Abstract

We introduce two new formulations for probabilistic constraints based on extended disjunctive formulations. Their strength results from considering multiple rows of the probabilistic constraints together. The properties of the first can be used to construct hierarchies of relaxations for probabilistic constraints, while the second provides computational advantages over other formulations.

Keywords: Mixed Integer Linear Programming, Formulations, Probabilistic Constraints, Chance Constraints

1. Introduction

We consider Mixed Integer Linear Programming (MILP) formulations of joint probabilistic or chance constraints for finitely distributed random variables. For arbitrary distributions such constraints have been extensively studied and have many applications (see for example [18, 22] and the references within). The discrete distribution case has been studied in [3, 7, 11, 13, 15, 21] and used in applications in [3, 4, 12, 16, 20]. Finite distributions also appear naturally in Sample Average Approximations (SAA) of general probabilistic constraints [14].

We concentrate on the probabilistically constrained set \( Q := \{ x \in \mathbb{R}^d : \mathbb{P}(x \geq \xi) \geq 1 - \delta \} \) where \( \delta \in (0,1) \) and \( \xi \) is a \( d \)-dimensional random vector with finite support \( \{ \xi^1, \ldots, \xi^S \} \subset \mathbb{R}_+^d \) and with \( \mathbb{P}(\xi = \xi^s) = 1/S \) for each \( s \in \{1, \ldots, S\} \). A standard MILP formulation for \( Q \) was introduced in [19] and is given by

\[
\begin{align*}
\sum_{s=1}^S z_s & \leq k, \quad (1a) \\
z_s & \in \{0,1\} \quad \forall s \in \{1, \ldots, S\} \quad (1b) \\
x \geq (1-z_s)\xi^s & \quad \forall s \in \{1, \ldots, S\} \quad (1c)
\end{align*}
\]

where \( k := \lfloor S \rfloor \). This formulation uses binary variables \( z \in \{0,1\}^S \) such that \( z_s = 1 \) if \( x \not\geq \xi^s \) and restricts the number of violated \( x \geq \xi^s \) inequalities through the cardinality constraint (1a). The Linear Programming (LP) relaxation of formulation (1) can be very weak, so valid inequalities for it have been developed in [11, 15]. In addition, a strengthened version of (1) was introduced in [15]. Because of the use of big-M type constraints based on lower bounds on \( \xi \), strengthened versions of (1) as Big-M and Strong Big-M formulations respectively.

Alternative MILP formulations for \( Q \) can be constructed using standard disjunctive programming arguments. Unfortunately, the sizes of the resulting formulations are exponential in \( S \) for fixed \( \delta \). Although this size can be significantly reduced by using so-called \( (1-\delta) \)-efficient points [3, 7, 18, 21], the resulting sizes usually remain exponential (e.g. see section 5.3 of [24] for an example in which the reduced formulation size is exponential in \( d \)). Hence, it is not practical to use these disjunctive formulations directly and they are mostly used as a base for specialized algorithms [3, 6, 7, 8] or to construct valid inequalities [19, 21, 23].

Our main contribution is to introduce two new MILP formulations for \( Q \). The first formulation can be used to construct a hierarchy of relaxations for \( Q \) and the second one provides a computational advantage over other formulations. In addition, both formulations can consider more than one row of (1c) at a time. To the best of our knowledge, no other existing formulation can do this without assuming a special structure for \( \{\xi^1, \ldots, \xi^S\} \).

The rest of this paper is organized as follows. In Section 2 we introduce the new formulations and their theoretical properties and in Section 3 we present results of computational experiments that illustrate the strength and effectiveness of existing and new formulations.

2. New Formulations

Our new formulations rely on the following disjunctive characterization of the feasible region of (1) when considering only a subset \( D \) of the rows of (1c).

