f:Float)):Void==
    output
    x case i => "Integer branch"
    x case s => "String branch"
    "Float branch"
\end{verbatim}

Note that \texttt{case} uses the selector name as its right-hand argument.
\spad{case}

If you accidentally use the branch type on the right-hand side of
\texttt{case}, \texttt{false} will be returned.

xtc{
Declare variable \texttt{u} to have a union type with selectors.
}
\spadpaste{u : Union(i : Integer, s : String) \bound{undec}}
}

xtc{
Give an initial value to \texttt{u}.
}

Use \axiom{case} to determine in which branch of a \pspadtype{Union} an object lies.

\spadpaste{u case i \free{u}}

\spadpaste{u case s \free{u}}

To access the element in a particular branch, use the selector.

\spadpaste{u.s \free{u}}
\spad{u := "good morning" \free{undec}}

\verbatim{(3) false Type: Boolean}
\verbatim{(4) true Type: Boolean}
\verbatim{(5) "good morning" Type: String}
The “Any” Domain

With the exception of objects of type \texttt{Record}, all Axiom data structures are homogenous, that is, they hold objects all of the same type. If you need to get around this, you can use type \texttt{Any}. Using \texttt{Any}, for example, you can create lists whose elements are integers, rational numbers, strings, and even other lists.

\begin{verbatim}
DECLARE \texttt{u} to have type \texttt{Any}.
\texttt{u: Any\bound{uany}}
\end{verbatim}

 Assign a list of mixed type values to \texttt{u}
\begin{verbatim}
\texttt{u := [1, 7.2, 3/2, x**2, "wally"]\free{uany}\bound{u}}
\end{verbatim}

 When we ask for the elements, Axiom displays these types.
\begin{verbatim}
\texttt{u.1 \free{u}}
\end{verbatim}

 Actually, these objects belong to \texttt{Any} but Axiom automatically converts them to their natural types for you.
\begin{verbatim}
\texttt{u.3 \free{u}}
\end{verbatim}

 Since type \texttt{Any} can be anything, it can only belong to type \texttt{Type}. Therefore it cannot be used in algebraic domains.
\begin{verbatim}
\texttt{v : Matrix(Any)}
\end{verbatim}

Perhaps you are wondering how Axiom internally represents
objects of type \texttt{Any}.
An object of type \texttt{Any} consists not only a data part
representing its normal value, but also a type part (a \texttt{badge}) giving
its type.
For example, the value \texttt{1} of type \texttt{PositiveInteger} as an
object of type \texttt{Any} internally looks like
\texttt{[1,PositiveInteger()]}.

%When should you use \texttt{Any} instead of a \texttt{Union} type?
%Can you plan ahead?
%For a \texttt{Union}, you must know in advance exactly which types you
%are
%\index{union!vs. Any@{vs. \nonLibAxiomType{Any}}}
%going to allow.
%For \texttt{Any}, anything that comes along can be accommodated.

\begin{spad}
\begin{verbatim}
Type: Void
\end{verbatim}
\end{spad}
\begin{verbatim}
(3) 1
Type: PositiveInteger
\end{verbatim}

\begin{verbatim}
(4) 2
Type: Fraction Integer
\end{verbatim}
Conversion

Conversion is the process of changing an object of one type into an object of another type. The syntax for conversion is:
\begin{verbatim}
object :: newType
\end{verbatim}

By default, 3 has the type PositiveInteger.

3

We can change this into an object of type Fraction Integer by using `::'

\begin{verbatim}
3 :: Fraction Integer
\end{verbatim}

A coercion is a special kind of conversion that Axiom is allowed to do automatically when you enter an expression. Coercions are usually somewhat safer than more general conversions. The Axiom library contains operations called coerce and convert. Only the coerce operations can be used by the interpreter to change an object into an object of another type unless you explicitly use a `::'.

By default, \axiom{3} has the type \axiomType{PositiveInteger}.

\spadpaste{3}
A coercion is a special kind of conversion that Axiom is allowed to do automatically when you enter an expression. Coercions are usually somewhat safer than more general conversions. The Axiom library contains operations called \axiomFun{coerce} and \axiomFun{convert}. Only the \axiomFun{coerce} operations can be used by the interpreter to change an object into an object of another type unless you explicitly use a \axiomSyntax{::}.

By now you will be quite familiar with what types and modes look like. It is useful to think of a type or mode as a pattern for what you want the result to be.

\xtc{Let's start with a square matrix of polynomials with complex rational number coefficients.}{
\spadpaste{m : SquareMatrix(2,POLY COMPLEX FRAC INT) \bound{mdec}}}
\xtc{}
\spadpaste{m := matrix \[[x-3/4*\%i,z*y**2+1/2],[3/7*\%i*y**4 - x,12-\%i*9/5]\] \bound{m}\free{mdec}}
\xtc{We first want to interchange the \axiomType{Complex} and \axiomType{Fraction} layers. We do the conversion by doing the interchange in the type expression.}{
\spadpaste{m1 := m :: SquareMatrix(2,POLY FRAC COMPLEX INT) \free{m}\bound{m1}}}
\xtc{Interchange the \axiomType{Polynomial} and the \axiomType{Fraction} levels.}{
\spadpaste{m2 := m1 :: SquareMatrix(2,FRAC POLY COMPLEX INT) \free{m1}\bound{m2}}}
\xtc{Interchange the \axiomType{Polynomial} and the \axiomType{Complex} levels.}{
\spadpaste{m3 := m2 :: SquareMatrix(2,FRAC POLY COMPLEX INT) \free{m2}\bound{m3}}}
\xtc{We can change this into an object of type \axiomType{Fraction Integer} by using \axiomSyntax{::}.}{
\spadpaste{3 :: Fraction Integer}}
All the entries have changed types, although in comparing the
last two results only the entry in the lower left corner looks different.
We did all the intermediate steps to show you what Axiom can do.

In fact, we could have combined all these into one conversion.

There are times when Axiom is not be able to do the conversion
in one step.
You may need to break up the transformation into several conversions
in order to get an object of the desired type.

We cannot move either \texttt{Fraction} or \texttt{Complex}
above (or to the left of, depending on how you look at it)
\texttt{SquareMatrix} because each of these levels requires that its
argument type have commutative multiplication, whereas
\texttt{SquareMatrix} does not. \footnote{\texttt{Fraction} requires
that its argument belong to the category \texttt{IntegralDomain} and
\texttt{Complex} requires that its argument belong to
\texttt{CommutativeRing}. See
\url{``The Basic Idea''}{ugTypesBasicPage}
in Section 2.1\ignore{ugTypesBasic} for a brief discussion of categories.}
The \texttt{Integer} level did not move anywhere
because it does not allow any arguments.
We also did not move the \texttt{SquareMatrix} part anywhere, but
we could have.

Recall that \texttt{m} looks like this.

If we want a polynomial with matrix coefficients rather than a matrix
with polynomial entries, we can just do the conversion.

We have not yet used modes for any conversions.
Modes are a great shorthand for indicating the type of the
object you want.
Instead of using the long type expression in the
last example, we could have simply said this.
}
\spadpaste{m :: POLY ? \free{m}}
}
\xtc{
We can also indicate more structure if we want the entries
of the matrices to be fractions.
}
\spadpaste{m :: POLY SquareMatrix(2,FRAC ?) \free{m}}
}

Subdomains Again

A \spadgloss{subdomain} \axiom{S} of a domain \axiom{D} is a domain consisting of
\begin{itemize}
\item those elements of \axiom{D} that satisfy some \spadgloss{predicate} (that is, a test that returns \axiom{true} or \axiom{false}) and
Every domain is a subdomain of itself, trivially satisfying the membership test: \( \text{true} \).

Currently, there are only two system-defined subdomains in Axiom that receive substantial use. \axiomType{PositiveInteger} and \axiomType{NonNegativeInteger} are subdomains of \axiomType{Integer}. An element \( \text{axiom}(x) \) of \axiomType{NonNegativeInteger} is an integer that is greater than or equal to zero, that is, satisfies \( x \geq 0 \). An element \( \text{axiom}(x) \) of \axiomType{PositiveInteger} is a nonnegative integer that is, in fact, greater than zero, that is, satisfies \( x > 0 \). Not all operations from \axiomType{Integer} are available for these subdomains. For example, negation and subtraction are not provided since the subdomains are not closed under those operations. When you use an integer in an expression, Axiom assigns to it the type that is the most specific subdomain whose predicate is satisfied.

\[ \begin{align*}
\text{This is a positive integer.} \\
\spadpaste{5}
\end{align*} \]

\[ \begin{align*}
\text{This is a nonnegative integer.} \\
\spadpaste{0}
\end{align*} \]

\[ \begin{align*}
\text{This is neither of the above.} \\
\spadpaste{-5}
\end{align*} \]

Furthermore, unless you are assigning an integer to a declared variable or using a conversion, any integer result has as type the most specific subdomain.

\[ \begin{align*}
\spadpaste{(-2) - (-3)}
\end{align*} \]
When necessary, Axiom converts an integer object into one belonging to a less specific subdomain. For example, in \axiom{3-2}, the arguments to \axiomOpFrom{-}{Integer} are both elements of \axiomType{PositiveInteger}, but this type does not provide a subtraction operation. Neither does \axiomType{NonNegativeInteger}, so \axiom{3} and \axiom{2} are viewed as elements of \axiomType{Integer}, where their difference can be calculated. The result is \axiom{1}, which Axiom then automatically assigns the type \axiomType{PositiveInteger}.

\xtc{
Certain operations are very sensitive to the subdomains to which their arguments belong.
This is an element of \axiomType{PositiveInteger}.
}{
\spadpaste{2 ** 2}
}
\xtc{
This is an element of \axiomType{Fraction Integer}.
}{
\spadpaste{2 ** (-2)}
}
\xtc{
It makes sense then that this is a list of elements of \axiomType{PositiveInteger}.
}{
\spadpaste{[10**i for i in 2..5]}
}
What should the type of \axiom{[10**(i-1) for i in 2..5]} be? On one hand, \axiom{i-1} is always an integer greater than zero as \axiom{i} ranges from \axiom{2} to \axiom{5} and so \axiom{10**i} is also always a positive integer. On the other, \axiom{i-1} is a very simple function of \axiom{i}. Axiom does not try to analyze every such function over the index’s range of values to determine whether it is always positive or nowhere negative.
For an arbitrary Axiom function, this analysis is not possible.

\xtc{
So, to be consistent no such analysis is done and we get this.
}{
\spadpaste{[10**(i-1) for i in 2..5]}
}
\xtc{
To get a list of elements of \axiomType{PositiveInteger} instead, you have two choices. You can use a conversion.
}{
\spadpaste{[10**((i-1) :: PI) for i in 2..5]}
}
Or you can use \axiom{pretend}.
\spadkey{pretend}
\spadpaste{[10**((i-1) pretend PI) for i in 2..5]}
}

The operation \axiom{pretend} is used to defeat the Axiom type system.
The expression \axiom{object pretend D} means ‘make a new object (without copying) of type \axiom{D} from \axiom{object}.’
If \axiom{object} were an integer and you told Axiom to pretend it was a list, you would probably see a message about a fatal error being caught and memory possibly being damaged.
Lists do not have the same internal representation as integers!

You use \axiom{pretend} at your peril.

Use \axiom{pretend} with great care!
Axiom trusts you that the value is of the specified type.

**Package Calling and Target Types**

⇒ "notitle" (ugTypesDeclarePage) 7 on page 1641
⇒ "notitle" (ugUserUsePage) 10 on page 1854

---

ug02.ht
Axiom works hard to figure out what you mean by an expression without your having to qualify it with type information. Nevertheless, there are times when you need to help it along by providing hints (or even orders!) to get Axiom to do what you want.

We saw in Section 2.3 that declarations using types and modes control the type of the results produced. For example, we can either produce a complex object with polynomial real and imaginary parts or a polynomial with complex integer coefficients, depending on the declaration.

\spadgloss{Package calling} is how you tell Axiom to use a particular function from a particular part of the library.

\xtc{Use the \axiomOpFrom{/}{Fraction} from \axiomType{Fraction Integer} to create a fraction of two integers.}{2/3}
\xtc{If we wanted a floating point number, we can say ‘‘use the \axiomOpFrom{/}{Float} in \axiomType{Float}.’’}{(2/3)\$Float}
\xtc{Perhaps we actually wanted a fraction of complex integers.}{(2/3)\$Fraction(Complex Integer)}

In each case, Axiom used the indicated operations, sometimes first needing to convert the two integers into objects of an appropriate type. In these examples, \axiomOpFrom{/}{Fraction} is written as an infix operator.

\beginImportant
To use package calling with an infix operator, use the following syntax:
\centerline{\tt ( \subscriptIt{arg}{1} \ \it op}
We used, for example, \texttt{axiom{(2/3)$\text{Float}$}}. The expression \texttt{axiom{(2 + 3 + 4)}} is equivalent to \texttt{axiom{(2+3) + 4.}} Therefore in the expression \texttt{axiom{(2 + 3 + 4)$\text{Float}$}} the second \texttt{axiomOp{+}} comes from the \texttt{\axiomType{Float}} domain. Can you guess whether the first \texttt{axiomOp{+}} comes from \texttt{\axiomType{Integer}} or \texttt{\axiomType{Float}}?\footnote{\texttt{\axiomType{Float}}, because the package call causes Axiom to convert \texttt{axiom{(2 + 3)}} and \texttt{axiom{4}} to type \texttt{\axiomType{Float}}. Before the sum is converted, it is given a target type (see below) of \texttt{\axiomType{Float}} by Axiom and then evaluated. The target type causes the \texttt{axiomOp{+}} from \texttt{\axiomType{Float}} to be used.}

For an operator written before its arguments, you must use parentheses around the arguments (even if there is only one), and follow the closing parenthesis by a \texttt{axiomSyntax{$\text{type}$}} and then the type.

\beginImportant
For example, to call the ‘‘minimum’’ function from \texttt{\axiomType{DoubleFloat}} on two integers, you could write \texttt{axiom{min(4,89)$\text{DoubleFloat}$}}.

Another use of package calling is to tell Axiom to use a library function rather than a function you defined. We discuss this in \texttt{ugUserUsePage} in Section 6.9\ignore{ugUserUse}.

Sometimes rather than specifying where an operation comes from, you just want to say what type the result should be. We say that you provide a \texttt{\spadglossSee{target type}{target}} for the expression. Instead of using a \texttt{axiomSyntax{$\text{type}$}}, use a \texttt{axiomSyntax{@}} to specify the requested target type.

Otherwise, the syntax is the same.

Note that giving a target type is not the same as explicitly doing a conversion.

The first says ‘‘try to pick operations so that the result has such-and-such a type.’’

The second says ‘‘compute the result and then convert to an object of such-and-such a type.’’

\xtc{}

Sometimes it makes sense, as in this expression, to say ‘‘choose the operations in this expression so that
the final result is a \texttt{Float}.
\spad{(2/3)@Float}

Here we used \texttt{@} to say that the target type of the left-hand side was \texttt{Float}.
In this simple case, there was no real difference between using \texttt{@} and \texttt{\$}.
You can see the difference if you try the following.
\spad{(2 + 3)@String}
\spad{(2 + 3)\$String}
(By the way, the operation \texttt{concat} or juxtaposition is used to concatenate two strings.)

When we have more than one operation in an expression, the difference is even more evident.
The following two expressions show that Axiom uses the target type to create different objects.
The \texttt{+}, \texttt{*} and \texttt{**} operations are all chosen so that an object of the correct final type is created.
\spad{((x + y * \%i)**2)@(Complex Polynomial Integer)}
\spad{((x + y * \%i)**2)@(Polynomial Complex Integer)}

What do you think might happen if we left off all target type and package call information in this last example?
We can convert it to \axiomType{Complex} as an afterthought. But this is more work than just saying making what we want in the first place.
\spadpaste{(x + y * \%i)**2 \free{prevC}}
\xtc{We can convert it to \axiomType{Complex} as an afterthought. But this is more work than just saying making what we want in the first place.}
\spadpaste{\% :: Complex \free{prevC}}
\xtc{We can convert it to \axiomType{Complex} as an afterthought. But this is more work than just saying making what we want in the first place.}

Finally, another use of package calling is to qualify fully an operation that is passed as an argument to a function.

\spadpaste{\% :: Complex \free{prevC}}
\xtc{Start with a small matrix of integers.}
\spadpaste{h := matrix [[8,6],[-4,9]] \free{h}}
\xtc{We want to produce a new matrix that has for entries the multiplicative inverses of the entries of \axiom{h}. One way to do this is by calling \axiomFunFrom{map}\{MatrixCategoryFunctions2\} with the \axiomFunFrom{inv}\{Fraction\} function from \axiomType{Fraction (Integer)}.}
\spadpaste{map(inv\$Fraction(Integer),h) \free{h}}
\xtc{We could have been a bit less verbose and used abbreviations.}
\spadpaste{map(inv\$FRAC(INT),h) \free{h}\free{h1}}
\xtc{As it turns out, Axiom is smart enough to know what we mean anyway. We can just say this.}
\spadpaste{map(inv,h) \free{h}}

\end{patch}
In this section we briefly describe an internal process by which
Axiom determines a type to which two objects of possibly
different types can be converted.
We do this to give you further insight into how Axiom takes
your input, analyzes it, and produces a result.

What happens when you enter \texttt{x + 1} to Axiom?
Let’s look at what you get from the two terms of this expression.

\begin{vmulticolumn}{c}{c}{This is a symbolic object whose type indicates the name.}
\end{vmulticolumn}
\begin{vmulticolumn}{c}{c}{\texttt{x}}
\end{vmulticolumn}
\begin{vmulticolumn}{c}{c}{This is a positive integer.}
\end{vmulticolumn}
\begin{vmulticolumn}{c}{c}{\texttt{1}}
\end{vmulticolumn}

There are no operations in \texttt{PositiveInteger} that add
positive integers to objects of type \texttt{Variable(x)} nor
are there any in \texttt{Variable(x)}.
Before it can add the two parts, Axiom must come up with
a common type to which both \texttt{x} and \texttt{1} can be
converted.
We say that Axiom must \texttt{resolve} the two types
into a common type.
In this example, the common type is \texttt{Polynomial(Integer)}.

\begin{vmulticolumn}{c}{c}{Once this is determined, both parts are converted into polynomials,
and the addition operation from \texttt{Polynomial(Integer)} is used
to get the answer.}
\end{vmulticolumn}
\begin{vmulticolumn}{c}{c}{\texttt{x + 1}}
\end{vmulticolumn}
\begin{vmulticolumn}{c}{c}{Axiom can always resolve two types: if nothing resembling
the original types can be found, then \texttt{Any} is be used.
This is fine and useful in some cases.}
\end{vmulticolumn}
In other cases objects of type \axiomType{Any} can’t be used by the operations you specified.

Although this example was contrived, your expressions may need to be qualified slightly to help Axiom resolve the types involved. You may need to declare a few variables, do some package calling, provide some target type information or do some explicit conversions.

We suggest that you just enter the expression you want evaluated and see what Axiom does. We think you will be impressed with its ability to ‘‘do what I mean.’’ If Axiom is still being obtuse, give it some hints. As you work with Axiom, you will learn where it needs a little help to analyze quickly and perform your computations.

Exposing Domains and Packages

In this section we discuss how Axiom makes some operations available to you while hiding others that are meant to be used by developers or only in rare cases. If you are a new user of Axiom, it is likely that everything you need is available by default and you may want to skip over this section on first reading.

Every domain and package in the Axiom library is either exposed (meaning that you can use its operations without doing anything special) or it is hidden (meaning you have to either package call (see Package Calling and Target Types) in Section 2.9) or explicitly expose it to use the operations).

The initial exposure status for a constructor is set in the file exposed.lsp (see the Installer’s Note for Axiom if you need to know the location of this file). Constructors are collected together in exposure groups. Categories are all in the exposure group ’categories’ and the bulk of the basic set of packages and domains that are exposed are in the exposure group ’basic’.

Here is an abbreviated sample of the file (without the Lisp parentheses):

```
\spadglossSee{exposed}{expose} (meaning that you can use its operations without doing anything special) or it is \it hidden (meaning you have to either package call (see Package Calling and Target Types) in Section 2.9) or explicitly expose it to use the operations).

The initial exposure status for a constructor is set in the file exposed.lsp (see the Installer’s Note for Axiom if you need to know the location of this file). Constructors are collected together in exposure groups. Categories are all in the exposure group ’categories’ and the bulk of the basic set of packages and domains that are exposed are in the exposure group ’basic’.

Here is an abbreviated sample of the file (without the Lisp parentheses):

