FLASH-Based 8-Bit CMOS Microcontrollers

Devices included in this data sheet:
• PIC16F627
• PIC16F628
Referred to collectively as PIC16F62X.

High Performance RISC CPU:
• Only 35 instructions to learn
• All single-cycle instructions (200 ns), except for program branches which are two-cycle
• Operating speed:
  - DC - 20 MHz clock input
  - DC - 200 ns instruction cycle

Interrupt capability
16 special function hardware registers
8-level deep hardware stack
Direct, Indirect and Relative addressing modes

Peripheral Features:
• 15 I/O pins with individual direction control
• High current sink/source for direct LED drive
• Analog comparator module with:
  - Two analog comparators
  - Programmable on-chip voltage reference (VREF) module
  - Programmable input multiplexing from device inputs and internal voltage reference
  - Comparator outputs are externally accessible
• Timer0: 8-bit timer/counter with 8-bit programmable prescaler
• Timer1: 16-bit timer/counter with external crystal/clock capability
• Timer2: 8-bit timer/counter with 8-bit period register, prescaler and postscaler
• Capture, Compare, PWM (CCP) module
  - Capture is 16-bit, max. resolution is 12.5 ns
  - Compare is 16-bit, max. resolution is 200 ns
  - PWM max. resolution is 10-bit
• Universal Synchronous/Asynchronous Receiver/Transmitter USART/SCI
• 16 Bytes of common RAM

Special Microcontroller Features:
• Power-on Reset (POR)
• Power-up Timer (PWRT) and Oscillator Start-up Timer (OST)
• Brown-out Detect (BOD)
• Watchdog Timer (WDT) with its own on-chip RC oscillator for reliable operation
• Multiplexed MCLR-pin
• Programmable weak pull-ups on PORTB
• Programmable code protection
• Low voltage programming
• Power saving SLEEP mode
• Selectable oscillator options
  - FLASH configuration bits for oscillator options
  - ER (External Resistor) oscillator
    - Reduced part count
  - Dual speed INTRC
    - Lower current consumption
  - EC External Clock input
  - XT oscillator mode
  - HS oscillator mode
  - LP oscillator mode
• Serial in-circuit programming (via two pins)
• Four user programmable ID locations

CMOS Technology:
• Low-power, high-speed CMOS FLASH technology
• Fully static design
• Wide operating voltage range
  - PIC16F627 - 3.0V to 5.5V
  - PIC16F628 - 3.0V to 5.5V
  - PIC16LF627 - 2.0V to 5.5V
  - PIC16LF628 - 2.0V to 5.5V
• Commercial, industrial and extended temperature range
• Low power consumption
  - < 2.0 mA @ 5.0V, 4.0 MHz
  - 15 μA typical @ 3.0V, 32 kHz
  - < 1.0 μA typical standby current @ 3.0V

To Our Valued Customers

Most Current Data Sheet

To obtain the most up-to-date version of this data sheet, please register at our Worldwide Web site at:

http://www.microchip.com

You can determine the version of a data sheet by examining its literature number found on the bottom outside corner of any page.
The last character of the literature number is the version number. e.g., DS30000A is version A of document DS30000.

New Customer Notification System

Register on our web site (www.microchip.com/cn) to receive the most current information on our products.

Errata

An errata sheet may exist for current devices, describing minor operational differences (from the data sheet) and recommended
workarounds. As device/documentation issues become known to us, we will publish an errata sheet. The errata will specify the re vision
of silicon and revision of document to which it applies.

To determine if an errata sheet exists for a particular device, please check with one of the following:

• Microchip’s Worldwide Web site; http://www.microchip.com
• Your local Microchip sales office (see last page)
• The Microchip Corporate Literature Center; U.S. FAX: (602) 786-7277

When contacting a sales office or the literature center, please specify which device, revision of silicon and data sheet (include litera ture number) you are using.

Corrections to this Data Sheet

We constantly strive to improve the quality of all our products and documentation. We have spent a great deal of time to ensure that this document is correct. However, we realize that we may have missed a few things. If you find any information that is missing or appears in error, please:

• Fill out and mail in the reader response form in the back of this data sheet.
• E-mail us at webmaster@microchip.com.

We appreciate your assistance in making this a better document.
1.0 GENERAL DESCRIPTION

The PIC16F62X are 18-Pin FLASH-based members of the versatile PIC16CXX family of low-cost, high-performance, CMOS, fully-static, 8-bit microcontrollers.

All PICmicro® microcontrollers employ an advanced RISC architecture. The PIC16F62X have enhanced core features, eight-level deep stack, and multiple internal and external interrupt sources. The separate instruction and data buses of the Harvard architecture allow a 14-bit wide instruction word with the separate 8-bit wide data. The two-stage instruction pipeline allows all instructions to execute in a single-cycle, except for program branches (which require two cycles). A total of 35 instructions (reduced instruction set) are available. Additionally, a large register set gives some of the architectural innovations used to achieve a very high performance.

PIC16F62X microcontrollers typically achieve a 2:1 code compression and a 4:1 speed improvement over other 8-bit microcontrollers in their class.

PIC16F62X devices have special features to reduce external components, thus reducing system cost, enhancing system reliability and reducing power consumption. There are eight oscillator configurations, of which the single pin ER oscillator provides a low-cost solution. The LP oscillator minimizes power consumption, XT is a standard crystal, INTRC is a self-contained internal oscillator and the HS is for High Speed crystals. The SLEEP (power-down) mode offers power savings. The user can wake up the chip from SLEEP through several external and internal interrupts and reset.

A highly reliable Watchdog Timer with its own on-chip RC oscillator provides protection against software lock-up.

Table 1-1 shows the features of the PIC16F62X mid-range microcontroller families.

A simplified block diagram of the PIC16F62X is shown in Figure 3-1.

The PIC16F62X series fits in applications ranging from battery chargers to low-power remote sensors. The FLASH technology makes customization of application programs (detection levels, pulse generation, timers, etc.) extremely fast and convenient. The small footprint packages make this microcontroller series ideal for all applications with space limitations. Low-cost, low-power, high-performance, ease of use and I/O flexibility make the PIC16F62X very versatile.

1.1 Development Support

The PIC16F62X family is supported by a full-featured macro assembler, a software simulator, an in-circuit emulator, a low-cost development programmer and a full-featured programmer. A Third Party "C" compiler support tool is also available.

All PICmicro® Family devices have Power-on Reset, selectable Watchdog Timer, selectable code protect and high I/O current capability. All PIC16F62X Family devices use serial programming with clock pin RB6 and data pin RB7.
2.0 PIC16F62X DEVICE VARIETIES

A variety of frequency ranges and packaging options are available. Depending on application and production requirements the proper device option can be selected using the information in the PIC16F62X Product Identification System section at the end of this data sheet. When placing orders, please use this page of the data sheet to specify the correct part number.

2.1 Flash Devices

These devices are offered in the lower cost plastic package, even though the device can be erased and reprogrammed. This allows the same device to be used for prototype development and pilot programs as well as production.

A further advantage of the electrically-erasable Flash version is that it can be erased and reprogrammed in-circuit, or by device programmers, such as Microchip's PICSTART® Plus or PRO MATE® II programmers.

2.2 Quick-Turnaround-Production (QTP) Devices

Microchip offers a QTP Programming Service for factory production orders. This service is made available for users who chose not to program a medium to high quantity of units and whose code patterns have stabilized. The devices are standard FLASH devices but with all program locations and configuration options already programmed by the factory. Certain code and prototype verification procedures apply before production shipments are available. Please contact your Microchip Technology sales office for more details.

2.3 Serialized Quick-Turnaround-Production (SQTPSM) Devices

Microchip offers a unique programming service where a few user-defined locations in each device are programmed with different serial numbers. The serial numbers may be random, pseudo-random or sequential.

Serial programming allows each device to have a unique number which can serve as an entry-code, password or ID number.
3.0 ARCHITECTURAL OVERVIEW

The high performance of the PIC16F62X family can be attributed to a number of architectural features commonly found in RISC microprocessors. To begin with, the PIC16F62X uses a Harvard architecture, in which, program and data are accessed from separate memories using separate busses. This improves bandwidth over traditional von Neumann architecture where program and data are fetched from the same memory. Separating program and data memory further allows instructions to be sized differently than 8-bit wide data word. Instruction opcodes are 14-bits wide making it possible to have all single word instructions. A 14-bit wide program memory access bus fetches a 14-bit instruction in a single cycle. A two-stage pipeline overlaps fetch and execution of instructions. Consequently, all instructions (35) execute in a single-cycle (200 ns @ 20 MHz) except for program branches.

The PIC16F62X can directly or indirectly address its register files or data memory. All special function registers including the program counter are mapped in the data memory. The PIC16F62X have an orthogonal (symmetrical) instruction set that makes it possible to carry out any operation on any register using any addressing mode. This symmetrical nature and lack of ‘special optimal situations’ make programming with the PIC16F62X simple yet efficient. In addition, the learning curve is reduced significantly.

The PIC16F62X devices contain an 8-bit ALU and working register. The ALU is a general purpose arithmetic unit. It performs arithmetic and Boolean functions between data in the working register and any register file.

The ALU is 8-bit wide and capable of addition, subtraction, shift and logical operations. Unless otherwise mentioned, arithmetic operations are two’s complement in nature. In two-operand instructions, typically one operand is the working register (W register). The other operand is a file register or an immediate constant. In single operand instructions, the operand is either the W register or a file register.

The W register is an 8-bit working register used for ALU operations. It is not an addressable register.

Depending on the instruction executed, the ALU may affect the values of the Carry (C), Digit Carry (DC), and Zero (Z) bits in the STATUS register. The C and DC bits operate as a Borrow and Digit Borrow out bit, respectively, bit in subtraction. See the SUBLW and SUBWF instructions for examples.

A simplified block diagram is shown in Figure 3-1, with a description of the device pins in Table 3-1.

Two types of data memory are provided on the PIC16F62X devices. Non-volatile EEPROM data memory is provided for long term storage of data such as calibration values, look up table data, and any other data which may require periodic updating in the field. This data is not lost when power is removed. The other data memory provided is regular RAM data memory. Regular RAM data memory is provided for temporary storage of data during normal operation. It is lost when power is removed.

**Legend:**
- O = output
- I/O = input/output
- P = power
- = Not used
- I = Input
- ST = Schmitt Trigger input
- TTL = TTL input
- I/OD = input/open drain output

**Note 1:** This buffer is a Schmitt Trigger input when configured as the external interrupt.

**Note 2:** This buffer is a Schmitt Trigger input when used in serial programming mode.

**Note 3:** This buffer is a Schmitt Trigger I/O when used in USART/Synchronous mode.

**Note 4:** This buffer is a Schmitt Trigger I/O when used in CCP mode.

**Note 5:** This buffer is a Schmitt Trigger input when used in low voltage program mode.
3.1 Clocking Scheme/Instruction Cycle

The clock input (OSC1/CLKIN/RA7 pin) is internally divided by four to generate four non-overlapping quadrature clocks namely Q1, Q2, Q3 and Q4. Internally, the program counter (PC) is incremented every Q1, the instruction is fetched from the program memory and latched into the instruction register in Q4. The instruction is decoded and executed during the following Q1 through Q4. The clocks and instruction execution flow is shown in Figure 3-2.

3.2 Instruction Flow/Pipelining

An “Instruction Cycle” consists of four Q cycles (Q1, Q2, Q3 and Q4). The instruction fetch and execute are pipelined such that fetch takes one instruction cycle while decode and execute takes another instruction cycle. However, due to the pipelining, each instruction effectively executes in one cycle. If an instruction causes the program counter to change (e.g., GOTO) then two cycles are required to complete the instruction (Example 3-1).

A fetch cycle begins with the program counter (PC) incrementing in Q1.

In the execution cycle, the fetched instruction is latched into the “Instruction Register (IR)” in cycle Q1. This instruction is then decoded and executed during the Q2, Q3, and Q4 cycles. Data memory is read during Q2 (operand read) and written during Q4 (destination write).

**EXAMPLE 3-1: INSTRUCTION PIPELINE FLOW**

1. MOVLW 55h
   - Fetch 1
   - Execute 1

2. MOVWF PORTB
   - Fetch 2
   - Execute 2

3. CALL SUB_1
   - Fetch 3
   - Execute 3

4. BSF PORTA, BIT3
   - Fetch 4
   - Flush
   - Fetch SUB_1
   - Execute SUB_1

All instructions are single cycle, except for any program branches. These take two cycles since the fetch instruction is “flushed” from the pipeline while the new instruction is being fetched and then executed.
4.0 MEMORY ORGANIZATION

4.1 Program Memory Organization

The PIC16F62X has a 13-bit program counter capable of addressing an 8K x 14 program memory space. Only the first 1K x 14 (0000h - 03FFh) for the PIC16F627 and 2K x 14 (0000h - 07FFh) for the PIC16F628 are physically implemented. Accessing a location above these boundaries will cause a wrap-around within the first 1K x 14 space (PIC16F627) or 2K x 14 space (PIC16F628). The reset vector is at 0000h and the interrupt vector is at 0004h (Figure 4-1 and Figure 4-2).

**FIGURE 4-1: PROGRAM MEMORY MAP AND STACK FOR THE PIC16F627**

![Program Memory Map and Stack for the PIC16F627](image)

**FIGURE 4-2: PROGRAM MEMORY MAP AND STACK FOR THE PIC16F628**

![Program Memory Map and Stack for the PIC16F628](image)

4.2 Data Memory Organization

The data memory (Figure 4-3) is partitioned into four Banks which contain the general purpose registers and the special function registers. The Special Function Registers are located in the first 32 locations of each Bank. Register locations 20h-7Fh, A0h-FFh, 120h-14Fh, 170h-17Fh and 1F0h-1FFh are general purpose registers implemented as static RAM.

The Table below lists how to access the four banks of registers:

<table>
<thead>
<tr>
<th>Bank</th>
<th>RP1</th>

<td>1</td>
</tr>
<tr>
<td>Bank2</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>Bank3</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

Addresses F0h-FFh, 170h-17Fh and 1F0h-1FFh are implemented as common RAM and mapped back to addresses 70h-7Fh.

4.2.1 GENERAL PURPOSE REGISTER FILE

The register file is organized as 224 x 8 in the PIC16F62X. Each is accessed either directly or indirectly through the File Select Register FSR (Section 4.4).

</table>

Unimplemented data memory locations, read as '0'.

* Not a physical register.
4.2.2 SPECIAL FUNCTION REGISTERS

The special function registers are registers used by the CPU and Peripheral functions for controlling the desired operation of the device (Table 4-1). These registers are static RAM.

The special registers can be classified into two sets (core and peripheral). The special function registers associated with the “core” functions are described in this section. Those related to the operation of the peripheral features are described in the section of that peripheral feature.

</table>

**Legend:** — = Unimplemented locations read as ‘0’, u = unchanged, x = unknown, q = value depends on condition, shaded = unimplemented

**Note 1:** Other (non power-up) resets include MCLR Reset, Brown-out Detect and Watchdog Timer Reset during normal operation.
### STATUS REGISTER

The STATUS register, shown in Register 4-1, contains the arithmetic status of the ALU, the RESET status and the bank select bits for data memory (SRAM).

The STATUS register can be the destination for any instruction, like any other register. If the STATUS register is the destination for an instruction that affects the Z, DC or C bits, then the write to these three bits is disabled. These bits are set or cleared according to the device logic. Furthermore, the TO and PD bits are not writable. Therefore, the result of an instruction with the STATUS register as destination may be different than intended.

For example, CLRF STATUS will clear the upper-three bits and set the Z bit. This leaves the status register as 000uuuu (where u = unchanged).

**REGISTER 4-1: STATUS REGISTER (ADDRESS 03H OR 83H)**

<table>
<thead>
<tr>
<th>Bit 7</th>
<th>Bit 6-5</th>
<th>Bit 4</th>
<th>Bit 3</th>
<th>Bit 2</th>
<th>Bit 1</th>
<th>Bit 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>IRP</td>
<td>RP1:RP0</td>
<td>TO</td>
<td>PD</td>
<td>Z</td>
<td>DC</td>
<td>C</td>
</tr>
</tbody>
</table>

**Legend:**

- R = Readable bit
- W = Writable bit
- U = Unimplemented bit, read as '0'
- -n = Value at POR reset
- -x = Unknown at POR reset

- IRP: Register Bank Select bit (used for indirect addressing)
  - 1 = Bank 2, 3 (100h - 1FFh)
  - 0 = Bank 0, 1 (00h - FFh)

- RP1:RP0: Register Bank Select bits (used for direct addressing)
  - 11 = Bank 3 (180h - 1FFh)
  - 10 = Bank 2 (100h - 17Fh)
  - 01 = Bank 1 (80h - FFh)
  - 00 = Bank 0 (00h - 7Fh)

- TO: Time-out bit
  - 1 = After power-up, CLRWD instruction, or SLEEP instruction
  - 0 = A WDT time-out occurred

- PD: Power-down bit
  - 1 = After power-up or by the CLRWD instruction
  - 0 = By execution of the SLEEP instruction

- Z: Zero bit
  - 1 = The result of an arithmetic or logic operation is zero
  - 0 = The result of an arithmetic or logic operation is not zero

- DC: Digit carry/borrow bit (ADDWF, ADDLW, SUBLW, SUBWF instructions) (for borrow the polarity is reversed)
  - 1 = A carry-out from the 4th low order bit of the result occurred
  - 0 = No carry-out from the 4th low order bit of the result

- C: Carry/borrow bit (ADDWF, ADDLW, SUBLW, SUBWF instructions)
  - 1 = A carry-out from the most significant bit of the result occurred
  - 0 = No carry-out from the most significant bit of the result occurred

**Note:** It is recommended, therefore, that only BCF, BSF, SWAPF and MOVWF instructions are used to alter the STATUS register because these instructions do not affect any status bit. For other instructions, not affecting any status bits, see the “Instruction Set Summary”.