For \( D \subset \{1, \ldots, d\} \) let \( x_D = (x_i)_{i \in D}, \xi_D = (\xi^s_i)_{i \in D} \) and define \( Q^D := \{(x,z) \in \mathbb{R}^D \times \{0,1\}^S : \sum_{s=1}^S z_s \leq k, x_D \geq (1-z_s)\xi_D^s \quad \forall s \in \{1, \ldots, S\}\} \). Additionally for \( D \subset \{1, \ldots, d\} \) and \( g \in \mathbb{R}^D \) let \( v_D(g) = \{ s \in \{1, \ldots, S\} : g \not\geq \xi_D^s \} \) be the set of scenarios for which \( g \) violates \( c \). Define \( Q^D_{g} := \{(x,z) \in \mathbb{R}^D \times \{0,1\}^S : x_D \geq g, \quad z_s = 1 \quad \forall s \in v_D(g), \quad \sum_{s \notin v_D(g)} z_s \leq (k - |v_D(g)|)\} \). We then have the following two lemmas whose proofs are straightforward.

**Proposition 1.** Let \( D \subset 2^{\{1, \ldots, d\}} \) be such that \( \bigcup_{D \in D} D = \{1, \ldots, d\} \), then \((x,z)\) satisfies (1) if and only if \((x_D,z) \in Q^D\) for all \( D \in D \).
Proposition 2. Let $G_D := \left\{ g \in \prod_{j \in D} \left( \xi_j \right)_{s=1}^S : |v_D(g)| \leq k \right\}$ where $\prod$ denotes the cartesian product. Then $Q^D = \bigcup_{g \in G_D} Q^D_g$.

Using these two propositions we can use standard MILP formulations for disjunctive constraints to obtain reformulations of (1). However, before we give them, we refine the characterization of $Q^D$ in Proposition 2 by reducing the number of points in $G_D$ as follows.

Proposition 3. Let $\tilde{G}_D := \bigcup_{l=0}^k \left\{ g \in \prod_{j \in D} (\xi_j^l)_{s=1}^S : |v_D(g)| \leq l \text{ and } |v_D(g - q)| > l \ \forall q \in \mathbb{R}^D_+ \setminus \{0\} \right\}$ then $Q^D = \bigcup_{g \in \tilde{G}_D} Q^D_g$. (2)

Proof. For the first inclusion let $(x^0, z^0) \in Q^D$ and for each $j \in D$ let $s_j := \arg \max_{s=1}^S \{ \xi_j^s : x_j^0 \geq \xi_j^s \}$. Let $g \in \mathbb{R}^D$ be such that $g_j := \xi_j^{s_j}$ for each $j$. Then $g \in \tilde{G}_D$ and $(x^0, z^0) \in Q^D_g$. The reverse inclusion is direct.

When $D$ is a singleton $G_D = \tilde{G}_D$, but when $|D| > 1 \tilde{G}_D$ can be significantly smaller that $G_D$. However, $\tilde{G}_D$ is usually a strict superset of the $(1 - \delta)$-efficient points associated with $Q^D$. These facts are illustrated in the following example.