```
```
For each constructor in a group, the full name and the abbreviation is given.

There are other groups in \texttt{exposed.lsp} but initially only the constructors in exposure groups \texttt{``basic''} \texttt{``categories''} \texttt{``naglink''} and \texttt{``anna''} are exposed.

As an interactive user of Axiom, you do not need to modify this file. Instead, use \texttt{\spadcmd{)set expose}} to expose, hide or query the exposure status of an individual constructor or exposure group. The reason for having exposure groups is to be able to expose or hide multiple constructors with a single command. For example, you might group together into exposure group \texttt{``quantum''} a number of domains and packages useful for quantum mechanical computations. These probably should not be available to every user, but you want an easy way to make the whole collection visible to Axiom when it is looking for operations to apply.

If you wanted to hide all the basic constructors available by default,
you would issue \spadcmd{)set expose drop group basic}. If, however, you discover that you have hidden all the basic constructors, you should issue \spadcmd{)set expose add group basic} to restore your default environment.

It is more likely that you would want to expose or hide individual constructors. In \downlink{``A Famous Triangle''}{ugUserTrianglePage} in Section 6.19\ignore{ugUserTriangle} we use several operations from \axiomType{OutputForm}, a domain usually hidden. To avoid package calling every operation from \axiomType{OutputForm}, we expose the domain and let Axiom conclude that those operations should be used. Use \spadcmd{)set expose add constructor} and \spadcmd{)set expose drop constructor} to expose and hide a constructor, respectively. You should use the constructor name, not the abbreviation. The \spadcmd{)set expose} command guides you through these options.

If you expose a previously hidden constructor, Axiom exhibits new behavior (that was your intention) though you might not expect the results that you get. \axiomType{OutputForm} is, in fact, one of the worst offenders in this regard. This domain is meant to be used by other domains for creating a structure that Axiom knows how to display. It has functions like \axiomOpFrom{+}{OutputForm} that form output representations rather than do mathematical calculations. Because of the order in which Axiom looks at constructors when it is deciding what operation to apply, \axiomType{OutputForm} might be used instead of what you expect. \xtc{ This is a polynomial. }{ \spadpaste{x + x} } \xtc{ Expose \axiomType{OutputForm}. }{ \spadpaste{)set expose add constructor OutputForm \bound{setexposeadd}}} \xtc{ This is what we get when \axiomType{OutputForm} is automatically available. }{ \spadpaste{x + x \free{setexposeadd}}} \xtc{ Hide \axiomType{OutputForm} so we don't run into problems with any later examples! }{ \spadpaste{)set expose drop constructor OutputForm \bound{setexposedrop}}} 

Finally, exposure is done on a frame-by-frame basis. A \spadgloss{frame} (see \downlink{``)frame''}{ugSysCmdframePage} in Section B.11 \ignore{ugSysCmdframe}) is one of possibly several logical Axiom workspaces within a physical one, each having its own environment (for example, variables and function definitions). If you have several Axiom workspace windows on your screen, they are all different frames, automatically created for you by Hyperdoc. Frames can be manually created, made active and destroyed by the \spadcmd{)frame} system command. They do not share exposure information, so you need to use \spadcmd{)set expose} in each one to add or drop constructors from view.
\begin{verbatim}
(1) 2x
\end{verbatim}

Type: Polynomial Integer

\begin{verbatim}
(2) x + x
\end{verbatim}

Type: OutputForm
To conclude this chapter, we introduce you to some system commands that you can use for getting more information about domains, packages, categories, and operations. The most powerful Axiom facility for getting information about constructors and operations is the \Browse{} component of Hyperdoc. This is discussed in \downlink{``Browse''}{ugBrowsePage} in Chapter 14\ignore{ugBrowse}.

Use the \spadsys{what} system command to see lists of system objects whose name contain a particular substring (uppercase or lowercase is not significant).

\xtc{Issue this to see a list of all operations with \tt{complex} in their names.}
{"\tt\spadpaste{\what operation complex}}
\xtc{If you want to see all domains with \tt{matrix} in their names, issue this.
Similarly, if you wish to see all packages whose names contain `'\{\tt gauss\}'`, enter this.

\spadpaste{)what package gauss}

\xtc{
This command shows all
the operations that \axiomType{Any} provides.
Wherever \axiomSyntax{\$} appears, it means `'\axiomType{Any}'`.
}

\spadpaste{)show Any}

\xtc{
This displays all operations with the name \axiomFun{complex}.
}

\spadpaste{)display operation complex}

Let’s analyze this output.

\xtc{
First we find out what some of the abbreviations mean.
}

\spadpaste{)abbreviation query COMPCAT}

\xtc{
\spadpaste{)abbreviation query COMRING}

So if \axiom{D1} is a commutative ring (such as the integers or
floats) and \axiom{D} belongs to \axiomType{ComplexCategory}
\axiom{D1}, then there is an operation called \axiomFun{complex} that
takes two elements of \axiom{D1} and creates an element of
\axiom{D}.

The primary example of a constructor implementing domains
belonging to \axiomType{ComplexCategory} is \axiomType{Complex}.
See \downlink{‘Complex’}{ComplexXmpPage}\ignore{Complex}
for more information on that and see
\downlink{‘Declaring the Type of Functions’}{ugUserDeclarePage} in
Section 6.4\ignore{ugUserDeclare}
for more information on function types.

⇒ “notitle” (ugHyperResourcesPage) 8 on page 1717
⇒ ugHyperPage{3. Using Hyperdoc}
⇒ ugHyperPage

Hyperdoc is the gateway to Axiom.
It’s both an on-line tutorial and an on-line reference manual.
It also enables you to use Axiom simply by using the mouse and
filling in templates.
Hyperdoc is available to you if you are running Axiom under the
X Window System.

Pages usually have active areas, marked in
\textbf{this font} (bold face).\textlink{this font}{YouTriedIt}
As you move the mouse pointer to an active area, the pointer changes from
a filled dot to an open circle.
The active areas are usually linked to other pages. When you click on an active area, you move to the linked page.

\text{Try clicking \downlink{here}{YouTriedIt} now.}

We suggest that you learn more about other features of Hyperdoc by clicking on an active area in the menu below.

\beginmenu
\menudownlink{{3.1. Headings}}{ugHyperHeadingsPage}
\menudownlink{{3.2. Key Definitions}}{ugHyperKeysPage}

Headings

--- ug03.ht ---

\begin{page}{ugHyperHeadingsPage}{3.1. Headings}
\beginscroll
%
Most pages have a standard set of buttons at the top of the page.
This is what they mean:

\indent{0}
\beginitems
\item{\StdHelpButton{} Click on this to get help.}
The button only appears if there is specific help for the page you are viewing.
You can get \text{\it general} help for Hyperdoc by clicking the help button on the home page.

\item{\UpButton{} Click here to go back one page.}
By clicking on this button repeatedly, you can go back several pages and then take off in a new direction.

\item{\ReturnButton{} Go back to the home page, that is,
the page on which you started.
Use Hyperdoc to explore, to make forays into new topics.
Don’t worry about how to get back.
Hyperdoc remembers where you came from.
Just click on this button to return.

\item[\StdExitButton{}]
From the root window (the one that is displayed when you start the system) this button leaves the Hyperdoc program, and it must be restarted if you want to use it again. From any other Hyperdoc window, it just makes that one window go away. You \{it must\} use this button to get rid of a window. If you use the window manager ‘‘Close’’ button, then all of Hyperdoc goes away.
\enditems
\indent{0}
%
The buttons are not displayed if they are not applicable to the page you are viewing.
For example, there is no \ReturnButton{} button on the top-level menu.

\endscroll

\end{page}

---

**Scroll Bars**

⇒ “notitle” (ugHyperInputPage) 8 on page 1711
— ug03.htm —

\begin{page}{ugHyperScrollPage}{3.3. Scroll Bars}
\beginscroll

Whenever there is too much text to fit on a page, a \it scroll bar automatically appears along the right side.

With a scroll bar, your page becomes an aperture, that is, a window into a larger amount of text than can be displayed at one time.
The scroll bar lets you move up and down in the text to see different parts.
It also shows where the aperture is relative to the whole text.
The aperture is indicated by a strip on the scroll bar.

Move the cursor with the mouse to the ‘‘down-arrow’’ at the bottom of the scroll bar and click.
See that the aperture moves down one line.
Do it several times.
Each time you click, the aperture moves down one line.
Move the mouse to the ‘‘up-arrow’’ at the top of the scroll bar and click.
The aperture moves up one line each time you click.
Next move the mouse to any position along the middle of the scroll bar and click. Hyperdoc attempts to move the top of the aperture to this point in the text.

You cannot make the aperture go off the bottom edge. When the aperture is about half the size of text, the lowest you can move the aperture is halfway down.

To move up or down one screen at a time, use the \	exttt{\fbox{\bf PageUp}} and \	exttt{\fbox{\bf PageDown}} keys on your keyboard. They move the visible part of the region up and down one page each time you press them.

If the Hyperdoc page does not contain an input area (see `\downlink{‘Input Areas’}{ugHyperInputPage} in Section 3.4\ignore{ugHyperInput}), you can also use the \texttt{\fbox{\bf Home}} and \texttt{\fbox{\uparrow}} and \texttt{\fbox{\downarrow}} arrow keys to navigate. When you press the \texttt{\fbox{\bf Home}} key, the screen is positioned at the very top of the page. Use the \texttt{\fbox{\uparrow}} and \texttt{\fbox{\downarrow}} arrow keys to move the screen up and down one line at a time, respectively.

\inputstring{one}{40}{some text}

As you can see, the input area has some initial text \{it some text\} followed by an underscore cursor (the character \{it _\}).
To enter characters, first move your mouse cursor to somewhere within the Hyperdoc page. Characters that you type are inserted in front of the underscore. This means that when you type characters at your keyboard, they go into this first input area.

The input area grows to accommodate as many characters as you type. Use the \textbackslash{	extbf{Backspace}} key to erase characters to the left. To modify what you type, use the right-arrow and left-arrow keys and the \textbackslash{	extbf{Insert}}, \textbackslash{	extbf{Delete}}, \textbackslash{	extbf{Home}}, and \textbackslash{	extbf{End}} keys. These keys are found immediately on the right of the standard IBM keyboard.

If you press the \textbackslash{	extbf{Home}} key, the cursor moves to the beginning of the line and if you press the \textbackslash{	extbf{End}} key, the cursor moves to the end of the line. Pressing \textbackslash{	extbf{Ctrl}--	extbf{End}} deletes all the text from the cursor to the end of the line.

A page may have more than one input area. Only one input area has an underscore cursor. When you first see a page, the top-most input area contains the cursor. To type information into another input area, use the \textbackslash{	extbf{Enter}} or \textbackslash{	extbf{Tab}} key to move from one input area to another. To move in the reverse order, use \textbackslash{	extbf{Shift}--	extbf{Tab}}.

You can also move from one input area to another using your mouse. Notice that each input area is active. Click on one of the areas. As you can see, the underscore cursor moves to that window.
Radio Buttons and Toggles

— ug03.ht —

Some pages have \textit{radio buttons} and \textit{toggles}. Radio buttons are a group of buttons like those on car radios: you can select only one at a time.

Here are three radio buttons:

%\texttt{radioboxes{sample}{htbfile{pick}}{htbfile{unpick}}}
\begingroup
\begin{center}
\begin{tabular}{l}
\texttt{\radiobox[1]{rone}{sample}} & First one \\
\texttt{\radiobox[0]{rtwo}{sample}} & Second one \\
\texttt{\radiobox[0]{rthree}{sample}} & Third one \\
\end{tabular}
\end{center}
\endgroup
Once you have selected a button, it appears to be inverted and contains a checkmark.

To change the selection, move the cursor with the mouse to a different radio button and click.

\texttt{Try it now.}

A toggle is an independent button that displays some on/off state. When \texttt{on}, the button appears to be inverted and contains a checkmark. When \texttt{off}, the button is raised.

\%\texttt{inputbox{one}{htbfile{pick}}{htbfile{unpick}}}
\begingroup
\begin{center}
\begin{tabular}{l}
\texttt{\inputbox[1]{one}{htbfile{pick}}{htbfile{unpick}}} & First one \\
\texttt{\inputbox[0]{two}{htbfile{pick}}{htbfile{unpick}}} & Second one \\
\texttt{\inputbox[1]{three}{htbfile{pick}}{htbfile{unpick}}} & Third one \\
\end{tabular}
\end{center}
\endgroup
To change toggle the selection, move the cursor with the mouse to the button and click.
Search Strings

A search string is used for searching some database. To learn about search strings, we suggest that you bring up the Hyperdoc glossary. To do this from the top-level page of Hyperdoc:

\begin{itemize}
  \item Click on Reference, bringing up the Axiom Reference page.
  \item Click on Glossary, bringing up the glossary.
\end{itemize}

You can also just click on the word ‘Glossary’ in the last sentence.

Once you get the window containing the glossary, move it so that it and this window are both visible.

The glossary has an input area at its bottom. We review the various kinds of search strings you can enter to search the glossary.

The simplest search string is a word, for example, \texttt{operation}. A word only matches an entry having exactly that spelling. Enter the word \texttt{operation} into the input area above then click on \texttt{Search}. As you can see, \texttt{operation} matches only one entry, namely with \texttt{operation} itself.

Normally matching is insensitive to whether the alphabetic characters of your search string are in uppercase or lowercase. Thus \texttt{operation} and \texttt{OperAtion} both have the same effect. If you prefer that matching be case-sensitive, issue the command \texttt{ HHyperName mixedCase} command to the interpreter.

You will very often want to use the wildcard \texttt{*} in your search string so as to match multiple entries in the list. The search
key $\texttt{cat*}$ matches every entry in the list. You can also use $\texttt{*}$ anywhere within a search string to match an arbitrary substring. Try $\texttt{cat*}$ for example: enter $\texttt{cat*}$ into the input area and click on $\texttt{Search}$. This matches several entries.

You use any number of wildcards in a search string as long as they are not adjacent. Try search strings such as $\texttt{*dom*}$. As you see, this search string matches $\texttt{domain}$, $\texttt{domain constructor}$, $\texttt{subdomain}$, and so on.

For more complicated searches, you can use $\texttt{and}$, $\texttt{or}$, and $\texttt{not}$ with basic search strings; write logical expressions using these three operators just as in the Axiom language. For example, $\texttt{domain or package}$ matches the two entries $\texttt{domain}$ and $\texttt{package}$. Similarly, $\texttt{dom* and *con*}$ matches $\texttt{domain constructor}$ and others. Also $\texttt{not *a*}$ matches every entry that does not contain the letter $\texttt{a}$ somewhere.

Use parentheses for grouping. For example, $\texttt{dom* and (not *con*)}$ matches $\texttt{domain}$ but not $\texttt{domain constructor}$.

There is no limit to how complex your logical expression can be. For example, $\texttt{a* or b* or c* or d* or e* and (not *a*)}$ is a valid expression.
Many pages have Axiom example commands.

Here are two:
\spadpaste{a:= x**2 + 1 \bound{a}}
\spadpaste{(a - 2)**2 \free{a}}

Each command has an active ‘‘button’’ along the left margin. When you click on this button, the output for the command is ‘‘pasted-in.’’

Click again on the button and you see that the pasted-in output disappears.

Maybe you would like to run an example?
To do so, just click on any part of its text!
When you do, the example line is copied into a new interactive Axiom buffer for this Hyperdoc page.

Sometimes one example line cannot be run before you run an earlier one. Don’t worry—Hyperdoc automatically runs all the necessary lines in the right order!
For instance, the second example line above refers to \spad{a} which is assigned in the first example line.
What happens if you first click on the second example line? Axiom first issues the first line (to assign \spad{a}), then the second (to do the computation using \spad{a}).

The new interactive Axiom buffer disappears when you leave Hyperdoc.
If you want to get rid of it beforehand, use the \bf{Cancel} button of the X Window manager or issue the Axiom system command \spadsys{)close.}
X Window Resources for Hyperdoc

— ug03.ht —

You can control the appearance of Hyperdoc while running under Version 11 of the X Window System by placing the following resources
in the file \{bf .Xdefaults\} in your home directory.
In what follows, \{it font\} is any valid X11 font name
(for example, \{tt Rom14\}) and \{it color\} is any valid X11 color
specification (for example, \{tt NavyBlue\}).
For more information about fonts and colors, refer to the
X Window documentation for your system.

\begin{itemize}
\item \t{\tt Axiom.hyperdoc.RmFont:} \{it font\} \\
    This is the standard text font. \xdefault{Rom14}
\item \t{\tt Axiom.hyperdoc.RmColor:} \{it color\} \\
    This is the standard text color. \xdefault{black}
\item \t{\tt Axiom.hyperdoc.ActiveFont:\} \{it font\} \\
    This is the font used for Hyperdoc link buttons. \xdefault{Bld14}
\item \t{\tt Axiom.hyperdoc.ActiveColor:\} \{it color\} \\
    This is the color used for Hyperdoc link buttons. \xdefault{black}
\item \t{\tt Axiom.hyperdoc.AxiomFont:} \{it font\} \\
    This is the font used for active Axiom commands.\footnote{

   — ug04.ht —

\begin{page}{ugInOutPage}{4. Input Files and Output Styles}
\beginscroll

In this chapter we discuss how to collect Axiom statements and commands into files and then read the contents into the workspace.
We also show how to display the results of your computations in several different styles including \texttt{\TeX}, FORTRAN and monospace two-dimensional format.\footnote{\texttt{\TeX} is a trademark of the American Mathematical Society.}

The printed version of this book uses the Axiom \texttt{\TeX} output formatter.
When we demonstrate a particular output style, we will need to turn \texttt{\TeX} formatting off and the output style on so that the correct output is shown in the text.
Input Files

⇒ “notitle” (ugLangBlocksPage) 9 on page 1753
— ug04.ht —

\begin{page}{ugInOutInPage}{4.1. Input Files}
\beginscroll
%
In this section we explain what an \textit{input file} is and why you would want to know about it. We discuss where Axiom looks for input files and how you can direct it to look elsewhere. We also show how to read the contents of an input file into the \spadgloss{workspace} and how to use the \spadgloss{history} facility to generate an input file from the statements you have entered directly into the workspace.

An \textit{input} file contains Axiom expressions and system commands. Anything that you can enter directly to Axiom can be put into an input file. This is how you save input functions and expressions that you wish to read into Axiom more than one time.

To read an input file into Axiom, use the \spadcmd{)read} system command. For example, you can read a file in a particular directory by issuing \begin{verbatim}
The "`\bf .input'" is optional; this also works:

\begin{verbatim}
)read /spad/src/input/matrix
\end{verbatim}

What happens if you just enter
\spadcmd{)read matrix.input} or even \spadcmd{)read matrix}?  
Axiom looks in your current working directory for input files 
that are not qualified by a directory name.
Typically, this directory is the directory from which you invoked 
Axiom.
To change the current working directory, use the \spadcmd{)cd} system 
command. The command \spadsys{)cd} by itself shows the current 
working 
directory.
To change it to 
the \spadsys{src/input} subdirectory for user `babar', 
issue 
\begin{verbatim}
)cd /u/babar/src/input
\end{verbatim}
Axiom looks first in this directory for an input file.
If it is not found, it looks in the system's directories, assuming 
you meant some input file that was provided with Axiom.

\beginImportant
If you have the Axiom history facility turned on (which it is 
by default), you can save all the lines you have entered into the 
workspace by entering 
\begin{verbatim}
)history )write
\end{verbatim}
Axiom tells you what input file to edit to see your 
statements.
The file is in your home directory or in the directory you 
specified with \spadsys{)cd}.
\endImportant

In \downlink{``Blocks''}{ugLangBlocksPage} in Section 5.2 
we discuss using indentation in input files to group statements 
into \it blocks.
The \texttt{.axiom.input} File

\begin{page}{ugInOutSpadprofPage}{4.2. The \texttt{.axiom.input} File}
\beginscroll

When Axiom starts up, it tries to read the input file \texttt{.axiom.input} from your home directory. If there is no \texttt{axiom.input} in your home directory, it reads the copy located in its own \texttt{src/input} directory. The file usually contains system commands to personalize your Axiom environment. In the remainder of this section we mention a few things that users frequently place in their \texttt{axiom.input} files.

In order to have FORTRAN output always produced from your computations, place the system command
\spadcmd{)set output fortran on}
in \texttt{axiom.input}.

If you do not want to be prompted for confirmation when you issue the \spadcmd{)quit} system command, place
\spadcmd{)set quit unprotected}
in \texttt{axiom.input}.

If you then decide that you do want to be prompted, issue
\spadcmd{)set quit protected}.

This is the default setting so that new users do not leave Axiom inadvertently.\footnote{The system command \spadcmd{)pquit} always prompts you for confirmation.}

To see the other system variables you can set, issue \spadcmd{)set} or use the Hyperdoc \texttt{Settings} facility to view and change Axiom system variables.

\endscroll
\autobuttons
\end{page}
Common Features of Using Output Formats

— ug04.ht —

\begin{page}{ugInOutOutPage}{4.3. Common Features of Using Output Formats}
\beginscroll

In this section we discuss how to start and stop the display of the different output formats and how to send the output to the screen or to a file.
To fix ideas, we use FORTRAN output format for most of the examples.

You can use the \texttt{)set output} system command to toggle or redirect the different kinds of output.
The name of the kind of output follows ‘output’ in the command.
The names are

\begin{itemize}
  \item \texttt{fortran} for FORTRAN output.
  \item \texttt{algebra} for monospace two-dimensional mathematical output.
  \item \texttt{tex} for \texttt{\TeX} output.
  \item \texttt{html} for HTML output.
  \item \texttt{mathml} for MathML output.
  \item \texttt{script} for IBM Script Formula Format output.
\end{itemize}

For example, issue \texttt{)set output fortran on} to turn on FORTRAN format and
issue \texttt{)set output fortran off} to turn it off.
By default, \texttt{algebra} is \texttt{on} and all others are \texttt{off}.
When output is started, it is sent to the screen.
To send the output to a file, give the file name without directory or extension.
Axiom appends a file extension depending on the kind of output being produced.
\xtc{
  Issue this to redirect FORTRAN output to, for example, the file \texttt{\bf linalg.sfort}.
}{\texttt{)set output fortran linalg}}
\noOutputXtc{
  You must \texttt{also} turn on the creation of FORTRAN output.
The above just says where it goes if it is created.
In what directory is this output placed?
It goes into the directory from which you started Axiom,
or if you have used the \spad{)cd} system command, the one
that you specified with \spad{)cd}.
You should use \spad{)cd} before you send the output to the file.

You can always direct output back to the screen by issuing this.

You can abbreviate the words \texttt{\textasciitilde\spad{on}}, \texttt{\textasciitilde\spad{off}}, and
\texttt{\textasciitilde\spad{console}} to the minimal number
of characters needed to distinguish them.

The width of the output on the page is set by
\spadcmd{)set output length} for all formats except FORTRAN.
Use \spadcmd{)set fortran fortlength} to
change the FORTRAN line length from its default value of \spad{72}.

TeX Format

Axiom can produce \TeX{} output for your expressions. The output is produced using macros from the \LaTeX{} document preparation system by Leslie Lamport.\footnote{See Leslie Lamport, \textit{\LaTeX{}: A Document Preparation System,} Reading, Massachusetts: Addison-Wesley Publishing Company, Inc., 1986.} The printed version of this book was produced using this formatter.

To turn on \TeX{} output formatting, issue this.
\begin{verbatim}
\spadpaste{)set output tex on \bound{texon}}
\end{verbatim}
Here is an example of its output.
\begin{verbatim}
matrix \[
\begin{array}{cc}
\displaystyle {{3 \ \%i \ {y \sp 3}}+x}&
\displaystyle {{3 \ \%i \ {y \sp 3}}+{2 \ \{x \ sp 2}\}} \\
\displaystyle {{4 \ \%i \ {y \sp 4}}+x}&
\displaystyle {{4 \ \%i \ {y \sp 4}}+{2 \ \{x \ sp 2}\}} \\
\end{array}
\right\] \leqno(3)
\end{verbatim}
To turn \TeX{} output formatting off, issue \spad{)set output tex off}.

The \LaTeX{} macros in the output generated by Axiom are all standard except for the following definitions:
\begin{verbatim}
\def\csch{\mathop{\rm csch}\nolimits}
\end{verbatim}

FORTRAN Format

---

ug04.ht

\begin{page}{ugInOutFortranPage}{4.7. FORTRAN Format}
\beginscroll

In addition to turning FORTRAN output on and off and stating where the output should be placed, there are many options that control the appearance of the generated code. In this section we describe some of the basic options. Issue \spadcmd{)set fortran} to see a full list with their current settings.

The output FORTRAN expression usually begins in column 7. If the expression needs more than one line, the ampersand character \spadSyntax{\&} is used in column 6. Since some versions of FORTRAN have restrictions on the number of lines per statement, Axiom breaks long expressions into segments with a maximum of 1320 characters (20 lines of 66 characters) per segment. If you want to change this, say, to 660 characters, issue the system command \spadcmd{)set fortran explength 660}. You can turn off the line breaking by issuing \spadcmd{)set fortran segment off}. Various code optimization levels are available. % \noOutputXtc{ FORTRAN output is produced after you issue this. }{ \spadpaste{)set output fortran on \bound{forton}} }

\noOutputXtc{ For the initial examples, we set the optimization level to 0, which is the lowest level. }{ \spadpaste{)set fortran optlevel 0 \bound{opt0}\free{forton}} }

\noOutputXtc{ The output is usually in columns 7 through 72, although fewer columns are used in the following examples so that the output fits nicely on the page. }{ \spadpaste{)set fortran fortlenght 60} }

\noOutputXtc{ By default, the output goes to the screen and is displayed before the standard Axiom two-dimensional output. In this example, an assignment to the variable \spad{R1} was generated because this is the result of step 1. }{ \spadpaste{\spad{\texttt{(x+y)**3 \free{opt0}}}} }

\noOutputXtc{ Here is an example that illustrates the line breaking. }{ \spadpaste{\texttt{(x+y+z)**3 \free{opt0}}} }

Note in the above examples that integers are generally converted to floating point numbers, except in exponents. This is the default behavior but can be turned off by issuing \spadcmd{)set fortran ints2floats off}. The rules governing when the conversion is done are:
1735

\indent{4}
\begin{itemize}
\item If an integer is an exponent, convert it to a floating point number if it is greater than 32767 in absolute value, otherwise leave it as an integer.
\item Convert all other integers in an expression to floating point numbers.
\end{itemize}
\indent{0}

These rules only govern integers in expressions. Numbers generated by Axiom for \spad{DIMENSION} statements are also integers.

To set the type of generated FORTRAN data, use one of the following:
\begin{verbatim}
)set fortran defaulttype REAL
)set fortran defaulttype INTEGER
)set fortran defaulttype COMPLEX
)set fortran defaulttype LOGICAL
)set fortran defaulttype CHARACTER
\end{verbatim}

When temporaries are created, they are given a default type of \tt{REAL.} Also, the \tt{REAL} versions of functions are used by default.

\spadpaste{sin(x) \free{opt1}}

At optimization level 1, Axiom removes common subexpressions.

\spadpaste{()set fortran optlevel 1 \bound{opt1}\free{forton}}

This changes the precision to \tt{DOUBLE}. Substitute \tt{single} for \tt{double} to return to single precision.

\spadpaste{()set fortran precision double \free{opt1}\bound{double1}}

Complex constants display the precision.

\spadpaste{2.3 + 5.6*\%i \free{double1}}
The function names that Axiom generates depend on the chosen precision.

```spad
sin π/2 \free{double1}
```

Reset the precision to \spad{single} and look at these two examples again.

```spad
)set fortran precision single \free{opt1}\bound{single1}
```

Expressions that look like lists, streams, sets or matrices cause array code to be generated.

```spad
[x+1,y+1,z+1] \free{opt1}
```

A temporary variable is generated to be the name of the array. This may have to be changed in your particular application.

```spad
set[2,3,4,3,5] \free{opt1}
```

By default, the starting index for generated FORTRAN arrays is \spad{0}.

```spad
matrix [[2.3,9.7],[0.0,18.778]] \free{opt1}
```

To change the starting index for generated FORTRAN arrays to be \spad{1}, issue this. This value can only be \spad{0} or \spad{1}.

```spad
)set fortran startindex 1 \free{opt1}\bound{start1}
```

Look at the code generated for the matrix again.