**Note 1:** The C and DC bits operate as a Borrow and Digit Borrow out bit, respectively, in subtraction. See the SUBLW and SUBWF instructions for examples.
4.2.2.2 OPTION REGISTER

The OPTION register is a readable and writable register which contains various control bits to configure the TMR0/WDT prescaler, the external RB0/INT interrupt, TMR0, and the weak pull-ups on PORTB.

**Note:** To achieve a 1:1 prescaler assignment for TMR0, assign the prescaler to the WDT (PSA = 1). See Section 6.3.1

**REGISTER 4-2: OPTION REGISTER (ADDRESS 81H)**

### 4.2.2.3 INTCON REGISTER

The INTCON register is a readable and writable register which contains the various enable and flag bits for all interrupt sources except the comparator module. See Section 4.2.2.4 and Section 4.2.2.5 for a description of the comparator enable and flag bits.

**REGISTER 4-3: INTCON REGISTER (ADDRESS 0BH OR 8BH)**

<table>
<thead>
<tr>
<th>R/W-0</th>
<th>R/W-0</th>
<th>R/W-0</th>
<th>R/W-0</th>
<th>R/W-0</th>
<th>R/W-0</th>

<td>RBIE</td>
<td>T0IF</td>
<td>INTF</td>
</tr>
</tbody>
</table>

| bit 7: GIE: Global Interrupt Enable bit  
1 = Enables all un-masked interrupts  
0 = Disables all interrupts  

| bit 6: PEIE: Peripheral Interrupt Enable bit  
1 = Enables all un-masked peripheral interrupts  
0 = Disables all peripheral interrupts  

| bit 5: T0IE: TMR0 Overflow Interrupt Enable bit  
1 = Enables the TMR0 interrupt  
0 = Disables the TMR0 interrupt  

| bit 4: INTE: RB0/INT External Interrupt Enable bit  
1 = Enables the RB0/INT external interrupt  
0 = Disables the RB0/INT external interrupt  

| bit 3: RBIE: RB Port Change Interrupt Enable bit  
1 = Enables the RB port change interrupt  
0 = Disables the RB port change interrupt  

| bit 2: T0IF: TMR0 Overflow Interrupt Flag bit  
1 = TMR0 register has overflowed (must be cleared in software)  
0 = TMR0 register did not overflow  

| bit 1: INTF: RB0/INT External Interrupt Flag bit  
1 = The RB0/INT external interrupt occurred (must be cleared in software)  
0 = The RB0/INT external interrupt did not occur  

| bit 0: RBIF: RB Port Change Interrupt Flag bit  
1 = When at least one of the RB7:RB4 pins changed state (must be cleared in software)  
0 = None of the RB7:RB4 pins have changed state  

**Note:** Interrupt flag bits get set when an interrupt condition occurs regardless of the state of its corresponding enable bit or the global enable bit, GIE (INTCON<7>).

R = Readable bit  
W = Writable bit  
U = Unimplemented bit, read as '0'  
-n = Value at POR reset  
-x = Unknown at POR reset
4.2.2.4 PIE1 REGISTER

This register contains interrupt enable bits.

**REGISTER 4-4: PIE1 REGISTER (ADDRESS 8CH)**

### 4.2.2.5 PIR1 REGISTER

This register contains interrupt flag bits.

**Note:** Interrupt flag bits get set when an interrupt condition occurs regardless of the state of its corresponding enable bit or the global enable bit, GIE (INTCON<7>). User software should ensure the appropriate interrupt flag bits are clear prior to enabling an interrupt.

4.2.2.6 PCON REGISTER

The PCON register contains flag bits to differentiate between a Power-on Reset, an external MCLR reset, WDT reset or a Brown-out Detect.

**Note:** BOD is unknown on Power-on Reset. It must then be set by the user and checked on subsequent resets to see if BOD is cleared, indicating a brown-out has occurred. The BOD status bit is a “don’t care” and is not necessarily predictable if the brown-out circuit is disabled (by programming BOREN bit in the Configuration word).

bit 7-4.2: **Unimplemented:** Read as ‘0’

bit 3: **OSCF:** INTRC/ER oscillator speed

- 1 = 4 MHz typical (1)
- 0 = 37 KHz typical

bit 1: **POR:** Power-on Reset Status bit

- 1 = No Power-on Reset occurred
- 0 = A Power-on Reset occurred (must be set in software after a Power-on Reset occurs)

bit 0: **BOD:** Brown-out Detect Status bit

- 1 = No Brown-out Reset occurred
- 0 = A Brown-out Reset occurred (must be set in software after a Brown-out Reset occurs)

**Note 1:** When in ER oscillator mode, setting OSCF = 1 will cause the oscillator speed to change to the speed specified by the external resistor.
4.3 PCL and PCLATH

The program counter (PC) is 13-bits wide. The low byte comes from the PCL register, which is a readable and writable register. The high byte (PC<12:8>) is not directly readable or writable and comes from PCLATH. On any reset, the PC is cleared. Figure 4-7 shows the two situations for the loading of the PC. The upper example in the figure shows how the PC is loaded on a write to PCL (PCLATH<4:0> → PCH). The lower example in the figure shows how the PC is loaded during a CALL or GOTO instruction (PCLATH<4:3> → PCH).

**FIGURE 4-7: LOADING OF PC IN DIFFERENT SITUATIONS**

4.3.1 COMPUTED GOTO

A computed GOTO is accomplished by adding an offset to the program counter (ADDWF PCL). When doing a table read using a computed GOTO method, care should be exercised if the table location crosses a PCL memory boundary (each 256 byte block). Refer to the application note “Implementing a Table Read” (AN556).

4.3.2 STACK

The PIC16F62X family has an 8 level deep x 13-bit wide hardware stack (Figure 4-1 and Figure 4-2). The stack space is not part of either program or data space and the stack pointer is not readable or writable. The PC is PUSHed onto the stack when a CALL instruction is executed or an interrupt causes a branch. The stack is POPed in the event of a RETURN, RETLW or a RETFIE instruction execution. PCLATH is not affected by a PUSH or POP operation.

The stack operates as a circular buffer. This means that after the stack has been PUSHed eight times, the ninth push overwrites the value that was stored from the first push. The tenth push overwrites the second push (and so on).

**Note 1:** There are no STATUS bits to indicate stack overflow or stack underflow conditions.

**Note 2:** There are no instructions/mnemonics called PUSH or POP. These are actions that occur from the execution of the CALL, RETURN, RETLW and RETFIE instructions, or the vectoring to an interrupt address.
4.4 **Indirect Addressing, INDF and FSR Registers**

The INDF register is not a physical register. Addressing the INDF register will cause indirect addressing.

Indirect addressing is possible by using the INDF register. Any instruction using the INDF register actually accesses data pointed to by the file select register (FSR). Reading INDF itself indirectly will produce 00h. Writing to the INDF register indirectly results in a no-operation (although status bits may be affected). An effective 9-bit address is obtained by concatenating the 8-bit FSR register and the IRP bit (STATUS<7>), as shown in Figure 4-8.

A simple program to clear RAM location 20h-2Fh using indirect addressing is shown in Example 4-1.

### Example 4-1: INDIRECT ADDRESSING

```assembly
movlw 0x20 ;initialize pointer
movwf FSR ;to RAM
NEXT  clrf INDF ;clear INDF register
incf FSR ;inc pointer
btfss FSR,4 ;all done?
goto NEXT ;no clear next
CONTINUE:
```

### Figure 4-8: DIRECT/INDIRECT ADDRESSING PIC16F62X

![Diagram showing direct and indirect addressing](image)

For memory map detail see Figure 4-3.
5.0 I/O PORTS

The PIC16F62X have two ports, PORTA and PORTB. Some pins for these I/O ports are multiplexed with an alternate function for the peripheral features on the device. In general, when a peripheral is enabled, that pin may not be used as a general purpose I/O pin.

5.1 PORTA and TRISA Registers

PORTA is an 8-bit wide latch. RA4 is a Schmitt Trigger input and an open drain output. Port RA4 is multiplexed with the T0CKI clock input. RA5 is a Schmitt Trigger input only and has no output drivers. All other RA port pins have Schmitt Trigger input levels and full CMOS output drivers. All pins have data direction bits (TRIS registers) which can configure these pins as input or output.

A ‘1’ in the TRISA register puts the corresponding output driver in a hi-impedance mode. A ‘0’ in the TRISA register puts the contents of the output latch on the selected pin(s).

Reading the PORTA register reads the status of the pins whereas writing to it will write to the port latch. All write operations are read-modify-write operations. So a write to a port implies that the port pins are first read, then this value is modified and written to the port data latch.

The PORTA pins are multiplexed with comparator and voltage reference functions. The operation of these pins is selected by control bits in the CMCON (comparator control register) and the VRCON (voltage reference control register) register. When selected as a comparator input, these pins will read as '0's.

Note 1: On reset, the TRISA register is set to all inputs. The digital inputs are disabled and the comparator inputs are forced to ground to reduce excess current consumption.

Note 2: When RA6/OSC2/CLKOUT is configured as CLKOUT, the corresponding TRIS bit is overridden and the pin is configured as an output. The PORTA data bit reads 0, and the PORTA TRIS bit reads 0.

TRISA controls the direction of the RA pins, even when they are being used as comparator inputs. The user must make sure to keep the pins configured as inputs when using them as comparator inputs.

The RA2 pin will also function as the output for the voltage reference. When in this mode, the VREF pin is a very high impedance output. The user must configure TRISA<2> bit as an input and use high impedance loads.

In one of the comparator modes defined by the CMCON register, pins RA3 and RA4 become outputs of the comparators. The TRISA<4:3> bits must be cleared to enable outputs to use this function.

EXAMPLE 5-1: INITIALIZING PORTA

```asm
CLRF PORTA ;Initialize PORTA by setting output data latches
MOVLW 0X07 ;Turn comparators off and enable pins for I/O functions
BCF STATUS, RP1
BSF STATUS, RP0 ;Select Bank1
MOVLW 0xF ;Value used to initialize data direction
MOVF TRISA ;Set RA<4:0> as inputs
;TRISA<7:5> are always read as '0'.
```

5.2 PORTB and TRISB Registers

PORTB is an 8-bit wide bi-directional port. The corresponding data direction register is TRISB. A '1' in the TRISB register puts the corresponding output driver in a high impedance mode. A '0' in the TRISB register puts the contents of the output latch on the selected pin(s).

PORTB is multiplexed with the interrupt, USART, CCP module and the TMR1 clock input/output. The standard port functions and the alternate port functions are shown in Table 5-3.

Reading PORTB register reads the status of the pins, whereas writing to it will write to the port latch. All write operations are read-modify-write operations. So a write to a port implies that the port pins are first read, then this value is modified and written to the port data latch.

Each of the PORTB pins has a weak internal pull-up (≈200 µA typical). A single control bit can turn on all the pull-ups. This is done by clearing the RBPU (OPTION<7>) bit. The weak pull-up is automatically turned off when the port pin is configured as an output. The pull-ups are disabled on Power-on Reset.

Four of PORTB’s pins, RB7:RB4, have an interrupt on change feature. Only pins configured as inputs can cause this interrupt to occur (i.e., any RB7:RB4 pin configured as an output is excluded from the interrupt on change comparison). The input pins (of RB7:RB4) are compared with the old value latched on the last read of PORTB. The “mismatch” outputs of RB7:RB4 are OR’ed together to generate the RBIF interrupt (flag latched in INTCON<0>).

This interrupt can wake the device from SLEEP. The user, in the interrupt service routine, can clear the interrupt in the following manner:

a) Any read or write of PORTB. This will end the mismatch condition.

b) Clear flag bit RBIF.

A mismatch condition will continue to set flag bit RBIF. Reading PORTB will end the mismatch condition, and allow flag bit RBIF to be cleared.

This interrupt on mismatch feature, together with software configurable pull-ups on these four pins allow easy interface to a key pad and make it possible for wake-up on key-depression. (See AN552 in the Microchip Embedded Control Handbook.)

Note: If a change on the I/O pin should occur when the read operation is being executed (start of the Q2 cycle), then the RBIF interrupt flag may not get set.

The interrupt on change feature is recommended for wake-up on key depression operation and operations where PORTB is only used for the interrupt on change feature. Polling of PORTB is not recommended while using the interrupt on change feature.

5.3 I/O Programming Considerations

5.3.1 BI-DIRECTIONAL I/O PORTS

Any instruction which writes, operates internally as a read followed by a write operation. The BCF and BSF instructions, for example, read the register into the CPU, execute the bit operation and write the result back to the register. Caution must be used when these instructions are applied to a port with both inputs and outputs defined. For example, a BSF operation on bit5 of PORTB will cause all eight bits of PORTB to be read into the CPU. Then the BSF operation takes place on bit5 and PORTB is written to the output latches. If another bit of PORTB is used as a bidirectional I/O pin (e.g., bit0) and it is defined as an input at this time, the input signal present on the pin itself would be read into the CPU and re-written to the data latch of this particular pin, overwriting the previous content. As long as the pin stays in the input mode, no problem occurs. However, if bit0 is switched into output mode later on, the content of the data latch may now be unknown.

Reading a port register, reads the values of the port pins. Writing to the port register writes the value to the port latch. When using read-modify-write instructions (ex. BCF, BSF, etc.) on a port, the value of the port pins is read, the desired operation is done to this value, and this value is then written to the port latch.

Example 5-2 shows the effect of two sequential read-modify-write instructions (ex., BCF, BSF, etc.) on an I/O port.

A pin actively outputting a Low or High should not be driven from external devices at the same time in order to change the level on this pin (“wired-or”, “wired-and”). The resulting high output currents may damage the chip.

**EXAMPLE 5-2: READ-MODIFY-WRITE INSTRUCTIONS ON AN I/O PORT**

```
; Initial PORT settings: PORTB<7:4> Inputs
; PORTB<3:0> Outputs
; PORTB<7:6> have external pull-up and are not connected to other circuitry
; PORT latch PORT pins
; ------------------
; BDF STATUS,RPO
; BCF PORTB, 7 ; 01pp pppp 11pp pppp
; BCF PORTB, 6 ; 10pp pppp 11pp pppp
; BSF STATUS,RPO
; BCF TRISB, 7 ; 10pp pppp 11pp pppp
; BCF TRISB, 6 ; 10pp pppp 10pp pppp
;
; Note that the user may have expected the pin values to be 00pp pppp. The 2nd BCF caused RB7 to be latched as the pin value (High).
```

5.3.2 SUCCESSIVE OPERATIONS ON I/O PORTS

The actual write to an I/O port happens at the end of an instruction cycle, whereas for reading, the data must be valid at the beginning of the instruction cycle (Figure 5-16). Therefore, care must be exercised if a write followed by a read operation is carried out on the same I/O port. The sequence of instructions should be such to allow the pin voltage to stabilize (load dependent) before the next instruction which causes that file to be read into the CPU is executed. Otherwise, the previous state of that pin may be read into the CPU rather than the new state. When in doubt, it is better to separate these instructions with a NOP or another instruction not accessing this I/O port.

**FIGURE 5-16: SUCCESSIVE I/O OPERATION**

This example shows write to PORTB followed by a read from PORTB.

Note that:

- data setup time = \((0.25 \text{T}_{\text{CY}} - \text{TPD})\)
- where \(\text{T}_{\text{CY}}\) = instruction cycle and \(\text{TPD}\) = propagation delay of Q1 cycle to output valid.

Therefore, at higher clock frequencies, a write followed by a read may be problematic.
6.0  TIMER0 MODULE

The Timer0 module timer/counter has the following features:

- 8-bit timer/counter
- Readable and writable
- 8-bit software programmable prescaler
- Internal or external clock select
- Interrupt on overflow from FFh to 00h
- Edge select for external clock

Figure 6-1 is a simplified block diagram of the Timer0 module.

Timer mode is selected by clearing the T0CS bit (OPTION<5>). In timer mode, the TMR0 will increment every instruction cycle (without prescaler). If Timer0 is written, the increment is inhibited for the following two cycles (Figure 6-2 and Figure 6-3). The user can work around this by writing an adjusted value to TMR0.

Counter mode is selected by setting the T0CS bit. In this mode Timer0 will increment either on every rising or falling edge of pin RA4/T0CKI. The incrementing edge is determined by the source edge (T0SE) control bit (OPTION<4>). Clearing the T0SE bit selects the rising edge. Restrictions on the external clock input are discussed in detail in Section 6.2.

The prescaler is shared between the Timer0 module and the Watchdog Timer. The prescaler assignment is controlled in software by the control bit PSA (OPTION<3>). Clearing the PSA bit will assign the prescaler to Timer0. The prescaler is not readable or writable. When the prescaler is assigned to the Timer0 module, prescale value of 1:2, 1:4, ..., 1:256 are selectable. Section 6.3 details the operation of the prescaler.

6.1  TIMER0 Interrupt

Timer0 interrupt is generated when the TMR0 register timer/counter overflows from FFh to 00h. This overflow sets the T0IF bit. The interrupt can be masked by clearing the T0IE bit (INTCON<5>). The T0IF bit (INTCON<2>) must be cleared in software by the Timer0 module interrupt service routine before re-enabling this interrupt. The Timer0 interrupt cannot wake the processor from SLEEP since the timer is shut off during SLEEP. See Figure 6-4 for Timer0 interrupt timing.
FIGURE 6-3: TIMER0 TIMING: INTERNAL CLOCK/PRESCALE 1:2

FIGURE 6-4: TIMER0 INTERRUPT TIMING

Note 1: T0IF interrupt flag is sampled here (every Q1).
Note 2: Interrupt latency = 3T CY, where T CY = instruction cycle time.
Note 3: CLKOUT is available only in ER and INTRC (with clockout) oscillator modes.
6.2 Using Timer0 with External Clock

When an external clock input is used for Timer0, it must meet certain requirements. The external clock requirement is due to internal phase clock (Tosc) synchronization. Also, there is a delay in the actual incrementing of Timer0 after synchronization.