Example 1. Let $d = 2$, $S = 4$, $\xi^1 = (0, 20)$, $\xi^2 = (10, 10)$, $\xi^3 = (20, 0)$, $\xi^4 = (30, 30)$ and $k = 2$. For this data the projection onto the $x$ space of (1) is given by the shaded region in Figure 1. This depicts the choice of $D = \{1, 2\}$ for which $\xi^i = \xi^i_{[1,2]}$ for $i \in \{1, \ldots, 4\}$. The figure also shows the projections onto the $x_1$ and $x_2$ variables which corresponds to the choices of $D = \{1\}$ and $D = \{2\}$ respectively. In these two last cases we can see that $G_D = \tilde{G}_D$ (points surrounded by triangles for $D = \{1\}$ and by squares for $D = \{2\}$). For instance, for $D = \{2\}$ we have that $|v_{[2]}(\xi^2_{[2]})| = 2$ and $|v_{[2]}(\xi^2_{[2]} + \lambda w)| \geq 3 \lambda$ for any $\lambda > 0$. In contrast, for $D = \{1, 2\}$ we have $\tilde{G}_D = \{(10, 20), (20, 10), (20, 20), (30, 30)\}$ (points surrounded by circles) while $G_D = \{(10, 20), (20, 10), (20, 20), (30, 30), (10, 30), (20, 30), (30, 20)\}$ (points surrounded by circles and diamonds). In particular, $(20, 20)$ is in $\tilde{G}_D$ because $|v_{[1,2]}((20, 20))| = 1$ and $|v_{[1,2]}((20, 20) - q)| \geq 2 \text{ for any } q \in \mathbb{R}^2_+$ (such as for $q = -u$ and $q = -v$), while $(30, 10)$ is not in $\tilde{G}_D$ because $|v_{[1,2]}((30, 10))| = 2$, but $|v_{[1,2]}((30, 10) + \lambda h)| = 2 \text{ for any sufficiently small } \lambda > 0$. Finally, note that $G_D$ strictly contains the set of $(1 - \delta)$-efficient points which is given by $\{(10, 20), (20, 10), (20, 20)\}$ (points surrounded by hexagons).

Using Propositions 1 and 3 we can construct the following two families of formulations for $Q$. 
Proposition 4. Let $\mathcal{D} \subset 2^{\{1,\ldots,d\}}$ be such that $\bigcup_{D \in \mathcal{D}} D = \{1, \ldots, d\}$. Then

$$x_j \geq \sum_{g \in \tilde{G}_D} y_g^D g_j \quad \forall j \in D, \; D \in \mathcal{D}$$  

$$\sum_{g \in \tilde{G}_D} y_g^D = 1 \quad \forall D \in \mathcal{D}$$  

$$y_g^D \in \{0, 1\} \quad \forall g \in \tilde{G}_D, \; D \in \mathcal{D}$$  

$$0 \leq z_{s,g}^D \leq y_g^D \quad \forall g \in \tilde{G}_D, \; s \in \{1, \ldots, S\}, \; D \in \mathcal{D}$$  

$$\sum_{s \in v_D(g)} z_{s,g}^D \leq y_g^D(k - |v_D(g)|) \quad \forall g \in \tilde{G}_D, \; D \in \mathcal{D}$$  

$$z_s = \sum_{g \in \tilde{G}_D} z_{s,g}^D \quad \forall s \in \{1, \ldots, S\}, \; D \in \mathcal{D}$$  

$$z_s \in \{0, 1\} \quad \forall s \in \{1, \ldots, S\}$$

is a valid formulation of $Q$. A smaller valid formulation is given by

$$x_j \geq \sum_{g \in \tilde{G}_D} y_g^D g_j \quad \forall j \in D, \; D \in \mathcal{D}$$  

$$\sum_{g \in \tilde{G}_D} y_g^D = 1 \quad \forall D \in \mathcal{D}$$  

$$y_g^D \in \{0, 1\} \quad \forall g \in \tilde{G}_D, \; D \in \mathcal{D}$$  

$$\sum_{s=1}^{S} z_s \leq k$$  

$$z_s \in \{0, 1\} \quad \forall s \in \{1, \ldots, S\}$$  

$$z_s \geq \sum_{g:s \in v_D(g)} y_g^D \quad \forall s \in \{1, \ldots, S\}, \; D \in \mathcal{D}.$$
Proof. For $D = \{ D \}$ we have that (3) with (3a) replaced by
\[
x_j^{D,g} \geq y_g y_j, \quad x_j = \sum_{g \in G_D} x_j^{D,g} \quad \forall g \in G_D, j \in D, D \in D
\] is the standard MILP formulation of disjunctive characterization (2) (e.g. Corollary 2.1.2 of [2]). Then, for $D = \{ D \}$, we have that (3) is a valid formulation for $Q^D$ as it is obtained from the standard disjunctive formulation by eliminating variables $x_j^{D,g}$ in a way that naturally preserves formulation validity (e.g. [1, 5, 10]). The result then follows from Proposition 1.

