Fuel Economy Numbers for Electric Vehicles

Energy efficiency of electric vehicles is generally expressed as Watt-hours per mile (Wh/mi). miles per gallon of gasoline equivalent (mpgge)

**Battery-to-wheel Fuel Economy:** Converting Wh/mi energy use into the equivalent battery-to-wheel fuel economy, expressed in mpgge, depends on only the energy density of gasoline:

\[
\text{mpgge}_{\text{battery-to-wheel}} = \frac{1}{[\text{Wh/mi}]} \times U_{\text{gasoline}}
\]

where, the energy density of gasoline by volume, \(U_{\text{gasoline}}\), is 115,000 Btu/gal or 33,705 Wh/gal[DOE 2000]. EPA sticker fuel economy labels are based on only this battery-to-wheel mpgge value, adjusted down to account for differences between real-world vehicle use and dynamometer testing.

**Full Cycle Fuel Economy:** The “full cycle” fuel economy equivalent value for an electric vehicle must include the efficiencies for electricity generation and transmission:

\[
\text{mpgge}_{\text{fuel-to-wheel}} = \frac{1}{[\text{Wh/mi}]} \times U_{\text{gasoline}} \times e_{\text{electricity}}
\]

where \(e_{\text{electricity}}\) is a lumped efficiency value of 0.303 that includes both average electricity generation efficiency (32.8%) and average transmission efficiency (92.4%). In the case of on-board charging (such as in a series hybrid), \(e_{\text{electricity}}\) should reflect the efficiency of the on-board fuel converter only.

Likewise, the full cycle fuel economy of a conventional vehicle can be expressed as:

\[
\text{mpgge}_{\text{fuel-to-wheel}} = \text{mpgge}_{\text{tank-to-wheel}} \times e_{\text{gasoline}}
\]

where, \(e_{\text{gasoline}}\) is a lumped efficiency value of 0.830 that includes both refining and distribution efficiencies.

**CAFE Fuel Economy:** When counting electric vehicles toward an automaker’s Corporate Average Fuel Economy (CAFE) value, the value used to measure compliance with fuel economy standards, the full cycle fuel economy value is further adjusted. The electric vehicle’s full cycle mpgge value is normalized by the well-to-tank efficiency for gasoline, \(e_{\text{gasoline}}\), and then further adjusted by a fuel-efficiency incentive factor of 6.667:

\[
\text{mpgge}_{\text{CAFE}} = \frac{1}{[\text{Wh/mi}]} \times U_{\text{gasoline}} \times \left( \frac{e_{\text{electricity}}}{e_{\text{gasoline}}} \right) \times 6.667
\]
**MIT Porsche 914 BEV:** The MIT Electric Vehicle Team (EVT) has converted a Porsche 914 into a battery electric vehicle (BEV) that uses roughly 185 Wh/mi (model results) over the EPA combined (city and highway) drive cycle. Consequently, the Porsche 914 BEV has a battery-to-wheel gasoline equivalent fuel economy of:

\[
\frac{1}{185 \cdot \text{Wh/mi}} \times \frac{33,705 \cdot \text{Wh}}{\text{gallon}_{\text{gasoline}}} = 182 \cdot \text{mpgge}
\]  

(5)

The full cycle fuel economy value of the Porsche 914 BEV is:

\[
\frac{1}{185 \cdot \text{Wh/mi}} \times \frac{33,705 \cdot \text{Wh}}{\text{gallon}_{\text{gasoline}}} \times 0.303 = 67 \cdot \text{mpgge}
\]  

(6)

Finally, were EVT to go into business producing automobiles, the Porsche 914 BEV would have a CAFE credit value of:

\[
\frac{1}{185 \cdot \text{Wh/mi}} \times \frac{33,705 \cdot \text{Wh}}{\text{gallon}_{\text{gasoline}}} \times \left( \frac{0.303}{0.830} \right) \times 6.667 = 444 \cdot \text{mpgge}
\]  

(7)

Table 1 below lists the equivalent fuel economy values for a range of electric vehicles, including the MIT vehicle, for comparison.