6.2.1 EXTERNAL CLOCK SYNCHRONIZATION

When no prescaler is used, the external clock input is the same as the prescaler output. The synchronization of T0CKI with the internal phase clocks is accomplished by sampling the prescaler output on the Q2 and Q4 cycles of the internal phase clocks (Figure 6-5). Therefore, it is necessary for T0CKI to be high for at least 2Tosc (and a small RC delay of 20 ns) and low for at least 2Tosc (and a small RC delay of 20 ns). Refer to the electrical specification of the desired device.

When a prescaler is used, the external clock input is divided by the asynchronous ripple-counter type prescaler so that the prescaler output is symmetrical. For the external clock to meet the sampling requirement, the ripple-counter must be taken into account. Therefore, it is necessary for T0CKI to have a period of at least 4Tosc (and a small RC delay of 40 ns) divided by the prescaler value. The only requirement on T0CKI high and low time is that they do not violate the minimum pulse width requirement of 10 ns. Refer to parameters 40, 41 and 42 in the electrical specification of the desired device.

6.2.2 TIMER0 INCREMENT DELAY

Since the prescaler output is synchronized with the internal clocks, there is a small delay from the time the external clock edge occurs to the time the TMR0 is actually incremented. Figure 6-5 shows the delay from the external clock edge to the timer incrementing.

FIGURE 6-5: TIMER0 TIMING WITH EXTERNAL CLOCK

Note 1: Delay from clock input change to Timer0 increment is 3Tosc to 7Tosc. (Duration of Q = Tosc). Therefore, the error in measuring the interval between two edges on Timer0 input = ±4Tosc max.

2: External clock if no prescaler selected, Prescaler output otherwise.

3: The arrows indicate the points in time where sampling occurs.
6.3 Prescaler

An 8-bit counter is available as a prescaler for the Timer0 module, or as a postscaler for the Watchdog Timer, respectively (Figure 6-6). For simplicity, this counter is being referred to as “prescaler” throughout this data sheet. Note that there is only one prescaler available which is mutually exclusive between the Timer0 module and the Watchdog Timer. Thus, a prescaler assignment for the Timer0 module means that there is no prescaler for the Watchdog Timer, and vice-versa.

The PSA and PS2:PS0 bits (OPTION<3:0>) determine the prescaler assignment and prescale ratio.

When assigned to the Timer0 module, all instructions writing to the TMR0 register (e.g., CLRF 1, MOVWF 1, BSF 1, x....etc.) will clear the prescaler. When assigned to WDT, a CLRWDT instruction will clear the prescaler along with the Watchdog Timer. The prescaler is not readable or writable.

FIGURE 6-6: BLOCK DIAGRAM OF THE TIMER0/WDT PRESCALER

Note: T0SE, T0CS, PSA, PS0-PS2 are bits in the OPTION register.
6.3.1 SWITCHING PRESCALER ASSIGNMENT

The prescaler assignment is fully under software control (i.e., it can be changed “on the fly” during program execution). To avoid an unintended device RESET, the following instruction sequence (Example 6-1) must be executed when changing the prescaler assignment from Timer0 to WDT.

EXAMPLE 6-1: CHANGING PRESCALER (TIMER0→WDT)

1. BCF STATUS, RP0 ;Skip if already in
   ; Bank 0
2. CLRWD ;Clear WDT
3. CLRF TMR0 ;Clear TMR0 & Prescaler
4. BSF STATUS, RP0 ;Bank 1
5. MOVW '00101111'b ;These 3 lines (5, 6, 7)
6. MOVWF OPTION ; are required only if
    ; desired PS<2:0> are
7. CLRWD ; 000 or 001
8. MOVW '00101xxx'b ;Set Postscaler to
9. MOVWF OPTION ; desired WDT rate
10. BCF STATUS, RP0 ;Return to Bank 0

To change prescaler from the WDT to the TMR0 module use the sequence shown in Example 6-2. This precaution must be taken even if the WDT is disabled.

EXAMPLE 6-2: CHANGING PRESCALER (WDT→TIMER0)

7.0 TIMER1 MODULE

The Timer1 module is a 16-bit timer/counter consisting of two 8-bit registers (TMR1H and TMR1L) which are readable and writable. The TMR1 Register pair (TMR1H:TMR1L) increments from 0000h to FFFFh and rolls over to 0000h. The TMR1 Interrupt, if enabled, is generated on overflow which is latched in interrupt flag bit TMR1IF (PIR1<0>). This interrupt can be enabled/disabled by setting/clearing TMR1 interrupt enable bit TMR1IE (PIE1<0>).

Timer1 can operate in one of two modes:
- As a timer
- As a counter

The operating mode is determined by the clock select bit, TMR1CS (T1CON<1>).

In timer mode, Timer1 increments every instruction cycle. In counter mode, it increments on every rising edge of the external clock input.

Timer1 can be enabled/disabled by setting/clearing control bit TMR1ON (T1CON<0>).

Timer1 also has an internal "reset input". This reset can be generated by the CCP module (Section 10.0). Register 7-1 shows the Timer1 control register.

For the PIC16F627 and PIC16F628, when the Timer1 oscillator is enabled (T1OSCEN is set), the RB7/T1OSI and RB6/T1OSO/T1CKI pins become inputs. That is, the TRISB<7:6> value is ignored.

- 11 = 1:8 Prescale value
- 10 = 1:4 Prescale value
- 01 = 1:2 Prescale value
- 00 = 1:1 Prescale value

bit 3: T1OSCEN: Timer1 Oscillator Enable Control bit
- 1 = Oscillator is enabled
- 0 = Oscillator is shut off

Note: The oscillator inverter and feedback resistor are turned off to eliminate power drain

bit 2: T1SYNC: Timer1 External Clock Input Synchronization Control bit

- TMR1CS = 1
  - 1 = Do not synchronize external clock input
  - 0 = Synchronize external clock input

- TMR1CS = 0
  This bit is ignored. Timer1 uses the internal clock when TMR1CS = 0.

bit 1: TMR1CS: Timer1 Clock Source Select bit
- 1 = External clock from pin RB6/T1OSO/T1CKI (on the rising edge)
- 0 = Internal clock (Fosc/4)

bit 0: TMR1ON: Timer1 On bit
- 1 = Enables Timer1
- 0 = Stops Timer1
7.1 Timer1 Operation in Timer Mode
Timer mode is selected by clearing the TMR1CS (T1CON<1>) bit. In this mode, the input clock to the timer is Fosc/4. The synchronize control bit T1SYNC (T1CON<2>) has no effect since the internal clock is always in sync.

7.2 Timer1 Operation in Synchronized Counter Mode
Counter mode is selected by setting bit TMR1CS. In this mode the timer increments on every rising edge of clock input on pin RB7/T1OSI when bit T1OSCEN is set or pin RB6/T1OSO/T1CKI when bit T1OSCEN is cleared.

If T1SYNC is cleared, then the external clock input is synchronized with internal phase clocks. The synchronization is done after the prescaler stage. The prescaler stage is an asynchronous ripple-counter.

In this configuration, during SLEEP mode, Timer1 will not increment even if the external clock is present, since the synchronization circuit is shut off. The prescaler however will continue to increment.

7.2.1 EXTERNAL CLOCK INPUT TIMING FOR SYNCHRONIZED COUNTER MODE
When an external clock input is used for Timer1 in synchronized counter mode, it must meet certain requirements. The external clock requirement is due to internal phase clock (Tosc) synchronization. Also, there is a delay in the actual incrementing of TMR1 after synchronization.

When the prescaler is 1:1, the external clock input is the same as the prescaler output. The synchronization of T1CKI with the internal phase clocks is accomplished by sampling the prescaler output on the Q2 and Q4 cycles of the internal phase clocks. Therefore, it is necessary for T1CKI to be high for at least 2Tosc (and a small RC delay of 20 ns) and low for at least 2Tosc (and a small RC delay of 20 ns). Refer to the appropriate electrical specifications, parameters 45, 46, and 47.

When a prescaler other than 1:1 is used, the external clock input is divided by the asynchronous ripple-counter type prescaler so that the prescaler output is symmetrical. In order for the external clock to meet the sampling requirement, the ripple-counter must be taken into account. Therefore, it is necessary for T1CKI to have a period of at least 4Tosc (and a small RC delay of 40 ns) divided by the prescaler value. The only requirement on T1CKI high and low time is that they do not violate the minimum pulse width requirements of 10 ns). Refer to the appropriate electrical specifications, parameters 40, 42, 45, 46, and 47.

Note 1: When the T1OSCEN bit is cleared, the inverter and feedback resistor are turned off. This eliminates power drain.
7.3 Timer1 Operation in Asynchronous Counter Mode

If control bit T1SYNC (T1CON<2>) is set, the external clock input is not synchronized. The timer continues to increment asynchronously to the internal phase clocks. The timer will continue to run during SLEEP and can generate an interrupt on overflow which will wake-up the processor. However, special precautions in software are needed to read/write the timer (Section 7.3.2).

In asynchronous counter mode, Timer1 can not be used as a time-base for capture or compare operations.

7.3.1 EXTERNAL CLOCK INPUT TIMING WITH UNSYNCHRONIZED CLOCK

If control bit T1SYNC is set, the timer will increment completely asynchronously. The input clock must meet certain minimum high time and low time requirements. Refer to the appropriate Electrical Specifications Section, timing parameters 45, 46, and 47.

7.3.2 READING AND WRITING TIMER1 IN ASYNCHRONOUS COUNTER MODE

Reading TMR1H or TMR1L while the timer is running, from an external asynchronous clock, will guarantee a valid read (taken care of in hardware). However, the user should keep in mind that reading the 16-bit timer in two 8-bit values itself poses certain problems since the timer may overflow between the reads.

For writes, it is recommended that the user simply stop the timer and write the desired values. A write contention may occur by writing to the timer registers while the register is incrementing. This may produce an unpredictable value in the timer register.

Reading the 16-bit value requires some care. Example 7-1 is an example routine to read the 16-bit timer value. This is useful if the timer cannot be stopped.

EXAMPLE 7-1: READING A 16-BIT FREE-RUNNING TIMER

; All interrupts are disabled
MOVF TMR1H, W ;Read high byte
MOVWF TMPH ;
MOVF TMR1L, W ;Read low byte

GOTO CONTINUE ;Good 16-bit read

; TMR1L may have rolled over between the read
; of the high and low bytes. Reading the high
; and low bytes now will read a good value.

MOVF TMR1H, W ;Read high byte
MOVWF TMPH ;
MOVF TMR1L, W ;Read low byte
MOVWF TMPL ;
; Re-enable the Interrupt (if required)
CONTINUE ;Continue with your code

7.4 Timer1 Oscillator

A crystal oscillator circuit is built in between pins T1OSI (input) and T1OSO (amplifier output). It is enabled by setting control bit T1OSCEN (T1CON<3>). The oscillator is a low power oscillator rated up to 200 kHz. It will continue to run during SLEEP. It is primarily intended for a 32 kHz crystal. Table 7-1 shows the capacitor selection for the Timer1 oscillator.

The Timer1 oscillator is identical to the LP oscillator. The user must provide a software time delay to ensure proper oscillator start-up.

7.5 Resetting Timer1 using a CCP Trigger Output

If the CCP1 module is configured in compare mode to generate a "special event trigger" (CCP1M3:CCP1M0 = 1011), this signal will reset Timer1.

**Note:** The special event triggers from the CCP1 module will not set interrupt flag bit TMR1IF (PIR1<0>).

Timer1 must be configured for either timer or synchronized counter mode to take advantage of this feature. If Timer1 is running in asynchronous counter mode, this reset operation may not work.

In the event that a write to Timer1 coincides with a special event trigger from CCP1, the write will take precedence.

In this mode of operation, the CCPRxH:CCPRxL registers pair effectively becomes the period register for Timer1.

---

7.6 Resetting of Timer1 Register Pair (TMR1H, TMR1L)

TMR1H and TMR1L registers are not reset to 00h on a POR or any other reset except by the CCP1 special event triggers.

T1CON register is reset to 00h on a Power-on Reset or a Brown-out Reset, which shuts off the timer and leaves a 1:1 prescale. In all other resets, the register is unaffected.

7.7 Timer1 Prescaler

The prescaler counter is cleared on writes to the TMR1H or TMR1L registers.

8.0 TIMER2 MODULE

Timer2 is an 8-bit timer with a prescaler and a postscaler. It can be used as the PWM time-base for PWM mode of the CCP module. The TMR2 register is readable and writable, and is cleared on any device reset.

The input clock (Fosc/4) has a prescale option of 1:1, 1:4 or 1:16, selected by control bits T2CKPS1:T2CKPS0 (T2CON<1:0>).

The Timer2 module has an 8-bit period register PR2. Timer2 increments from 00h until it matches PR2 and then resets to 00h on the next increment cycle. PR2 is a readable and writable register. The PR2 register is initialized to FFh upon reset.

The match output of TMR2 goes through a 4-bit postscaler (which gives a 1:1 to 1:16 scaling inclusive) to generate a TMR2 interrupt (latched in flag bit TMR2IF, (PIR1<1>)).

Timer2 can be shut off by clearing control bit TMR2ON (T2CON<2>) to minimize power consumption.

Register 8-1 shows the Timer2 control register.

8.1 Timer2 Prescaler and Postscaler

The prescaler and postscaler counters are cleared when any of the following occurs:

- a write to the TMR2 register
- a write to the T2CON register
- any device reset (Power-on Reset, MCLR reset, Watchdog Timer reset, or Brown-out Reset)

TMR2 is not cleared when T2CON is written.

8.2 Output of TMR2

The output of TMR2 (before the postscaler) is fed to the Synchronous Serial Port module which optionally uses it to generate shift clock.

FIGURE 8-1: TIMER2 BLOCK DIAGRAM

Note 1: TMR2 register output can be software selected by the SSP Module as a baud clock.

9.1 Comparator Configuration

There are eight modes of operation for the comparators. The CMCON register is used to select the mode. Figure 9-1 shows the eight possible modes. The TRISA register controls the data direction of the comparator pins for each mode. If the comparator mode is changed, the comparator output level may not be valid for the specified mode change delay shown in Table 12-2.

Note: Comparator interrupts should be disabled during a comparator mode change otherwise a false interrupt may occur.

A = Analog Input, port reads zeros always.
D = Digital Input.
CIS (CMCON<3>) is the Comparator Input Switch.
The code example in Example 9-1 depicts the steps required to configure the comparator module. RA3 and RA4 are configured as digital output. RA0 and RA1 are configured as the V- inputs and RA2 as the V+ input to both comparators.

**EXAMPLE 9-1: INITIALIZING COMPARATOR MODULE**

```assembly
FLAG_REG  EQU  0x20
CLRF  FLAG_REG ; Init flag register
CLRF  PORTA ; Init PORTA
MOVF  CMCON, W ; Load comparator bits
ANDLW  0xC0 ; Mask comparator bits
IORWF  FLAG_REG, F ; Store bits in flag register
MOVWF  CMCON ; CM<2:0> = 011
BSF  STATUS, RP0 ; Select Bank 1
MOVLW  0x07 ; Initialize data direction
MOVF  TRISA ; Set RA<2:0> as inputs
        ; RA<4:3> as outputs
        ; TRISA<7:5> always read '0'
BCF  STATUS, RP0 ; Select Bank 0
CALL  DELAY 10 ; 10µs delay
MOVF  CMCON, F ; Read CMCON to end change condition
BCF  PIR1, CMIF ; Clear pending interrupts
BSF  STATUS, RP0 ; Select Bank 1
BSF  TRISA, CMIE ; Enable comparator interrupts
BSF  INTCON, PIE1 ; Enable peripheral interrupts
BSF  INTCON, GIE ; Global interrupt enable
```

### 9.2 Comparator Operation

A single comparator is shown in Figure 9-2 along with the relationship between the analog input levels and the digital output. When the analog input at V\text{IN–} is less than the analog input V\text{IN+}, the output of the comparator is a digital low level. When the analog input at V\text{IN+} is greater than the analog input V\text{IN–}, the output of the comparator is a digital high level. The shaded areas of the output of the comparator in Figure 9-2 represent the uncertainty due to input offsets and response time.

### 9.3 Comparator Reference

An external or internal reference signal may be used depending on the comparator operating mode. The analog signal that is present at V\text{IN–} is compared to the signal at V\text{IN+}, and the digital output of the comparator is adjusted accordingly (Figure 9-2).

**FIGURE 9-2: SINGLE COMPARATOR**

#### 9.3.1 EXTERNAL REFERENCE SIGNAL

When external voltage references are used, the comparator module can be configured to have the comparators operate from the same or different reference sources. However, threshold detector applications may require the same reference. The reference signal must be between V\text{SS} and V\text{DD}, and can be applied to either pin of the comparator(s).

#### 9.3.2 INTERNAL REFERENCE SIGNAL

The comparator module also allows the selection of an internally generated voltage reference for the comparators. Section 13, Instruction Sets, contains a detailed description of the Voltage Reference Module that provides this signal. The internal reference signal is used when the comparators are in mode CM<2:0>=010 (Figure 9-1). In this mode, the internal voltage reference is applied to the V\text{IN+} pin of both comparators.
9.4 Comparator Response Time

Response time is the minimum time, after selecting a new reference voltage or input source, before the comparator output is guaranteed to have a valid level. If the internal reference is changed, the maximum delay of the internal voltage reference must be considered when using the comparator outputs. Otherwise the maximum delay of the comparators should be used (Table 12-2).