Formulation (4) is valid for $Q$ because it is obtained by similarly eliminating variables $z_s^{D,g}$ and $x_j^{D,g}$ from the standard disjunctive formulation of (2) when using the equivalent definition of $Q^D$ given by $Q^D := \{(x, z) \in \mathbb{R}^D \times \{0, 1\}^S : x_D \geq g, \quad z_s = 1 \quad \forall s \in v_D(g), \quad \sum_{s=1}^S z_s \leq k \}$.

The following two examples illustrate both formulations.

Example 2. For the data in Example 1 with $D = \{ D \} = \{1, 2\}$ formulation (3) is
\[
10y_{10}^D + 20y_{20}^D + 20y_{30}^D \leq x_1, \quad 20y_{10}^D + 10y_{20}^D + 20y_{30}^D \leq x_2
\]
\[
y_{10}^D + y_{20}^D + y_{30}^D = 1, \quad y_{20}^D \in \{0, 1\} \quad \forall g \in \{(10, 20), (20, 10), (20, 20), (30, 30)\}
\]
\[
0 \leq z_s^{D,g} \leq y_g
\]
\[
z_3^{D,10}, z_4^{D,10} \geq y_{10}^D, \quad z_2^{D,10}, z_3^{D,10} \geq y_{20}^D
\]
\[
z_1^{D,20} + z_2^{D,20} + z_3^{D,20} \leq 0, \quad z_2^{D,30}, z_3^{D,30} \leq z_s^{D,30}
\]
\[
z_2^{D,30}, z_3^{D,30} = z_s, \quad z_s \in \{0, 1\} \quad \forall s \in \{1, \ldots, 4\}
\]
and formulation (4) is
\[
10y_{10}^D + 20y_{20}^D + 20y_{30}^D \leq x_1, \quad 20y_{10}^D + 10y_{20}^D + 20y_{30}^D \leq x_2
\]
\[
y_{10}^D + y_{20}^D + y_{30}^D = 1, \quad y_{20}^D \in \{0, 1\} \quad \forall g \in \{(10, 20), (20, 10), (20, 20), (30, 30)\}
\]
\[
\sum_{s=1}^4 z_s \leq 2, \quad z_s \in \{0, 1\}, \quad \forall s \in \{1, \ldots, 4\}, \quad z_4 \geq y_{10}^D + y_{20}^D + y_{30}^D, \quad z_1 \geq y_{20}^D, \quad z_3 \geq y_{10}^D.
\]