```spad
matrix [[2.3,9.7],[0.0,18.778]] \free{start1}
```

In this chapter we look at some of the basic components of the Axiom language that you can use interactively. We show how to create a \spadgloss{block} of expressions, how to form loops and list iterations, how to modify the sequential evaluation of a block and how to use \{\tt if-then-else\} to evaluate parts of your program conditionally.

We suggest you first read the boxed material in each section and then proceed to a more thorough reading of the chapter.
Immediate and Delayed Assignments

A \spadgloss{variable} in Axiom refers to a value. A variable has a name beginning with an uppercase or lowercase alphabetic character, \axiomSyntax{\%}, or \axiomSyntax{!}. Successive characters (if any) can be any of the above, digits, or \axiomSyntax{?}. Case is distinguished. The following are all examples of valid, distinct variable names:

\begin{verbatim}
a tooBig? a1B2c3%!? A %j numberOfPoints beta6 %J numberofpoints
\end{verbatim}

The \axiomSyntax{:=} operator is the immediate \spadgloss{assignment} operator. Use it to associate a value with a variable.

\beginImportant
The syntax for immediate assignment for a single variable is
\centerline{{{\it variable} \axiom{:=} {{\it expression}}}}
The value returned by an immediate assignment is the value of {{\it expression}}.
\endImportant

\xtc{The right-hand side of the expression is evaluated, yielding \axiom{1}. This value is then assigned to \axiom{a}.}{\spadpaste{a := 1 \bound{a}}} 
\xtc{The right-hand side of the expression is evaluated, yielding \axiom{1}. This value is then assigned to \axiom{b}. Thus \axiom{a} and \axiom{b} both have the value \axiom{1} after the sequence of assignments.}{\spadpaste{b := a \free{a}\bound{b}}} 
\xtc{What is the value of \axiom{b} if \axiom{a} is assigned the value \axiom{2}?}
Axiom provides delayed assignment with \texttt{==}. This implements a delayed evaluation of the right-hand side and dependency checking.

\beginImportant
The syntax for delayed assignment is
\texttt{\textit{variable} \texttt{==} \textit{expression}}
The value returned by a delayed assignment is \texttt{\texttt{void}}.
\endImportant

Using \texttt{a} and \texttt{b} as above, these are the corresponding delayed assignments.
\begin{verbatim}
\spadpaste{a := 1 \bound{ad}}
\end{verbatim}
\begin{verbatim}
\spadpaste{b == a \free{ad}\bound{bd}}
\end{verbatim}
The right-hand side of each delayed assignment is left unevaluated until the variables on the left-hand sides are evaluated. Therefore this evaluation and \ldots
\begin{verbatim}
\spadpaste{a \free{ad}}
\end{verbatim}
\begin{verbatim}
\spadpaste{b \free{bd}}
\end{verbatim}
this evaluation seem the same as before.

If we change \(a\) to \(2\)

\[
\text{spadpaste}(a == 2)\text{ad2}
\]

then

\[
\text{spadpaste}(a)\text{ad2}
\]

the value of \(b\) reflects the change to \(a\).

It is possible to set several variables at the same time

by using

a \text{spadgloss{tuple}} of variables and a tuple of expressions.\footnote{A \text{spadgloss{tuple}} is a collection of things separated by commas, often surrounded by parentheses.}

\beginImportant
The syntax for multiple immediate assignments is

\[
\text{Centerline}{\{\texttt{( } \subscriptIt{var}{1}, \subscriptIt{var}{2}, \ldots, \subscriptIt{var}{N} \text{ ) := ( } \subscriptIt{expr}{1}, \subscriptIt{expr}{2}, \ldots, \subscriptIt{expr}{N} \text{ )}}\}
\]

The value returned by an immediate assignment is the value of \(\subscriptIt{expr}{N}\).
\endImportant

This sets \(x\) to \(1\) and \(y\) to \(2\).

\[
\text{spadpaste}{(x,y) := (1,2) x y \text{bound{swap}}}
\]

Multiple immediate assignments are parallel in the sense that the

expressions on the right are all evaluated before any assignments

on the left are made.

However, the order of evaluation of these expressions is undefined.

You can use multiple immediate assignment to swap the

values held by variables.

\[
\text{spadpaste}{(x,y) := (y,x) x y \text{free{x y}}\text{bound{swap}}}
\]

\[
\text{spadpaste}{x \text{has the previous value of y}}\}
\]
\spadpaste{x \free{swap}}
\}
\xtc{
\axiom{y} has the previous value of \axiom{x}.
}\}
\spadpaste{y \free{swap}}
\}

There is no syntactic form for multiple delayed assignments. See the discussion in \downlink{``Delayed Assignments vs. Functions with No Arguments''} in Section 6.8\ignore{ugUserDelay} about how Axiom differentiates between delayed assignments and user functions of no arguments.

%% We should handle tabs in pile correctly but so far we do not.

A \spadgloss{block} is a sequence of expressions evaluated in the order that they appear, except as modified by control expressions such as \axiom{break}, \spadkey{break}, \axiom{return}, \spadkey{return}, \axiom{iterate} and \spadkey{iterate} \axiom{if-then-else} constructions. The value of a block is the value of the expression last evaluated in the block.

To leave a block early, use \axiomSyntax{=>}. For example, \axiom{i < 0 => x}. The expression before the \axiomSyntax{=>} must evaluate to \axiom{true} or \axiom{false}. The expression following the \axiomSyntax{=>} is the return value for the block.

A block can be constructed in two ways:
\begin{itemize}
\item[1.] the expressions can be separated by semicolons and the resulting expression surrounded by parentheses, and
\item[2.] the expressions can be written on succeeding lines with each line indented the same number of spaces (which must be greater
A block entered in this form is called a \spadgloss{pile}.

Only the first form is available if you are entering expressions directly to Axiom. Both forms are available in \bf{.input} files.

\beginImportant
The syntax for a simple block of expressions entered interactively is
\centerline{{\tt ( \subscriptIt{expression}{1}; \ldots; \subscriptIt{expression}{N} )}}
\endImportant

In \bf{.input} files, blocks can also be written using \spadglossSee{piles}{pile}.
The examples throughout this book are assumed to come from \bf{.input} files.

\xtc{In this example, we assign a rational number to \axiom{a} using a block consisting of three expressions. This block is written as a pile.
Each expression in the pile has the same indentation, in this case two spaces to the right of the first line.}{
\begin{spadsrc}
a :=
  i := \gcd(234,672)
  i := 3*i**5 - i + 1
  1 / i
\end{spadsrc}
}

\xtc{Here is the same block written on one line. This is how you are required to enter it at the input prompt.}{
\spadpaste{a := (i := \gcd(234,672); i := 3*i**5 - i + 1; 1 / i)}
}

\xtc{Blocks can be used to put several expressions on one line. The value returned is that of the last expression.}{
\spadpaste{(a := 1; b := 2; c := 3; [a,b,c]) \bound{a b c}}
}
Axiom gives you two ways of writing a block and the preferred way in an `.input` file is to use a pile. Roughly speaking, a pile is a block whose constituent expressions are indented the same amount. You begin a pile by starting a new line for the first expression, indenting it to the right of the previous line. You then enter the second expression on a new line, vertically aligning it with the first line. And so on. If you need to enter an inner pile, further indent its lines to the right of the outer pile. Axiom knows where a pile ends. It ends when a subsequent line is indented to the left of the pile or the end of the file.

\xtc{Blocks can be used to perform several steps before an assignment (immediate or delayed) is made.}
\begin{spadsrc}\free{a b}
d := 
    c := a**2 + b**2 
    \sqrt{c * 1.3}
\end{spadsrc}
\xtc{Blocks can be used in the arguments to functions. (Here \axiom{h} is assigned \axiom{2.1 + 3.5}.)}
\begin{spadsrc}\bound{h}
h := 2.1 + 
    1.0 
    3.5
\end{spadsrc}
\xtc{Here the second argument to \axiomFun{eval} is \axiom{x = z}, where the value of \axiom{z} is computed in the first line of the block starting on the second line.}
\begin{spadsrc}
\text{eval}(x**2 - x*y**2, 
    z := \%pi/2.0 - \exp(4.1) 
    x = z
\end{spadsrc}
\xtc{Blocks can be used in the clauses of \axiom{if-then-else} expressions (see \downlink{``if-then-else''}{ugLangIfPage} in Section 5.3\ignore{ugLangIf}).}
This is the pile version of the last block.

}{
\begin{spadsrc}
if h > 3.1 then 1.0 else (z := \cos(h); \max(z,0.5)) \free{h}
\end{spadsrc}

This is the pile version of the last block.

}{
\begin{spadsrc}
a := (b := \text{factorial}(12); c := (d := \text{eulerPhi}(22); \text{factorial}(d)); b+c)
\end{spadsrc}

This is the pile version of the last block.

}{
\begin{spadsrc}
a :=
\begin{align*}
b &= \text{factorial}(12) \\
c &= \\
d &= \text{eulerPhi}(22) \\
&\quad \text{factorial}(d) \\
&b+c
\end{align*}
\end{spadsrc}

Since \\texttt{c + d} does equal \\texttt{3628855}, \\texttt{a} has the value of \\texttt{c} and the last line is never evaluated.

}{
\begin{spadsrc}
a :=
\begin{align*}
c &= \text{factorial} 10 \\
d &= \text{fibonacci} 10 \\
c + d &= 3628855 \Rightarrow c \\
&d

\textbf{if-then-else}

⇒ "notitle" (ugTypesResolvePage) 7 on page 1696
Like many other programming languages, Axiom uses the three keywords \spadkey{if} \axiom{if, then} \spadkey{then} and \axiom{else} \spadkey{else} to form conditional expressions.

The \axiom{else} part of the conditional is optional.

The expression between the \axiom{if} and \axiom{then} keywords is a \spadgloss{predicate}: an expression that evaluates to or is convertible to either \tt{true} or \tt{false}, that is, a \axiomType{Boolean}.

An \axiom{if-then-else} expression always returns a value.

If the \axiom{else} clause is missing then the entire expression returns \void{}.

If both clauses are present, the type of the value returned by \axiom{if} is obtained by resolving the types of the values of the two clauses.

The predicate must evaluate to, or be convertible to, an object of type \axiomType{Boolean}: \tt{true} or \tt{false}.

By default, the equal sign \spadopFrom{=}{Equation} creates an equation.

This is an equation.

In particular, it is an object of type \axiomType{Equation Polynomial Integer}.

However, for predicates in \axiom{if} expressions, Axiom places a default target type of \axiomType{Boolean} on the predicate and equality testing is performed.
Thus you need not qualify the \axiom{=} in any way. In other contexts you may need to tell Axiom that you want to test for equality rather than create an equation. In those cases, use \axiom{=} and a target type of \axiomType{Boolean}. See \downlink{``Package Calling and Target Types''}{ugTypesPkgCallPage} in Section 2.9 \ignore{ugTypesPkgCall} for more information.

The compound symbol meaning 'not equal' in Axiom is \texttt{\$\sim=\$\axiom{~=}}. This can be used directly without a package call or a target specification. The expression \axiom{a} \texttt{\$\sim=\$\axiom{~=}} \axiom{b} is directly translated into \axiom{not (a = b)}.

Many other functions have return values of type \axiomType{Boolean}. These include \axiom{<}, \axiom{<=}, \axiom{>}, \axiom{>=}, \texttt{\$\sim=\$\axiom{~=}} and \axiom{member?}. By convention, operations with names ending in \axiom{?} return \axiomType{Boolean} values.

The usual rules for piles are suspended for conditional expressions. In {\bf .input} files, the \axiom{then} and \axiom{else} keywords can begin in the same column as the corresponding \axiom{if} but may also appear to the right. Each of the following styles of writing \axiom{if-then-else} expressions is acceptable:

\begin{verbatim}
if i>0 then output("positive") else output("nonpositive")

if i > 0 then output("positive")
  else output("nonpositive")

if i > 0 then output("positive")
else output("nonpositive")

if i > 0 then output("positive")
else output("nonpositive")

if i > 0
  then output("positive")
else output("nonpositive")

if i > 0
  then output("positive")
  else output("nonpositive")
\end{verbatim}

A block can follow the \axiom{then} or \axiom{else} keywords. In the following two assignments to \axiom{a}, the \axiom{then} and \axiom{else} clauses each are followed by two-line piles.
The value returned in each is the value of the second line.

\begin{verbatim}
a :=
if i > 0 then
  j := sin(i * \pi())
  exp(j + 1/j)
else
  j := cos(i * 0.5 * \pi())
  log(abs(j)**5 + 1)
\end{verbatim}

These are both equivalent to the following:

\begin{verbatim}
a :=
if i > 0
  then
    j := sin(i * \pi())
    exp(j + 1/j)
  else
    j := cos(i * 0.5 * \pi())
    log(abs(j)**5 + 1)
\end{verbatim}
A \spadgloss{loop} is an expression that contains another expression, called the \spadgloss{loop body}, which is to be evaluated zero or more times. All loops contain the \axiom{repeat} keyword and return \void{}. Loops can contain inner loops to any depth.

\beginImportant
The most basic loop is of the form
\centerline{\axiom{repeat} \it loopBody} \important
Unless \it loopBody contains a \axiom{break} or \axiom{return} expression, the loop repeats forever.
The value returned by the loop is \void{}.
\endImportant
Compiling vs. Interpreting Loops

Axiom tries to determine completely the type of every object in a loop and then to translate the loop body to LISP or even to machine code. This translation is called \spadglossSee{compiler}{compilation}. If Axiom decides that it cannot compile the loop, it issues a message stating the problem and then the following message:

\centerline{\bf We will attempt to step through and interpret the code.}

It is still possible that Axiom can evaluate the loop but in \spadgloss{interpret-code mode}. See \downlink{Compiling vs. Interpreting'}{ugUserCompIntPage} in Section 6.10 where this is discussed in terms of compiling versus interpreting functions.
return in Loops

A \texttt{return} expression is used to exit a function with a particular value. In particular, if a \texttt{return} is in a loop within the \texttt{return} function, the loop is terminated whenever the \texttt{return} is evaluated.

%> This is a bug! The compiler should never accept allow %> Void to be the return type of a function when it has to use %> resolve to determine it.

\xtc{Suppose we start with this.}
\begin{spadsrc}
\bound{f}
f() ==
  i := 1
  repeat
    if factorial(i) > 1000 then return i
  i := i + 1
\end{spadsrc}

\xtc{When \texttt{factorial(i)} is big enough, control passes from inside the loop all the way outside the function, returning the value of \texttt{factorial(i)} (or so we think).}

\spadpaste{f() \free{f}}

What went wrong?
Isn’t it obvious that this function should return an integer?
Well, Axiom makes no attempt to analyze the structure of a loop to determine if it always returns a value because, in general, this is impossible.
So Axiom has this simple rule: the type of the function is determined by the type of its body, in this case a block. The normal value of a block is the value of its last expression, in this case, a loop. And the value of every loop is \texttt{void}!
So the return type of \userfun{f} is \axiomType{Void}.

There are two ways to fix this.
The best way is for you to tell Axiom what the return type of \axiom{f} is.
You do this by giving \axiom{f} a declaration \axiom{f: () -> Integer} prior to calling for its value.
This tells Axiom: 'trust me---an integer is returned.'
We'll explain more about this in the next chapter.
Another clumsy way is to add a dummy expression as follows.

\begin{spadsrc}
\begin{verbatim}
bound{f1}
f() ==
  i := 1
  repeat
    if factorial(i) > 1000 then return i
    i := i + 1
  0
\end{verbatim}
\end{spadsrc}

When we try \userfun{f} again we get what we wanted.
See \downlink{``Functions Defined with Blocks''}{ugUserBlocksPage} in Section 6.15\ignore{ugUserBlocks} for more information.

break in Loops

⇒ “notitle” (ugLangLoopsReturnPage) 9 on page 1767
—— ug05.ht ——

The \axiom{break} keyword is often more useful in terminating a loop. 
%> and more in keeping with the ideas of structured programming. 
A \axiom{break} causes control to transfer to the expression immediately following the loop.
As loops always return \void{}, you cannot return a value with \axiom{break}.
That is, \axiom{break} takes no argument.

\xtc{
This example is a modification of the last example in 
\texttt{the previous section}{
\downlink{‘return in Loops’}{ugLangLoopsReturnPage}
in Section 5.4.2}\ignore{ugLangLoopsReturn}).
Instead of using \texttt{\texttt{axiom\{return\}}}, we'll use \texttt{\texttt{axiom\{break\}}}.

\begin{spadsrc}
\texttt{f1}\texttt{f1}
\begin{axiom}
f() ==
i := 1
repeat
  if factorial(i) > 1000 then break
  i := i + 1
i
\end{axiom}
\end{spadsrc}

The loop terminates when \texttt{factorial(i)} gets big enough, the last line of the function evaluates to the corresponding \texttt{\texttt{\{good\}}} value of \texttt{axiom\{i\}}, and the function terminates, returning that value.

\begin{spadpaste}
f() \free{f1}
\end{spadpaste}

You can only use \texttt{\texttt{axiom\{break\}}} to terminate the evaluation of one loop. Let's consider a loop within a loop, that is, a loop with a nested loop. First, we initialize two counter variables.

\begin{spadpaste}
(i, j) := (1, 1) \bound{i}\bound{j}
\end{spadpaste}

Nested loops must have multiple \texttt{\texttt{axiom\{break\}}} expressions at the appropriate nesting level. How would you rewrite this so \texttt{\texttt{axiom\{i + j\} > 10\}} is only evaluated once?

\begin{spadsrc}
repeat
  repeat
    if (i + j) > 10 then break
    j := j + 1
  if (i + j) > 10 then break
  i := i + 1
\end{spadsrc}

break vs. => in Loop Bodies

--- ug05.ht ---

Compare the following two loops:

\begin{verbatim}
i := 1
repeat
i := i + 1
i > 3 => i
\end{verbatim}

\begin{verbatim}
i := 1
repeat
i := i + 1
i > 3 => i
if i > 3 then break
\end{verbatim}

--- ug05.ht ---
In the example on the left, the values \mathOrSpad{2} and \mathOrSpad{3} for \axiom{i} are displayed but then the \axiomSyntax{=>} does not allow control to reach the call to \axiomFunFrom{output}{OutputForm} again. The loop will not terminate until you run out of space or interrupt the execution. The variable \axiom{i} will continue to be incremented because the \axiomSyntax{=>} only means to leave the \spad{it block}, not the loop.

In the example on the right, upon reaching \mathOrSpad{4}, the \axiom{break} will be executed, and both the block and the loop will terminate. This is one of the reasons why both \axiomSyntax{=>} and \axiom{break} are provided. Using a \axiom{while} clause (see below) with the \axiomSyntax{=>}

\spadkey{while} lets you simulate the action of \axiom{break}.

More Examples of break

⇒ “notitle” (ugLangLoopsForInPage) 9 on page 1790
— ug05.ht —

Here we give four examples of \axiom{repeat} loops that terminate when a value exceeds a given bound.

First, initialize \axiom{i} as the loop counter.
\begin{verbatim}
\spadpaste{i := 0 \bound{i}}
\end{verbatim}

Here is the first loop. When the square of \axiom{i} exceeds \axiom{100}, the loop terminates.
\begin{spadsrc}
\begin{spadlisting}
\free{i} \bound{i1}
\repeat
\begin{spadlisting}
i := i + 1
\end{spadlisting}
\begin{spadlisting}
if i**2 > 100 then break
\end{spadlisting}
\xtc{
Upon completion, \axiom{i} should have the value \axiom{i1}.
}
\spadpaste{i \free{i1}}
\xact{
Do the same thing except use \axiomSyntax{=>} instead an \axiom(if-then) expression.
}
\spadpaste{i := 0 \bound{i2}}
\xtc{
}
\spadpaste{i \free{i3}}
\xact{
As a third example, we use a simple loop to compute \axiom{n!}.
}
\spadpaste{(n, i, f) := (100, 1, 1) \bound{n}\bound{i4}\bound{f}}
\xtc{
Use \axiom{i} as the iteration variable and \axiom{f} to compute the factorial.
}
\begin{spadlisting}
\bound{f1}\bound{i5}\free{f i4 n}
\repeat
\begin{spadlisting}
if i > n then break
f := f * i
i := i + 1
\end{spadlisting}
\end{spadlisting}
\end{spadsrc}
Look at the value of $f$.

```spadpaste
f \free{f1}
```

Finally, we show an example of nested loops.
First define a four by four matrix.

```spadpaste
m := matrix [[21,37,53,14], [8,-24,22,-16], [2,10,15,14],
[26,33,55,-13]] \bound{m2}
```

Next, set row counter $r$ and column counter $c$ to 1.
Note: if we were writing a function, these would all be local variables rather than global workspace variables.

```spadpaste
(r, c) := (1, 1) \bound{r}\bound{c}
```

Also, let $lastrow$ and $lastcol$ be the final row and column index.

```spadpaste
(lastrow, lastcol) := (nrows(m), ncols(m)) \bound{lastrow}\bound{lastcol}\free{m2}
```

Scan the rows looking for the first negative element.
We remark that you can reformulate this example in a better, more concise form by using a `for` clause with `repeat`.

```spadsrc
\free{m2 r c lastrow lastcol}\begin{spadsrc}
repeat
  if r > lastrow then break
  c := 1
  repeat
    if c > lastcol then break
    if elt(m,r,c) < 0 then
      output [r, c, elt(m,r,c)]
      r := lastrow
      break -- don't look any further
```

See \link{``for Loops''}{ugLangLoopsForInPage} in Section 5.4.8 for more information.
\begin{spadsrc}
c := c + 1
r := r + 1
\end{spadsrc}

while Loops

\begin{page}{ugLangLoopsWhilePage}{5.4.7. while Loops}
\beginscroll

The \axiom{repeat} in a loop can be modified by adding one or more \axiom{while} clauses.

\spadkey{while}

Each clause contains a \spadgloss{predicate} immediately following the \axiom{while} keyword. The predicate is tested \textit{before} the evaluation of the body of the loop. The loop body is evaluated whenever the predicates in a \axiom{while} clause are all \axiom{true}.

\beginImportant
The syntax for a simple loop using \axiom{while} is
\[\text{\axiom{while} \{it predicate\} \axiom{repeat} \{it loopBody\}}\]

The \{it predicate\} is evaluated before \{it loopBody\} is evaluated. A \axiom{while} loop terminates immediately when \{it predicate\} evaluates to \axiom{false} or when a \axiom{break} or \axiom{return} expression is evaluated in \{it loopBody\}. The value returned by the loop is \void{}.
\endImportant

\xtc{
Here is a simple example of using \axiom{while} in a loop. We first initialize the counter.
}{
\spadpaste{i := 1 \bound{i}}
}

\xtc{
The steps involved in computing this example are
\begin{enumerate}
\item set \axiom{i} to \axiom{1},
\item test the condition \axiom{i < 1} and determine that it is not true, and
\item do not evaluate the loop body and therefore do not display \axiom{"hello"}.
\end{enumerate}
}{
\begin{spadsrc}\free{i}
while i < 1 repeat
   output "hello"
   i := i + 1
\end{spadsrc}
}

\xtc{
If you have multiple predicates to be tested use the logical \axiom{and} operation to separate them. Axiom evaluates these predicates from left to right.
}
\spadpaste{(x, y) := (1, 1) \bound{x} \bound{y}}
}
\xtc{
\begin{spadsrc}\free{x y}
while x < 4 and y < 10 repeat
   output [x, y]
   x := x + 1
   y := y + 2
\end{spadsrc}
}
\xtc{A \axiom{break} expression can be included in a loop body to terminate
a loop even if the predicate in any \axiom{while} clauses are not
\axiom{false}.
}
\spadpaste{(x, y) := (1, 1) \bound{x1} \bound{y1}}
}
\xtc{This loop has multiple \axiom{while} clauses and the loop terminates
before any one of their conditions evaluates to \axiom{false}.
}
\spadpaste{m := matrix [[21,37,53,14], [8,-24,22,-16], [2,10,15,14],
[26,33,55,-13]] \bound{m2}}
\xtc{Initialized the row index to \axiom{1} and
get the number of rows and columns.
If we were writing a function, these would all be
local variables.
}
\spadpaste{r := 1 \bound{r}}
\xtc{
\spadpaste{(lastrow, lastcol) := (nrows(m), ncols(m)) \bound{lastrow}\bound{lastcol}\free{m2}}
Scan the rows looking for the first negative element.