9.5 Comparator Outputs

The comparator outputs are read through the CMCON register. These bits are read only. The comparator outputs may also be directly output to the RA3 and RA4 I/O pins. When the CM<2:0> = 110 or 001, multiplexors in the output path of the RA3 and RA4/T0CK1 pins will switch and the output of each pin will be the unsynchronized output of the comparator. The uncertainty of each of the comparators is related to the input offset voltage and the response time given in the specifications. Figure 9-3 shows the comparator output block diagram.

The TRISA bits will still function as an output enable/disable for the RA3 and RA4/T0CK1 pins while in this mode.

Note 1: When reading the PORT register, all pins configured as analog inputs will read as a ‘0’. Pins configured as digital inputs will convert an analog input according to the Schmitt Trigger input specification.

2: Analog levels on any pin that is defined as a digital input may cause the input buffer to consume more current than is specified.

FIGURE 9-3: MODIFIED COMPARATOR OUTPUT BLOCK DIAGRAM
9.6 Comparator Interrupts

The comparator interrupt flag is set whenever there is a change in the output value of either comparator. Software will need to maintain information about the status of the output bits, as read from CMCON<7:6>, to determine the actual change that has occurred. The CMIF bit, PIR1<6>, is the comparator interrupt flag. The CMIF bit must be reset by clearing '0'. Since it is also possible to write a '1' to this register, a simulated interrupt may be initiated.

The CMIE bit (PIE1<6>) and the PEIE bit (INTCON<6>) must be set to enable the interrupt. In addition, the GIE bit must also be set. If any of these bits are clear, the interrupt is not enabled, though the CMIF bit will still be set if an interrupt condition occurs.

Note: If a change in the CMCON register (C1OUT or C2OUT) should occur when a read operation is being executed (start of the Q2 cycle), then the CMIF (PIR1<6>) interrupt flag may not get set.

The user, in the interrupt service routine, can clear the interrupt in the following manner:

a) Any read or write of CMCON. This will end the mismatch condition.
b) Clear flag bit CMIF.

A mismatch condition will continue to set flag bit CMIF. Reading CMCON will end the mismatch condition, and allow flag bit CMIF to be cleared.

9.7 Comparator Operation During SLEEP

When a comparator is active and the device is placed in SLEEP mode, the comparator remains active and the interrupt is functional if enabled. This interrupt will wake up the device from SLEEP mode when enabled. While the comparator is powered-up, higher sleep currents than shown in the power down current specification will occur. Each comparator that is operational will consume additional current as shown in the comparator specifications. To minimize power consumption while in SLEEP mode, turn off the comparators, CM<2:0> = 111, before entering sleep. If the device wakes-up from sleep, the contents of the CMCON register are not affected.

9.8 Effects of a RESET

A device reset forces the CMCON register to its reset state. This forces the comparator module to be in the comparator reset mode, CM2:CM0 = 000. This ensures that all potential inputs are analog inputs. Device current is minimized when analog inputs are present at reset time. The comparators will be powered-down during the reset interval.

9.9 Analog Input Connection Considerations

A simplified circuit for an analog input is shown in Figure 9-4. Since the analog pins are connected to a digital output, they have reverse biased diodes to VDD and VSS. The analog input therefore, must be between VSS and VDD. If the input voltage deviates from this range by more than 0.6V in either direction, one of the diodes is forward biased and a latch-up may occur. A maximum source impedance of 10 kΩ is recommended for the analog sources. Any external component connected to an analog input pin, such as a capacitor or a Zener diode, should have very little leakage current.

10.0 CAPTURE/COMPARE/PWM (CCP) MODULE

The CCP (Capture/Compare/PWM) module contains a 16-bit register which can operate as a 16-bit capture register, as a 16-bit compare register or as a PWM master/slave Duty Cycle register. Table 10-1 shows the timer resources of the CCP module modes.

CCP1 Module

Capture/Compare/PWM Register1 (CCPR1) is comprised of two 8-bit registers: CCPR1L (low byte) and CCPR1H (high byte). The CCP1CON register controls the operation of CCP1. All are readable and writable.

</thead>
<tbody>
<tr>
<td>Capture</td>
<td>Timer1</td>
</tr>
<tr>
<td>Compare</td>
<td>Timer1</td>
</tr>
<tr>
<td>PWM</td>
<td>Timer2</td>
</tr>
</tbody>
</table>
10.1 Capture Mode

In Capture mode, CCPR1H:CCPR1L captures the 16-bit value of the TMR1 register when an event occurs on pin RB3/CCP1. An event is defined as:

- every falling edge
- every rising edge
- every 4th rising edge
- every 16th rising edge

An event is selected by control bits CCP1M3:CCP1M0 (CCP1CON<3:0>). When a capture is made, the interrupt request flag bit CCP1IF (PIR1<2>) is set. It must be cleared in software. If another capture occurs before the value in register CCPR1 is read, the old captured value will be lost.

10.1.1 CCP PIN CONFIGURATION

In Capture mode, the RB3/CCP1 pin should be configured as an input by setting the TRISB<3> bit.

**Note:** If the RB3/CCP1 is configured as an output, a write to the port can cause a capture condition.

10.1.2 TIMER1 MODE SELECTION

Timer1 must be running in timer mode or synchronized counter mode for the CCP module to use the capture feature. In asynchronous counter mode, the capture operation may not work.

10.1.3 SOFTWARE INTERRUPT

When the Capture mode is changed, a false capture interrupt may be generated. The user should keep bit CCP1IE (PIE1<2>) clear to avoid false interrupts and should clear the flag bit CCP1IF following any such change in operating mode.

10.1.4 CCP PRESCALER

There are four prescaler settings, specified by bits CCP1M3:CCP1M0. Whenever the CCP module is turned off, or the CCP module is not in capture mode, the prescaler counter is cleared. This means that any reset will clear the prescaler counter.

Switching from one capture prescaler to another may generate an interrupt. Also, the prescaler counter will not be cleared, therefore the first capture may be from a non-zero prescaler. Example 10-1 shows the recommended method for switching between capture prescalers. This example also clears the prescaler counter and will not generate the “false” interrupt.

**EXAMPLE 10-1: CHANGING BETWEEN CAPTURE PRESCALERS**

```assembly
CLRF CCP1CON ;Turn CCP module off
MOVLW NEW_CAPT_PS ;Load the W reg with
; the new prescaler
; mode value
MOVWF CCP1CON ;Load CCP1CON with this
; value
```

Note: If the RB3/CCP1 is configured as an output, a write to the port can cause a capture condition.
10.2 Compare Mode

In Compare mode, the 16-bit CCPR1 register value is constantly compared against the TMR1 register pair value. When a match occurs, the RB3/CCP1 pin is:
- driven High
- driven Low
- remains Unchanged

The action on the pin is based on the value of control bits CCP1M3:CCP1M0 (CCP1CON<3:0>). At the same time, interrupt flag bit CCP1IF is set.

**FIGURE 10-2: COMPARE MODE OPERATION BLOCK DIAGRAM**

Special event trigger will reset Timer1, but not set interrupt flag bit TMR1IF (PIR1<0>)

- u = unchanged,  
- = unimplemented read as '0'. Shaded cells are not used by Capture and Timer1.

10.2.1 CCP PIN CONFIGURATION

The user must configure the RB3/CCP1 pin as an output by clearing the TRISB<3> bit.

**Note:** Clearing the CCP1CON register will force the RB3/CCP1 compare output latch to the default low level. This is not the data latch.

10.2.2 TIMER1 MODE SELECTION

Timer1 must be running in Timer mode or Synchronized Counter mode if the CCP module is using the compare feature. In Asynchronous Counter mode, the compare operation may not work.

10.2.3 SOFTWARE INTERRUPT MODE

When generate software interrupt is chosen the CCP1 pin is not affected. Only a CCP interrupt is generated (if enabled).

10.2.4 SPECIAL EVENT TRIGGER

In this mode, an internal hardware trigger is generated which may be used to initiate an action.

The special event trigger output of CCP1 resets the TMR1 register pair. This allows the CCPR1 register to effectively be a 16-bit programmable period register for Timer1.
10.3 PWM Mode

In Pulse Width Modulation (PWM) mode, the CCP1 pin produces up to a 10-bit resolution PWM output. Since the CCP1 pin is multiplexed with the PORTC data latch, the TRISB<3> bit must be cleared to make the CCP1 pin an output.

**Note:** Clearing the CCP1CON register will force the CCP1 PWM output latch to the default low level. This is not the PORTB I/O data latch.

Figure 10-3 shows a simplified block diagram of the CCP module in PWM mode.

For a step by step procedure on how to set up the CCP module for PWM operation, see Section 10.3.3.

**FIGURE 10-3: SIMPLIFIED PWM BLOCK DIAGRAM**

A PWM output (Figure 10-4) has a time base (period) and a time that the output stays high (duty cycle). The frequency of the PWM is the inverse of the period (1/period).

**FIGURE 10-4: PWM OUTPUT**

10.3.1 PWM PERIOD

The PWM period is specified by writing to the PR2 register. The PWM period can be calculated using the following formula:

\[
\text{PWM period} = \frac{(\text{PR2}) + 1}{4 \cdot \frac{\text{TOSC}}{(\text{TMR2 prescale value})}}
\]

PWM frequency is defined as 1 / [PWM period].

When TMR2 is equal to PR2, the following three events occur on the next increment cycle:

- TMR2 is cleared
- The CCP1 pin is set (exception: if PWM duty cycle = 0%, the CCP1 pin will not be set)
- The PWM duty cycle is latched from CCPR1L into CCPR1H

**Note:** The Timer2 prescaler (see Section 8.0) is not used in the determination of the PWM frequency. The prescaler could be used to have a servo update rate at a different frequency than the PWM output.

10.3.2 PWM DUTY CYCLE

The PWM duty cycle is specified by writing to the CCPR1L register and to the CCP1CON<5:4> bits. Up to 10-bit resolution is available: the CCPR1L contains the eight MSbs and the CCP1CON<5:4> contains the two LSbs. This 10-bit value is represented by CCPR1L:CCP1CON<5:4>. The following equation is used to calculate the PWM duty cycle in time:

\[
\text{PWM duty cycle} = \frac{(\text{CCPR1L}:\text{CCP1CON}<5:4>) \cdot \frac{\text{Tsec}}{(\text{TMR2 prescale value})}}{2}
\]

CCPR1L and CCP1CON<5:4> can be written to at any time, but the duty cycle value is not latched into CCP1H until after a match between PR2 and TMR2 occurs (i.e., the period is complete). In PWM mode, CCP1H is a read-only register.

The CCPR1H register and a 2-bit internal latch are used to double buffer the PWM duty cycle. This double buffering is essential for glitchless PWM operation.

When the CCPR1H and 2-bit latch match TMR2 concatenated with an internal 2-bit Q clock or 2 bits of the TMR2 prescaler, the CCP1 pin is cleared.

**Note:** If the PWM duty cycle value is longer than the PWM period the CCP1 pin will not be cleared.

For an example PWM period and duty cycle calculation, see the PICmicro™ Mid-Range Reference Manual (DS33023).
10.3.3 SET-UP FOR PWM OPERATION

The following steps should be taken when configuring the CCP module for PWM operation:

1. Set the PWM period by writing to the PR2 register.
2. Set the PWM duty cycle by writing to the CCPR1L register and CCP1CON<5:4> bits.
3. Make the CCP1 pin an output by clearing the TRISB<3> bit.
4. Set the TMR2 prescale value and enable Timer2 by writing to T2CON.
5. Configure the CCP1 module for PWM operation.

11.0 VOLTAGE REFERENCE MODULE

The Voltage Reference is a 16-tap resistor ladder network that provides a selectable voltage reference. The resistor ladder is segmented to provide two ranges of VREF values and has a power-down function to conserve power when the reference is not being used. The VRCON register controls the operation of the reference as shown in Figure 11-1. The block diagram is given in Figure 11-2.

11.1 Configuring the Voltage Reference

The Voltage Reference can output 16 distinct voltage levels for each range.

The equations used to calculate the output of the Voltage Reference are as follows:

\[
\text{if } \text{VRR} = 1: \text{VREF} = \frac{\text{VR}<3:0>}{24} \times \text{VDD}
\]
\[
\text{if } \text{VRR} = 0: \text{VREF} = \left(\frac{\text{VDD}}{4}\right) + \frac{\text{VR}<3:0>}{32} \times \text{VDD}
\]

The setting time of the Voltage Reference must be considered when changing the VREF output (Table 12-2). Example 11-1 shows an example of how to configure the Voltage Reference for an output voltage of 1.25V with VDD = 5.0V.

11.2 Voltage Reference Accuracy/Error

The full range of VSS to VDD cannot be realized due to the construction of the module. The transistors on the top and bottom of the resistor ladder network (Figure 11-2) keep VREF from approaching VSS or VDD. The Voltage Reference is VDD derived and therefore, the VREF output changes with fluctuations in VDD. The tested absolute accuracy of the Voltage Reference can be found in Table 17-2.

11.3 Operation During Sleep

When the device wakes up from sleep through an interrupt or a Watchdog Timer time-out, the contents of the VRCON register are not affected. To minimize current consumption in SLEEP mode, the Voltage Reference should be disabled.

11.4 Effects of a Reset

A device reset disables the Voltage Reference by clearing bit VREN (VRCON<7>). This reset also disconnects the reference from the RA2 pin by clearing bit VR0E (VRCON<6>) and selects the high voltage range by clearing bit VR (VRCON<5>). The VREF value select bits, VRCON<3:0>, are also cleared.

11.5 Connection Considerations

The Voltage Reference Module operates independently of the comparator module. The output of the reference generator may be connected to the RA2 pin if the TRISA<2> bit is set and the VR0E bit, VRCON<6>, is set. Enabling the Voltage Reference output onto the RA2 pin with an input signal present will increase current consumption. Connecting RA2 as a digital output with VREF enabled will also increase current consumption.

The RA2 pin can be used as a simple D/A output with limited drive capability. Due to the limited drive capability, a buffer must be used in conjunction with the Voltage Reference output for external connections to VREF. Figure 11-3 shows an example buffering technique.

FIGURE 11-3: VOLTAGE REFERENCE OUTPUT BUFFER EXAMPLE

Note 1: R is dependent upon the Voltage Reference Configuration VRCON<3:0> and VRCON<5>.

12.0 UNIVERSAL SYNCHRONOUS ASYNCHRONOUS RECEIVER TRANSMITTER (USART)

The Universal Synchronous Asynchronous Receiver Transmitter (USART) module is one of the two serial I/O modules. (USART is also known as a Serial Communications Interface or SCI). The USART can be configured as a full duplex asynchronous system that can communicate with peripheral devices such as CRT terminals and personal computers, or it can be configured as a half duplex synchronous system that can communicate with peripheral devices such as A/D or D/A integrated circuits, Serial EEPROMs etc.

The USART can be configured in the following modes:
- Asynchronous (full duplex)
- Synchronous - Master (half duplex)
- Synchronous - Slave (half duplex)

Bit SPEN (RCSTA<7>), and bits TRISB<2:1>, have to be set in order to configure pins RB2/TX/CK and RB1/RX/DT as the Universal Synchronous Asynchronous Receiver Transmitter.

Asynchronous mode:  
1 = Enables continuous receive  
0 = Disables continuous receive  
Synchronous mode:  
1 = Enables continuous receive until enable bit CREN is cleared (CREN overrides SREN)  
0 = Disables continuous receive  

**bit 3**: **ADEN**: Address Detect Enable bit  
Asynchronous mode 9-bit (RX9 = 1):  
1 = Enables address detection, enable interrupt and load of the receive buffer when RSR<8> is set  
0 = Disables address detection, all bytes are received, and ninth bit can be used as parity bit  
Asynchronous mode 8-bit (RX9=0):  
Unused in this mode  
Synchronous mode  
Unused in this mode  

**bit 2**: **FERR**: Framing Error bit  
1 = Framing error (Can be updated by reading RCREG register and receive next valid byte)  
0 = No framing error  

**bit 1**: **OERR**: Overrun Error bit  
1 = Overrun error (Can be cleared by clearing bit CREN)  
0 = No overrun error  

**bit 0**: **RX9D**: 9th bit of received data (Can be parity bit)
12.1 USART Baud Rate Generator (BRG)

The BRG supports both the Asynchronous and Synchronous modes of the USART. It is a dedicated 8-bit baud rate generator. The SPBRG register controls the period of a free running 8-bit timer. In asynchronous mode bit BRGH (TXSTA<2>) also controls the baud rate. In synchronous mode bit BRGH is ignored. Table 12-1 shows the formula for computation of the baud rate for different USART modes which only apply in master mode (internal clock).

Given the desired baud rate and Fosc, the nearest integer value for the SPBRG register can be calculated using the formula in Table 12-1. From this, the error in baud rate can be determined.

Example 12-1 shows the calculation of the baud rate error for the following conditions:

- \( F_{OSC} = 16 \text{ MHz} \)
- Desired Baud Rate = 9600
- BRGH = 0
- SYNC = 0

**EXAMPLE 12-1: CALCULATING BAUD RATE ERROR**

Desired Baud rate = \( F_{OSC} / (64 (X + 1)) \)
\[
9600 = \frac{16000000}{(64 (X + 1))}
\]
\[
X = \lfloor 25.042 \rfloor = 25
\]

Calculated Baud Rate = \( 16000000 / (64 (25 + 1)) \)
\[
= 9615
\]

Error = \( \frac{(\text{Calculated Baud Rate} - \text{Desired Baud Rate})}{\text{Desired Baud Rate}} \)
\[
= \frac{(9615 - 9600)}{9600}
\]
\[
= 0.16\%
\]

It may be advantageous to use the high baud rate (BRGH = 1) even for slower baud clocks. This is because the \( F_{OSC}/(16(X + 1)) \) equation can reduce the baud rate error in some cases.

Writing a new value to the SPBRG register, causes the BRG timer to be reset (or cleared), this ensures the BRG does not wait for a timer overflow before outputting the new baud rate.