Example 3. For the data in Example 1 with $D = \{1, 2\}$ formulation (3) is
\[
10y_{10}^j + 20y_{20}^j + 30y_{30}^j \leq x_j, \quad \forall j \in \{1, 2\}
\]
\[
y_{10}^j + y_{20}^j + y_{30}^j = 1, \quad y_{20}^j \in \{0, 1\} \quad \forall g \in \{10, 20, 30\}, j \in \{1, 2\}
\]
\[
0 \leq z_s^{j,g} \leq y_g^j
\]
\[
z_3^{1,10} \geq y_{10}^j, \quad z_4^{1,10} \geq y_{10}^j, \quad z_4^{1,20} \geq y_{20}^j
\]
\[
z_2^{1,10} + z_3^{1,10} \leq 0, \quad z_2^{1,20} + z_3^{1,20} \leq 0
\]
\[
z_4^{1,30} = z_s, \quad z_s \in \{0, 1\} \quad \forall s \in \{1, \ldots, 4\}, j \in \{1, 2\},
\]
and formulation (4) is
\[
10y_{10}^j + 20y_{20}^j + 30y_{30}^j \leq x_j, \quad \forall j \in \{1, 2\}
\]
\[
y_{10}^j + y_{20}^j + y_{30}^j = 1, \quad y_{20}^j \in \{0, 1\} \quad \forall g \in \{10, 20, 30\}, j \in \{1, 2\}
\]
\[
\sum_{s=1}^4 z_s \leq 2, \quad z_s \in \{0, 1\} \quad \forall s \in \{1, \ldots, 4\}, \quad z_3 \geq y_{10}^j, \quad z_4 \geq y_{10}^j + y_{20}^j, \quad z_1 \geq y_{10}^j, \quad z_4 \geq y_{10}^j + y_{20}^j.
\]
As shown in Examples 2 and 3, different choices of \( \mathcal{D} \) yield different formulations. For instance, if we take \( \mathcal{D} = \{ D_i \}_{i=1}^d \) for \( D_i = \{ i \} \) formulation (3) is equal to a known formulation that was first introduced in [11] and which can also be obtained by combining Corollary 1 of [15] and Proposition 1 of [17]. Because it is based on sets \( Q^D \) that only consider one row of \( (1c) \) at a time we refer to this formulation as the 1-row Extended Disjunctive Formulation and denote it by \( \text{Ext-1-row}. \) Similarly, if \( x^1 \geq x^2 \geq \ldots \geq x^S \) and \( \mathcal{D} = \{ D \} \) for \( D = \{ 1, \ldots, d \} \) then (3) reduces to the formulation in Theorem 9 of [11]. To the best of our knowledge these are the only two special cases of formulations (3) and (4) that have previously appeared in the literature. In particular, (4) with \( \mathcal{D} = \{ D_i \}_{i=1}^d \) for \( D_i = \{ i \} \) is a new formulation which we denote by \( \text{Proj-1-row} \) as it is obtained from \( \text{Ext-1-row} \) by a variable elimination procedure that is akin to projection. Similarly, for even \( d \), we denote formulations (3) and (4) with \( \mathcal{D} = \{ D_i \}_{i=1}^{d/2} \) for \( D_i = \{ 2l-1, 2l \} \) as \( \text{Ext-2-row} \) and \( \text{Proj-2-row} \) respectively. These two formulations are also new to this paper. In fact, to the best of our knowledge these are the only two special cases of formulations (3) and (4) that have previously appeared in the literature. In particular, (4) with \( \mathcal{D} \) as in Theorem 9 of [11] we get \( \tilde{\mathcal{D}} = k + 1 \) or for very small values of \( \max_{D \in \mathcal{D}} |D| \). Even in those cases, the formulations can be tractable only in a theoretical sense. For instance, \( \text{Ext-1-row} \) is theoretically compact in the sense that it has a polynomial number of variables and constraints: \( S + d(2 + k + S + kS) \) variables besides \( x \) and \( d/2(6 + 4S + k(3 + k + 2S)) \) constraints excluding variable bounds. However, as noted in [11], it is still too large to be of direct practical use. Fortunately, \( \text{Proj-1-row} \) has a much smaller size: \( S + (k + 1)d \) variables besides \( x \) and \( (k + 2)d + 1 \) constraints. As we will see in Section 3, this smaller size allows \( \text{Proj-1-row} \) to be of direct computational use.

2.1. Formulation Strength

The variable eliminations used to construct (3) and (4) clearly preserve formulation validity, but do not always preserve formulation strength [1, 5, 10]. However, strength preservation is shown to hold for \( \text{Ext-1-row} \) in [11]. A direct extension of the proof in [11] shows that this holds for all versions of (3).

**Proposition 5.** The projection of the LP relaxation of (3) onto the \((x, z)\) variables is equal to \( \bigcap_{D \in \mathcal{D}} \text{conv}(Q^D) \).