```spad
\begin{spadsrc}
\free{m2 r lastrow lastcol}
while r <= lastrow repeat
  c := 1 -- index of first column
  while c <= lastcol repeat
    if elt(m,r,c) < 0 then
      output [r, c, elt(m,r,c)]
      r := lastrow
      break -- don't look any further
    c := c + 1
  r := r + 1
\end{spadsrc}
\end{scroll}
```

for Loops

—— ug05.ht ——

Axiom provides the `axiom(for)`
`spadkey(for)`
and `axiom(in)`
`spadkey(in)`
keywords in `axiom(repeat)` loops,
allowing you to iterate across all
elements of a list, or to have a variable take on integral values from a lower bound to an upper bound. We shall refer to these modifying clauses of \axiom{repeat} loops as \axiom{for} clauses. These clauses can be present in addition to \axiom{while} clauses. As with all other types of \axiom{repeat} loops, \axiom{break} can be used to prematurely terminate the evaluation of the loop.

\beginImportant
The syntax for a simple loop using \axiom{for} is
\begin{center}
{\axiom{for} \{\it iterator\} \axiom{repeat} \{\it loopBody\}}
\end{center}
The \{\it iterator\} has several forms. Each form has an end test which is evaluated before \{\it loopBody\} is evaluated. A \axiom{for} loop terminates immediately when the end test succeeds (evaluates to \axiom{true}) or when a \axiom{break} or \axiom{return} expression is evaluated in \{\it loopBody\}. The value returned by the loop is \void{}.
\endImportant

\endscroll

\begin{page}{ugLangLoopsForInNMPage}{5.4.9. for i in n..m repeat}
\beginscroll
If \axiom{for} is followed by a variable name, the \axiom{in} keyword and then an integer segment of the form \axiom{n..m}, the end test for this loop is the predicate \axiom{i > m}. The body of the loop is evaluated \axiom{m-n+1} times if this number is greater than 0. If this number is less than or equal to 0, the loop body is not evaluated at all.

The variable \axiom{i} has the value
The loop variable is a \spadgloss{local variable} within the loop body: its value is not available outside the loop body and its value and type within the loop body completely mask any outer definition of a variable with the same name.

\xtc{This loop prints the values of $10^3$, $11^3$, and $12^3$:}

Type: Matrix Integer
for i in n..m by s repeat

— ug05.ht —

By default, the difference between values taken on by a variable in loops such as \texttt{for i in n..m repeat ...} is \texttt{mathOrSpad{1}}.
It is possible to supply another, possibly negative, step value by using the \texttt{by} keyword along with \texttt{for} and \texttt{in}.
Like the upper and lower bounds, the step value following the \texttt{by} keyword must be an integer.
Note that the loop \texttt{for i in 1..2 by 0 repeat output(i)}
will not terminate by itself, as the step value does not change the index from its initial value of \texttt{mathOrSpad{1}}.
This expression displays the odd integers between two bounds.
}\spadpaste{for i in 1..5 by 2 repeat output(i)}

\indentrel{-3}\end{patch}
for x in l repeat

--- ug05.ht ---

\begin{page}{ugLangLoopsForInXLPage}{5.4.12. for x in l repeat}
\beginscroll
Another variant of the \axiom{for} loop has the form:
\begin{centerline}{\it \axiom{for} x \axiom{in} list \axiom{repeat} loopBody}}}
This form is used when you want to iterate directly over the
elements of a list.
In this form of the \axiom{for} loop, the variable
\axiom{x} takes on the value of each successive element in \axiom{l}.
The end test is most simply stated in English: "are there no more
\axiom{x} in \axiom{l}?"

\xtc{
If \axiom{l} is this list,
}{
\spadpaste{l := [0,-5,3] \bound{l}}
}
\xtc{
display all elements of \axiom{l}, one per line.}
}{
\spadpaste{for x in l repeat output(x) \free{l}}
}

Since the list constructing expression \axiom{\[n..m\]} creates the
list \axiom{\[n, n+1, \ldots, m\]}\footnote{This list is empty if \axiom{n > m}.}, you might be tempted to think that the loops
\begin{verbatim}
for i in n..m repeat output(i)
\end{verbatim}
and
\begin{verbatim}
for x in expand [n..m] repeat output(x)
\end{verbatim}
are equivalent.
The second form first creates the list \axiom{\[n..m\]} (no matter how large it might be) and
then does the iteration.
The first form potentially runs in much less space, as the index variable
\axiom{i} is simply incremented once per loop and the list is not actually
created.
Using the first form is much more efficient.
%\xtc{
Of course, sometimes you really want to iterate across a specific list.
This displays each of the factors of \axiom{2400000}.\openup12pt

\end{patch}
Parallel Iteration

The last example of the previous section gives an example of nested iteration: a loop is contained in another loop. Sometimes you want to iterate across two lists in parallel, or perhaps you want to traverse a list while incrementing a variable.

The general syntax of a repeat loop is
\[ \text{for } i \text{ in } 1 \ldots 50 \text{ repeat for } j \text{ in } 1 \ldots 50 \mid \text{factorial}(i+j) < 25 \text{ repeat output } [i,j] \]

Here we write a loop to iterate across two lists, computing the sum of the pairwise product of elements. Here is the first list.

\begin{spad}{l := [1,3,5,7] \bound{l}}
\end{spad}

Here we write a loop to iterate across two lists, computing the sum of the pairwise product of elements. Here is the first list.

\begin{spad}{l := [1,3,5,7] \bound{l}}
\end{spad}
And the second.

\spadpaste{m := [100,200] \bound{m}}

\xtc{}
The initial value of the sum counter.
\spadpaste{sum := 0 \bound{sum}}
\xtc{}
The last two elements of \axiom{l} are not used in the calculation because \axiom{m} has two fewer elements than \axiom{l}.
\begin{spadsrc}
\begin{verbatim}
for x in l for y in m repeat
  sum := sum + x*y
\end{verbatim}
\end{spadsrc}
\xtc{}
Display the ``dot product.''
\spadpaste{sum \free{doit}}
\xtc{}
Next, we write a loop to compute the sum of the products of the loop elements with their positions in the loop.
\spadpaste{l := [2,3,5,7,11,13,17,19,23,29,31,37] \bound{l1}}
\xtc{}
The initial sum.
\spadpaste{sum := 0 \bound{sum1}}
\xtc{}
Here looping stops when the list \axiom{l} is exhausted, even though the \axiom{for i in 0..} specifies no terminating condition.
\spadpaste{
  for i in 0.. for x in l repeat sum := i * x \bound{doit1}\free{sum1 l1}}
\xtc{}
Display this weighted sum.
\spadpaste{sum \free{doit1}}

When \axiomSyntax{|} is used to qualify any of the \axiom{for} clauses in a
parallel iteration, the variables in the predicates can be from an outer scope or from a \axiom{for} clause in or to the left of a modified clause.

This is correct:
\begin{verbatim}
for i in 1..10 repeat
  for j in 200..300 | odd? (i+j) repeat
    output [i,j]
\end{verbatim}

This is not correct since the variable \axiom{j} has not been defined outside the inner loop.
\begin{verbatim}
for i in 1..10 | odd? (i+j) repeat -- wrong, j not defined
  for j in 200..300 repeat
    output [i,j]
\end{verbatim}

This example shows that it is possible to mix several of the forms of \axiom{repeat} modifying clauses on a loop.
\begin{spadsrc}
for i in 1..10
  for j in 151..160 | odd? j
    while i + j < 160 repeat
      output [i,j]
\end{spadsrc}

Here are useful rules for composing loop expressions:
\begin{itemize}
\item \axiom{while} predicates can only refer to variables that are global (or in an outer scope) or that are defined in \axiom{for} clauses to the left of the predicate.
\item A ‘‘such that’’ predicate (something following \axiomSyntax{[]}) must directly follow a \axiom{for} clause and can only refer to variables that are global (or in an outer scope) or defined in the modified \axiom{for} clause or any \axiom{for} clause to the left.
\end{itemize}
\begin{verbatim}

Creating Lists and Streams with Iterators

⇒ “notitle” (ugLangLoopsPage) 9 on page 1765
⇒ “notitle” (ListXmpPage) 3.64 on page 866
⇒ “notitle” (StreamXmpPage) 3.102 on page 1263
— ug05.ht —

All of what we did for loops in
in Section 5.4\ignore{ugLangLoops}
can be transformed into expressions that create lists
and streams.
The \axiom{repeat,} \axiom{break} or \axiom{iterate} words are not used but
all the other ideas carry over.
Before we give you the general rule, here are some examples which
give you the idea.

\xtc{
This creates a simple list of the integers from \axiom{1} to \axiom{10}.
}{
\spadpaste{list := [i for i in 1..10] \text{bound}(list)}
}\xtc{Create a stream of the integers greater than or equal to \axiom{1}.}{\spadpaste{stream := [i for i in 1..] \text{bound}(stream)}}\xtc{This is a list of the prime integers between \axiom{1} and \axiom{10}, inclusive.}{\spadpaste{[i for i in 1..10 \text{ | prime? i}]} \xtc{This is a stream of the prime integers greater than or equal to \axiom{1}.}{\spadpaste{[i for i in 1.. \text{ | prime? i}]} \xtc{This is a list of the integers between \axiom{1} and \axiom{10}, inclusive, whose squares are less than \axiom{700}.}{\spadpaste{[i for i in 1..10 \text{ while } i\ast i < 700]}}\xtc{This is a stream of the integers greater than or equal to \axiom{1} whose squares are less than \axiom{700}.}{\spadpaste{[i for i in 1.. \text{ while } i\ast i < 700]}}\begin{Important}
The general syntax of a collection is
\centerline{\tt [ it collectExpression } \text{subsriptIt}(\text{iterator})\{i\} \text{subsriptIt}(\text{iterator})\{2\} \ldots \text{subsriptIt}(\text{iterator})\{N\} ]}where each \text{subsriptIt}(\text{iterator})\{i\} is either a \axiom{for} or a \axiom{while} clause.
The loop terminates immediately when the end test of any \text{subsriptIt}(\text{iterator})\{i\} succeeds or when a \axiom{return} expression is evaluated in \text{collectExpression}.
The value returned by the collection is either a list or a stream of elements, one for each iteration of the \text{collectExpression}.
\end{Important}
Be careful when you use \axiom{while}
to create a stream.
By default, Axiom tries to compute and display the first ten elements
of a stream. If the \axiom{while} condition is not satisfied quickly, Axiom can spend a long (possibly infinite) time trying to compute the elements. Use \spadcmd{)set streams calculate} to change the default to something else. This also affects the number of terms computed and displayed for power series. For the purposes of this book, we have used this system command to display fewer than ten terms.

Use nested iterators to create lists of lists which can then be given as an argument to \axiomFun{matrix}. 

\spadpaste{matrix [[x**i+j for i in 1..3] for j in 10..12]}

You can also create lists of streams, streams of lists and streams of streams. Here is a stream of streams.

\spadpaste{[[i/j for i in j+1..] for j in 1..]}

You can use parallel iteration across lists and streams to create new lists.

\spadpaste{[i/j for i in 3.. by 10 for j in 2..]}

Iteration stops if the end of a list or stream is reached.

\spadpaste{[i**j for i in 1..7 for j in 2..]}

or a while condition fails.

\spadcommand{[i**j for i in 1.. for j in 2.. while i + j < 5]}

As with loops, you can combine these modifiers to make very complicated conditions.

\spadpaste{[[i,j] for i in 10..15 | prime? i] for j in 17..22 | j = squareFreePart j]}

See \downlink{'List'}{ListXmpPage}\ignore{List} and \downlink{'Stream'}{StreamXmpPage}\ignore{Stream} for more information on creating and
manipulating lists and streams, respectively.

An Example: Streams of Primes

--- ug05.ht ---

We conclude this chapter with an example of the creation and manipulation of infinite streams of prime integers. This might be useful for experiments with numbers or other applications where you are using sequences of primes over and over again. As for all streams, the stream of primes is only computed as far out as you need. Once computed, however, all the primes up to that point are saved for future reference.

Two useful operations provided by the Axiom library are \axiomFunFrom{prime?}{IntegerPrimesPackage} and \axiomFunFrom{nextPrime}{IntegerPrimesPackage}.

A straightforward way to create a stream of prime numbers is to start with the stream of positive integers \axiom{[2,..]} and filter out those that are prime.
\xtc{Create a stream of primes.}{
A more elegant way, however, is to use the \( \text{generate} \) operation from \( \text{Stream} \). Given an initial value \( a \) and a function \( f \), \( \text{generate}(a, f) \) constructs the stream \( \{a, f(a), f(f(a)), \ldots\} \). This function gives you the quickest method of getting the stream of primes.

This is how you use \( \text{generate} \) to generate an infinite stream of primes.

\[
\text{primes} := \text{generate}(\text{nextPrime}, 2)
\]

Once the stream is generated, you might only be interested in primes starting at a particular value.

\[
\text{smallPrimes} := \{p \mid p \in \text{primes} \land p > 1000\}
\]

Here are the first 11 primes greater than 1000.

\[
\{p \mid p \in \text{smallPrimes} \land 1 \leq i \leq 11\}
\]

Here is a stream of primes between 1000 and 1200.

\[
\{p \mid p \in \text{smallPrimes} \land 1000 < p < 1200\}
\]

To get these expanded into a finite stream, you call \( \text{complete} \) on the stream.

Twin primes are consecutive odd number pairs which are prime. Here is the stream of twin primes.

\[
\text{twinPrimes} := \{[p, p+2] \mid p \in \text{primes} \land \text{prime?}(p+2)\}
\]

Since we already have the primes computed we can avoid the call to \( \text{prime?} \) by using a double iteration. This time we’ll just generate a stream of the first of the twin primes.
Let's try to compute the infinite stream of triplet primes, the set of primes :math:`\{p\}` such that :math:`\{p, p+2, p+4\}` are primes. For example, :math:`\{3, 5, 7\}` is a triple prime. We could do this by a triple :axiom:`for` iteration. A more economical way is to use :userfun:`firstOfTwins`. This time however, put a semicolon at the end of the line.

\[\text{Create the stream of} \text{firstTriplets.} \text{Put a semicolon at the end so that no elements are computed.}\]
\begin{verbatim}
\text{firstTriplets := [p for p in firstOfTwins for q in rest firstOfTwins | q = p+2];}
\end{verbatim}

What happened? As you know, by default Axiom displays the first ten elements of a stream when you first display it. And, therefore, it needs to compute them! If you want \{\it no\} elements computed, just terminate the expression by a semicolon \{\text{\text{axiomSyntax}{;}}\}. Why does this happen? The semi-colon prevents the display of the result of evaluating the expression. Since no stream elements are needed for display (or anything else, so far), none are computed.

\text{Compute the first triplet prime.}
\begin{verbatim}
\text{firstTriplets.1}
\end{verbatim}

If you want to compute another, just ask for it. But wait a second! Given three consecutive odd integers, one of them must be divisible by 3. Thus there is only one triplet prime. But suppose that you did not know this and wanted to know what was the tenth triplet prime.
\begin{verbatim}
\text{firstTriples.10}
\end{verbatim}

To compute the tenth triplet prime, Axiom first must compute the second, the third, and so on. But since there isn't even a second triplet prime, Axiom will compute forever. Nonetheless, this effort can produce a useful result. After waiting a bit, hit \texttt{\fbox{\textbf{Ctrl}--\fbox{\textbf{c}}}{{\textbf{Ctrl-c}}}}.
The system responds as follows.

\begin{verbatim}
>> System error:
Console interrupt.
You are being returned to the top level of
the interpreter.
\end{verbatim}

Let’s say that you want to know how many primes have been computed. Issue

\begin{verbatim}
numberOfComputedEntries primes
\end{verbatim}

and, for this discussion, let’s say that the result is $\text{axiom}(2045.)$

\xtc{
How big is the $\eth{\text{axiom}(2045)}$ prime? 
}

\spadpaste{primes.2045}

What you have learned is that there are no triplet primes between 5 and 17837. Although this result is well known (some might even say trivial), there are many experiments you could make where the result is not known. What you see here is a paradigm for testing of hypotheses. Here our hypothesis could have been: ‘‘there is more than one triplet prime.’’ We have tested this hypothesis for 17837 cases. With streams, you can let your machine run, interrupt it to see how far it has progressed, then start it up and let it continue from where it left off.

16. Free and Local Variables
17. Anonymous Functions
18. Example: A Database
19. Example: A Famous Triangle
20. Example: Testing for Palindromes
21. Rules and Pattern Matching
Functions vs. Macros

A function is a program to perform some computation. Most functions have names so that it is easy to refer to them. A simple example of a function is one named \spadFunFrom{abs}{Integer} which computes the absolute value of an integer.

\begin{verbatim}
\spad{abs(-8)}
\end{verbatim}

Functions can be used alone or serve as the building blocks for larger programs. Usually they return a value that you might want to use in the next stage of a computation, but not always (for example, see \downlink{`Exit'}{ExitXmpPage} and \downlink{`Void'}{VoidXmpPage}). They may also read data from your keyboard, move information from one place to another, or format and display results on your screen.

In Axiom, as in mathematics, functions are usually parameterized. Each time you \spad{call} (some people say \spad{apply}) or \spad{invoke} a function, you give values to the parameters (variables). Such a value is called an \spad{argument} of the function. Axiom uses the arguments for the computation. In this way you get different results depending on what you \spad{feed} the function.
Functions can have local variables or refer to global variables in the workspace.

Axiom can often compile functions so that they execute very efficiently.

Functions can be passed as arguments to other functions.

Macros are textual substitutions. They are used to clarify the meaning of constants or expressions and to be templates for frequently used expressions. Macros can be parameterized but they are not objects that can be passed as arguments to functions. In effect, macros are extensions to the Axiom expression parser.

\begin{spadcommand}{abs(-8)}
(1) 8
Type: PositiveInteger
\end{spadcommand}

\begin{spadcommand}{(x +-> if x < 0 then -x else x)(-8)}
(2) 8
Type: PositiveInteger
\end{spadcommand}
Macros

— ug06.ht —

A \spadgloss{macro} provides general textual substitution of an Axiom expression for a name. You can think of a macro as being a generalized abbreviation. You can only have one macro in your workspace with a given name, no matter how many arguments it has.

\beginImportant
The two general forms for macros are
\centerline{{\tt macro} \{it name\} \{tt ==\} \{it body\} }}
\centerline{{\tt macro} \{it name(arg1,...)\} \{tt ==\} \{it body\} }}
where the body of the macro can be any Axiom expression.
\endImportant

% \xtc{
For example, suppose you decided that you like to use \axiom{df} for \axiomFun{D}. You define the macro \axiom{df} like this. 
}\{ 
\spadpaste{macro df == D \bound{df}}
\}
\xtc{
Whenever you type \axiom{df}, the system expands it to \axiomFun{D}.
}\{ 
\spadpaste{df(x**2 + x + 1,x) \free{df}}
\}
\xtc{
Macros can be parameterized and so can be used for many different kinds of objects.
}\{ 
\spadpaste{macro ff(x) == x**2 + 1 \bound{ff}}
\}
\xtc{
Apply it to a number, a symbol, or an expression.
}\{ 
\spadpaste{ff z \free{ff}}
\}
\xtc{
Macros can also be nested, but you get an error message if you run out of space because of an infinite nesting loop.
}\spadpaste{macro gg(x) == ff(2*x - 2/3) \bound{gg}\free{ff}}
\xtc{
This new macro is fine as it does not produce a loop.
}\spadpaste{gg(1/w) \free{gg}}
%
\xtc{
This, however, loops since \axiom{gg} is defined in terms of \axiom{ff}.
}\spadpaste{macro ff(x) == gg(-x) \free{gg}}
\xtc{
The body of a macro can be a block.
}\spadpaste{macro next == (past := present; present := future; future := past + present) \bound{next}}
\xtc{
Before entering \axiom{next}, we need values for \axiom{present} and \axiom{future}.
}\spadpaste{present : Integer := 0 \bound{present}}
\xtc{
}\spadpaste{future : Integer := 1 \bound{future}}
\xtc{
Repeatedly evaluating \axiom{next} produces the next Fibonacci number.
}\spadpaste{next \free{future}\free{present}}
\xtc{
And the next one.
}\spadpaste{next \free{future}\free{present}}
\xtc{
Here is the infinite stream of the rest of the Fibonacci numbers.
}\spadpaste{[next for i in 1..] \free{future}\free{present}}
\xtc{
Bundle all the above lines into a single macro.
macro fibStream ==
  present : Integer := 1
  future : Integer := 1
  [next for i in 1..] where
    macro next ==
      past := present
      present := future
      future := past + present
\end{spadsrc}

Use \axiomFun{concat}(Stream) to start with the first two
Fibonacci numbers.

\spadpaste{concat([0,1],fibStream) \free{fibstr}}

An easier way to compute these numbers is to
use the library operation \axiomFun{fibonacci}.

\spadpaste{[fibonacci i for i in 1..]}

\endscroll

\begin{patch}{ugUserMacrosPagePatch1}

Introduction to Functions

Each name in your workspace can refer to a single object. This may be any kind of object including a function. You can use interactively any function from the library or any that you define in the workspace.

In the library the same name can have very many functions, but you can have only one function with a given name, although it can have any number of arguments that you choose.

If you define a function in the workspace that has the same name and number of arguments as one in the library, then your definition takes precedence. In fact, to get the library function you must \spadglossSee{package-call}{package call} it (see \downlink{‘‘Package Calling and Target Types’’}{ugTypesPkgCallPage} in Section 2.9\ignore{ugTypesPkgCall}).

To use a function in Axiom, you apply it to its arguments. Most functions are applied by entering the name of the function followed by its argument or arguments.

\begin{verbatim}
\spadpaste{factor(12)}
\end{verbatim}

Some functions like \axiomOp{+} have \spadgloss{infix} operators as names.

\begin{verbatim}
\spadpaste{3 + 4}
\end{verbatim}

The function \axiomOp{+} has two arguments. When you give it more than two arguments, Axiom groups the arguments to the left. This expression is equivalent to \axiom{(1 + 2) + 7}.

\begin{verbatim}
\spadpaste{1 + 2 + 7}
\end{verbatim}
All operations, including infix operators, can be written in prefix form, that is, with the operation name followed by the arguments in parentheses. For example, \axiom{2 + 3} can alternatively be written as \axiom{+(2,3)}. But \axiom{+(2,3,4)} is an error since \axiomOp{+} takes only two arguments.

Prefix operations are generally applied before the infix operation. Thus \axiom{factorial 3 + 1} means \axiom{factorial(3) + 1} producing \axiom{7}, and \axiom{- 2 + 5} means \axiom{(-2) + 5} producing \axiom{3}.

An example of a prefix operator is prefix \axiomOp{-}. For example, \axiom{- 2 + 5} converts to \axiom{((-2) + 5)} producing the value \axiom{3}.

Any prefix function taking two arguments can be written in an infix manner by putting an ampersand (\axiomSyntax{&}) before the name. Thus \axiom{D(2*x,x)} can be written as \axiom{2*x \&D x} returning \axiom{2}.

Every function in Axiom is identified by a \spadgloss{name} and \spadgloss{type}. An exception is an "anonymous function" discussed in \downlink{"Anonymous Functions"}{ugUserAnonPage} in Section 6.17 of ugUserAnon.

The type of a function is always a mapping of the form \spadsig{Source}{Target} where \axiom{Source} and \axiom{Target} are types. To enter a type from the keyboard, enter the arrow by using a hyphen \axiomSyntax{-} followed by a greater-than sign \axiomSyntax{>}, e.g. \tt{Integer -> Integer}.

Let's go back to \axiomOp{+}. There are many \axiomOp{+} functions in the Axiom library: one for integers, one for floats, another for rational numbers, and so on. These \axiomOp{+} functions have different types and thus are different functions. You've seen examples of this \spadgloss{overloading} before---using the same name for different functions. Overloading is the rule rather than the exception. You can add two integers, two polynomials, two matrices or two power series. These are all done with the same function name but with different functions.

Declaring the Type of Functions

⇒ “notitle” (ugTypesDeclarePage) 7 on page 1641
— ug06.ht —

\begin{page}{ugUserDeclarePage}{6.4. Declaring the Type of Functions}
\beginscroll

In \downlink{``Declarations’’}{ugTypesDeclarePage} in Section 2.3\ignore{ugTypesDeclare} we discussed how to declare a variable to restrict the kind of values that can be assigned to it. In this section we show how to declare a variable that refers to function objects.

\beginImportant
A function is an object of type \spadsig{Source}{Type} where \axiom{Source} and \axiom{Target} can be any type. A common type for \axiom{Source} is \axiomType{Tuple}(\subscriptIt{T}{1}, \ldots, \subscriptIt{T}{n}), usually written \spad{\langle T_1, \ldots, T_n \rangle}, to indicate a function of \axiom{n} arguments.
\endImportant

\xtc{If \axiom{g} takes an \axiomType{Integer}, a \axiomType{Float} and another \axiomType{Integer}, and returns a \axiomType{String}, the declaration is written this way.}{
\spadpaste{g: (Integer,Float,Integer) -> String}}

\xtc{The types need not be written fully; using abbreviations, the above declaration is:}{
\spadpaste{g: (INT,FLOAT,INT) -> STRING}}

\xtc{It is possible for a function to take no arguments. If \axiom{h} takes no arguments but returns a \axiomType{Polynomial} \axiomType{Integer}, any of the following declarations is acceptable.}{
Functions can also be declared when they are being defined. The syntax for combined declaration/definition is:
\begin{verbatim}
{\it functionName}(\subscript{parm}{1}: \subscript{parmType}{1}, \ldots, \subscript{parm}{N}: \subscript{parmType}{N}):
{\it functionReturnType}}
\end{verbatim}

The following definition fragments show how this can be done for the functions \texttt{g} and \texttt{h} above.
\begin{verbatim}
g(arg1: INT, arg2: FLOAT, arg3: INT): STRING == ...

h(): POLY INT == ...
\end{verbatim}

A current restriction on function declarations is that they must involve fully specified types (that is, cannot include modes involving explicit or implicit \texttt{axiomSyntax(?)}).
For more information on declaring things in general, see \downlink{``Declarations''}{ugTypesDeclarePage} in Section 2.3\ignore{ugTypesDeclare}.

One-Line Functions

--- ug06.ht ---

As you use Axiom, you will find that you will write many short functions to codify sequences of operations that you often perform. In this section we write some simple one-line functions.

\begin{verbatim}
This is a simple recursive factorial function for positive integers.
\end{verbatim}

\begin{verbatim}
fac n == if n < 3 then n else n * fac(n-1)
\end{verbatim}

\begin{verbatim}
fac 10
\end{verbatim}

%>> Thankfully, the $ is no longer needed in the next example.

\begin{verbatim}
This function computes $\text{axiom}{1 + 1/2 + 1/3 + \ldots + 1/n}$.
\end{verbatim}

\begin{verbatim}
s n == reduce(+,[1/i for i in 1..n])
\end{verbatim}

\begin{verbatim}
s 50
\end{verbatim}
This function computes a Mersenne number, several of which are prime.

\spad{mersenne i == 2**i - 1}

If you type \texttt{mersenne}, Axiom shows you the function definition.

\spad{mersenne \free{mersenne}}

Generate a stream of Mersenne numbers.

\spad{[mersenne i for i in 1..] \free{mersenne}}

Create a stream of those values of \texttt{i} such that \texttt{mersenne(i)} is prime.

\spad{mersenneIndex := [n for n in 1.. | prime?(mersenne(n))] \free{mersenne}}

Finally, write a function that returns the $n^{\text{th}}$ Mersenne prime.

\spad{mersennePrime n == mersenne mersenneIndex(n) \free{mersenne mersenneIndex}}

\endscroll

Declared vs. Undeclared Functions

If you declare the type of a function, you can apply it to any data that can be converted to the source type of the function.

\begin{scroll}
Define \texttt{f} with type \texttt{Integer}\{\texttt{Integer}\}.
\begin{spad}{f(x: Integer): Integer == x + 1\bound{f}}
\end{spad}
\texttt{The function \texttt{f} can be applied to integers, \ldots}
\begin{spad}{f 9 \free{f}}
\end{spad}
\texttt{and to values that convert to integers, \ldots}
\begin{spad}{f(-2.0) \free{f}}
\end{spad}
\texttt{but not to values that cannot be converted to integers.}
\begin{spad}{f(2/3) \free{f}}
\end{spad}
\end{scroll}

To make the function over a wide range of types, do not declare its type.
\begin{scroll}
Give the same definition with no declaration.
\begin{spad}{g x == x + 1\bound{g}}
\end{spad}
\texttt{If \texttt{\axiom{x + 1}} makes sense, you can apply \texttt{\userfun{g}} to \texttt{\axiom{x}.}}
\begin{spad}{g 9 \free{g}}
\end{spad}
\end{scroll}
A version of \userfun{g} with different argument types get compiled for each new kind of argument used.
\spadpaste{g(2/3) \free{g}}

Here \axiom{x+1} for \axiom{x = "axiom"} makes no sense.
\spadpaste{g("axiom")\free{g}}

As you will see in \downlink{"Categories"}{ugCategoriesPage} in Chapter 12\ignore{ugCategories}, Axiom has a formal idea of categories for what \textquote{makes sense.}'

Functions vs. Operations

A function is an object that you can create, manipulate, pass to, and return from functions (for some interesting examples of library functions that manipulate functions, see \url{MappingPackage1}). Yet, we often seem to use the term operation and function interchangeably in Axiom. What is the distinction?

First consider values and types associated with some variable \texttt{n} in your workspace. You can make the declaration \texttt{n: Integer}, then assign \texttt{n} an integer value. You then speak of the integer \texttt{n}. However, note that the integer is not the name \texttt{n} itself, but the value that you assign to \texttt{n}.

Similarly, you can declare a variable \texttt{f} in your workspace to have type \texttt{Integer,Integer}, then assign \texttt{f}, through a definition or an assignment of an anonymous function. You then speak of the function \texttt{f}. However, the function is not \texttt{f}, but the value that you assign to \texttt{f}.

A function is a value, in fact, some machine code for doing something. Doing what? Well, performing some operation. Formally, an operation consists of the constituent parts of \texttt{f} in your workspace, excluding the value; thus an operation has a name and a type. An operation is what domains and packages export. Thus \texttt{Ring} exports one operation \texttt{+}. Every ring also exports this operation. Also, the author of every ring in the system is obliged under contract (see Section 11.3 in \url{Abstract Datatypes}) to provide an implementation for this operation.

This chapter is all about functions---how you create them interactively and how you apply them to meet your needs. In \url{Packages} in Chapter 11, you will learn how to create them
for the Axiom library. Then in 
\downlink{``Categories''}{ugCategoriesPage} in Chapter 12\ignore{ugCategories}, you will learn about categories and exported operations.

\begin{page}{ugUserDelayPage}
6.8. Delayed Assignments vs. Functions with No Arguments
\beginscroll

In \downlink{``Immediate and Delayed Assignments''} {ugLangAssignPage} in Section 5.1\ignore{ugLangAssign} we discussed the difference between immediate and delayed assignments.

In this section we show the difference between delayed assignments and functions of no arguments.

\labelSpace{2pc}
\xtc{A function of no arguments is sometimes called a \{it nullary function.\} }
\{\spadpaste{sin24() == sin(24.0) \bound{sin24}}
\}
\xtc{You must use the parentheses (\axiomSyntax{()}) to evaluate it. Like a delayed assignment, the right-hand-side of a function evaluation is not evaluated until the left-hand-side is used. }
\{\spadpaste{sin24() \free{sin24}}
\}
\xtc{If you omit the parentheses, you just get the function definition. (%Note how the explicit floating point number in the definition %has been translated into a function call involving a mantissa, %exponent and radix.)}
\{
You do not use the parentheses \texttt{()} in a delayed assignment.

\texttt{cos24 == cos(24.0) \bound{cos24}}

nor in the evaluation.

The only syntactic difference between delayed assignments and nullary functions is that you use \texttt{()} in the latter case.

\begin{verbatim}
(2) - 0.9055783620 0662384514
Type: Float
\end{verbatim}
\begin{verbatim}
(3) sin24 () == sin(24.0)
Type: FunctionCalled sin24
\end{verbatim}
\begin{verbatim}
Type: Void
\end{verbatim}

How Axiom Determines What Function to Use

⇒ “notitle” (ugTypesPkgCallPage) 7 on page 1686
⇒ “notitle” (ugTypesResolvePage) 7 on page 1696
— ug06.ht —

\begin{page}{ugUserUsePage}
{6.9. How Axiom Determines What Function to Use}
\beginscroll

What happens if you define a function that has the same name as a library function? Well, if your function has the same name and number of arguments (we sometimes say \spadgloss{arity}) as another function in the library, then your function covers up the library function. If you want then to call the library function, you will have to package-call it. Axiom can use both the functions you write and those that come from the library. Let's do a simple example to illustrate this.

\xtc{Suppose you (wrongly!) define \userfun{sin} in this way.}
{\spadpaste{sin x == 1.0 \bound{sin}}}
\xtc{The value \axiom{1.0} is returned for any argument.}
{\spadpaste{sin 4.3 \free{sin}}}
\xtc{If you want the library operation, we have to package-call it (see \downlink{``Package Calling and Target Types''}{ugTypesPkgCallPage} in Section 2.9\ignore{ugTypesPkgCall} for more information).}
{\spadpaste{sin(4.3)\$Float}}
\xtc{}
{\spadpaste{sin(34.6)\$Float}}
\xtc{Even worse, say we accidentally used the same name as a library function in the function.}
{\spadpaste{sin x == sin x \bound{sin1}}}
\end{scroll}

— ug06.ht —
Then Axiom definitely does not understand us.
\spadpaste{sin 4.3 \free{sin1}}

Again, we could package-call the inside function.
\spadpaste{sin x == sin(x)\$Float \bound{sin2}}

Of course, you are unlikely to make such obvious errors.
It is more probable that you would write a function and in the body use a function that you think is a library function.
If you had also written a function by that same name, the library function would be invisible.

How does Axiom determine what library function to call? It very much depends on the particular example, but the simple case of creating the polynomial \axiom{x + 2/3} will give you an idea.

\begin{enumerate}
\item The \axiom{x} is analyzed and its default type is \axiomType{Variable(x)}.
\item The \axiom{2} is analyzed and its default type is \axiomType{PositiveInteger}.
\item The \axiom{3} is analyzed and its default type is \axiomType{PositiveInteger}.
\item Because the arguments to \axiomOp{/} are integers, Axiom gives the expression \axiom{2/3} a default target type of \axiomType{Fraction(Integer)}.
\item Axiom looks in \axiomType{PositiveInteger} for \axiomOp{/}. It is not found.
\item Axiom looks in \axiomType{Fraction(Integer)} for \axiomOp{/}. It is found for arguments of type \axiomType{Integer}.
\item The \axiom{2} and \axiom{3} are converted to objects of type \axiomType{Integer} (this is trivial) and \axiomOp{/} is applied, creating an object of type \axiomType{Fraction(Integer)}.
\item No \axiomOp{+} for arguments of types \axiomType{Variable(x)} and \axiomType{Fraction(Integer)} are found in either domain.
\item Axiom resolves (see \downlink{``Resolving Types''}{ugTypesResolvePage} in Section 2.10\ignore{ugTypesResolve}) the types and gets \axiomType{Polynomial (Fraction (Integer))}.
\item The \axiom{x} and the \axiom{2/3} are converted to objects of this type and \axiomOp{+} is applied, yielding the answer, an object
of type \axiomType{Polynomial (Fraction (Integer))}.

Compiling vs. Interpreting

⇒ "notitle" (ugTypesSubdomainsPage) 7 on page 1679
— ug06.ht —

When possible, Axiom completely determines the type of every object in a function, then translates the function definition to \Lisp{} or to machine code (see next section). This translation, called \spadglossSee{compilation}{compiler}, happens the first time you call the function and results in a computational delay. Subsequent function calls with the same argument types use the compiled version
of the code without delay.

If Axiom cannot determine the type of everything, the function may still be executed but in \spadglossSee{interpret-code mode}{interpreter} : each statement in the function is analyzed and executed as the control flow indicates. This process is slower than executing a compiled function, but it allows the execution of code that may involve objects whose types change.

\beginImportant
If Axiom decides that it cannot compile the code, it issues a message stating the problem and then the following message:
\centerline{\textbf{We will attempt to step through and interpret the code.}}}
\centerline{This is not a time to panic.}
Rather, it just means that what you gave to Axiom is somehow ambiguous: either it is not specific enough to be analyzed completely, or it is beyond Axiom’s present interactive compilation abilities.
\endImportant

This function runs in interpret-code mode, but it does not compile.}{
\begin{spadsrc}
\bound{varPolys}
varPolys(vars) ==
  for var in vars repeat
    output(1 :: UnivariatePolynomial(var,Integer))
\end{spadsrc}
\xtc{For \axiom{vars} equal to \axiom{['x, 'y, 'z]}, this function displays \axiom{3} three times.}{
\spadpaste{varPolys ['x,'y,'z] \free{varPolys}}
}\xtc{The type of the argument to \axiomFun{output} changes in each iteration, so Axiom cannot compile the function. In this case, even the inner loop by itself would have a problem:}{
\begin{spadsrc}
for var in ['x,'y,'z] repeat
  output(1 :: UnivariatePolynomial(var,Integer))
\end{spadsrc}
Sometimes you can help a function to compile by using an extra conversion or by using \axiom{pretend}. See \downlink{``Subdomains Again''} in Section 2.8 for details.

When a function is compilable, you have the choice of whether it is compiled to \Lisp{} and then interpreted by the \Lisp{} interpreter or then further compiled from \Lisp{} to machine code. The option is controlled via \spadcmd{)set functions compile}. Issue \spadcmd{)set functions compile on} to compile all the way to machine code. With the default setting \spadcmd{)set functions compile off}, Axiom has its \Lisp{} code interpreted because the overhead of further compilation is larger than the run-time of most of the functions our users have defined. You may find that selectively turning this option on and off will give you the best performance in your particular application. For example, if you are writing functions for graphics applications where hundreds of points are being computed, it is almost certainly true that you will get the best performance by issuing \spadcmd{)set functions compile on}.

\begin{verbatim}
varPolys(vars) == for var in vars repeat output(1 :: UnivariatePolynomial(var,Integer))
bound(varPolys)

Type: Void
\end{verbatim}
Piece-Wise Function Definitions

⇒ “notitle” (ugUserPieceBasicPage) 10 on page 1862
⇒ “notitle” (ugUserPiecePickingPage) 10 on page 1869
⇒ “notitle” (ugUserPiecePredPage) 10 on page 1876
— ug06.ht —
To move beyond functions defined in one line, we introduce in this section functions that are defined piece-by-piece. That is, we say ‘use this definition when the argument is such-and-such and use this other definition when the argument is that-and-that.’

---

**A Basic Example**

There are many other ways to define a factorial function for nonnegative integers. You might say

factorial of \texttt{axiom}(0) is \texttt{axiom}(1), otherwise factorial of \texttt{axiom}(n) is \texttt{axiom}(n) times factorial of \texttt{axiom}(n-1).

Here is one way to do this in Axiom.

\[
\texttt{fact(0) == 1}
\]

Here is the value for \texttt{axiom}(n = 0).

\[
\texttt{fact(0) == 1}
\]

Here is the value for \texttt{axiom}(n > 0).

The vertical bar \texttt{axiomSyntax}{} means ‘such that’.

\[
\texttt{fact(n \mid n > 0) == n * fact(n - 1)}
\]
What is the value for \texttt{n = 3}?
\spadpaste{\texttt{fact(3)}}\free{\texttt{factn}}
\xtc{\texttt{fact(3)}}

What is the value for \texttt{n = -3}?
\spadpaste{\texttt{fact(-3)}}\free{\texttt{factn}}
\xtc{\texttt{fact(-3)}}

Now for a second definition.
Here is the value for \texttt{n = 0}.
\spadpaste{\texttt{facto(0) == 1}}\bound{\texttt{facto0}}
\xtc{\texttt{facto(0) == 1}}

Give an error message if \texttt{n < 0}.
\spadpaste{\texttt{facto(n | n < 0) == error "arguments to facto must be non-negative"}}\free{\texttt{facto0}}\bound{\texttt{factop}}
\xtc{\texttt{error "arguments to facto must be non-negative"}}

Here is the value otherwise.