12.1.1 SAMPLING

The data on the RB1/RX/DT pin is sampled three times by a majority detect circuit to determine if a high or a low level is present at the RX pin. If bit BRGH (TXSTA<2>) is clear (i.e., at the low baud rates), the sampling is done on the seventh, eighth and ninth falling edges of a x16 clock (Figure 12-3). If bit BRGH is set (i.e., at the high baud rates), the sampling is done on the 3 clock edges preceding the second rising edge after the first falling edge of a x4 clock (Figure 12-4 and Figure 12-5).

12.2 USART Asynchronous Mode

In this mode, the USART uses standard nonreturn-to-zero (NRZ) format (one start bit, eight or nine data bits and one stop bit). The most common data format is 8-bits. An on-chip dedicated 8-bit baud rate generator can be used to derive standard baud rate frequencies from the oscillator. The USART transmits and receives the LSb first. The USART's transmitter and receiver are functionally independent but use the same data format and baud rate. The baud rate generator produces a clock either x16 or x64 of the bit shift rate, depending on bit BRGH (TXSTA<2>). Parity is not supported by the hardware, but can be implemented in software (and stored as the ninth data bit). Asynchronous mode is stopped during SLEEP.

Asynchronous mode is selected by clearing bit SYNC (TXSTA<4>).

The USART Asynchronous module consists of the following important elements:
- Baud Rate Generator
- Sampling Circuit
- Asynchronous Transmitter
- Asynchronous Receiver

12.2.1 USART ASYNCHRONOUS TRANSmitter

The USART transmitter block diagram is shown in Figure 12-5. The heart of the transmitter is the transmit (serial) shift register (TSR). The shift register obtains its data from the read/write transmit buffer, TXREG. The TXREG register is loaded with data in software. The TSR register is not loaded until the STOP bit has been transmitted from the previous load. As soon as the STOP bit is transmitted, the TSR is loaded with new data from the TXREG register (if available). Once the TXREG register transfers the data to the TSR register (occurs in one Tcy), the TXREG register is empty and flag bit TXIF (PIR1<4>) is set. This interrupt can be enabled/disabled by setting/clearing enable bit TXIE (PIE1<4>). Flag bit TXIF will be set regardless of the state of enable bit TXIE and cannot be cleared in software. It will reset only when new data is loaded into the TXREG register. While flag bit TXIF indicated the status of the TXREG register, another bit TRMT (TXSTA<1>) shows the status of the TSR register. Status bit TRMT is a read only bit which is set when the TSR register is empty. No interrupt logic is tied to this bit, so the user has to poll this bit in order to determine if the TSR register is empty.

**Note 1:** The TSR register is not mapped in data memory so it is not available to the user.

**Note 2:** Flag bit TXIF is set when enable bit TXEN is set.

Transmission is enabled by setting enable bit TXEN (TXSTA<5>). The actual transmission will not occur until the TXREG register has been loaded with data and the baud rate generator (BRG) has produced a shift clock (Figure 12-5). The transmission can also be started by first loading the TXREG register and then setting enable bit TXEN. Normally when transmission is first started, the TSR register is empty, so a transfer to the TXREG register will result in an immediate transfer to TSR resulting in an empty TXREG. A back-to-back transfer is thus possible (Figure 12-7). Clearing enable bit TXEN during a transmission will cause the transmission to be aborted and will reset the transmitter. As a result the RB2/TX/CK pin will revert to high-impedance.

In order to select 9-bit transmission, transmit bit TX9 (TXSTA<6>) should be set and the ninth bit should be written to TX9D (TXSTA<0>). The ninth bit must be written before writing the 8-bit data to the TXREG register. This is because a data write to the TXREG register can result in an immediate transfer of the data to the TSR register (if the TSR is empty). In such a case, an incorrect ninth data bit may be loaded in the TSR register.

---

**FIGURE 12-5: USART TRANSMIT BLOCK DIAGRAM**

![USART Transmit Block Diagram](image-url)
Steps to follow when setting up an Asynchronous Transmission:

1. Initialize the SPBRG register for the appropriate baud rate. If a high speed baud rate is desired, set bit BRGH. (Section 12.1)
2. Enable the asynchronous serial port by clearing bit SYNC and setting bit SPEN.
3. If interrupts are desired, then set enable bit TXIE.
4. If 9-bit transmission is desired, then set transmit bit TX9.
5. Enable the transmission by setting bit TXEN, which will also set bit TXIF.
6. If 9-bit transmission is selected, the ninth bit should be loaded in bit TX9D.
7. Load data to the TXREG register (starts transmission).

12.2.2 USART ASYNCHRONOUS RECEIVER

The receiver block diagram is shown in Figure 12-8. The data is received on the RB1/RX/DT pin and drives the data recovery block. The data recovery block is actually a high speed shifter operating at x16 times the baud rate, whereas the main receive serial shifter operates at the bit rate or at FOsc.

Once Asynchronous mode is selected, reception is enabled by setting bit CREN (RCSTA<4>).

The heart of the receiver is the receive (serial) shift register (RSR). After sampling the STOP bit, the received data in the RSR is transferred to the RCREG register (if it is empty). If the transfer is complete, flag bit RCIF (PIR1<5>) is set. The actual interrupt can be enabled/disabled by setting/clearing enable bit RCIE (PIE1<5>). Flag bit RCIF is a read only bit which is cleared by the hardware. It is cleared when the RCREG register has been read and is empty. The RCREG is a double buff-

FIGURE 12-8: USART RECEIVE BLOCK DIAGRAM

ered register, i.e. it is a two deep FIFO. It is possible for two bytes of data to be received and transferred to the RCREG FIFO and a third byte begin shifting to the RSR register. On the detection of the STOP bit of the third byte, if the RCREG register is still full then overrun error bit OERR (RCSTA<1>) will be set. The word in the RSR will be lost. The RCREG register can be read twice to retrieve the two bytes in the FIFO. Overrun bit OERR has to be cleared in software. This is done by resetting the receive logic (CREN is cleared and then set). If bit OERR is set, transfers from the RSR register to the RCREG register are inhibited, so it is essential to clear error bit OERR if it is set. Framing error bit FERR (RCSTA<2>) is set if a stop bit is detected as clear. Bit FERR and the 9th receive bit are buffered the same way as the receive data. Reading the RCREG, will load bits RX9D and FERR with new values, therefore it is essential for the user to read the RCSTA register before reading RCREG register in order to lose the old FERR and RX9D information.
FIGURE 12-9: ASYNCHRONOUS RECEPTION WITH ADDRESS DETECT

Note: This timing diagram shows a data byte followed by an address byte. The data byte is not read into the RCREG (receive buffer) because ADEN = 1 and bit8 = 0.

FIGURE 12-10: ASYNCHRONOUS RECEPTION WITH ADDRESS BYTE FIRST

Note: This timing diagram shows an address byte followed by a data byte. The data byte is not read into the RCREG (receive buffer) because ADEN was not updated (still = 1) and bit8 = 0.

FIGURE 12-11: ASYNCHRONOUS RECEPTION WITH ADDRESS BYTE FIRST FOLLOWED BY VALID DATA BYTE

Note: This timing diagram shows an address byte followed by a data byte. The data byte is read into the RCREG (receive buffer) because ADEN was updated after an address match, and was cleared to a '0', so the contents of the receive shift register (RSR) are read into the receive buffer regardless of the value of bit8.
Steps to follow when setting up an Asynchronous Reception:

1. Initialize the SPBRG register for the appropriate baud rate. If a high speed baud rate is desired, set bit BRGH. (Section 12.1).
2. Enable the asynchronous serial port by clearing bit SYNC, and setting bit SPEN.
3. If interrupts are desired, then set enable bit RCIE.
4. If 9-bit reception is desired, then set bit RX9.
5. Enable the reception by setting bit CREN.

6. Flag bit RCIF will be set when reception is complete and an interrupt will be generated if enable bit RCIE was set.
7. Read the RCSTA register to get the ninth bit (if enabled) and determine if any error occurred during reception.
8. Read the 8-bit received data by reading the RCREG register.
9. If any error occurred, clear the error by clearing enable bit CREN.

12.3 USART Function

The USART function is similar to that on the PIC16C74B, which includes the BRGH = 1 fix.

12.3.1 USART 9-BIT RECEIVER WITH ADDRESS DETECT

When the RX9 bit is set in the RCSTA register, 9-bits are received and the ninth bit is placed in the RX9D bit of the RCSTA register. The USART module has a special provision for multi-processor communication. Multiprocessor communication is enabled by setting the ADEN bit (RCSTA<3>) along with the RX9 bit. The port is now programmed such that when the last bit is received, the contents of the receive shift register (RSR) are transferred to the receive buffer, the ninth bit of the RSR (RSR<8>) is transferred to RX9D, and the receive interrupt is set if and only if RSR<8> = 1. This feature can be used in a multi-processor system as follows:

A master processor intends to transmit a block of data to one of many slaves. It must first send out an address byte that identifies the target slave. An address byte is identified by setting the ninth bit (RSR<8>) to a '1' (instead of a '0' for a data byte). If the ADEN and RX9 bits are set in the slave's RCSTA register, enabling multiprocessor communication, all data bytes will be ignored. However, if the ninth received bit is equal to a '1', indicating that the received byte is an address, the slave will be interrupted and the contents of the RSR register will be transferred into the receive buffer. This allows the slave to be interrupted only by addresses, so that the slave can examine the received byte to see if it is being addressed. The addressed slave will then clear its ADEN bit and prepare to receive data bytes from the master.

When ADEN is enabled (=1), all data bytes are ignored. Following the STOP bit, the data will not be loaded into the receive buffer, and no interrupt will occur. If another byte is shifted into the RSR register, the previous data byte will be lost.

The ADEN bit will only take effect when the receiver is configured in 9-bit mode (RX9 = '1'). When ADEN is disabled (=0), all data bytes are received and the 9th bit can be used as the parity bit.

The receive block diagram is shown in Figure 12-8.

Reception is enabled by setting bit CREN (RCSTA<4>).

12.3.1.1 SETTING UP 9-BIT MODE WITH ADDRESS DETECT

Steps to follow when setting up an Asynchronous or Synchronous Reception with Address Detect Enabled:

1. Initialize the SPBRG register for the appropriate baud rate. If a high speed baud rate is desired, set bit BRGH.
2. Enable asynchronous or synchronous communication by setting or clearing bit SYNC and setting bit SPEN.
3. If interrupts are desired, then set enable bit RCIE.
4. Set bit RX9 to enable 9-bit reception.
5. Set ADEN to enable address detect.
6. Enable the reception by setting enable bit CREN or SREN.
7. Flag bit RCIF will be set when reception is complete, and an interrupt will be generated if enable bit RCIE was set.
8. Read the 8-bit received data by reading the RCREG register to determine if the device is being addressed.
9. If any error occurred, clear the error by clearing enable bit CREN if it was already set.
10. If the device has been addressed (RSR<8> = 1 with address match enabled), clear the ADEN and RCIF bits to allow data bytes and address bytes to be read into the receive buffer and interrupt the CPU.

### 12.4 USART Synchronous Master Mode

In Synchronous Master mode, the data is transmitted in a half-duplex manner, i.e. transmission and reception do not occur at the same time. When transmitting data, the reception is inhibited and vice versa. Synchronous mode is entered by setting bit SYNC (TXSTA<4>). In addition enable bit SPEN (RCSTA<7>) is set in order to configure the RB2/TX/CK and RB1/RX/DT I/O pins to CK (clock) and DT (data) lines respectively. The Master mode indicates that the processor transmits the master clock on the CK line. The Master mode is entered by setting bit CSRC (TXSTA<7>).

#### 12.4.1 USART SYNCHRONOUS MASTER TRANSMISSION

The USART transmitter block diagram is shown in Figure 12-5. The heart of the transmitter is the transmit (serial) shift register (TSR). The shift register obtains its data from the read/write transmit buffer register TXREG. The TXREG register is loaded with data in software. The TSR register is not loaded until the last bit has been transmitted from the previous load. As soon as the last bit is transmitted, the TSR is loaded with new data from the TXREG (if available). Once the TXREG register transfers the data to the TSR register (occurs in one T cycle), the TXREG is empty and interrupt bit, TXIF (PIR1<4>) is set. The interrupt can be enabled/disabled by setting/clearing enable bit TXIE (PIE1<4>). Flag bit TXIF will be set regardless of the state of enable bit TXIE and cannot be cleared in software. It will reset only when new data is loaded into the TXREG register. While flag bit TXIF indicates the status of the TXREG register, another bit TRMT (TXSTA<1>) shows the status of the TSR register. TRMT is a read only bit which is set when the TSR is empty. No interrupt logic is tied to this bit, so the user has to poll this bit in order to determine if the TSR register is empty. The TSR is not mapped in data memory so it is not available to the user.

Transmission is enabled by setting enable bit TXEN (TXSTA<5>). The actual transmission will not occur until the TXREG register has been loaded with data. The first data bit will be shifted out on the next available rising edge of the clock on the CK line. Data out is stable around the falling edge of the synchronous clock (Figure 12-12). The transmission can also be started by first loading the TXREG register and then setting bit TXEN (Figure 12-13). This is advantageous when slow baud rates are selected, since the BRG is kept in reset when bits TXEN, CREN, and SREN are clear. Setting enable bit TXEN will start the BRG, creating a shift clock immediately. Normally when transmission is first started, the TSR register is empty, so a transfer to the TXREG register will result in an immediate transfer to TSR resulting in an empty TXREG. Back-to-back transfers are possible.

Clearing enable bit TXEN, during a transmission, will cause the transmission to be aborted and will reset the transmitter. The DT and CK pins will revert to hi-impedance. If either bit CREN or bit SREN is set, during a transmission, the transmission is aborted and the DT pin reverts to a hi-impedance state (for a reception). The CK pin will remain an output if bit CSRC is set (internal clock). The transmitter logic however is not reset although it is disconnected from the pins. In order to reset the transmitter, the user has to clear bit TXEN. If bit SREN is set (to interrupt an on-going transmission and receive a single word), then after the single word is received, bit SREN will be cleared and the serial port will revert back to transmitting since bit TXEN is still set. The DT line will immediately switch from hi-impedance receive mode to transmit and start driving. To avoid this, bit TXEN should be cleared.

In order to select 9-bit transmission, the TX9 (TXSTA<6>) bit should be set and the ninth bit should be written to bit TX9D (TXSTA<0>). The ninth bit must be written before writing the 8-bit data to the TXREG register. This is because a data write to the TXREG can result in an immediate transfer of the data to the TSR register (if the TSR is empty). If the TSR was empty and the TXREG was written before writing the "new" TX9D, the "present" value of bit TX9D is loaded.
Steps to follow when setting up a Synchronous Master Transmission:
1. Initialize the SPBRG register for the appropriate baud rate (Section 12.1).
2. Enable the synchronous master serial port by setting bits SYNC, SPEN, and CSRC.
3. If interrupts are desired, then set enable bit TXIE.
4. If 9-bit transmission is desired, then set bit TX9.
5. Enable the transmission by setting bit TXEN.
6. If 9-bit transmission is selected, the ninth bit should be loaded in bit TX9D.
7. Start transmission by loading data to the TXREG register.

12.4.2 USART SYNCHRONOUS MASTER RECEPTION

Once Synchronous mode is selected, reception is enabled by setting either enable bit SREN (RCSTA<5>) or enable bit CREN (RCSTA<4>). Data is sampled on the RB1/RX/DT pin on the falling edge of the clock. If enable bit SREN is set, then only a single word is received. If enable bit CREN is set, the reception is continuous until CREN is cleared. If both bits are set then CREN takes precedence. After clocking the last bit, the received data in the Receive Shift Register (RSR) is transferred to the RCREG register (if it is empty). When the transfer is complete, interrupt flag bit RCIF (PIR1<5>) is set. The actual interrupt can be enabled/disabled by setting/clearing enable bit RCIE (PIE1<5>). Flag bit RCIF is a read only bit which is reset by the hardware. In this case it is reset when the RCREG register has been read and is empty. The RCREG is a double buffered register, i.e. it is a two deep FIFO. It is possible for two bytes of data to be received and transferred to the RCREG FIFO and a third byte to begin shifting into the RSR register. On the clocking of the last bit of the third byte, if the RCREG register is still full then overrun error bit OERR (RCSTA<1>) is set. The word in the RSR will be lost. The RCREG register can be read twice to retrieve the two bytes in the FIFO. Bit OERR has to be cleared in software (by clearing bit CREN). If bit OERR is set, transfers from the RSR to the RCREG are inhibited, so it is essential to clear bit OERR if it is set. The 9th receive bit is buffered the same way as the receive data. Reading the RCREG register, will load bit RX9D with a new value, therefore it is essential for the user to read the RCSTA register before reading RCREG in order not to lose the old RX9D information.

Steps to follow when setting up a Synchronous Master Reception:

1. Initialize the SPBRG register for the appropriate baud rate. (Section 12.1)
2. Enable the synchronous master serial port by setting bits SYNC, SPEN, and CSRC.
3. Ensure bits CREN and SREN are clear.
4. If interrupts are desired, then set enable bit RCIE.
5. If 9-bit reception is desired, then set bit RX9.
6. If a single reception is required, set bit SREN. For continuous reception set bit CREN.
7. Interrupt flag bit RCIF will be set when reception is complete and an interrupt will be generated if enable bit RCIE was set.
8. Read the RCSTA register to get the ninth bit (if enabled) and determine if any error occurred during reception.
9. Read the 8-bit received data by reading the RCREG register.
10. If any error occurred, clear the error by clearing bit CREN.