**Proof.** It suffices to show the result for \( \mathcal{D} = \{ D \} \), that is to show that (3) for a single \( D \) is equal to \( \text{conv}(Q^D) \). In this case we have that (3) with (3a) replaced by (5) is the standard disjunctive formulation of \( \bigcup_{g \in \tilde{G}_D} Q^D_g \) and hence its LP relaxation is equal to \( \text{conv} \left( \bigcup_{g \in \tilde{G}_D} Q^D_g \right) \) (e.g. Corollary 2.1.2 of [2]). Because the extreme points of the LP relaxation of \( Q^D_g \) have integer \( z \) variables we additionally have that the projection onto the \((x, z)\) variables of the LP relaxation of this disjunctive formulation is also equal to \( \text{conv}(Q^D) \). The result then follows by noting that any solution to the LP relaxation of (3) can be easily extended to a solution to the standard disjunctive formulation (e.g. pick \( g^0 \in \tilde{G}_D \), let \( x^0_j = g^0 y^0_j \) for all \( j \in D \), \( g \in \tilde{G}_D \setminus \{ g^0 \} \) and \( x^0_j = g^0 y^0_j + x_j - \sum_{g \in \tilde{G}_D} y^0_g j \).

As a direct corollary we obtain the following hierarchies of relaxations of \( \text{conv}(Q) \).

**Corollary 6.** Let \( \{ D_p \}_{p=1}^P \) be a family of partitions of \( \{ 1, \ldots, d \} \) such that \( D_1 = \{ D_j \}_{j=1}^d \) for \( D_j = \{ j \} \), \( D_p = \{ D \} \) for \( D = \{ 1, \ldots, d \} \) and \( D_p \) is a refinement of \( D_{p+1} \) (That is \( D_p \) is obtained from \( D_{p+1} \) by partitioning some of its elements). For each \( p \in \{ 1, \ldots, P \} \) let \( H^p \) be the projection onto the \((x, z)\) variables of the LP relaxation of formulation (3) for \( \mathcal{D} = D_p \). Then \( H^p = \bigcap_{D \in D_p} \text{conv}(Q^D) \) and hence \( H^1 \supset H^2 \supset \ldots \supset H^P = \text{conv}(Q) \).

In general, the strength of the LP relaxation of (3) will be equivalent to \( \text{conv}(Q) \) only when \( \mathcal{D}_P = \{ D \} \) for \( D = \{ 1, \ldots, d \} \). However, in Section 3.2 we will see that even Ext-2-row and Ext-1-row can be very strong formulations. Furthermore, Theorem 8 of [11] shows that Ext-1-row is always at least as strong as
Strong Big-M and, although the LP relaxation of Ext-1-row can yield bounds arbitrarily close to the ones provided by Strong Big-M (see Section 5.4.1 of [24]), it is usually a significantly stronger formulation (see Section 5.4.2 and 5.5 of [24]).

With regards to formulation (4) we have that the additional variable eliminations necessary to construct it do result in a loss of strength. However, in Section 3.2 we will see that the loss of strength can be quite small. Furthermore, we have that the strength of Proj-1-row is equivalent to that of another known strong formulation for \( Q \). This formulation was introduced in [15] and is given by

\[
\sum_{s=1}^{S} z_s \leq k \tag{6a}
\]

\[
z_s \in \{0, 1\} \quad \forall s \in \{1, \ldots, k\} \tag{6b}
\]

\[
x_j \geq \xi_{[j]}^{[1]} + \sum_{s=1}^{k} (\xi_{[j]}^{[s+1]} - \xi_{[j]}^{[s]}) w_s^j \quad \forall j \in \{1, \ldots, d\} \tag{6c}
\]

\[
w_s^j \geq w_{s+1}^j \quad \forall s \in \{1, \ldots, k-1\}, j \in \{1, \ldots, d\} \tag{6d}
\]

\[
z_{[j]}^{[s]} \geq w_s^j \quad \forall s \in \{1, \ldots, k\}, j \in \{1, \ldots, d\} \tag{6e}
\]

\[
w_s^j \in \{0, 1\} \quad \forall s \in \{1, \ldots, k\}, j \in \{1, \ldots, d\} \tag{6f}
\]

where \([\cdot]_j : \{1, \ldots, S\} \rightarrow \{1, \ldots, S'\}\) is the one to one function such that \(\xi_{[j]}^{[1]} \geq \xi_{[j]}^{[2]} \geq \ldots \geq \xi_{[j]}^{[S']}\). Because constraint (6c) forces \(x_j \geq \xi_{[j]}\) in an incremental fashion we refer to this formulation as the Incremental Model and denote it by Inc. Besides \(x\) this formulation has \(S + kd\) variables that are all binary and \(2kd + 1\) constraints excluding variable bounds.