\spadpaste{\texttt{facto(n) == n * facto(n - 1)}}\free{\texttt{factop}}\bound{\texttt{facton}}
\xtc{\texttt{facto(n) == n * facto(n - 1)}}

What is the value for \texttt{n = 7}?
\spadpaste{\texttt{facto(7)}}\free{\texttt{facton}}
\xtc{\texttt{facto(7)}}

What is the value for \texttt{n = -7}?
\spadpaste{\texttt{facto(-7)}}\free{\texttt{facton}}
\xtc{\texttt{facto(-7)}}

To see the current piece-wise definition of a function, use \spad{)display value}.
\spadpaste{\texttt{)display value facto}}\free{\texttt{facton}}
\xtc{\texttt{)display value facto}}

In general a \{\texttt{it piece-wise definition}\} of a function consists of two or more parts. Each part gives a \texttt{"piece"} of the entire definition. Axiom collects the pieces of a function as you enter them. When you ask for a value of the function, it then \texttt{"glues"} the pieces together to form a function.
The two piece-wise definitions for the factorial function are examples of recursive functions, that is, functions that are defined in terms of themselves. Here is an interesting doubly-recursive function. This function returns the value \(11\) for all positive integer arguments.

Here is the first of two pieces.

\[
\text{eleven}(n | n < 1) == n + 11
\]

And the general case.

\[
\text{eleven}(m) == \text{eleven}(\text{eleven}(m - 12))
\]

Compute \(\text{eleven},\) the infinite stream of values of \(\text{eleven}.\)

\[
\text{eleven} := [\text{eleven}(i) \text{ for } i \in 0..]
\]

What is the value at \(n = 200\) ?

\[
\text{eleven}(200)
\]

What is the Axiom’s definition of \(\text{eleven}\) ?

\[
)\text{display value eleven}
\]

Picking Up the Pieces

Here are the details about how Axiom creates a function from its pieces. Axiom converts the \texttt{\texttt{\texttt{axiom(i)}}} piece of a function definition into a conditional expression of the form: \texttt{\texttt{axiom(if \ pred(i) \ axiom(then) \ expr(i). If any new piece has a \pred{i} that is identical\footnote{after all variables are uniformly named} to an earlier \pred{j}, the earlier piece is removed. Otherwise, the new piece is always added at the end.}

% 
\texttt{\hspace*{3pc}}{	ab{6}}
\texttt{if \ pred(n) \ then \ expr(n) \ else\newline
\hspace*{3pc}}{	ab{12}}. . . \newline
\texttt{\hspace*{3pc}}{	ab{6}}
\texttt{error "You did not define f for argument \arg."}
You can give definitions of any number of mutually recursive function definitions, piece-wise or otherwise. No computation is done until you ask for a value. When you do ask for a value, all the relevant definitions are gathered, analyzed, and translated into separate functions and compiled.

\begin{spadsrc}
minusEleven(n) ==
  n >= 0 => n - 11
  minusEleven (5 + minusEleven(n + 7))
\end{spadsrc}

A similar doubly-recursive function below produces \texttt{-11} for all negative positive integers. If you haven't worked out why or how \texttt{eleven} works, the structure of this definition gives a clue.

This definition we write as a block.

\begin{spadsrc}
\texttt{s(0) == 1}
\texttt{s(n) == (eleven(n) + minusEleven(n))/n}
\end{spadsrc}

What are the first ten values of \texttt{s(n)}?
Axiom can create infinite streams in the positive direction (for example, for index values \(\text{axiom}(0,1, \ldots)\)) or negative direction (for example, for index values \(\text{axiom}(0,-1,-2, \ldots)\)). Here we would like a stream of values of \(\text{axiom}(s(n))\) that is infinite in both directions. The function \(\text{axiom}(t(n))\) below returns the \(\text{eth}(\text{axiom}(n))\) term of the infinite stream \(\text{axiom}([s(0), s(1), s(-1), s(2), s(-2), \ldots])\). Its definition has three pieces.

\xtc{
Define the initial term.
}{
\spadpaste{t(1) == s(0)}\free{rf4}
}
\xtc{
The even numbered terms are the \(\text{axiom}(s(i))\) for positive \(\text{axiom}(i)\). We use \(\text{axiomOp}(\text{quo})\) rather than \(\text{axiomOp}(\text{/})\) since we want the result to be an integer.
}{
\spadpaste{t(n | \text{even?}(n)) == s(n \text{ quo } 2)}\free{t1}\bound{t2}
}
\xtc{
Finally, the odd numbered terms are the \(\text{axiom}(s(i))\) for negative \(\text{axiom}(i)\). In piece-wise definitions, you can use different variables to define different pieces. Axiom will not get confused.
}{
\spadpaste{t(p) == s(- p \text{ quo } 2)}\free{t2}\bound{t3}
}
\xtc{
Look at the definition of \(\text{axiom}(t)\).
In the first piece, the variable \(\text{axiom}(n)\) was used; in the second piece, \(\text{axiom}(p)\). Axiom always uses your last variable to display your definitions back to you.
}{
\spadpaste{\text{display value } t}\free{t2}
}
\xtc{
Create a series of values of \(\text{axiom}(s)\) applied to alternating positive and negative arguments.
}{
\spadpaste{[t(i) for i in 1..]}\free{t3}\bound{t4}
}
\xtc{
Evidently \(\text{axiom}(t(n) = 1)\) for all \(\text{axiom}(i)\). Check it at \(\text{axiom}(n=100)\).
}{

\spadpaste{t(100)\free{t4}}

}

We have already seen some examples of predicates (in Section 6.11.1). Predicates are \axiomType{Boolean}-valued expressions and Axiom uses them for filtering collections and for placing constraints on function arguments. In this section we discuss their latter usage.

The simplest use of a predicate is one you don't see at all.

\spadpaste{opposite 'right == 'left}

Here is a longer way to give the 'opposite definition.'

\spadpaste{opposite (x | x = 'left) == 'right}

Try it out.

Explicit predicates tell Axiom that the given function definition piece is to be applied if the predicate evaluates to \tt{true} for the arguments to the function. You can use such 'constant' arguments for integers, strings, and quoted symbols. The \axiomType{Boolean} values \axiom{true} and \axiom{false} can also be used if qualified with '\spad{0}' or '\spad{1}' and \axiomType{Boolean}. The following are all valid function definition fragments using constant arguments.

\begin{verbatim}
a(1) == ... b("unramified") == ...
\end{verbatim}
If a function has more than one argument, each argument can have its own predicate. However, if a predicate involves two or more arguments, it must be given \{it after\} all the arguments mentioned in the predicate have been given. You are always safe to give a single predicate at the end of the argument list.

\xtc{A function involving predicates on two arguments.}{
\spadpaste{inFirstHalfQuadrant(x \mid x > 0, y \mid y < x) == true}
}
\xtc{This is incorrect as it gives a predicate on \axiom{y} before the argument \axiom{y} is given.}{

By default, Axiom does not save the values of any function. You can cause it to save values and not to recompute unnecessarily by using \spad{)set functions cache}. This should be used before the functions are defined or, at least, before they are executed. The word following ‘cache’ should be \axiom{0} to turn off caching, a positive integer \axiom{n} to save the last \axiom{n} computed values or ‘all’ to save all computed values. If you then give a list of names of functions, the caching only affects those functions. Use no list of names or ‘all’ when you want to define the default behavior for functions not specifically mentioned in other \spad{set functions cache} statements. If you give no list of names, all functions will have the caching behavior. If you explicitly turn on caching for one or more names, you must explicitly turn off caching for those names when you want to stop saving their values.

This causes the functions \userfun{f} and \userfun{g} to have the last three computed values saved.

\spad{set functions cache 3 f g \bound{cache}}

This is a sample definition for \userfun{f}.

\spad{f x == factorial(2**x) \bound{fundef}\free{cache}}
A message is displayed stating what \texttt{f} will cache.
\spadpaste{f(4) \texttt{free}\texttt{\{}\texttt{cache}}
\xtc{}
This causes all other functions to have all computed values saved by
default.
\spadpaste{\texttt{set functions cache all}}
\xtc{}
This causes all functions that have not been specifically cached in
some way to have no computed values saved.
\spadpaste{\texttt{set functions cache 0}}
\xtc{}
We also make \texttt{f} and \texttt{g} uncached.
\spadpaste{\texttt{set functions cache 0 f g}}
\beginImportant
Be careful about caching functions that have \texttt{side
effects}. Such a function might destructively modify the
elements of an array or issue a \texttt{draw} command, for example.
A function that you expect to execute every time it is called should
not be cached. Also, it is highly unlikely that a function with no
arguments should be cached.
\endImportant
You should also be careful about caching functions that depend on
free variables.
See \link{Free and Local Variables}{ugUserFreeLocalPage} in
Section 6.16 for an example.

Recurrence Relations

One of the most useful classes of function are those defined via a "recurrence relation." A \cite{ug06} recurrence relation makes each successive value depend on some or all of the previous values. A simple example is the ordinary "factorial" function:
\begin{verbatim}
fact(0) == 1
fact(n | n > 0) == n * fact(n-1)
\end{verbatim}

The value of \axiom{fact(10)} depends on the value of \axiom{fact(9)}, \axiom{fact(9)} on \axiom{fact(8)}, and so on. Because it depends on only one previous value, it is usually called a \{it first order recurrence relation\}. You can easily imagine a function based on two, three or more previous values. The Fibonacci numbers are probably the most famous function defined by a second order recurrence relation.

\xtc{
The library function \axiomFun{fibonacci} computes Fibonacci numbers. It is obviously optimized for speed.}
{s叩irstpaste{[fibonacci(i) for i in 0..]}}

\xtc{Define the Fibonacci numbers ourselves using a piece-wise definition.}
{s叩irstpaste{fib(1) == 1 \bound{fib0}}}

{s叩irstpaste{fib(2) == 1 \bound{fib1}\free{fib0}}}

{s叩irstpaste{fib(n) == fib(n-1) + fib(n-2) \bound{fibn}\free{fib1}}}

As defined, this recurrence relation is obviously doubly-recursive. To compute \axiom{fib(10)}, we need to compute \axiom{fib(9)} and \axiom{fib(8)}. And to \axiom{fib(9)}, we need to compute \axiom{fib(8)} and \axiom{fib(7)}. And so on. It seems that to compute \axiom{fib(10)} we need to compute \axiom{fib(9)} once, \axiom{fib(8)} twice, \axiom{fib(7)} three times. Look familiar? The number of function calls needed to compute \{it any\} second order recurrence relation in the obvious way is exactly \axiom{fib(n)}.

These numbers grow! For example, if Axiom actually did this, then \axiom{fib(500)} requires more than \texht{$10^{104}$} \axiom{10**104} function calls. And, given all this, our definition of \userfun{fib} obviously could not be used to calculate the five-hundredth Fibonacci number.

\xtc{Let’s try it anyway.}
{s叩irstpaste{fib(500) \free{fihn}}}

Since this takes a short time to compute, it obviously didn't do as many as $10^{104}$ operations! By default, Axiom transforms any recurrence relation it recognizes into an iteration. Iterations are efficient. To compute the value of the $n$th term of a recurrence relation using an iteration requires only $n$ function calls. If you compare the speed of our `fib` function to the library function, our version is still slower. This is because the library function from `IntegerNumberTheoryFunctions` uses a 'powering algorithm' with a computing time proportional to $\log^3(n)$ to compute $\text{fibonacci}(n)$.

To turn off this special recurrence relation compilation, issue
\begin{verbatim}
)set functions recurrence off
\end{verbatim}
To turn it back on, substitute '{tt on}' for '{tt off}'.

The transformations that Axiom uses for `fib` caches the last two values. For a more general $k$th order recurrence relation, Axiom caches the last $k$ values.

If, after computing a value for `fib`, you ask for some larger value, Axiom picks up the cached values and continues computing from there.

See `Free and Local Variables` for an example of a function definition that has this same behavior. Also see `Caching Previously Computed Results` for a more general discussion of how you can cache function values.

Recurrence relations can be used for defining recurrence relations involving polynomials, rational functions, or anything you like. Here we compute the infinite stream of Legendre polynomials.

The Legendre polynomial of degree 0.
\begin{verbatim}
\spadpaste{p(0) == 1\bound{p0}}

Making Functions from Objects

There are many times when you compute a complicated expression and then wish to use that expression as the body of a function. Axiom provides an operation called `function` to do this. It creates a function object and places it into the workspace. There are several versions, depending on how many arguments the function has. The first argument to `function` is always the expression to be converted into the function body, and the second is always the name to be used for the function.

For more information, see `MakeFunction`.

\xtc{Start with a simple example of a polynomial in three variables.}\
\spadpaste{p := -x + y**2 - z**3 \free{p}}
\xtc{To make this into a function of no arguments that simply returns the polynomial, use the two argument form of `function`.}
\spadpaste{function(p,'f0) \free{p}\bound{f0}}
\xtc{To avoid possible conflicts (see below), it is a good idea to quote always this second argument.}
\spadpaste{f0 \free{f0}}
\xtc{This is what you get when you evaluate the function.}
To make a function in \texttt{x}, use a version of \texttt{function} that takes three arguments. The last argument is the name of the variable to use as the parameter. Typically, this variable occurs in the expression and, like the function name, you should quote it to avoid possible confusion. 

\begin{Verbatim}
\texttt{function(p,'f1,'x) \free{p}\bound{f1}}
\end{Verbatim}

This is what the new function looks like. 

\begin{Verbatim}
\texttt{f1 \free{f1}}
\end{Verbatim}

This is the value of \texttt{f1} at \texttt{x = 3}. Notice that the return type of the function is \texttt{Polynomial(Integer)}, the same as \texttt{p}. 

\begin{Verbatim}
\texttt{f1(3) \free{f1}}
\end{Verbatim}

To use \texttt{x} and \texttt{y} as parameters, use the four argument form of \texttt{function}. 

\begin{Verbatim}
\texttt{function(p,'f2,'x,'y) \free{p}\bound{f2}}
\end{Verbatim}

\begin{Verbatim}
\texttt{f2 \free{f2}}
\end{Verbatim}

Evaluate \texttt{f2} at \texttt{x = 3} and \texttt{y = 0}. The return type of \texttt{f2} is still \texttt{Polynomial(Integer)} because the variable \texttt{z} is still present and not one of the parameters. 

\begin{Verbatim}
\texttt{f2(3,0) \free{f2}}
\end{Verbatim}

Finally, use all three variables as parameters. There is no five argument form of \texttt{function}, so use the one with three arguments, the third argument being a list of the parameters. 

\begin{Verbatim}
\texttt{function(p,'f3,['x,'y,'z]) \free{p}\bound{f3}}
\end{Verbatim}
Evaluate this using the same values for \axiom{x} and \axiom{y} as above, but let \axiom{z} be \axiom{-6}. The result type of \userfun{f3} is \axiomType{Integer}.

\spadpaste{f3 \free{f3}}

\xtc{
  \spadpaste{f3(3,0,-6) \free{f3}}
}

The four functions we have defined via \axiom{p} have been undeclared. To declare a function whose body is to be generated by \axiomFun{function}, issue the declaration \textit{before} the function is created.

\spadpaste{g: (Integer, Integer) -> Float \bound{g}}

\xtc{
  \spadpaste{D(sin(x-y)/cos(x+y),x) \bound{prev}}
}

\xtc{
  \spadpaste{function(\%,'g,'x,'y) \free{g}\free{prev}}
}

\xtc{
  \spadpaste{g \free{g}}
}

It is an error to use \axiom{g} without the quote in the penultimate expression since \axiom{g} had been declared but did not have a value. Similarly, since it is common to overuse variable names like \axiom{x}, \axiom{y}, and so on, you avoid problems if you always quote the variable names for \axiomFun{function}. In general, if \axiom{x} has a value and you use \axiom{x} without a quote in a call to \axiomFun{function}, then Axiom does not know what you are trying to do.

What kind of object is allowable as the first argument to \axiomFun{function}? Let's use the \Browse{} facility of Hyperdoc to find out. At the main \Browse{} menu, enter the string \tt{function} and then click on \tt{Operations.} The exposed operations called \axiomFun{function} all take an object whose type belongs to category \axiomType{ConvertibleTo InputForm}. What domains are those? Go back to the main \Browse{} menu, erase \tt{function}, enter \tt{ConvertibleTo} in the input area, and click on \tt{categories} on the \tt{Constructors} line. At the bottom of the page, enter \tt{InputForm} in the input area following \tt{S =}. Click on \tt{Cross
Reference} and then on \{\bf Domains}. The list you see contains over forty domains that belong to the category \axiomType{ConvertibleTo InputForm}. Thus you can use \axiomFun{function} for \axiomType{Integer}, \axiomType{Float}, \axiomType{Symbol}, \axiomType{Complex}, \axiomType{Expression}, and so on.

Functions Defined with Blocks

You need not restrict yourself to functions that only fit on one line or are written in a piece-wise manner. The body of the function can be a block, as discussed in the "Blocks" section in Section 5.2.

Here is a short function that swaps two elements of a list, array or vector.

\begin{spadsrc}
\swap{\text{swap}(m,i,j) == }
\text{temp := m.i}
\text{m.i := m.j}
\text{m.j := temp}
\end{spadsrc}

The significance of \text{\texttt{swap}} is that it has a destructive effect on its first argument.

You see that the second and fourth elements are interchanged.

Using this, we write a couple of different sort functions. First, a simple bubble sort. The operation \axiomOp{\#}{List} returns the number of elements in an aggregate.
bubbleSort(m) ==
  n := #m
  for i in 1..(n-1) repeat
    for j in n..(i+1) by -1 repeat
      if m.j < m.(j-1) then swap(m,j,j-1)
  m

Let this be the list we want to sort.

\spadpaste{m := [8,4,-3,9] \bound{m}}

This is the result of sorting.

\spadpaste{bubbleSort(m) \free{m swap bubbleSort}\bound{sortm}}

Moreover, \axiom{m} is destructively changed to be the sorted version.

\spadpaste{m \free{sortm}}

This function implements an insertion sort.
The basic idea is to traverse the list and insert the \eth{\axiom{i}} element in its correct position among the \axiom{i-1} previous elements.
Since we start at the beginning of the list, the list elements before the \eth{\axiom{i}} element have already been placed in ascending order.

\begin{spadsrc}\{\bound{insertionSort}\}
insertionSort(m) ==
  for i in 2..#m repeat
    j := i
    while j > 1 and m.j < m.(j-1) repeat
      swap(m,j,j-1)
      j := j - 1
  m
\end{spadsrc}\}

As with our bubble sort, this is a destructive function.

\spadpaste{m := [8,4,-3,9] \bound{m1}}

\{\}
\{\}
\{\spadpaste{insertionSort(m) \free{m1 swap insertionSort}\bound{sortm1}}\}
Neither of the above functions is efficient for sorting large lists since they reference elements by asking for the \(\text{eth}()\) element of the structure \(\text{axiom}()\).

Here is a more efficient bubble sort for lists.

\begin{spad}{bubbleSort2}
\textbf{bubbleSort2}(m: \text{List Integer}): \text{List Integer} ==
\begin{spad}{if}
\text{null } m \Rightarrow m \\
1 := m \\
\text{while } \text{not null } (r := 1.\text{rest}) \text{ repeat} \\
r := \text{bubbleSort2 } r \\
x := 1.\text{first} \\
\text{if } x < r.\text{first} \text{ then} \\
1.\text{first} := r.\text{first} \\
r.\text{first} := x \\
1.\text{rest} := r \\
1 := 1.\text{rest} \\
m
\end{spad}
\end{spad}

Try it out.

\begin{spad}{bubbleSort2}
\text{bubbleSort2 } [3,7,2]
\end{spad}

This definition is both recursive and iterative, and is tricky! Unless you are really curious about this definition, we suggest you skip immediately to the next section.

Here are the key points in the definition. First notice that if you are sorting a list with less than two elements, there is nothing to do: just return the list. This definition returns immediately if there are zero elements, and skips the entire \texttt{while} loop if there is just one element.

The second point to realize is that on each outer iteration, the bubble sort ensures that the minimum element is propagated leftmost. Each iteration of the \texttt{while} loop calls \texttt{bubbleSort2} recursively to sort all but the first element. When finished, the minimum element is either in the first or second position. The conditional expression ensures that it comes first. If it is in the
second, then a swap occurs. In any case, the \axiomFun{rest} of the original list must be updated to hold the result of the recursive call.

Free and Local Variables
\end{verbatim}

⇒ “notitle” (ugUserCachePage) 10 on page 1880
⇒ “notitle” (ugUserRecurPage) 10 on page 1883
— ug06.ht —
When you want to refer to a variable that is not local to your function, use a `\texttt{free}` declaration. Variables declared to be `\texttt{free}` are assumed to be defined globally in the workspace.

\begin{spadsrc}
\free{counter}
\end{spadsrc}

This function refers to the global `\texttt{counter}`.

\begin{spadsrc}
f() ==
  \free{counter}
  counter := counter + 1
\end{spadsrc}

The global `\texttt{counter}` is incremented by `1`.

\begin{spadsrc}
f() \free{f}
\end{spadsrc}

Usually Axiom can tell that you mean to refer to a global variable and so `\texttt{free}` isn't always necessary. However, for clarity and the sake of self-documentation, we encourage you to use it.

\begin{spadsrc}
\texttt{counter} \free{f1}
\end{spadsrc}

Declare a variable to be `\texttt{local}` when you do not want to refer to a global variable by the same name.

\begin{spadsrc}
\local{counter}
\end{spadsrc}

This function uses `\texttt{counter}` as a local variable.

\begin{spadsrc}
g() ==
  \local{counter}
  counter := 7
\end{spadsrc}

Apply the function.
Parameters to a function are local variables in the function. Even if you issue a `\axiom{free}` declaration for a parameter, it is still local.

What happens if you do not declare that a variable `\axiom{x}` in the body of your function is `\axiom{local}` or `\axiom{free}`?

Well, Axiom decides on this basis:

1. Axiom scans your function line-by-line, from top-to-bottom. The right-hand side of an assignment is looked at before the left-hand side.
2. If \axiom{x} is referenced before it is assigned a value, it is a \axiom{free} (global) variable.
3. If \axiom{x} is assigned a value before it is referenced, it is a \axiom{local} variable.

Set two global variables to 1.

Refer to \axiom{a} before it is assigned a value, but assign a value to \axiom{b} before it is referenced.

Can you predict this result?
How about this one?
}
\spadpaste{[a, b] \free{hhh}}
}

What happened? In the first line of the function body for $h$, $a$ is referenced on the right-hand side of the assignment. Thus $a$ is a free variable. The variable $b$ is not referenced in that line, but it is assigned a value. Thus $b$ is a local variable and is given the value $a + 1 = 2$. In the second line, the free variable $a$ is assigned the value $b + a$ which equals $2 + 1 = 3$. This is the value returned by the function. Since $a$ was free in $h$, the global variable $a$ has value $3$. Since $b$ was local in $h$, the global variable $b$ is unchanged---it still has the value $1$.

It is good programming practice always to declare global variables. However, by far the most common situation is to have local variables in your functions. No declaration is needed for this situation, but be sure to initialize their values.

Be careful if you use free variables and you cache the value of your function (see \downlink{‘Caching Previously Computed Results’}{ugUserCachePage} in Section 6.12). Caching only checks if the values of the function arguments are the same as in a function call previously seen. It does not check if any of the free variables on which the function depends have changed between function calls.

\xtc{Turn on caching for $p$.
}\spadpaste{)set fun cache all p \bound{pcache}}
\)
\xtc{Define $p$ to depend on the free variable $N$.
}\spadpaste{p(i, x) == ( free N; reduce( + , [ (x-i)**n for n in 1..N ] ) ) \free{pcache}\bound{pdef}}
\)
\xtc{Set the value of $N$.
}\spadpaste{N := 1 \bound{Nass}}
\)
\xtc{Evaluate $p$ the first time.
}\spadpaste{p(0, x) \free{pdef Nass}\bound{pfirst}}
\xtc{Change the value of \axiom{N}.}
\spadpaste{N := 2 \bound{Nass2}}
\xtc{Evaluate \userfun{p} the second time.}
\spadpaste{p(0, x) \free{pfirst Nass2}}
If caching had been turned off, the second evaluation would have reflected the changed value of \axiom{N}.
\xtc{Turn off caching for \userfun{p}.}
\spadpaste{)set fun cache 0 p}
Axiom does not allow {\it fluid variables}, that is, variables bound by a function \spad{f} that can be referenced by functions called by \spad{f}.
\xtc{Values are passed to functions by \spad{reference}: a pointer to the value is passed rather than a copy of the value or a pointer to a copy.}
\xtc{This is a global variable that is bound to a record object.}
\spadpaste{r : Record(i : Integer) := [1] \free{r}}
\xtc{This function first modifies the one component of its record argument and then rebinds the parameter to another record.}
\begin{spadsrc}
resetRecord rr ==
   rr.i := 2
   rr := [10]
\end{spadsrc}
\xtc{Pass \axiom{r} as an argument to \userfun{resetRecord}.}
\spadpaste{resetRecord r \free{r resetRecord\bound{rr}}}
\xtc{The value of \axiom{r} was changed by the expression \axiom{rr.i := 2} but not by \axiom{rr := [10]}.}
To conclude this section, we give an iterative definition of a function that computes Fibonacci numbers. This definition approximates the definition into which Axiom transforms the recurrence relation definition of \userfun{fib} in \downlink{''Recurrence Relations''}{ugUserRecurPage} in Section 6.13\ignore{ugUserRecur}.

\xtc{
Global variables \axiom{past} and \axiom{present} are used to hold the last computed Fibonacci numbers.
}\{
\spadpaste{past := present := 1\bound{f0}}
\}
\xtc{
Global variable \axiom{index} gives the current index of \axiom{present}.
}\{
\spadpaste{index := 2\bound{f1}\free{f0}}
\}
\xtc{
Here is a recurrence relation defined in terms of these three global variables.
}\{
\begin{spadsrc}
\bound{f3}\free{f2}
\xtc{Global variables \axiom{past}, \axiom{present}, \axiom{index} are used in the definition.}
\end{spadsrc}
\xtc{Compute the infinite stream of Fibonacci numbers.}
}\{
\spadpaste{fibs := [fib(n) for n in 1..] \bound{fibs}\free{f3}}
\}
\xtc{What is the 1000th Fibonacci number?}
}\{
As an exercise, we suggest you write a function in an iterative style that computes the value of the recurrence relation

\[ p(n) = p(n-1) - 2 \cdot p(n-2) + 4 \cdot p(n-3) \]

having the initial values

\[ p(1) = 1, \quad p(2) = 3 \quad \text{and} \quad p(3) = 9. \]

How would you write the function using an element \( \text{OneDimensionalArray} \) or \( \text{Vector} \) to hold the previously computed values?

Anonymous Functions

⇒ “notitle” (ugUserAnonExampPage) 10 on page 1922
⇒ “notitle” (ugUserAnonDeclarePage) 10 on page 1927
— ug06.ht —
An *anonymous function* is a function that is defined by giving a list of parameters, the ‘maps-to’ compound symbol \(\mapsto\)\textit{(from the mathematical symbol $\mapsto$)}, and by an expression involving the parameters, the evaluation of which determines the return value of the function.

\[
\text{( \texttt{parm}_1, \texttt{parm}_2, \ldots, \texttt{parm}_N ) \mapsto \textit{expression}}
\]

You can apply an anonymous function in several ways.

1. Place the anonymous function definition in parentheses directly followed by a list of arguments.
2. Assign the anonymous function to a variable and then use the variable name when you would normally use a function name.
3. Use\(\mathrel{==}\) to use the anonymous function definition as the arguments and body of a regular function definition.
4. Have a named function contain a declared anonymous function and use the result returned by the named function.

Some Examples
Anonymous functions are particularly useful for defining functions ‘on the fly.’ That is, they are handy for simple functions that are used only in one place.

In the following examples, we show how to write some simple anonymous functions.

\texttt{This is a simple absolute value function.}
\begin{verbatim}
\spadpaste{x +-> if x < 0 then -x else x \bound{anon0}}
\end{verbatim}
\texttt{This function returns \tt true if the absolute value of the first argument is greater than the absolute value of the second, \tt false otherwise.}
\begin{verbatim}
\spadpaste{(x,y) +-> abs1(x) > abs1(y) \bound{anon1}\free{abs1}}
\end{verbatim}
\texttt{We use the above function to ‘sort’ a list of integers.}
\begin{verbatim}
\spadpaste{sort(\%,[3,9,-4,10,-3,-1,-9,5]) \free{anon1}}
\end{verbatim}
\texttt{This function returns \axiom{1} if \axiom{i + j} is even, \axiom{-1} otherwise.}
\begin{verbatim}
\spadpaste{ev := ( (i,j) +-> if even?(i+j) then 1 else -1) \bound{ev}}
\end{verbatim}
\texttt{We create a four-by-four matrix containing \axiom{1} or \axiom{-1} depending on whether the row plus the column index is even or not.}
\begin{verbatim}
\spadpaste{matrix([[ev(row,col) for row in 1..4] for col in 1..4]) \free{ev}}
\end{verbatim}
\texttt{This function returns \tt true if a polynomial in \axiom{x} has multiple roots, \tt false otherwise. It is defined and applied in the same expression.}
\begin{verbatim}
\spadpaste{( p +-> not one?(gcd(p,D(p,x))) )(x**2+4*x+4)}
\end{verbatim}
This and the next expression are equivalent.
\spadpaste{g(x,y,z) == cos(x + sin(y + tan(z)))}
\xtc{}
The one you use is a matter of taste.
\spadpaste{g == (x,y,z) +-> cos(x + sin(y + tan(z)))}
\xtc{}

\begin{verbatim}

Declaring Anonymous Functions

— ug06.ht —

If you declare any of the arguments you must declare all of them. Thus,

\begin{verbatim}
(x: INT,y): FRAC INT +-> (x + 2*y)/(y - 1)
\end{verbatim}

is not legal.

\xtc{
This is an example of a fully declared anonymous function.
}
The output shown just indicates that the object you created is a particular kind of map, that is, function.

\spadpaste{(x: INT,y: INT): FRAC INT +-> (x + 2*y)/(y - 1)}

Axiom allows you to declare the arguments and not declare the return type.

\spadpaste{(x: INT,y: INT) +-> (x + 2*y)/(y - 1)}

The return type is computed from the types of the arguments and the body of the function. You cannot declare the return type if you do not declare the arguments. Therefore,

\begin{verbatim}
(x,y): FRAC INT +-> (x + 2*y)/(y - 1)
\end{verbatim}

is not legal.

This and the next expression are equivalent.

\spadpaste{h(x: INT,y: INT): FRAC INT == (x + 2*y)/(y - 1)}

The one you use is a matter of taste.

\spadpaste{h == (x: INT,y: INT): FRAC INT +-> (x + 2*y)/(y - 1)}

When should you declare an anonymous function?

\begin{itemize}
\item[1.] If you use an anonymous function and Axiom can’t figure out what you are trying to do, declare the function.
\item[2.] If the function has nontrivial argument types or a nontrivial return type that Axiom may be able to determine eventually, but you are not willing to wait that long, declare the function.
\item[3.] If the function will only be used for arguments of specific types and it is not too much trouble to declare the function, do so.
\item[4.] If you are using the anonymous function as an argument to another function (such as \axiomFun{map} or \axiomFun{sort}), consider declaring the function.
\item[5.] If you define an anonymous function inside a named function, you \{it must\} declare the anonymous function.
\end{itemize}
This is an example of a named function for integers that returns a function.

\spadpaste{addx x == ((y: Integer): Integer +-> x + y) \bound{addx}}

We define \userfun{g} to be a function that adds \axiom{10} to its argument.

\spadpaste{g := addx 10 \free{addx}\bound{g}}

Try it out.

\spadpaste{g 3 \free{g}}

\spadpaste{g(-4) \free{g}}

An anonymous function cannot be recursive: since it does not have a name, you cannot even call it within itself!

If you place an anonymous function inside a named function, the anonymous function must be declared.
(2) theMap(NIL)

Example: A Database

This example shows how you can use Axiom to organize a database of lineage data and then query the database for relationships.

The database is entered as ‘assertions’ that are really pieces of a function definition.

\spadpaste{children("albert") == ["albertJr","richard","diane"]}\bound{d1}

Each piece \(\text{children}(x) = y\) means ‘the children of \(\text{axiom}(x)\) are \(\text{axiom}(y)\)’.

\spadpaste{children("richard") == ["douglas","daniel","susan"]}\free{d1}\bound{d2}

This family tree thus spans four generations.

\spadpaste{children("douglas") == ["dougie","valerie"]}\free{d2}\bound{d3}

Say ‘no one else has children.’

\spadpaste{children(x) == []}\free{d3}\bound{d4}

We need some functions for computing lineage. Start with \text{childOf}.
\begin{spadsrc}
\texttt{childOf(x,y) == member?(x,children(y))}
\end{spadsrc}

To find the \texttt{parentOf} someone, you have to scan the database of people applying \texttt{children}.

\begin{spadsrc}
\texttt{parentOf(x) ==}
\texttt{for y in people repeat}
\texttt{  (if childOf(x,y) then return y)}
\texttt{"unknown"}
\end{spadsrc}

And a grandparent of \texttt{x} is just a parent of a parent of \texttt{x}.

\begin{spadsrc}
\texttt{grandParentOf(x) == parentOf parentOf x}
\end{spadsrc}

The grandchildren of \texttt{x} are the people \texttt{y} such that \texttt{x} is a grandparent of \texttt{y}.

\begin{spadsrc}
\texttt{grandchildren(x) == [y for y in people | grandParentOf(y) = x]}
\end{spadsrc}

Suppose you want to make a list of all great-grandparents. Well, a great-grandparent is a grandparent of a person who has children.

\begin{spadsrc}
\texttt{greatGrandParents == [x for x in people |}
\texttt{  reduce(_or,[not empty? children(y) for y in grandchildren(x)],[false])}
\end{spadsrc}

Define \texttt{descendants} to include the parent as well.

\begin{spadsrc}
\texttt{descendants(x) ==}
\texttt{  kids := children(x)}
\texttt{  null kids => [x]}
\texttt{  concat(x,reduce(concat,[descendants(y)
    for y in kids],[]))}
\end{spadsrc}

Finally, we need a list of people.
Since all people are descendants of "albert", let's say so.

{\spadpaste{people == descendants "albert"}\free{d4}\bound{d5}}

We have used \axiomSyntax{==} to define the database and some functions to query the database. But no computation is done until we ask for some information. Then, once and for all, the functions are analyzed and compiled to machine code for run-time efficiency. Notice that no types are given anywhere in this example. They are not needed.

{\xtc{\Who are the grandchildren of "richard"\?
\spadpaste{grandchildren "richard"}\bound{d10}\free{d11}}

\xtc{\Who are the great-grandparents?
\spadpaste{greatGrandParents}\bound{d11}\free{d12}}

Example: A Famous Triangle

In this example we write some functions that display Pascal's triangle. It demonstrates the use of piece-wise definitions and some output operations you probably haven't seen before.

To make these output operations available, we have to expose the domain \texttt{OutputForm}. See \texttt{Exposing Domains and Packages} in Section 2.11 for more information about exposing domains and packages.

Define the values along the first row and any column \texttt{i}.

Define the values for when the row and column index \texttt{i} are equal. Repeating the argument name indicates that the two index values are equal.

Now that we have defined the coefficients in Pascal's triangle, let's write a couple of one-liners to display it.
First, define a function that gives the \( \text{eth}\{\text{axiom}(n)\} \) row.

{\spad{\text{pascalRow}(n) == [\text{pascal}(i,n) \text{ for } i \text{ in } 1..n] \\
 bound\{\text{pascalRow}\} free\{pas3\}}}

\xtc{Next, we write the function \userfun{displayRow} to display the row, separating entries by blanks and centering.}

{\spad{\text{displayRow}(n) == output center blankSeparate \text{pascalRow}(n) \\
 free\{\text{pascalRow}\} bound\{\text{displayRow}\} free\{expose\}}
}

Here we have used three output operations. Operation \axiomFunFrom{output}{OutputForm} displays the printable form of objects on the screen, \axiomFunFrom{center}{OutputForm} centers a printable form in the width of the screen, and \axiomFunFrom{blankSeparate}{OutputForm} takes a list of printable forms and inserts a blank between successive elements.

\xtc{Look at the result.}

{\spad{\text{for } i \text{ in } 1..7 \text{ repeat } \text{displayRow } i \ free\{\text{displayRow}\}} }

Being purists, we find this less than satisfactory. Traditionally, elements of Pascal's triangle are centered between the left and right elements on the line above.

\xtc{To fix this misalignment, we go back and redefine \userfun{pascalRow} to right adjust the entries within the triangle within a width of four characters.}

{\spad{\text{pascalRow}(n) == [\text{right}(\text{pascal}(i,n),4) \text{ for } i \text{ in } 1..n] \\
 bound\{\text{pascalRow2}\}}
}

\xtc{Finally let's look at our purely reformatted triangle.}

{\spad{\text{for } i \text{ in } 1..7 \text{ repeat } \text{displayRow } i \ free\{\text{pascalRow2}\} \\
 free\{\text{displayRow}\} }}

\xtc{Unexpose \axiomType{OutputForm} so we don't get unexpected results later.}

Example: Testing for Palindromes

⇒ “notitle” (ugUserTrianglePage) 10 on page 1939

---

In this section we define a function \texttt{\userfun{pal?}} that tests whether its argument is a \{\it palindrome\}, that is, something that reads the same backwards and forwards. For example, the string ‘‘Madam I’am Adam’’ is a palindrome (excluding blanks and punctuation) and so is the number \texttt{\axiom{123454321.}} The definition works for any datatype that has \texttt{\axiom{n}} components that are accessed by the indices \texttt{\axiom{1\ldots n}}.

\xtc{Here is the definition for \texttt{\userfun{pal?}}. It is simply a call to an auxiliary function called \texttt{\userfun{palAux?}}. We are following the convention of ending a function’s name with \texttt{\axiomSyntax{?}} if the function returns a \texttt{\axiomType{Boolean}} value.}
Here is \texttt{\texttt{palAux?}}. It works by comparing elements that are equidistant from the start and end of the object.

\begin{spadsrc}
\texttt{palAux?}(s,i,j) ==
\begin{itemize}
  \item \texttt{j > i =>}
  \begin{itemize}
    \item \texttt{(s.i = s.j) and palAux?}(s,i+1,i-1)
    \item \texttt{true}
  \end{itemize}
\end{itemize}
\end{spadsrc}

Try \texttt{\texttt{pal?}} on some examples. First, a string.

\begin{spadpaste}
\texttt{pal?} "Oxford"
\end{spadpaste}

A list of polynomials.

\begin{spadpaste}
\texttt{pal?} \{4,a,x-1,0,x-1,a,4\}
\end{spadpaste}

A list of integers from the example in \texth{\texttt{A Famous Triangle'}}\ignore{ugUserTriangle}. \texttt{\texttt{pal?}}\{1,6,15,20,15,6,1\}

To use \texttt{\texttt{pal?}} on an integer, first convert it to a string.

\begin{spadpaste}
\texttt{pal?}(1441::String)
\end{spadpaste}

Compute an infinite stream of decimal numbers, each of which is an obvious palindrome.

\begin{spadpaste}
\texttt{ones := \{reduce(+,[10**j for j in 0..i]) for i in 1..\}}
\end{spadpaste}

\begin{spadpaste}
\texttt{squares := \{x**2 for x in ones\}}
\end{spadpaste}
Well, let's test them all!
}\spadpaste{[pal?(x::String) for x in squares]\free{pal6}}\}

Rules and Pattern Matching

--- ug06.htm ---

A common mathematical formula is
\[
\log(x) + \log(y) = \log(x \cdot y) \quad \forall \, x \text{ and } y.
\]
The presence of the word "any" indicates that \(x\) and \(y\) can stand for arbitrary mathematical expressions in the above formula.
You can use such mathematical formulas in Axiom to specify "rewrite rules".
Rewrite rules are objects in Axiom that can be assigned to variables for later use, often for the purpose of simplification.
Rewrite rules look like ordinary function definitions except that they are preceded by the reserved word \(\text{axiom}\{\text{rule}\}\).

For example, a rewrite rule for the above formula is:
\begin{verbatim}
rule log(x) + log(y) == log(x * y)
\end{verbatim}
Like function definitions, no action is taken when a rewrite rule is issued.
Think of rewrite rules as functions that take one argument.
When a rewrite rule \(\text{axiom}(A = B)\) is applied to an argument \(\text{axiom}(f)\), its meaning is: "rewrite every subexpression of \(\text{axiom}(f)\) that \{it matches\} ."
The left-hand side of a rewrite rule is called a \texttt{pattern}; its right-hand side is called its \texttt{substitution}.

\begin{verbatim}
\texttt{Create a rewrite rule named \texttt{logrule}.}
\texttt{The generated symbol beginning with a \texttt{\%} is a place-holder for any other terms that might occur in the sum.}
\texttt{Create an expression with logarithms.}
\texttt{Apply \texttt{logrule} to \texttt{f}.}
\end{verbatim}

The meaning of our example rewrite rule is:

```
for all expressions \texttt{x} and \texttt{y}, rewrite \texttt{log(x) + log(y)} by \texttt{log(x * y)}.''
```

Patterns generally have both operation names (here, \texttt{\texttt{log}} and \texttt{\texttt{+}}) and variables (here, \texttt{x} and \texttt{y}).

By default, every operation name stands for itself. Thus \texttt{\texttt{log}} matches only ‘‘\texttt{\texttt{log}}’’ and not any other operation such as \texttt{\texttt{\texttt{sin}}}.

On the other hand, variables do not stand for themselves. Rather, a variable denotes a \texttt{pattern variable} that is free to match any expression whatsoever.

When a rewrite rule is applied, a process called \texttt{pattern matching} goes to work by systematically scanning the subexpressions of the argument. When a subexpression is found that ‘‘matches’’ the pattern, the subexpression is replaced by the right-hand side of the rule. The details of what happens will be covered later.

The customary Axiom notation for patterns is actually a shorthand for a longer, more general notation. Pattern variables can be made explicit by using a percent (\texttt{\%}) as the first character of the variable name. To say that a name stands for itself, you can prefix that name with a quote operator (\texttt{'}). Although the current Axiom parser does not let you quote an operation name, this more general notation gives you an alternate way of giving the same rewrite rule:

\begin{verbatim}
\end{verbatim}
\begin{verbatim}
rule log(%x) + log(%y) == log(x * y)
\end{verbatim}
This longer notation gives you patterns that the standard notation won’t handle.
For example, the rule
\begin{verbatim}
rule %f(c * 'x) == c*%f(x)
\end{verbatim}
means ‘for all \axiom{f} and \axiom{c}, replace \axiom{f(y)} by \axiom{c * f(x)} when \axiom{y} is the product of \axiom{c} and the explicit variable \axiom{x}.’’

Thus the pattern can have several adornments on the names that appear there. Normally, all these adornments are dropped in the substitution on the right-hand side.

To summarize:

\begin{verbatim}
\begin{Important}
To enter a single rule in Axiom, use the following syntax:
\spadkey{rule}
\centerline{{\tt rule \it leftHandSide} == \it rightHandSide}}
The \{\it leftHandSide\} is a pattern to be matched and the \{\it rightHandSide\} is its substitution.
The rule is an object of type \axiomType{RewriteRule} that can be assigned to a variable and applied to expressions to transform them.
\end{Important}
\end{verbatim}

Rewrite rules can be collected into rulesets so that a set of rules can be applied at once. Here is another simplification rule for logarithms. \begin{verbatim}
\texttt{y * log(x) == log(x ** y)} for any \axiom{x} and \axiom{y}.\) If instead of giving a single rule following the reserved word \axiom{rule} you give a ‘‘pile’’ of rules, you create what is called a \{\it ruleset\}. Like rules, rulesets are objects in Axiom and can be assigned to variables. You will find it useful to group commonly used rules into input files, and read them in as needed.
\xtc{Create a ruleset named \axiom{logrules}.}
\begin{spadsrc}
\bound{logrules} := rule
log(x) + log(y) == log(x * y)
y * log x == log(x ** y)
\end{spadsrc}
\xtc{Again, create an expression \axiom{f} containing logarithms.
We have allowed pattern variables to match arbitrary expressions in the above examples. Often you want a variable only to match expressions satisfying some predicate. For example, we may want to apply the transformation `\text{\narrowDisplay{y \log(x) = \log(x^y)}}` only when `\axiom{y}` is an integer.

The way to restrict a pattern variable `\axiom{y}` by a predicate `\axiom{f(y)}` is by using a vertical bar `\axiomSyntax{|}`, which means 'such that,' in much the same way it is used in function definitions. You do this only once, but at the earliest (meaning deepest and leftmost) part of the pattern.

This restricts the logarithmic rule to create integer exponents only.