FIGURE 12-14: SYNCHRONOUS RECEPTION (MASTER MODE, SREN)

Note: Timing diagram demonstrates SYNC master mode with bit SREN = '1' and bit BRG = '0'.
12.5 USART Synchronous Slave Mode

Synchronous slave mode differs from the Master mode in the fact that the shift clock is supplied externally at the RB2/TX/CK pin (instead of being supplied internally in master mode). This allows the device to transfer or receive data while in SLEEP mode. Slave mode is entered by clearing bit CSRC (TXSTA<7>).

12.5.1 USART SYNCHRONOUS SLAVE TRANSMIT

The operation of the synchronous master and slave modes are identical except in the case of the SLEEP mode.

If two words are written to the TXREG and then the SLEEP instruction is executed, the following will occur:

a) The first word will immediately transfer to the TSR register and transmit.
b) The second word will remain in TXREG register.
c) Flag bit TXIF will not be set.
d) When the first word has been shifted out of TSR, the TXREG register will transfer the second word to the TSR and flag bit TXIF will now be set.
e) If enable bit TXIE is set, the interrupt will wake the chip from SLEEP and if the global interrupt is enabled, the program will branch to the interrupt vector (0004h).

Steps to follow when setting up a Synchronous Slave Transmission:

1. Enable the synchronous slave serial port by setting bits SYNC and SPEN and clearing bit CSRC.
2. Clear bits CREN and SREN.
3. If interrupts are desired, then set enable bit TXIE.
4. If 9-bit transmission is desired, then set bit TX9.
5. Enable the transmission by setting enable bit TXEN.
6. If 9-bit transmission is selected, the ninth bit should be loaded in bit TX9D.
7. Start transmission by loading data to the TXREG register.

12.5.2 USART SYNCHRONOUS SLAVE RECEPTION

The operation of the synchronous master and slave modes is identical except in the case of the SLEEP mode. Also, bit SREN is a don’t care in slave mode.

If receive is enabled, by setting bit CREN, prior to the SLEEP instruction, a word may be received during SLEEP. On completely receiving the word, the RSR register will transfer the data to the RCREG register and if enable bit RCIE bit is set, the interrupt generated will wake the chip from SLEEP. If the global interrupt is enabled, the program will branch to the interrupt vector (0004h).

Steps to follow when setting up a Synchronous Slave Reception:

1. Enable the synchronous master serial port by setting bits SYNC and SPEN and clearing bit CSRC.
2. If interrupts are desired, then set enable bit RCIE.
3. If 9-bit reception is desired, then set bit RX9.
4. To enable reception, set enable bit CREN.
5. Flag bit RCIF will be set when reception is complete and an interrupt will be generated, if enable bit RCIE was set.
6. Read the RCSTA register to get the ninth bit (if enabled) and determine if any error occurred during reception.
7. Read the 8-bit received data by reading the RCREG register.
8. If any error occurred, clear the error by clearing bit CREN.

13.0 DATA EEPROM MEMORY

The EEPROM data memory is readable and writable during normal operation (full VDD range). This memory is not directly mapped in the register file space. Instead it is indirectly addressed through the Special Function Registers. There are four SFRs used to read and write this memory. These registers are:

- EECON1
- EECON2 (Not a physically implemented register)
- EEDATA
- EEADR

EEDATA holds the 8-bit data for read/write, and EEADR holds the address of the EEPROM location being accessed. PIC16F62X devices have 128 bytes of data EEPROM with an address range from 0h to 7Fh.

The EEPROM data memory allows byte read and write. A byte write automatically erases the location and writes the new data (erase before write). The EEPROM data memory is rated for high erase/write cycles. The write time is controlled by an on-chip timer. The write-time will vary with voltage and temperature as well as from chip to chip. Please refer to AC specifications for exact limits.

When the device is code protected, the CPU may continue to read and write the data EEPROM memory. The device programmer can no longer access this memory.

Additional information on the Data EEPROM is available in the PICmicro™ Mid-Range Reference Manual, (DS33023).

REGISTER 13-1: EEADR REGISTER (ADDRESS 9Bh)

<table>

<tr>
<td>bit 6:0 EEADR: Specifies one of 128 locations for EEPROM Read/Write Operation</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

13.1 EEADR

The EEADR register can address up to a maximum of 256 bytes of data EEPROM. Only the first 128 bytes of data EEPROM are implemented and only seven of the eight bits in the register (EEADR<6:0>) are required.

The upper bit is address decoded. This means that this bit should always be '0' to ensure that the address is in the 128 byte memory space.
13.2 **EECON1 AND EECON2 REGISTERS**

EECON1 is the control register with five low order bits physically implemented. The upper-three bits are non-existent and read as ‘0’ s.

Control bits RD and WR initiate read and write, respectively. These bits cannot be cleared, only set, in software. They are cleared in hardware at completion of the read or write operation. The inability to clear the WR bit in software prevents the accidental, premature termination of a write operation.

The WREN bit, when set, will allow a write operation. On power-up, the WREN bit is clear. The WRERR bit is set when a write operation is interrupted by a MCLR reset or a WDT time-out reset during normal operation. In these situations, following reset, the user can check the WRERR bit and rewrite the location. The data and address will be unchanged in the EEDATA and EEADR registers.

Interrupt flag bit EEIF in the PIR1 register is set when write is complete. This bit must be cleared in software. EECON2 is not a physical register. Reading EECON2 will read all ‘0’ s. The EECON2 register is used exclusively in the Data EEPROM write sequence.

### REGISTER 13-2: EECON1 REGISTER (ADDRESS 9Ch) DEVICES

| bit7:4 | Unimplemented: Read as ‘0’ |
| bit3  | WRERR: EEPROM Error Flag bit |
|       | 1 = A write operation is prematurely terminated |
|       | (any MCLR reset, any WDT reset during normal operation or BOD detect) |
|       | 0 = The write operation completed |
| bit2  | WREN: EEPROM Write Enable bit |
|       | 1 = Allows write cycles |
|       | 0 = Inhibits write to the data EEPROM |
| bit1  | WR: Write Control bit |
|       | 1 = initiates a write cycle. (The bit is cleared by hardware once write is complete. The WR bit can only be set (not cleared) in software. |
|       | 0 = Write cycle to the data EEPROM is complete |
| bit0  | RD: Read Control bit |
|       | 1 = Initiates an EEPROM read (read takes one cycle. RD is cleared in hardware. The RD bit can only be set (not cleared) in software. |
|       | 0 = Does not initiate an EEPROM read |
13.3 READING THE EEPROM DATA MEMORY

To read a data memory location, the user must write the address to the EEADR register and then set control bit RD (EECON1<0>). The data is available, in the very next cycle, in the EEDATA register; therefore it can be read in the next instruction. EEDATA will hold this value until another read or until it is written to by the user (during a write operation).

EXAMPLE 13-1: DATA EEPROM READ

```
BCF STATUS, RP0 ; Bank 0
MOVLW CONFIG_ADDR ;
MOVF EEADR, W ; Address to read
BSF STATUS, RP0 ; Bank 1
BSF EECON1, RD ; EE Read
BCF STATUS, RP0 ; Bank 0
MOVF EEDATA, W ; W = EEDATA
```

13.4 WRITING TO THE EEPROM DATA MEMORY

To write an EEPROM data location, the user must first write the address to the EEADR register and the data to the EEDATA register. Then the user must follow a specific sequence to initiate the write for each byte.

EXAMPLE 13-2: DATA EEPROM WRITE

```
BSF STATUS, RP0 ; Bank 0
BSF EECON1, WREN ; Enable write
BCF INTCON, GIE ; Disable INTs.
MOVLW 55h ;
MOVF EECON2, W ; Write 55h
MOVLW AAh ;
MOVF EECON2, W ; Write AAh
BSF EECON1, WR ; Set WR bit
begin write
BSF INTCON, GIE ; Enable INTs.
```

The write will not initiate if the above sequence is not exactly followed (write 55h to EECON2, write AAh to EECON2, then set WR bit) for each byte. We strongly recommend that interrupts be disabled during this code segment. A cycle count is executed during the required sequence. Any number what is not equal to the required cycles to execute the required sequence will cause the data not to be written into the EEPROM.

Additionally, the WREN bit in EECON1 must be set to enable write. This mechanism prevents accidental writes to data EEPROM due to errant (unexpected) code execution (i.e., lost programs). The user should keep the WREN bit clear at all times, except when updating EEPROM. The WREN bit is not cleared by hardware.

After a write sequence has been initiated, clearing the WREN bit will not affect this write cycle. The WR bit will be inhibited from being set unless the WREN bit is set.

At the completion of the write cycle, the WR bit is cleared in hardware and the EE Write Complete Interrupt Flag bit (EEIF) is set. The user can either enable this interrupt or poll this bit. The EEIF bit in the PIR1 registers must be cleared by software.

13.5 WRITE VERIFY

Depending on the application, good programming practice may dictate that the value written to the Data EEPROM should be verified (Example 13-3) to the desired value to be written. This should be used in applications where an EEPROM bit will be stressed near the specification limit.

EXAMPLE 13-3: WRITE VERIFY

```
BCF STATUS, RP0 ; Bank 0
: Any code can go here :
MOV EEDATA, W ; Must be in Bank 0
BSF STATUS, RP0 ; Bank 1 READ
BSF EECON1, RD ; YES, Read the ; value written
BCF STATUS, RP0 ; Bank 0
;
; Is the value written (in W reg) and ; read (in EEDATA) the same?
;
SUBWF EEDATA, W ;
BTFSS STATUS, Z ; Is difference 0?
GOTO WRITE_ERR ; NO, Write error
: YES, Good write
: Continue program
```

13.6 PROTECTION AGAINST SPURIOUS WRITE

There are conditions when the device may not want to write to the data EEPROM memory. To protect against spurious EEPROM writes, various mechanisms have been built in. On power-up, WREN is cleared. Also, the Power-up Timer (72 ms duration) prevents EEPROM write.

The write initiate sequence and the WREN bit together help prevent an accidental write during brown-out, power glitch, or software malfunction.

13.7 DATA EEPROM OPERATION DURING CODE PROTECT

When the device is code protected, the CPU is able to read and write unscrambled data to the Data EEPROM.

**Note 1:** EECON2 is not a physical register.
14.0 SPECIAL FEATURES OF THE CPU

Special circuits to deal with the needs of real time applications are what sets a microcontroller apart from other processors. The PIC16F62X family has a host of such features intended to maximize system reliability, minimize cost through elimination of external components, provide power saving operating modes and offer code protection.

These are:
1. OSC selection
2. Reset
   - Power-on Reset (POR)
   - Power-up Timer (PWRT)
   - Oscillator Start-Up Timer (OST)
   - Brown-out Reset (BOD)
3. Interrupts
4. Watchdog Timer (WDT)
5. SLEEP
6. Code protection
7. ID Locations
8. In-circuit serial programming

The PIC16F62X has a Watchdog Timer which is controlled by configuration bits. It runs off its own RC oscillator for added reliability. There are two timers that offer necessary delays on power-up. One is the Oscillator Start-up Timer (OST), intended to keep the chip in reset until the crystal oscillator is stable. The other is the Power-up Timer (PWRT), which provides a fixed delay of 72 ms (nominal) on power-up only, designed to keep the part in reset while the power supply stabilizes. There is also circuitry to reset the device if a brown-out occurs which provides at least a 72 ms reset. With these three functions on-chip, most applications need no external reset circuitry.

The SLEEP mode is designed to offer a very low current power-down mode. The user can wake-up from SLEEP through external reset, Watchdog Timer wake-up or through an interrupt. Several oscillator options are also made available to allow the part to fit the application. The ER oscillator option saves system cost while the LP crystal option saves power. A set of configuration bits are used to select various options.
14.1 Configuration Bits

The configuration bits can be programmed (read as '0') or left unprogrammed (read as '1') to select various device configurations. These bits are mapped in program memory location 2007h.

The user will note that address 2007h is beyond the user program memory space. In fact, it belongs to the special configuration memory space (2000h – 3FFFh), which can be accessed only during programming.

</table>

**Note 1:** Enabling Brown-out Reset automatically enables Power-up Timer (PWRT) regardless of the value of bit PWRT. Ensure the Power-up Timer is enabled anytime Brown-out Reset is enabled.

**Note 2:** All of the CP1:CP0 pairs have to be given the same value to enable the code protection scheme listed.

**Note 3:** The entire data EEPROM will be erased when the code protection is turned off.

**Note 4:** When MCLR is asserted in INTRC or ER mode, the internal clock oscillator is disabled.
14.2 Oscillator Configurations

14.2.1 Oscillator Types

The PIC16F62X can be operated in eight different oscillator options. The user can program three configuration bits (FOSC2 thru FOSC0) to select one of these eight modes:

- LP Low Power Crystal
- XT Crystal/Resonator
- HS High Speed Crystal/Resonator
- ER External Resistor (2 modes)
- INTRC Internal Resistor/Capacitor (2 modes)
- EC External Clock In

14.2.2 Crystal Oscillator / Ceramic Resonators

In XT, LP or HS modes a crystal or ceramic resonator is connected to the OSC1 and OSC2 pins to establish oscillation (Figure 14-2). The PIC16F62X oscillator design requires the use of a parallel cut crystal. Use of a series cut crystal may give a frequency out of the crystal manufacturers specifications. When in XT, LP or HS modes, the device can have an external clock source to drive the OSC1 pin (Figure 14-3).

**FIGURE 14-2: CRYSTAL OPERATION (OR CERAMIC RESONATOR) (HS, XT OR LP OSC CONFIGURATION)**

![Crystal Oscillator Diagram]

See Table 14-1 and Table 14-2 for recommended values of C1 and C2.

**Note:** A series resistor may be required for AT strip cut crystals.

**TABLE 14-1: CAPACITOR SELECTION FOR CERAMIC RESONATORS**

<table>
<thead>
<tr>
<th>Mode</th>
<th>Freq</th>
<th>OSC1(C1)</th>
<th>OSC2(C2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>XT</td>
<td>455 kHz</td>
<td>22 - 100 pF</td>
<td>15 - 100 pF</td>
</tr>
<tr>
<td></td>
<td>2.0 MHz</td>
<td>15 - 80 pF</td>
<td>15 - 68 pF</td>
</tr>
<tr>
<td></td>
<td>4.0 MHz</td>

</tr>
<tr>
<td></td>
<td>16.0 MHz</td>
<td>10 - 68 pF</td>
<td>10 - 22 pF</td>
</tr>
</tbody>
</table>

Higher capacitance increases the stability of the oscillator but also increases the start-up time. These values are for design guidance only. Since each resonator has its own characteristics, the user should consult the resonator manufacturer for appropriate values of external components.

</tbody>
</table>

Higher capacitance increases the stability of the oscillator but also increases the start-up time. These values are for design guidance only. Rs may be required in HS mode as well as XT mode to avoid overdriving crystals with low drive level specification. Since each crystal has its own characteristics, the user should consult the crystal manufacturer for appropriate values of external components.
14.2.3 EXTERNAL CRYSTAL OSCILLATOR CIRCUIT

Either a prepackaged oscillator can be used or a simple oscillator circuit with TTL gates can be built. Prepackaged oscillators provide a wide operating range and better stability. A well-designed crystal oscillator will provide good performance with TTL gates. Two types of crystal oscillator circuits can be used: one with series resonance, or one with parallel resonance.

Figure 14-4 shows implementation of a parallel resonant oscillator circuit. The circuit is designed to use the fundamental frequency of the crystal. The 74AS04 inverter performs the 180° phase shift that a parallel oscillator requires. The 4.7 kΩ resistor provides the negative feedback for stability. The 10 kΩ potentiometers bias the 74AS04 in the linear region. This could be used for external oscillator designs.

**FIGURE 14-4: EXTERNAL PARALLEL RESONANT CRYSTAL OSCILLATOR CIRCUIT**

![Parallel Resonant Oscillator Circuit Diagram]

Figure 14-5 shows a series resonant oscillator circuit. This circuit is also designed to use the fundamental frequency of the crystal. The inverter performs a 180° phase shift in a series resonant oscillator circuit. The 330 kΩ resistors provide the negative feedback to bias the inverters in their linear region.

**FIGURE 14-5: EXTERNAL SERIES RESONANT CRYSTAL OSCILLATOR CIRCUIT**

![Series Resonant Oscillator Circuit Diagram]

14.2.4 EXTERNAL CLOCK IN

For applications where a clock is already available elsewhere, users may directly drive the PIC16F62X provided that this external clock source meets the AC/DC timing requirements listed in Section 17.4. Figure 14-6 below shows how an external clock circuit should be configured.

**FIGURE 14-6: EXTERNAL CLOCK INPUT OPERATION (HS, XT OR LP OSC CONFIGURATION)**

![External Clock Input Circuit Diagram]

14.2.5 ER OSCILLATOR

For timing insensitive applications, the ER (External Resistor) clock mode offers additional cost savings. Only one external component, a resistor to VSS, is needed to set the operating frequency of the internal oscillator. The resistor draws a DC bias current which controls the oscillation frequency. In addition to the resistance value, the oscillator frequency will vary from unit to unit, and as a function of supply voltage and temperature. Since the controlling parameter is a DC current and not a capacitance, the particular package type and lead frame will not have a significant effect on the resultant frequency.

Figure 14-7 shows how the controlling resistor is connected to the PIC16F62X. For Rext values below 38k, the oscillator operation may become unstable, or stop completely. For very high Rext values (e.g. 1M), the oscillator becomes sensitive to noise, humidity and leakage. Thus, we recommend keeping Rext between 38k and 1M.

**FIGURE 14-7: EXTERNAL RESISTOR**

![External Resistor Circuit Diagram]

The Electrical Specification section shows the relationship between the resistance value and the operating frequency as well as frequency variations due to operating temperature for given R and VDD values.

The ER oscillator mode has two options that control the unused OSC2 pin. The first allows it to be used as a general purpose I/O port. The other configures the pin as an output providing the Fosc signal (internal clock divided by 4) for test or external synchronization purposes.
14.2.6 INTERNAL 4 MHz OSCILLATOR

The internal RC oscillator provides a fixed 4 MHz (nominal) system clock at \( V_{dd} = 5 \text{V} \) and \( 25^\circ \text{C} \), see “Electrical Specifications” section for information on variation over voltage and temperature.