**Proposition 7.** The projection onto the \((x, z)\) variables of the LP relaxations of Proj-1-row and Inc are identical.

**Proof.** For any \((x, z, w)\) feasible to the LP relaxation of Inc we have that \((x, z, y)\) is a solution to the LP relaxations of Proj-1-row for \(y_{i,s} = w_{s-1}^j - w_s^j\) for \(s \in \{2, \ldots, k+1\}\) and \(y_{i,1} = 1 - \sum_{t=2}^{k+1} y_{i,t}\). Conversely, for any \((x, z, y)\) feasible to the LP relaxation of Proj-1-row we have that \((x, z, w)\) is a solution to the LP relaxations of Inc for \(w_s^j = \sum_{t=s+1}^{k+1} y_{j,t}\).

### 3. Computational Results

In this section we present some computational results illustrating properties of the two new formulations introduced in the previous section. For this we use the probabilistically constrained fixed charge transportation problem given by

\[
\min \sum_{i=1}^{n} \sum_{j=1}^{d} (c_{i,j}w_{i,j} + f_{i,j}y_{i,j}) \tag{7a}
\]

s.t.

\[
\sum_{j=1}^{d} w_{i,j} \leq b_i \quad \forall i \in \{1, \ldots, n\} \tag{7b}
\]

\[
\sum_{i=1}^{n} w_{i,j} = x_j \quad \forall j \in \{1, \ldots, d\} \tag{7c}
\]

\[
0 \leq w_{i,j} \leq b_i y_{i,j} \quad \forall i \in \{1, \ldots, n\}, j \in \{1, \ldots, d\} \tag{7d}
\]

\[
y_{i,j} \in \{0, 1\} \quad \forall i \in \{1, \ldots, n\}, j \in \{1, \ldots, d\} \tag{7e}
\]

\[
P(x \geq \xi) \geq 1 - \delta \tag{7f}
\]
where \( \xi \) is a \( d \)-dimensional random vector of uncertain demands with finite support on \( \{\xi^1, \ldots, \xi^S\} \subset \mathbb{R}^d \) and with \( P(\xi = \xi^s) = 1/S \) for each \( s \in \{1, \ldots, S\} \). We use instances with \( n = 40 \) supply nodes, \( d = 10 \) demand nodes and varying number of samples of the uncertain demands \( S \). Each instance is generated as follows. \( c_{i,j} \)'s are independently chosen from the uniform distribution on \([1, 100]\) and \( \xi^s \)'s are independently chosen from the uniform distribution on \([1, 50]\). To generate \( b \) we first independently chose \( d_i \) from the uniform distribution on \([1, 100]\) and then rescale it so the problem is feasible for each \( \xi^s \). Finally, \( f_{i,j} \)'s are all identical to 0 or 100 depending on the type of instance. All models are generated using IBM ILOG Concert Technology and solved with IBM CPLEX v12 \([9]\) on an 2.93GHz Xeon workstation. Our aim is to compare the models out of the box without the need to add specialized cutting planes to CPLEX. Because of this we are only able to test small and medium sized instances. Larger instances require the use of specialized techniques such as the ones introduced in \([11, 13, 15]\).

3.1. Solve Times

We begin by comparing the solve times for the MILP problems obtained when using different formulations of (7f). In preliminary tests we discovered that the only formulations that could solve instances of non-trivial sizes were Inc and Proj-1-row. These formulations have similar sizes and Proposition 7 shows they have the same strength. In this section we illustrate how both formulations can provide a computational advantage under different circumstances.