```spadsrc```
logrules2 := rule
    log(x) + log(y) == log(x * y)
    (y | integer? y) * log x == log(x ** y)
```

Compare this with the result of applying the previous set of rules.

```spadpaste```
f
```

You should be aware that you might need to apply a function like \spadfun{integer} within your predicate expression to actually apply the test function.

Here we use \spadfun{integer} because \spad{n} has type \spadtype{Expression Integer} but \spadfun{even?} is an operation defined on integers.

```spadpaste```
evenRule := rule cos(x)**(n | integer? n and even? integer n) == (1-sin(x)**2)**(n/2)
```

Here is the application of the rule.
\begin{spadpaste}
\text{evenRule}(\cos(x)^2)
\end{spadpaste}

This is an example of some of the usual identities involving products of sines and cosines.
\begin{spadsrc}
\begin{axiom}
\bound{sinCosProducts} == rule
\sin(x) * \sin(y) == (\cos(x-y) - \cos(x + y))/2 \\
\cos(x) * \cos(y) == (\cos(x-y) + \cos(x+y))/2 \\
\sin(x) * \cos(y) == (\sin(x-y) + \sin(x + y))/2
\end{axiom}
\end{spadsrc}

Another qualification you will often want to use is to allow a pattern to match an identity element. Using the pattern \axiom{x + y}, for example, neither \axiom{x} nor \axiom{y} matches the expression \axiom{0}. Similarly, if a pattern contains a product \axiom{x*y} or an exponentiation \axiom{x**y}, then neither \axiom{x} or \axiom{y} matches \axiom{1}.

If identical elements were matched, pattern matching would generally loop. Here is an expansion rule for exponentials.
\begin{spadpaste}
\text{exprule} := \text{rule exp(a + b) == exp(a) * exp(b)}
\end{spadpaste}

This rule would cause infinite rewriting on this if either \axiom{a} or \axiom{b} were allowed to match \axiom{0}.
\begin{spadpaste}
\text{exprule exp x}
\end{spadpaste}

There are occasions when you do want a pattern variable in a sum or product to match \axiom{0} or \axiom{1}. If so, prefix its name with a \axiomSyntax{?} whenever it appears in a left-hand side of a rule.
For example, consider the following rule for the exponential integral:
\[
\int \left(\frac{y+e^x}{x}\right)\, dx = \int \frac{y}{x}\, dx + \text{Ei}(x) \quad \forall \, x \text{ and } y.
\]
for any \(x\) and \(y\). This rule is valid for \(y = 0\). One solution is to create a \texttt{Ruleset} with two rules, one with and one without \texttt{y}. A better solution is to use an ‘optional’ pattern variable.

\[
\texttt{Define rule } \texttt{eirule} \texttt{ with a pattern variable } \texttt{?y} \texttt{ to indicate that an expression may or may not occur.}
\]

\[
\texttt{eirule := rule integral((?y + \exp x)/x,x) == integral(y/x,x) + \text{Ei} x \bound{eirule}}
\]

\[
\texttt{Apply rule } \texttt{eirule} \texttt{ to an integral without this term.}
\]

\[
\texttt{eirule integral(\exp u/u, u) \free{eirule}}
\]

\[
\texttt{Apply rule } \texttt{eirule} \texttt{ to an integral with this term.}
\]

\[
\texttt{eirule integral(sin u + \exp u/u, u) \free{eirule}}
\]

Here is one final adornment you will find useful. When matching a pattern of the form \texttt{x + y} to an expression containing a long sum of the form \texttt{a +\ldots+ b}, there is no way to predict in advance which subset of the sum matches \texttt{x} and which matches \texttt{y}. Aside from efficiency, this is generally unimportant since the rule holds for any possible combination of matches for \texttt{x} and \texttt{y}. In some situations, however, you may want to say which pattern variable is a sum (or product) of several terms, and which should match only a single term. To do this, put a prefix colon \texttt{Syntax{}} before the pattern variable that you want to match multiple terms.

\[
\texttt{The remaining rules involve operators } \texttt{u} \texttt{ and } \texttt{v}.
\]

\[
\texttt{u := operator 'u \bound{u}}
\]

\[
\texttt{These definitions tell Axiom that } \texttt{u} \texttt{ and } \texttt{v} \texttt{ are formal operators to be used in expressions.}
\]

\[
\texttt{v := operator 'v \bound{v}}
\]
First define \texttt{myRule} with no restrictions on the pattern variables \texttt{x} and \texttt{y}.

\begin{verbatim}
\spadpaste{myRule := rule u(x + y) == u x + v y \free{u v}\bound{m}}
\end{verbatim}

Apply \texttt{myRule} to an expression.

\begin{verbatim}
\spadpaste{myRule u(a + b + c + d) \free{m}}
\end{verbatim}

Define \texttt{myOtherRule} to match several terms so that the rule gets applied recursively.

\begin{verbatim}
\spadpaste{myOtherRule := rule u(:x + y) == u x + v y \free{u v}\bound{m2}}
\end{verbatim}

Apply \texttt{myOtherRule} to the same expression.

\begin{verbatim}
\spadpaste{myOtherRule u(a + b + c + d) \free{m2}}
\end{verbatim}

Here are some final remarks on pattern matching. Pattern matching provides a very useful paradigm for solving certain classes of problems, namely, those that involve transformations of one form to another and back. However, it is important to recognize its limitations.

First, pattern matching slows down as the number of rules you have to apply increases. Thus it is good practice to organize the sets of rules you use optimally so that irrelevant rules are never included.

Second, careless use of pattern matching can lead to wrong answers. You should avoid using pattern matching to handle hidden algebraic relationships that can go undetected by other programs. As a simple example, a symbol such as ‘‘J’’ can easily be used to represent the square root of \texttt{axiom{-1}} or some other important algebraic quantity. Many algorithms branch on whether an expression is zero or not, then divide by that expression if it is not. If you fail to simplify an expression involving powers of \texttt{axiom{J}} to \texttt{axiom{-1,}} algorithms may incorrectly assume an expression is non-zero, take a wrong branch, and produce a meaningless result.

Pattern matching should also not be used as a substitute for a domain. In Axiom, objects of one domain are transformed to objects of other domains using well-defined \texttt{axiomFun{coerce}} operations.
Pattern matching should be used on objects that are all the same type. Thus if your application can be handled by type \texttt{\textbackslash axiomType\{Expression\}} in Axiom and you think you need pattern matching, consider this choice carefully. You may well be better served by extending an existing domain or by building a new domain of objects for your application.

This chapter shows how to use the Axiom graphics facilities under the X Window System. Axiom has \twodim{} and \threedim{} drawing and rendering packages that allow the drawing, coloring, transforming, mapping, clipping, and combining of graphic output from Axiom computations. This facility is particularly useful for investigating
problems in areas such as topology. The graphics package is capable of plotting functions of one or more variables or plotting parametric surfaces and curves. Various coordinate systems are also available, such as polar and spherical.

A graph is displayed in a viewport window and it has a control-panel that uses interactive mouse commands. PostScript and other output forms are available so that Axiom images can be printed or used by other programs.\footnote{PostScript is a trademark of Adobe Systems Incorporated, registered in the United States.}

Plotting Two-Dimensional Functions of One Variable

⇒ “notitle” (ugGraphTwoDOptionsPage) 11 on page 1978
— ug07.ht —

\begin{page}{ugGraphTwoDPlotPage}
\{7.1.1. Plotting Two-Dimensional Functions of One Variable\}
\beginscroll
The first kind of \texttt{twodim} graph is that of a curve defined by a function \texttt{y = f(x)} over a finite interval of the \texttt{x} axis.

\beginImportant
The general format for drawing a function defined by a formula \texttt{f(x)} is:
\beginverbatim
\tt draw(f(x), x = a..b, \{it options\})
\endverbatim
where \texttt{a..b} defines the range of \texttt{x}, and where \{\texttt{it options}\} prescribes zero or more options as described in \link{``Two-Dimensional Options''}{ugGraphTwoDOptionsPage} in Section 7.1.4. An example of an option is \texttt{curveColor == bright red()}. An alternative format involving functions \texttt{f} and \texttt{g} is also available.
\endImportant

A simple way to plot a function is to use a formula. The first argument is the formula. For the second argument, write the name of the independent variable (here, \texttt{x}), followed by an \texttt{=}, and the range of values.

\psXtc{Display this formula over the range $0 \leq x \leq 6$. Axiom converts your formula to a compiled function so that the results can be computed quickly and efficiently.}{\graphpaste{draw(sin(tan(x)) - tan(sin(x)), x = 0..6)}}

Notice that Axiom compiled the function before the graph was put on the screen.

\psXtc{Here is the same graph on a different interval. This time we give the graph a title.}{\graphpaste{draw(sin(tan(x)) - tan(sin(x)), x = 10..16)}}

Once again the formula is converted to a compiled function before
any points were computed. If you want to graph the same function on several intervals, it is a good idea to define the function first so that the function has to be compiled only once.
\xtc{
This time we first define the function.
}
\spadpaste{f(x) == (x-1)*(x-2)*(x-3) \bound{f}}
\psXtc{
To draw the function, the first argument is its name and the second is just the range with no independent variable.
}
\graphpaste{draw(f, 0..4) \free{f}}
\epsffile[0 0 295 295]{../ps/2d1vard.ps}
\endscroll
autoscroll
endbuttons
end{page}
The second kind of \twodim{} graph is that of curves produced by parametric equations. Let \axiom{x = f(t)} and \axiom{y = g(t)} be formulas or two functions \axiom{f} and \axiom{g} as the parameter \axiom{t} ranges over an interval \axiom{[a,b]}.

The function \axiomFun{curve} takes the two functions \axiom{f} and \axiom{g} as its parameters.

The general format for drawing a \twodim{} plane curve defined by

\begin{verbatim}
f(x) == (x-1)*(x-2)*(x-3)
end{verbatim}

Type: Void
parametric formulas \(\texttt{x = f(t)}\) and \(\texttt{y = g(t)}\) is:
\[
\texttt{draw(curve(f(t), g(t)), t = a..b, \{it options\})}
\]
where \(\texttt{a..b}\) defines the range of the independent variable \(\texttt{t}\),
and where \(\{\text{it options}\}\) prescribes zero or more options as
described in
\[
\texttt{draw(curve(f(t), g(t)), t = a..b, \{it options\})}
\]
in Section 7.2.4\ignore{ugGraphThreeDOptions}. An example of an option is
\(\texttt{curveColor == bright red()}\).

Here's an example:
\[
\texttt{Define a parametric curve using a range involving}
\texttt{\%pi}, Axiom's way of saying \(\pi\).
\]
For parametric curves, Axiom compiles two
functions, one for each of the functions \(\texttt{f}\) and \(\texttt{g}\).
\[
\texttt{draw(curve(sin(t)*sin(2*t)*sin(3*t),}
\sin(4*t)*sin(5*t)*sin(6*t)), t = 0..2\%pi)}
\]\[
\texttt{draw(curve(cos(t), sin(t)), t = 0..2\%pi)}
\]\[
\texttt{draw(curve(f(t), g(t)), t = a..b, \{it options\})}
\]
if you plan on plotting \(\texttt{x = f(t)}\), \(\texttt{y = g(t)}\) as \(\texttt{t}\)
ranges over several intervals, you may want to define functions
\(\texttt{f}\) and \(\texttt{g}\) first, so
that they need not be recompiled every time you create a new graph. Here's an example:
\[
\texttt{As before, you can first define the functions you wish to draw.}
\]
\[
\texttt{f(t:DFLOAT):DFLOAT == sin(3*t/4) \bound{f}}
\]
Give to `\tt curve` the names of the functions, then write the range without the name of the independent variable.
}
\graphpaste{draw(curve(f,g),0..\%pi) \free{f g}}
}
\epsffile[0 0 295 295]{../ps/2dppcc.ps}

Here is another look at the same curve but over a different range. Notice that `\axiom{f}` and `\axiom{g}` are not recompiled. Also note that Axiom provides a default title based on the first function specified in `\axiomFun{curve}`.
}
\graphpaste{draw(curve(f,g),-4*\%pi..4*\%pi) \free{f g}}
}
\epsffile[0 0 295 295]{../ps/2dppce.ps}

\endscroll
\autobuttons
\end{page}
\spadcommand{f(t:DFLOAT):DFLOAT == sin(3*t/4)}
\indentrel{3}\begin{verbatim}
Type: Void
\end{verbatim}
\indentrel{-3}

\spadcommand{g(t:DFLOAT):DFLOAT == sin(t)}
\indentrel{3}\begin{verbatim}
Type: Void
\end{verbatim}
\indentrel{-3}

\spadgraph{draw(curve(f,g),0..\%pi)}
A third kind of \twodim{} graph is a non-singular ‘‘solution curve’’ in a rectangular region of the plane. A solution curve is a curve defined by a polynomial equation \axiom{p(x,y) = 0}. Non-singular means that the curve is ‘‘smooth’’ in that it does not cross itself or come to a point (cusp). Algebraically, this means that for any point \axiom{(x,y)} on the curve, that is, a point such that \axiom{p(x,y) = 0}, the partial derivatives \texht{${{{\partial p}\over{\partial x}}(x,y)}$} and \texht{${{{\partial p}\over{\partial y}}(x,y)}$} are not both zero.

\% \beginImportant
The general format for drawing a non-singular solution curve given by a polynomial of the form \axiom{p(x,y) = 0} is:
\% \beginverbatim
\tt draw(p(x,y) = 0, x, y, range == [a..b, c..d], 
{\it options})
\endverbatim\nwhere the second and third arguments name the first and second independent variables of \axiom{p}. A \{\tt range\} option is always given to designate a bounding rectangular region of the plane \texht{$a \leq x \leq b, c \leq y \leq d$}. Zero or more additional options as described in \downlink{‘Two-Dimensional Options’}{ugGraphTwoDOptionsPage}.

Plotting Plane Algebraic Curves

⇒ “notitle” (ugGraphTwoDOptionsPage) 11 on page 1978

— ug07.ht —

\beginverbatim
\tt draw(curve(f,g),-4*%pi..4*%pi)\free{f g }
\endverbatim

\beginverbatim
\tt draw(curve(f,g),-4*%pi..4*%pi)\free{f g }
\endverbatim
in Section 7.1.4\ignore{ugGraphTwoDOptions} may be given.
\endImportant
\xtc{We require that the polynomial has rational or integral coefficients. Here is an algebraic curve example (‘‘Cartesian ovals’’):
}{
\spadpaste{p := ((x**2 + y**2 + 1) - 8*x)**2 - (8*(x**2 + y**2 + 1)-4*x-1) \bound{p}}
}
\psXtc{The first argument is always expressed as an equation of the form
\axiom{p = 0} where \axiom{p} is a polynomial.
}{
\graphpaste{draw(p = 0, x, y, range == [-1..11, -7..7]) \free{p}}
}\epsffile[0 0 295 295]{../ps/2dpaca.ps}
}
Two-Dimensional Options

⇒ “notitle” (ugGraphColorPage) 11 on page 1983
⇒ “notitle” (ugGraphColorPalettePage) 11 on page 1985
⇒ “notitle” (ugGraphColorPage) 11 on page 1983
⇒ “notitle” (ugGraphColorPalettePage) 11 on page 1985

The \axiomFun{draw} commands take an optional list of options, such as \{\tt title\} shown above. Each option is given by the syntax: \{\it name\} \{\tt ==\} \{\it value\}. Here is a list of the available options in the order that they are described below.

<table>
<thead>
<tr>
<th>Adaptive</th>
<th>Clip</th>
<th>Unit</th>
<th>Curve Color</th>
<th>Range</th>
</tr>
</thead>
</table>

The \axiom{adaptive} option turns adaptive plotting on or off. Adaptive plotting uses an algorithm that traverses a graph and computes more points for those parts of the graph with high curvature. The higher the curvature of a region is, the more points the algorithm computes.

\psXtc{The \{\tt adaptive\} option is normally on. Here we turn it off.}{
\graphpaste{draw(sin(1/x),x=-2*%pi..2*%pi, adaptive == false)}
}{
\epsffile[0 0 295 295]{../ps/2doptad.ps}
}

\psXtc{The \{\tt adaptive\} option is normally on. Here we turn it off.}{
\graphpaste{draw(sin(1/x),x=-2*%pi..2*%pi, adaptive == false)}
}{
\epsffile[0 0 295 295]{../ps/2doptad.ps}
}
The `\tt clip` option turns clipping on or off. If on, large values are cut off according to `\axiomFunFrom{clipPointsDefault}{GraphicsDefaults}`.

\graphpaste{draw(tan(x),x=-2*\%pi..2*\%pi, clip == true)}
\epsffile[0 0 295 295]{../ps/2doptcp.ps}

Option `\tt toScale` does plotting to scale if `\tt true` or uses the entire viewport if `\tt false`. The default can be determined using `\axiomFunFrom{drawToScale}{GraphicsDefaults}`.

\graphpaste{draw(sin(x),x=-\%pi..\%pi, toScale == true, unit == [1.0,1.0])}
\epsffile[0 0 295 295]{../ps/2doptsc.ps}

Option `\tt clip` with a range sets point clipping of a graph within the ranges specified in the list `\axiom{[x range,y range]}`. If only one range is specified, clipping applies to the y-axis.

\graphpaste{draw(sec(x),x=-2*\%pi..2*\%pi, clip == [-2*\%pi..2*\%pi, -\%pi..\%pi], unit == [1.0,1.0])}
\epsffile[0 0 295 295]{../ps/2doptcpr.ps}

Option `\tt curveColor` sets the color of the graph curves or lines to be the indicated palette color (see `\downlink{``Color''}{ugGraphColorPage}` in Section 7.1.5\ignore{ugGraphColor} and `\downlink{``Palette''}{ugGraphColorPalettePage}` in Section 7.1.6\ignore{ugGraphColorPalette}).

\graphpaste{draw(sin(x),x=-\%pi..\%pi, curveColor == bright red())}
\epsffile[0 0 295 295]{../ps/2doptcvc.ps}

Option `\tt pointColor` sets the color of the graph points to the indicated palette color.
(see \link{``Color''}{ugGraphColorPage} in Section 7.1.5\ignore{ugGraphColor} and \link{``Palette''}{ugGraphColorPalettePage} in Section 7.1.6\ignore{ugGraphColorPalette}).

\begin{example}
\graphpaste{draw(sin(x),x=-\pi..\pi, pointColor == pastel yellow())}
\end{example}

\begin{example}
\epsffile[0 0 295 295]{../ps/2doptptc.ps}
\end{example}

Option \tti{unit} sets the intervals at which the axis units are plotted according to the indicated steps \axiom{x} interval, \axiom{y} interval.

\begin{example}
\graphpaste{draw(curve(9*sin(3*t/4),8*sin(t)), 
t = -4*\pi..4*\pi, unit == [2.0,1.0])}
\end{example}

\begin{example}
\epsffile[0 0 295 295]{../ps/2doptut.ps}
\end{example}

Option \tti{range} sets the range of variables in a graph to be within the ranges for solving plane algebraic curve plots.

\begin{example}
\graphpaste{draw(y**2 + y - (x**3 - x) = 0, x, y, 
range == [-2..2,-2..1], unit==[1.0,1.0])}
\end{example}

\begin{example}
\epsffile[0 0 295 295]{../ps/2doptrga.ps}
\end{example}

A second example of a solution plot.

\begin{example}
\graphpaste{draw(x**2 + y**2 = 1, x, y, 
range == [-3/2..3/2,-3/2..3/2], unit==[0.5,0.5])}
\end{example}

\begin{example}
\epsffile[0 0 295 295]{../ps/2doptrgb.ps}
\end{example}

Option \tti{coordinates} indicates the coordinate system in which the graph is plotted. 
The default is to use the Cartesian coordinate system. 
For more details, see \link{``Coordinate System Transformations''}{ugGraphCoordPage} in
Section 7.2.7\ignore{ugGraphCoord} \texttt{.}{or \axiomType{CoordinateSystems}.}

\graphpaste{draw(curve(sin(5*t),t),t=0..2*\%pi, coordinates == polar)}

\hline
Color

— ug07.ht —
The domain \texttt{Color} provides operations for manipulating colors in \texttt{twodim} graphs. Colors are objects of \texttt{Color}. Each color has a \texttt{hue} and a \texttt{weight}. Hues are represented by integers that range from \texttt{1} to the \texttt{numberOfHues()}\{Color\}, normally \texttt{27}. Weights are floats and have the value \texttt{1.0} by default.

\begin{itemize}
\item \texttt{color}\funArgs{integer} creates a color of hue \texttt{integer} and weight \texttt{1.0}.
\item \texttt{hue}\funArgs{color} returns the hue of \texttt{color} as an integer.
\item \texttt{red}, \texttt{blue}, \texttt{green}, and \texttt{yellow} create colors of that hue with weight \texttt{1.0}.
\item \texttt{color} \texttt{1} + \texttt{color} \texttt{2} returns the color that results from additively combining the indicated \texttt{color} \texttt{1} and \texttt{color} \texttt{2}. Color addition is not commutative: changing the order of the arguments produces different results.
\item \texttt{integer} \texttt{* color} changes the weight of \texttt{color} by \texttt{integer} without affecting its hue.
\end{itemize}

These functions can be used to change the point and curve colors for \texttt{twodim} and \texttt{threedim} graphs. Use the \texttt{pointColor} option for points.

\begin{itemize}
\item \texttt{pointColor \texttt{color}}
\end{itemize}

\begin{verbatim}

**Palette**

---