14.2.7 CLKOUT

The PIC16F62X can be configured to provide a clock out signal by programming the configuration word. The oscillator frequency, divided by 4 can be used for test purposes or to synchronize other logic.

14.3 Special Feature: Dual Speed Oscillator Modes

A software programmable dual speed oscillator mode is provided when the PIC16F62X is configured in either ER or INTRC oscillator modes. This feature allows users to dynamically toggle the oscillator speed between 4MHz and 37kHz. In ER mode, the 4MHz setting will vary depending on the size of the external resistor. Also in ER mode, the 37kHz operation is fixed and does not vary with resistor size. Applications that require low current power savings, but cannot tolerate putting the part into sleep, may use this mode.

The OSCF bit in the PCON register is used to control dual speed mode. See Section 4.2.2.6, Figure 4-9.

14.4 Reset

The PIC16F62X differentiates between various kinds of reset:

- a) Power-on reset (POR)
- b) MCLR reset during normal operation
- c) MCLR reset during SLEEP
- d) WDT reset (normal operation)
- e) WDT wake-up (SLEEP)
- f) Brown-out Detect (BOD)

Some registers are not affected in any reset condition; their status is unknown on POR and unchanged in any other reset. Most other registers are reset to a “reset state” on Power-on reset, MCLR reset, WDT reset and MCLR reset during SLEEP. They are not affected by a WDT wake-up, since this is viewed as the resumption of normal operation. TO and PD bits are set or cleared differently in different reset situations as indicated in Table 14-4. These bits are used in software to determine the nature of the reset. See Table 14-7 for a full description of reset states of all registers.

A simplified block diagram of the on-chip reset circuit is shown in Figure 14-8.

The MCLR reset path has a noise filter to detect and ignore small pulses. See Table 12-6 for pulse width specification.
FIGURE 14-8: SIMPLIFIED BLOCK DIAGRAM OF ON-CHIP RESET CIRCUIT

Note 1: This is a separate oscillator from the INTRC/EC oscillator.
14.5 Power-on Reset (POR), Power-up Timer (PWRT), Oscillator Start-up Timer (OST) and Brown-out Detect (BOD)

14.5.1 POWER-ON RESET (POR)

The on-chip POR circuit holds the chip in reset until VDD has reached a high enough level for proper operation. To take advantage of the POR, just tie the MCLR pin through a resistor to VDD. This will eliminate external RC components usually needed to create Power-on Reset. A maximum rise time for VDD is required. See Electrical Specifications for details.

The POR circuit does not produce an internal reset when VDD declines.

When the device starts normal operation (exits the reset condition), device operating parameters (voltage, frequency, temperature, etc.) must be met to ensure operation. If these conditions are not met, the device must be held in reset until the operating conditions are met.

For additional information, refer to Application Note AN607 “Power-up Trouble Shooting”.

14.5.2 POWER-UP TIMER (PWRT)

The Power-up Timer provides a fixed 72 ms (nominal) time-out on power-up only, from POR or Brown-out Reset. The Power-up Timer operates on an internal RC oscillator. The chip is kept in reset as long as PWRT is active. The PWRT delay allows the VDD to rise to an acceptable level. A configuration bit, PWRTEN can disable (if set) or enable (if cleared or programmed) the Power-up Timer. The Power-up Timer should always be enabled when Brown-out Reset is enabled.

The Power-Up Time delay will vary from chip to chip and due to VDD, temperature and process variation. See DC parameters for details.

14.5.3 OSCILLATOR START-UP TIMER (OST)

The Oscillator Start-Up Timer (OST) provides a 1024 oscillator cycle (from OSC1 input) delay after the PWRT delay is over. This ensures that the crystal oscillator or resonator has started and stabilized.

The OST time-out is invoked only for XT, LP and HS modes and only on power-on reset or wake-up from SLEEP.

14.5.4 BROWN-OUT DETECT (BOD)

The PIC16F62X members have on-chip Brown-out Detect circuitry. A configuration bit, BODEN, can disable (if clear/programmed) or enable (if set) the Brown-out Detect circuitry. If VDD falls below 4.0V, refer to VBOH parameter D005(VBOH) for greater than parameter (TBOD) in Table 17.1, the brown-out situation will reset the chip. A reset is not guaranteed to occur if VDD falls below 4.0V for less than parameter (TBOD).

On any reset (Power-on, Brown-out, Watchdog, etc.) the chip will remain in Reset until VDD rises above BVDD. The Power-up Timer will now be invoked and will keep the chip in reset an additional 72 ms.

If VDD drops below BVDD while the Power-up Timer is running, the chip will go back into a Brown-out Reset and the Power-up Timer will be re-initialized. Once VDD rises above BVDD, the Power-Up Timer will execute a 72 ms reset. The Power-up Timer should always be enabled when Brown-out Detect is enabled. Figure 14-9 shows typical Brown-out situations.

FIGURE 14-9: BROWN-OUT SITUATIONS

![Brown-out Situations Diagram]
14.5.5 TIME-OUT SEQUENCE

On power-up the time-out sequence is as follows: First PWRT time-out is invoked after POR has expired. Then OST is activated. The total time-out will vary based on oscillator configuration and PWRT bit status. For example, in ER mode with PWRT bit erased (PWRT disabled), there will be no time-out at all. Figure 14-10, Figure 14-11 and Figure 14-12 depict time-out sequences.

Since the time-outs occur from the POR pulse, if MCLR is kept low long enough, the time-outs will expire. Then bringing MCLR high will begin execution immediately (see Figure 14-11). This is useful for testing purposes or to synchronize more than one PIC16F62X device operating in parallel.

Table 14-6 shows the reset conditions for some special registers, while Table 14-7 shows the reset conditions for all the registers.

Legend:  
- = unchanged,  
× = unknown,  
= unimplemented bit, reads as '0',  
q = value depends on condition.

Note 1: If VDD goes too low, Power-on Reset will be activated and registers will be affected differently.
2: One or more bits in INTCON, PIR1 and/or PIR2 will be affected (to cause wake-up).
3: When the wake-up is due to an interrupt and the GIE bit is set, the PC is loaded with the interrupt vector (0004h).
4: See Table 14-6 for reset value for specific condition.
5: If wake-up was due to comparator input changing, then bit 6 = 1. All other interrupts generating a wake-up will cause bit 6 = u.
6: If reset was due to brown-out, then bit 0 = 0. All other resets will cause bit 0 = u.

FIGURE 14-13: EXTERNAL POWER-ON
RESET CIRCUIT (FOR SLOW VDD POWER-UP)

Note 1: External power-on reset circuit is required only if VDD power-up slope is too slow. The diode D helps discharge the capacitor quickly when VDD powers down.

2: < 40 kΩ is recommended to make sure that voltage drop across R does not violate the device’s electrical specification.

3: R1 = 100Ω to 1 kΩ will limit any current flowing into MCLR from external capacitor C in the event of MCLR/VPP pin breakdown due to Electrostatic Discharge (ESD) or Electrical Overstress (EOS).

FIGURE 14-14: EXTERNAL BROWN-OUT
PROTECTION CIRCUIT 1

Note 1: This circuit will activate reset when VDD goes below (Vz + 0.7V) where Vz = Zener voltage.

2: Internal Brown-out Reset circuitry should be disabled when using this circuit.

FIGURE 14-15: EXTERNAL BROWN-OUT
PROTECTION CIRCUIT 2

Note 1: This brown-out circuit is less expensive, albeit less accurate. Transistor Q1 turns off when VDD is below a certain level such that:

\[ V_{DD} \times \frac{R_1}{R_1 + R_2} = 0.7 \text{ V} \]

2: Internal brown-out reset should be disabled when using this circuit.

3: Resistors should be adjusted for the characteristics of the transistor.
14.6  Interrupts

The PIC16F62X has 10 sources of interrupt:

- External Interrupt RB0/INT
- TMR0 Overflow Interrupt
- PortB Change Interrupts (pins RB7:RB4)
- Comparator Interrupt
- USART Interrupt
- CCP Interrupt
- TMR1 Overflow Interrupt
- TMR2 Match Interrupt

The interrupt control register (INTCON) records individual interrupt requests in flag bits. It also has individual and global interrupt enable bits.

A global interrupt enable bit, GIE (INTCON<7>) enables (if set) all un-masked interrupts or disables (if cleared) all interrupts. Individual interrupts can be disabled through their corresponding enable bits in INTCON register. GIE is cleared on reset.

The “return from interrupt” instruction, RETFIE, exits interrupt routine as well as sets the GIE bit, which re-enable RB0/INT interrupts.

The INT pin interrupt, the RB port change interrupt and the TMR0 overflow interrupt flags are contained in the INTCON register.

The peripheral interrupt flag is contained in the special register PIR1. The corresponding interrupt enable bit is contained in special registers PIE1.

When an interrupt is responded to, the GIE is cleared to disable any further interrupt, the return address is pushed into the stack and the PC is loaded with 0004h. Once in the interrupt service routine the source(s) of the interrupt can be determined by polling the interrupt flag bits. The interrupt flag bit(s) must be cleared in software before re-enabling interrupts to avoid RB0/INT recursive interrupts.

For external interrupt events, such as the INT pin or PORTB change interrupt, the interrupt latency will be three or four instruction cycles. The exact latency depends when the interrupt event occurs (Figure 14-17). The latency is the same for one or two cycle instructions. Once in the interrupt service routine the source(s) of the interrupt can be determined by polling the interrupt flag bits. The interrupt flag bit(s) must be cleared in software before re-enabling interrupts to avoid multiple interrupt requests. Individual interrupt flag bits are set regardless of the status of their corresponding mask bit or the GIE bit.

Note 1: Individual interrupt flag bits are set regardless of the status of their corresponding mask bit or the GIE bit.

2: When an instruction that clears the GIE bit is executed, any interrupts that were pending for execution in the next cycle are ignored. The CPU will execute a NOP in the cycle immediately following the instruction which clears the GIE bit. The interrupts which were ignored are still pending to be serviced when the GIE bit is set again.

FIGURE 14-16: INTERRUPT LOGIC

[Diagram showing interrupt logic]
14.6.1 RB0/INT INTERRUPT

External interrupt on RB0/INT pin is edge triggered: either rising if INTEDG bit (OPTION<6>) is set, or falling, if INTEDG bit is clear. When a valid edge appears on the RB0/INT pin, the INTF bit (INTCON<1>) is set. This interrupt can be disabled by clearing the INTE control bit (INTCON<4>). The INTF bit must be cleared in software in the interrupt service routine before re-enabling this interrupt. The RB0/INT interrupt can wake-up the processor from SLEEP, if the INTE bit was set prior to going into SLEEP. The status of the GIE bit decides whether or not the processor branches to the interrupt vector following wake-up. See Section 14.9 for details on SLEEP and Figure 14-19 for timing of wake-up from SLEEP through RB0/INT interrupt.

14.6.2 TMR0 INTERRUPT

An overflow (FFh → 00h) in the TMR0 register will set the T0IF (INTCON<2>) bit. The interrupt can be enabled/disabled by setting/clearing T0IE (INTCON<5>) bit. For operation of the Timer0 module, see Section 6.0.

14.6.3 PORTB INTERRUPT

An input change on PORTB <7:4> sets the RBIF (INTCON<0>) bit. The interrupt can be enabled/disabled by setting/clearing the RBIE (INTCON<4>) bit. For operation of PORTB (Section 5.2).

Note: If a change on the I/O pin should occur when the read operation is being executed (start of the Q2 cycle), then the RBIF interrupt flag may not get set.

14.6.4 COMPARATOR INTERRUPT

See Section 9.6 for complete description of comparator interrupts.

---

Note 1: Other (non power-up) resets include MCLR reset, Brown-out Reset and Watchdog Timer Reset during normal operation.
14.7 Context Saving During Interrupts

During an interrupt, only the return PC value is saved on the stack. Typically, users may wish to save key registers during an interrupt e.g. W register and STATUS register. This will have to be implemented in software.

Example 14-1 stores and restores the STATUS and W registers. The user register, W_TEMP, must be defined in both banks and must be defined at the same offset from the bank base address (i.e., W_TEMP is defined at 0x20 in Bank 0 and it must also be defined at 0xA0 in Bank 1). The user register, STATUS_TEMP, must be defined in Bank 0. The Example 14-1:

- Stores the W register
- Stores the STATUS register in Bank 0
- Executes the ISR code
- Restores the STATUS (and bank select bit register)
- Restores the W register

**EXAMPLE 14-1: SAVING THE STATUS AND W REGISTERS IN RAM**

```assembly
MOVWF W_TEMP ;copy W to temp register, ;could be in either bank
SWAPF STATUS, W ;swap status to be saved into W
BCF STATUS, RP0 ;change to bank 0 regardless ;of current bank
MOVWF STATUS_TEMP ;save status to bank 0 ;register
: (ISR)
:
SWAPF STATUS_TEMP, W ;swap STATUS_TEMP register ;into W, sets bank to original ;state
MOVWF STATUS ;move W into STATUS register
SWAPF W_TEMP, F ;swap W_TEMP
SWAPF W_TEMP, W ;swap W_TEMP into W
```

14.8 Watchdog Timer (WDT)

The watchdog timer is a free running on-chip RC oscillator which does not require any external components. This RC oscillator is separate from the ER oscillator of the CLKIN pin. That means that the WDT will run, even if the clock on the OSC1 and OSC2 pins of the device has been stopped, for example, by execution of a SLEEP instruction. During normal operation, a WDT time-out generates a device RESET. If the device is in SLEEP mode, a WDT time-out causes the device to wake-up and continue with normal operation. The WDT can be permanently disabled by programming the configuration bit WDTE as clear (Section 14.1).

14.8.1 WDT PERIOD

The WDT has a nominal time-out period of 18 ms, (with no prescaler). The time-out periods vary with temperature, VDD and process variations from part to part (see DC specs). If longer time-out periods are desired, a prescaler with a division ratio of up to 1:128 can be assigned to the WDT under software control by writing to the OPTION register. Thus, time-out periods up to 2.3 seconds can be realized.

The CLRWD T and SLEEP instructions clear the WDT and the postscaler, if assigned to the WDT, and prevent it from timing out and generating a device RESET.

The TO bit in the STATUS register will be cleared upon a Watchdog Timer time-out.

14.8.2 WDT PROGRAMMING CONSIDERATIONS

It should also be taken in account that under worst case conditions (VDD = Min., Temperature = Max., max. WDT prescaler) it may take several seconds before a WDT time-out occurs.
FIGURE 14-18: WATCHDOG TIMER BLOCK DIAGRAM

Note: T0SE, T0CS, PSA, PS0-PS2 are bits in the OPTION register.

Legend: Shaded cells are not used by the Watchdog Timer.

Note: 
- _ = Unimplemented location, read as “0”
+ = Reserved for future use
14.9 Power-Down Mode (SLEEP)

The Power-down mode is entered by executing a SLEEP instruction.

If enabled, the Watchdog Timer will be cleared but keeps running, the PD bit in the STATUS register is cleared, the TO bit is set, and the oscillator driver is turned off. The I/O ports maintain the status they had before SLEEP was executed (driving high, low, or hi-impedance).

For lowest current consumption in this mode, all I/O pins should be either at VDD or VSS, with no external circuitry drawing current from the I/O pin and the comparators and VREF should be disabled. I/O pins that are hi-impedance inputs should be pulled high or low externally to avoid switching currents caused by floating inputs. The T0CKI input should also be at VDD or VSS for lowest current consumption. The contribution from on chip pull-ups on PORTB should be considered. The MCLR pin must be at a logic high level (VIHMC).

The first event will cause a device reset. The two latter events are considered a continuation of program execution. The TO and PD bits in the STATUS register can be used to determine the cause of device reset. PD bit, which is set on power-up is cleared when SLEEP is invoked. TO bit is cleared if WDT Wake-up occurred.

When the SLEEP instruction is being executed, the next instruction (PC + 1) is pre-fetched. For the device to wake-up through an interrupt event, the corresponding interrupt enable bit must be set (enabled). Wake-up is regardless of the state of the GIE bit. If the GIE bit is clear (disabled), the device continues execution at the instruction after the SLEEP instruction. If the GIE bit is set (enabled), the device executes the instruction after the SLEEP instruction and then branches to the interrupt address (0004h). In cases where the execution of the instruction following SLEEP is not desirable, the user should have an NOP after the SLEEP instruction.

If the global interrupts are disabled (GIE is cleared), but any interrupt source has both its interrupt enable bit and the corresponding interrupt flag bits set, the device will immediately wakeup from sleep. The sleep instruction is completely executed.

The WDT is cleared when the device wakes-up from sleep, regardless of the source of wake-up.

Note: It should be noted that a RESET generated by a WDT time-out does not drive MCLR pin low.

14.9.1 WAKE-UP FROM SLEEP

The device can wake-up from SLEEP through one of the following events:

1. External reset input on MCLR pin
2. Watchdog Timer Wake-up (if WDT was enabled)
3. Interrupt from RB0/INT pin, RB Port change, or the Peripheral Interrupt (Comparator).

FIGURE 14-19: WAKE-UP FROM SLEEP THROUGH INTERRUPT

The WDT is cleared when the device wakes-up from sleep, regardless of the source of wake-up.

Note 1: XT, HS or LP oscillator mode assumed.
2: \( T_{SLEEP} = 1024T_{osc} \) (drawing not to scale). Approximately 1 µs delay will be there for ER osc mode.
3: GIE = "1" assumed. In this case after wake- up, the processor jumps to the interrupt routine. If GIE = "0", execution will continue in-line.
4: CLKOUT is not available in these osc modes, but shown here for timing reference.
14.10 Code Protection

If the code protection bit(s) have not been programmed, the on-chip program memory can be read out for verification purposes.