In our first experiment we consider a transportation problem without fixed charges (i.e. \( f_{i,j} = 0 \) for all \( i, j \)). We can then remove the \( y \) variables and the only binary variables of the resulting MILP are the ones used to formulate (7f). We choose \( \delta \in \{0.10, 0.20\} \) and \( S \in \{2000, 3000\} \). Table 1(a) shows statistics for the solve times over ten instances for each choice of \( \delta \) and \( S \). Solve times include the time required to generate the formulations. In our second experiment we consider a transportation problem with fixed charges, so that we have a MILP problem even with a deterministic version of (7f). These problems are much harder so we now choose \( S \in \{200, 300\} \). Table 1(b) shows statistics for the solve times over ten instances for each choice of \( \delta \) and \( S \).

(b) Transportation Problems with Fixed Charges

We see that for the problems without fixed charges Inc provides a substantial advantage over Proj-1-row, while the reverse is true, although to a lesser extent, for problems with fixed charges. Tables 2 and 3 show some solve statistics that shed some light on this behavior.

For example, we observe that Proj-1-row’s fewer rows seems to allow CPLEX’s preprocessing and cuts to close more GAP at the root node for this formulation than for Inc. However, Inc’s smaller number of non-zero coefficients seems to make the LP solve times smaller. We also observe that Inc seems to need fewer branch-and-bound nodes to solve the problem. This could be due to branching being more efficient for this model, which is a common property of incremental type formulations (see \([25]\)). The relative effectiveness of

the formulations will then depend on which of these advantages is stronger for a particular class of problems. For instance, it is possible that for the problems with fixed charges the efficient branching of Inc is diminished by the existence of additional binary variables, which results in Proj-1-row having a better performance.

3.2. LP GAPs for Transportation Problems

Our final experiment compares the LP GAPs for the different formulations calculated as $100 \times \frac{z_{IP} - z_{LP}}{z_{IP}}$ where $z_{IP}$ is the optimal value of (7) and $z_{LP}$ is the optimal value of its LP relaxation. We compare formulations Ext-$k$-row and Proj-$k$-row for $k \in \{1, 2\}$ and include Strong Big-M as a reference. Because the larger formulations are very hard to solve we consider a transportation problem without fixed charges and choose $\delta \in \{0.10, 0.20\}$ and $S \in \{200, 300\}$. The sets $G_D$ for $|D| = 2$ were generated by enumeration, which can be done relatively fast by first sorting the components of $\{\xi_s\}_{s=1}^S$. Table 4 shows statistics for the GAPs over ten instances for each choice of $\delta$ and $S$.

\hline
\end{array}
$$

Table 4: LP GAPs for Transportation Problems without Fixed Charges [%]

As expected the $k$-row formulations are significantly better than the Strong Big-M formulation, the extended formulations are better than the corresponding projected formulations and the 2-row formulations are better than the corresponding 1-row formulations. However, we see that the loss in strength from the extended to the projected formulations is quite small and can be smaller than the gain in strength from 1-row formulations to 2-row formulations. In particular, this allows Proj-2-row to be stronger on average than Ext-1-row for $\delta = 0.20$.

4. Future Work

Proposition 1 does not require that the sets in $D$ be disjoint. Hence it is possible to strengthen the formulations by considering subsets of rows that have some overlap. For instance, we could consider $D = \{D_i\}_{i=1}^{d-1}$ for $D_i = \{l, l+1\}$ which would yield a strengthening of the 2-row formulations. Preliminary results in smaller problems showed that the strengthened formulations can indeed provide slightly better LP bounds,
but the increased size usually prevents them from performing better than the original 2-row formulations, which are already outperformed by the 1-row formulations. Still, careful selection of the overlaps (e.g. by considering correlations among the components of $\xi$) could provide a theoretical or computational advantage in some problems.