```plaintext
\begin{page}{ugGraphColorPalettePage}{7.1.6. Palette}
\beginscroll
```
Domain \texttt{Palette} is the domain of shades of colors: \texttt{dark}, \texttt{dim}, \texttt{bright}, \texttt{pastel}, and \texttt{light},
designated by the integers \texttt{1} through \texttt{5}, respectively.

Colors are normally ‘bright.’

To change the shade of a color, apply the name of a shade to it.

The expression \texttt{shade(color)} returns the value of a shade of \texttt{color}.

The expression \texttt{hue(color)} returns its hue.

Palettes can be used in specifying colors in \texttt{twodim{}} graphs.

The expression \texttt{shade(red())} returns the value of a shade of \texttt{red}.

Once you have created a viewport, move your mouse to the viewport and click with your left mouse button to display a control-panel. The panel is displayed on the side of the viewport closest to where you clicked. Each of the buttons which toggle on and off show the current state of the graph.

\subsubsection{Transformations}

Object transformations are executed from the control-panel by mouse-activated potentiometer windows. 

\item [Scale:] To scale a graph, click on a mouse button within the \{\bf Scale\} window in the upper left corner of the control-panel. The axes along which the scaling is to occur are indicated by setting the toggles above the arrow. With \{\tt X On\} and \{\tt Y On\} appearing, both axes are selected and scaling is uniform. If either is not selected, for example, if \{\tt X Off\} appears, scaling is non-uniform.

\item [Translate:] To translate a graph, click the mouse in the \{\bf Translate\} window in the direction you wish the graph to move. This window is located in the upper right corner of the control-panel.
Along the top of the \bf{Translate} window are two buttons for selecting the direction of translation. Translation along both coordinate axes results when \tt{X On} and \tt{Y On} appear or along one axis when one is on, for example, \tt{X On} and \tt{Y Off} appear.

\subsubsection{Messages}

The window directly below the transformation potentiometer windows is used to display system messages relating to the viewport and the control-panel. The following format is displayed:

\centerline{\[scaleX, scaleY\] \axiom{>} graph\axiom{<} [translateX, translateY] \newline}

The two values to the left show the scale factor along the \tt{X} and \tt{Y} coordinate axes. The two values to the right show the distance of translation from the center in the \tt{X} and \tt{Y} directions. The number in the center shows which graph in the viewport this data pertains to. When multiple graphs exist in the same viewport, the graph must be selected (see ‘‘Multiple Graphs,’’ below) in order for its transformation data to be shown, otherwise the number is 1.

\subsubsection{Multiple Graphs}

The \bf{Graphs} window contains buttons that allow the placement of \twodim{} graphs into one of nine available slots in any other \twodim{} viewport. In the center of the window are numeral buttons from one to nine that show whether a graph is displayed in the viewport. Below each number button is a button showing whether a graph that is present is selected for application of some transformation. When the caret symbol is displayed, then the graph in that slot will be manipulated. Initially, the graph for which the viewport is created occupies the first slot, is displayed, and is selected.

\item[Clear:] The \bf{Clear} button deselects every viewport graph slot. A graph slot is reselected by selecting the button below its number.

\item[Query:] The \bf{Query} button is used to display the scale and translate data for the indicated graph. When this button is selected the message ‘‘Click on the graph to query’’ appears. Select a slot number button from the \bf{Graphs} window. The scaling factor and
The translation offset of the graph are then displayed in the message window.

\item[Pick:] The \{bf Pick\} button is used to select a graph to be placed or dropped into the indicated viewport. When this button is selected, the message \``Click on the graph to pick\'\' appears. Click on the slot with the graph number of the desired graph. The graph information is held waiting for you to execute a \{bf Drop\} in some other graph.

\item[Drop:] Once a graph has been picked up using the \{bf Pick\} button, the \{bf Drop\} button places it into a new viewport slot. The message \``Click on the graph to drop\'\' appears in the message window when the \{bf Drop\} button is selected. By selecting one of the slot number buttons in the \{bf Graphs\} window, the graph currently being held is dropped into this slot and displayed.

Operations for Two-Dimensional Graphics

— ug07.ht —

\begin{page}{ugGraphTwoDopsPage}
{7.1.8. Operations for Two-Dimensional Graphics}
\beginscroll

Here is a summary of useful Axiom operations for \twodim{} graphics. Each operation name is followed by a list of arguments. Each argument is written as a variable informally named according to the type of the argument (for example, {\it integer}). If appropriate, a default value for an argument is given in parentheses immediately following the name.

\%\texht{\bgroup\hbadness = 10001\sloppy}{% \item[axiomFun{adaptive}]\funArgs{\optArg{boolean\argDef{true}}} sets or indicates whether graphs are plotted according to the adaptive refinement algorithm.

\item[axiomFun{axesColorDefault}]\funArgs{\optArg{color\argDef{dark blue()}}} sets or indicates the default color of the axes in a \twodim{} graph viewport.

\item[axiomFun{clipPointsDefault}]\funArgs{\optArg{boolean\argDef{false}}} sets or indicates whether point clipping is to be applied as the default for graph plots.

\item[axiomFun{drawToScale}]\funArgs{\optArg{boolean\argDef{false}}} sets or
indicates whether the plot of a graph is ‘to scale’ or uses the entire viewport space as the default.

\item \texttt{\texttt{lineColorDefault}} \funArgs{\optArg{color\argDef{pastel yellow()}}} sets or indicates the default color of the lines or curves in a \texttt{\texttt{twodim()}} graph viewport.

\item \texttt{\texttt{maxPoints}} \funArgs{\optArg{integer\argDef{500}}}
sets or indicates the default maximum number of possible points to be used when constructing a \texttt{\texttt{twodim()}} graph.

\item \texttt{\texttt{minPoints}} \funArgs{\optArg{integer\argDef{21}}}
sets or indicates the default minimum number of possible points to be used when constructing a \texttt{\texttt{twodim()}} graph.

\item \texttt{\texttt{pointColorDefault}} \funArgs{\optArg{color\argDef{bright red()}}} sets or indicates the default color of the points in a \texttt{\texttt{twodim()}} graph viewport.

\item \texttt{\texttt{pointSizeDefault}} \funArgs{\optArg{integer\argDef{5}}}
sets or indicates the default size of the dot used to plot points in a \texttt{\texttt{twodim()}} graph.

\item \texttt{\texttt{screenResolution}} \funArgs{\optArg{integer\argDef{600}}}
sets or indicates the default screen resolution constant used in setting the computation limit of adaptively generated curve plots.

\item \texttt{\texttt{unitsColorDefault}} \funArgs{\optArg{color\argDef{dim green()}}} sets or indicates the default color of the unit labels in a \texttt{\texttt{twodim()}} graph viewport.

\item \texttt{\texttt{viewDefaults}} \funArgs{}
resets the default settings for the following attributes: point color, line color, axes color, units color, point size, viewport upper left-hand corner position, and the viewport size.

\item \texttt{\texttt{viewPosDefault}} \funArgs{\optArg{list\argDef{\[100,100\]}}}
sets or indicates the default position of the upper left-hand corner of a \texttt{\texttt{twodim()}} viewport, relative to the display root window. The upper left-hand corner of the display is considered to be at the (0, 0) position.

\item \texttt{\texttt{viewSizeDefault}} \funArgs{\optArg{list\argDef{\[200,200\]}}}
sets or indicates the default size in which two dimensional viewport windows are shown. It is defined by a width and then a height.

\item \texttt{\texttt{viewWriteAvailable}} \funArgs{\optArg{list\argDef{\[" pixmap", "bitmap", "postscript", "image"\]}}}
indicates the possible file types
that can be created with the \axiomFunFrom{write}{TwoDimensionalViewport} function.

\item\[\axiomFun{viewWriteDefault}\]\funArgs{\optArg{\list\argDef{[]}}} sets or indicates the default types of files, in addition to the \bf{data} file, that are created when a \axiomFun{write} function is executed on a viewport.

\item\[\axiomFun{units}\]\funArgs{viewport, integer\argDef{1}, string\argDef{"off"}} turns the units on or off for the graph with index \it{integer}.

\item\[\axiomFun{axes}\]\funArgs{viewport, integer\argDef{1}, string\argDef{"on"}} turns the axes on or off for the graph with index \it{integer}.

\item\[\axiomFun{close}\]\funArgs{viewport} closes \it{viewport}.

\item\[\axiomFun{connect}\]\funArgs{viewport, integer\argDef{1}, string\argDef{"on"}} declares whether lines connecting the points are displayed or not.

\item\[\axiomFun{controlPanel}\]\funArgs{viewport, string\argDef{"off"}} declares whether the \twodim{} control-panel is automatically displayed or not.

\item\[\axiomFun{graphs}\]\funArgs{viewport} returns a list describing the state of each graph. If the graph state is not being used this is shown by \tt{"undefined"}, otherwise a description of the graph's contents is shown.

\item\[\axiomFun{graphStates}\]\funArgs{viewport} displays a list of all the graph states available for \it{viewport}, giving the values for every property.

\item\[\axiomFun{key}\]\funArgs{viewport} returns the process ID number for \it{viewport}.

\item\[\axiomFun{move}\]\funArgs{viewport, \subscriptText{integer}{x}(viewPosDefault), \subscriptText{integer}{y}(viewPosDefault)} moves \it{viewport} on the screen so that the
upper left-hand corner of \{\text{viewport}\} is at the position \{(x,y)\}.
%
\item \textbf{options}\{\text{viewport}\} 
returns a list of all the \texttt{DrawOption}s used by \{\text{viewport}\}.
%
\item \textbf{points}\{\text{viewport}, \text{integer}\argDef{1}, \text{string}\argDef{"on"}\}
specifies whether the graph points for graph \{\text{integer}\} are to be displayed or not.
%
\item \textbf{region}\{\text{viewport}, \text{integer}\argDef{1}, \text{string}\argDef{"off"}\}
declares whether graph \{\text{integer}\} is or is not to be displayed with a bounding rectangle.
%
\item \textbf{reset}\{\text{viewport}\} 
resets all the properties of \{\text{viewport}\}.
%
\item \textbf{resize}\{\text{viewport}, \text{integer}\argDef{\text{width}}, \text{integer}\argDef{\text{height}}\}
resizes \{\text{viewport}\} with a new \{\text{width}\} and \{\text{height}\}.
%
\item \textbf{scale}\{\text{viewport}, \text{integer}\argDef{n}, \text{float}\argDef{x}, \text{float}\argDef{y}\}
scales values for the \{\text{x}\} and \{\text{y}\} coordinates of graph \{\text{n}\}.
%
\item \textbf{show}\{\text{viewport}, \text{integer}\argDef{n}, \text{string}\argDef{"on"}\}
indicates if graph \{\text{n}\} is shown or not.
%
\item \textbf{title}\{\text{viewport}, \text{string}\argDef{"Axiom 2D"}\}
designates the title for \{\text{viewport}\}.
%
\item \textbf{translate}\{\text{viewport}, \text{integer}\argDef{n}, \text{float}\argDef{x}, \text{float}\argDef{y}\}
causes graph \{\text{n}\} to be moved \{\text{x}\} and \{\text{y}\} units in the respective directions.
%
\item \textbf{write}\{\text{viewport}, \text{string}\argDef{directory}, \text{optArg}\{\text{strings}\}\}
if no third argument is given, writes the \{\text{bf data}\} file onto the directory
with extension \{\textbf{data}\}.

The third argument can be a single string
or a list of strings with some or
all the entries \{\texttt{" pixmap"}, \texttt{" bitmap"},
\texttt{" postscript"}, and
\texttt{" image"}\}.

Addendum: Building Two-Dimensional Graphs

---

\begin{page}{ugGraphTwoDbuildPage}
{7.1.9. Addendum: Building Two-Dimensional Graphs}
\beginscroll

In this section we demonstrate how to create \twodim{} graphs from
lists of points and give an example showing how to read the lists
of points from a file.

\subsubsection{Creating a Two-Dimensional Viewport from a List of Points}

Axiom creates lists of points in a \twodim{} viewport by utilizing the
\axiomType{GraphImage} and \axiomType{TwoDimensionalViewport} domains.
In this example, the \axiomFunFrom{makeGraphImage}{GraphImage} function takes a list of lists of points parameter, a list of colors
for each point in the graph, a list of colors for each line in the
graph, and a list of sizes for each point in the graph.

\xtc{
The following expressions create a list of lists of points which will
be read by Axiom and made into a \twodim{} viewport.
}
\spadpaste{p1 := point [1,1]\$(Point DFLOAT) \bound{p1}}

\xtc{
}
\spadpaste{p2 := point [0,1]\$(Point DFLOAT) \bound{p2}}
\}
\[\text{Finally, here is the list.}\]

\[
\text{llp := \{p1, p2, p3, p4, p5, p6, p7, p8, p9, p10, p11, p12\}}\]

\[
\text{Now we set the point sizes for all components of the graph.}\]
Here are the colors for the points.

Here are the colors for the lines.

Now the \axiomType{GraphImage} is created according to the component specifications indicated above.
The \axiomFun{makeViewport2D}{TwoDimensionalViewport} function now creates a \axiomType{TwoDimensionalViewport} for this graph according to the list of options specified within the brackets.

\begin{axiom}
\graph{makeViewport2D(g,[title("Lines")])\$VIEW2D \free{g}}
\end{axiom}

\%See Figure #.#.

This example demonstrates the use of the \axiomType{GraphImage} functions \axiomFun{component}{GraphImage} and \axiomFun{appendPoint}{GraphImage} in adding points to an empty \axiomType{GraphImage}.

\begin{axiom}
\spad{)clear all \bound{clearAll}}
\end{axiom}

\begin{axiom}
\spad{g := graphImage()\$GRIMAGE \bound{Sg}\free{clearAll}}
\end{axiom}

\begin{axiom}
\spad{p1 := point [0,0]\$(Point DFLOAT) \bound{Sp1}}
\end{axiom}

\begin{axiom}
\spad{p2 := point [.25,.25]\$(Point DFLOAT) \bound{Sp2}}
\end{axiom}

\begin{axiom}
\spad{p3 := point [.5,.5]\$(Point DFLOAT) \bound{Sp3}}
\end{axiom}

\begin{axiom}
\spad{p4 := point [.75,.75]\$(Point DFLOAT) \bound{Sp4}}
\end{axiom}

\begin{axiom}
\spad{p5 := point [1,1]\$(Point DFLOAT) \bound{Sp5}}
\end{axiom}

\begin{axiom}
\spad{component(g,p1)\$GRIMAGE\free{Sg Sp1}\bound{gp1}}
\end{axiom}

\begin{axiom}
\spad{component(g,p2)\$GRIMAGE\free{Sg Sp2}\bound{gp2}}
\end{axiom}
Here is the graph.

\begin{verbatim}
\texttt{g1 := makeGraphImage(g)}
\end{verbatim}

A list of points can also be made into a \axiomType{GraphImage} by using the operation \axiomFun{coerce}{GraphImage}. It is equivalent to adding each point to \axiom{g2} using \axiomFun{component}{GraphImage}.

\begin{verbatim}
\texttt{g2 := coerce([[p1],[p2],[p3],[p4],[p5]])}
\end{verbatim}

Now, create an empty \axiomType{TwoDimensionalViewport}.

\begin{verbatim}
\texttt{v := viewport2D()}
\end{verbatim}

Place the graph into the viewport.

\begin{verbatim}
\texttt{putGraph(v,g2,1)}
\end{verbatim}
Take a look.

\begin{verbatim}
0.0 0.0 1.0 1.0 2.0 4.0
3.0 9.0 4.0 16.0 5.0 25.0
\end{verbatim}

Important

\begin{verbatim}
1. drawPoints(lp:List Point DoubleFloat):VIEW2D ==}
2. g := graphImage()$GRIMAGE
3. for p in lp repeat
4. component(g, p, pointColorDefault(), lineColorDefault(), pointSizeDefault())$GRIMAGE

Addendum: Appending a Graph to a Viewport Window Containing a Graph

--- ug07.ht ---

This section demonstrates how to append a \twodim{} graph to a viewport already containing other graphs. The default \axiomFun{draw} command places a graph into the first \axiomType{GraphImage} slot position of the \axiomType{TwoDimensionalViewport}.

\xtc{
This graph is in the first slot in its viewport.
}
\spadpaste{v1 := draw(sin(x),x=0..2*\%pi) \bound{v1}}
\xtc{So is this graph.}
The operation \axiomFunFrom{getGraph}{TwoDimensionalViewport} retrieves the \axiomType{GraphImage} \axiom{g1} from the first slot position in the viewport \axiom{v1}.

\axiom{g1 := getGraph(v1,1)}

Now \axiomFunFrom{putGraph}{TwoDimensionalViewport} places \axiom{g1} into the the second slot position of \axiom{v2}.

\axiom{putGraph(v2,g1,2)}

Display the new \axiomType{TwoDimensionalViewport} containing both graphs.

\axiom{makeViewport2D(v2)}

%See Figure #.#.

The Axiom \three{} graphics package provides the ability to
generate surfaces defined by a function of two real variables
\item generate space curves and tubes defined by parametric equations
\item generate surfaces defined by parametric equations

These graphs can be modified by using various options, such as calculating points in the spherical coordinate system or changing the polygon grid size of a surface.
Plotting Three-Dimensional Functions of Two Variables

The simplest \three{} graph is that of a surface defined by a function of two variables, \axiom{z = f(x,y)}. 
The general format for drawing a surface defined by a formula $f(x,y)$ of two variables $x$ and $y$ is:

\begin{verbatim}
\tt draw(f(x,y), x = a..b, y = c..d, \{it options\})
\end{verbatim}

where \tt{a..b} and \tt{c..d} define the range of \tt{x} and \tt{y}, and where \{it options\} prescribes zero or more options as described in \downlink{"Three-Dimensional Options"}{ugGraphThreeDOptionsPage} in Section 7.2.4\ignore{ugGraphThreeDOptions}. An example of an option is \tt{title = "Title of Graph".}

An alternative format involving a function \tt{f} is also available.

\begin{verbatim}
\tt draw(f(-\pi..\pi,-\pi..\pi))
\end{verbatim}

The simplest way to plot a function of two variables is to use a formula. With formulas you always precede the range specifications with the variable name and an \spad{=} sign.

\begin{verbatim}
\graphpaste{draw(cos(x*y),x=-3..3,y=-3..3)}
\end{verbatim}

If you intend to use a function more than once, or it is long and complex, then first give its definition to Axiom.

\begin{verbatim}
\spad{f(x,y) == sin(x)*cos(y)}
\end{verbatim}

To draw the function, just give its name and drop the variables from the range specifications.

\begin{verbatim}
\graphpaste{draw(f,-\pi..\pi,-\pi..\pi)}
\end{verbatim}