Note: The entire data EEPROM and FLASH program memory will be erased when the code protection is turned off. The INTRC calibration data is not erased.

14.11 ID Locations

Four memory locations (2000h-2003h) are designated as ID locations where the user can store checksum or other code-identification numbers. These locations are not accessible during normal execution but are readable and writable during program/verify. Only the least significant 4 bits of the ID locations are used.

14.12 In-Circuit Serial Programming

The PIC16F62X microcontrollers can be serially programmed while in the end application circuit. This is simply done with two lines for clock and data, and three other lines for power, ground, and the programming voltage. This allows customers to manufacture boards with unprogrammed devices, and then program the microcontroller just before shipping the product. This also allows the most recent firmware or a custom firmware to be programmed.

The device is placed into a program/verify mode by holding the RB6 and RB7 pins low while raising the MCLR (VPP) pin from VIIL to VIHH (see programming specification). RB6 becomes the programming clock and RB7 becomes the programming data. Both RB6 and RB7 are Schmitt Trigger inputs in this mode.

After reset, to place the device into programming/verify mode, the program counter (PC) is at location 00h. A 6-bit command is then supplied to the device. Depending on the command, 14-bits of program data are then supplied to or from the device, depending if the command was a load or a read. For complete details of serial programming, please refer to the Programming Specifications.

A typical in-circuit serial programming connection is shown in Figure 14-20.

14.13 Low Voltage Programming

The LVP bit of the configuration word enables the low voltage programming. This mode allows the microcontroller to be programmed via ICSP using only a 5V source. This mode removes the requirement of VIHH to be placed on the MCLR pin. The LVP bit is normally erased to ‘1’ which enables the low voltage programming. In this mode, the RB4/PGM pin is dedicated to the programming function and ceases to be a general purpose I/O pin. The device will enter programming mode when a ‘1’ is placed on the RB4/PGM pin. The HV programming mode is still available by placing VIHH on the MCLR pin.

If Low-voltage programming mode is not used, the LVP bit can be programmed to a ‘0’ and RB4/PGM becomes a digital I/O pin. To program the device, VIHH must be placed onto MCLR during programming. The LVP bit may only be programmed when programming is entered with VIHH on MCLR. The LVP bit cannot be programmed when programming is entered with RB4/PGM.

It should be noted that once the LVP bit is programmed to 0, only the high voltage programming mode is available and only high voltage programming mode can be used to program the device.
15.0 INSTRUCTION SET SUMMARY

Each PIC16F62X instruction is a 14-bit word divided into an OPCODE which specifies the instruction type and one or more operands which further specify the operation of the instruction. The PIC16F62X instruction set summary in Table 15-2 lists byte-oriented, bit-oriented, and literal and control operations. Table 15-1 shows the opcode field descriptions.

For byte-oriented instructions, 'f' represents a file register designator and 'd' represents a destination designator. The file register designator specifies which file register is to be used by the instruction. The destination designator specifies where the result of the operation is to be placed. If 'd' is zero, the result is placed in the W register. If 'd' is one, the result is placed in the file register specified in the instruction.

For bit-oriented instructions, 'b' represents a bit field designator which selects the number of the bit affected by the operation, while 'f' represents the number of the file in which the bit is located.

For literal and control operations, 'k' represents an eight or eleven bit constant or literal value.

</table>

The instruction set is highly orthogonal and is grouped into three basic categories:

- **Byte-oriented operations**
- **Bit-oriented operations**
- **Literal and control operations**

All instructions are executed within one single instruction cycle, unless a conditional test is true or the program counter is changed as a result of an instruction. In this case, the execution takes two instruction cycles with the second cycle executed as a NOP. One instruction cycle consists of four oscillator periods. Thus, for an oscillator frequency of 4 MHz, the normal instruction execution time is 1 µs. If a conditional test is true or the program counter is changed as a result of an instruction, the instruction execution time is 2 µs.

Table 15-1 lists the instructions recognized by the MPASM assembler.

Figure 15-1 shows the three general formats that the instructions can have.

Note: To maintain upward compatibility with future PICmicro® products, do not use the OPTION and TRIS instructions.

All examples use the following format to represent a hexadecimal number:

```
0xhh
```

where h signifies a hexadecimal digit.

### FIGURE 15-1: GENERAL FORMAT FOR INSTRUCTIONS

**Byte-oriented file register operations**

```
13 8 7 6 0
| OPCODE | d | f (FILE #) |
```

- d = 0 for destination W
- d = 1 for destination f
- f = 7-bit file register address

**Bit-oriented file register operations**

```
13 10 9 7 6 0
| OPCODE | b (BIT #) | f (FILE #) |
```

- b = 3-bit bit address
- f = 7-bit file register address

**Literal and control operations**

**General**

```
13 8 7 0
| OPCODE | k (literal) |
```

- k = 8-bit immediate value

**CALL and GOTO instructions only**

```
13 11 10 0
| OPCODE | k (literal) |
```

- k = 11-bit immediate value

</table>

**Note 1:** When an I/O register is modified as a function of itself (e.g., **MOVf PORTB, 1**), the value used will be that value present on the pins themselves. For example, if the data latch is ‘1’ for a pin configured as input and is driven low by an external device, the data will be written back with a ‘0’.

**Note 2:** If this instruction is executed on the TMRO register (and, where applicable, d = 1), the prescaler will be cleared if assigned to the Timer0 Module.

**Note 3:** If Program Counter (PC) is modified or a conditional test is true, the instruction requires two cycles. The second cycle is executed as a NOP.
15.1 Instruction Descriptions

<table>
<thead>
<tr>
<th>ADDLW</th>
<th>Add Literal and W</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax:</td>
<td><code>[ label ]  ADDLW   k</code></td>
</tr>
<tr>
<td>Operands:</td>
<td>$0 \leq k \leq 255$</td>
</tr>
<tr>
<td>Operation:</td>
<td>$(W) + k \rightarrow (W)$</td>
</tr>
<tr>
<td>Status Affected:</td>
<td>C, DC, Z</td>
</tr>
<tr>
<td>Encoding:</td>
<td>11 111x kkkk kkkk</td>
</tr>
<tr>
<td>Description:</td>
<td>The contents of the W register are added to the eight bit literal ‘k’ and the result is placed in the W register.</td>
</tr>
<tr>
<td>Words:</td>
<td>1</td>
</tr>
<tr>
<td>Cycles:</td>
<td>1</td>
</tr>
<tr>
<td>Example</td>
<td>ADDLW 0x15</td>
</tr>
<tr>
<td>Before Instruction</td>
<td>W = 0x10</td>
</tr>
<tr>
<td>After Instruction</td>
<td>W = 0x25</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>ANDLW</th>
<th>AND Literal with W</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax:</td>
<td><code>[ label ]  ANDLW   k</code></td>
</tr>
<tr>
<td>Operands:</td>
<td>$0 \leq k \leq 255$</td>
</tr>
<tr>
<td>Operation:</td>
<td>$(W) \cdot \text{AND} (k) \rightarrow (W)$</td>
</tr>
<tr>
<td>Status Affected:</td>
<td>Z</td>
</tr>
<tr>
<td>Encoding:</td>
<td>11 1001 kkkk kkkk</td>

<tr>
<td>Description:</td>
<td>The contents of W register are AND’ed with the eight bit literal ‘k’. The result is placed in the W register.</td>
</tr>
<tr>
<td>Words:</td>
<td>1</td>
</tr>
<tr>
<td>Cycles:</td>
<td>1</td>
</tr>
<tr>
<td>Example</td>
<td>ANDLW 0x5F</td>
</tr>
<tr>
<td>Before Instruction</td>
<td>W = 0xA3</td>
</tr>
<tr>
<td>After Instruction</td>
<td>W = 0x03</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>ADDWF</th>
<th>Add W and f</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax:</td>
<td><code>[ label ]  ADDWF   f,d</code></td>
</tr>
</tbody>
</table>
| Operands: | $0 \leq f \leq 127$  
| d \in [0,1] |
| Operation: | $(W) + (f) \rightarrow (\text{dest})$ |
| Status Affected: | C, DC, Z |
| Encoding: | 00 0111 dfff ffff |
| Description: | Add the contents of the W register with register ‘f’. If ‘d’ is 0 the result is stored in the W register. If ‘d’ is 1 the result is stored back in register ‘f’. |
| Words: | 1 |
| Cycles: | 1 |
| Example | ADDWF FSR, 0 |
| Before Instruction | W = 0x17  
| FSR = 0xC2 |
| After Instruction | W = 0xD9  
| FSR = 0xC2 |

<table>
<thead>
<tr>
<th>ANDWF</th>
<th>AND W with f</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax:</td>
<td><code>[ label ]  ANDWF   f,d</code></td>
</tr>
</tbody>
</table>
| Operands: | $0 \leq f \leq 127$  
| d \in [0,1] |
| Operation: | $(W) \cdot \text{AND} (f) \rightarrow (\text{dest})$ |
| Status Affected: | Z |
| Encoding: | 00 0101 dfff ffff |
| Description: | AND the W register with register ‘f’. If ‘d’ is 0 the result is stored in the W register. If ‘d’ is 1 the result is stored back in register ‘f’. |
| Words: | 1 |
| Cycles: | 1 |
| Example | ANDWF FSR, 1 |
| Before Instruction | W = 0x17  
| FSR = 0xC2 |
| After Instruction | W = 0x09  
| FSR = 0xC2 |
### BCF

**Bit Clear f**

<table>
<thead>
<tr>
<th>Syntax:</th>
<th>[ label ] BCF f,b</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operands:</td>
<td>0 ≤ f ≤ 127</td>
</tr>
<tr>
<td></td>
<td>0 ≤ b ≤ 7</td>
</tr>
<tr>
<td>Operation:</td>
<td>0 → (f&lt;b&gt;)</td>
</tr>
<tr>
<td>Status Affected:</td>
<td>None</td>
</tr>
<tr>
<td>Encoding:</td>
<td>01 00bb bfff ffff</td>
</tr>
<tr>
<td>Description:</td>
<td>Bit 'b' in register 'f' is cleared.</td>
</tr>
<tr>
<td>Words:</td>
<td>1</td>
</tr>
<tr>
<td>Cycles:</td>
<td>1</td>
</tr>
<tr>
<td>Example</td>
<td>BCF FLAG_REG, 7</td>
</tr>
</tbody>
</table>

**Before Instruction**

FLAG_REG = 0xC7

**After Instruction**

FLAG_REG = 0x47

### BSF

**Bit Set f**

<table>
<thead>
<tr>
<th>Syntax:</th>
<th>[ label ] BSF f,b</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operands:</td>
<td>0 ≤ f ≤ 127</td>
</tr>
<tr>
<td></td>
<td>0 ≤ b ≤ 7</td>
</tr>
<tr>
<td>Operation:</td>
<td>1 → (f&lt;b&gt;)</td>
</tr>
<tr>
<td>Status Affected:</td>
<td>None</td>
</tr>
<tr>
<td>Encoding:</td>
<td>01 01bb bfff ffff</td>
</tr>
<tr>
<td>Description:</td>
<td>Bit 'b' in register 'f' is set.</td>
</tr>
<tr>
<td>Words:</td>
<td>1</td>
</tr>
<tr>
<td>Cycles:</td>
<td>1</td>
</tr>
<tr>
<td>Example</td>
<td>BSF FLAG_REG, 7</td>
</tr>
</tbody>
</table>

**Before Instruction**

FLAG_REG = 0xA

**After Instruction**

FLAG_REG = 0x8A

### BTSC

**Bit Test, Skip if Clear**

<table>
<thead>
<tr>
<th>Syntax:</th>
<th>[ label ] BTSC f,b</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operands:</td>
<td>0 ≤ f ≤ 127</td>
</tr>
<tr>
<td></td>
<td>0 ≤ b ≤ 7</td>
</tr>
<tr>
<td>Operation:</td>
<td>skip if (f&lt;b&gt;) = 0</td>
</tr>
<tr>
<td>Status Affected:</td>
<td>None</td>
</tr>
<tr>
<td>Encoding:</td>
<td>01 10bb bfff ffff</td>
</tr>
<tr>
<td>Description:</td>
<td>If bit 'b' in register 'f' is '0' then the next instruction is skipped.</td>
</tr>
<tr>
<td></td>
<td>If bit 'b' is '0' then the next instruction fetched during the current instruction execution is discarded, and a NOP is executed instead, making this a two-cycle instruction.</td>
</tr>
<tr>
<td>Words:</td>
<td>1</td>
</tr>
<tr>
<td>Cycles:</td>
<td>1 (2)</td>
</tr>
<tr>
<td>Example</td>
<td>HERE BTFSC FLAG,1</td>
</tr>
<tr>
<td></td>
<td>FALSE GOTO PROCESS_CODE</td>
</tr>
<tr>
<td></td>
<td>TRUE</td>
</tr>
</tbody>
</table>

**Before Instruction**

if FLAG<1> = 0, PC = address HERE

if FLAG<1>=1, PC = address FALSE
## BTFSS
### Bit Test f, Skip if Set

**Syntax:** \[ label \] BTFSS _f,b_  

**Operands:**  
0 ≤ _f_ ≤ 127  
0 ≤ _b_ < 7  

**Operation:** skip if (_f_<_b>) = 1  

**Status Affected:** None  

**Encoding:**  

<table>
<thead>
<tr>
<th>01</th>
<th>11bb</th>
<th>bfff</th>
<th>ffff</th>
</tr>
</thead>
</table>

**Description:** If bit 'b' in register 'f' is '1' then the next instruction is skipped. If bit 'b' is '1', then the next instruction fetched during the current instruction execution, is discarded and a NOP is executed instead, making this a two-cycle instruction.

**Words:** 1  
**Cycles:** 1(2)

**Example**  

<table>
<thead>
<tr>
<th>HERE</th>
<th>BTFSS</th>
<th>FLAG,1</th>
</tr>
</thead>
<tbody>
<tr>
<td>FALSE</td>
<td>GOTO</td>
<td>PROCESS_CODE</td>
</tr>
<tr>
<td>TRUE</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Before Instruction  
PC = address HERE  

After Instruction  
if FLAG<1> = 0,  
PC = address FALSE  
if FLAG<1> = 1,  
PC = address TRUE

## CALL
### Call Subroutine

**Syntax:** \[ label \] CALL _k_  

**Operands:** 0 ≤ _k_ ≤ 2047  

**Operation:**  
(PC)+ 1 → TOS,  
k → PC<10:0>,  
(PCLATH<4:3>) → PC<12:11>  

**Status Affected:** None  

**Encoding:**  

<table>
<thead>
<tr>
<th>10</th>
<th>0kkk</th>
<th>kkkk</th>
<th>kkkk</th>
</tr>
</thead>
</table>

**Description:** Call Subroutine. First, return address (PC+1) is pushed onto the stack. The eleven bit immediate address is loaded into PC bits <10:0>. The upper bits of the PC are loaded from PCLATH. CALL is a two-cycle instruction.

**Words:** 1  
**Cycles:** 2

**Example**  

| HERE | CALL | THERE |

Before Instruction  
PC = Address HERE  

After Instruction  
PC = Address THERE  
TOS = Address HERE+1

## CLRF
### Clear f

**Syntax:** \[ label \] CLRF _f_  

**Operands:** 0 ≤ _f_ ≤ 127  

**Operation:**  
00h → (_f_)  
1 → Z  

**Status Affected:** Z  

**Encoding:**  

<table>
<thead>
<tr>
<th>00</th>
<th>0001</th>
<th>lfff</th>
<th>ffff</th>
</tr>
</thead>
</table>

**Description:** The contents of register T are cleared and the Z bit is set.

**Words:** 1  
**Cycles:** 1

**Example**  

CLRF FLAG_REG  
Before Instruction  
FLAG_REG = 0x5A  
After Instruction  
FLAG_REG = 0x00  
Z = 1

## CLRW
### Clear W

**Syntax:** \[ label \] CLRW  

**Operands:** None  

**Operation:**  
00h → (W)  
1 → Z  

**Status Affected:** Z  

**Encoding:**  

<table>
<thead>
<tr>
<th>00</th>
<th>0001</th>
<th>0000</th>
<th>0011</th>
</tr>
</thead>
</table>

**Description:** W register is cleared. Zero bit (Z) is set.

**Words:** 1  
**Cycles:** 1

**Example**  

CLRW  
Before Instruction  
W = 0x5A  
After Instruction  
W = 0x00  
Z = 1
### CLRWDT — Clear Watchdog Timer

**Syntax:**

```
[label] CLRWDT
```

**Operands:**

None

**Operation:**

- \( 00h \rightarrow \text{WDT} \)
- \( 0 \rightarrow \text{WDT prescaler} \)
- \( 1 \rightarrow \text{TO} \)
- \( 1 \rightarrow \text{PD} \)

**Status Affected:**

- TO
- PD

**Encoding:**

```
00 0000 0110 0100
```

**Description:**

The CLRWDT instruction resets the Watchdog Timer. It also resets the prescaler of the WDT. Status bits TO and PD are set.

**Words:**

1

**Cycles:**

1

**Example**

Before Instruction

- WDT counter = ?

After Instruction

- WDT counter = 0x00
- WDT prescaler = 0
- TO = 1
- PD = 1

### COMF — Complement f

**Syntax:**

```
[label] COMF f,d
```

**Operands:**

- \( 0 \leq f \leq 127 \)
- \( d \in \{0,1\} \)

**Operation:**

- \( (f) \rightarrow (\text{dest}) \)

**Status Affected:**

- Z

**Encoding:**

```
00 1001 dfff ffff
```

**Description:**

The contents of register ‘f’ are complemented. If ‘d’ is 0 the result is stored in W. If ‘d’ is 1 the result is stored back in register ‘f’.

**Words:**

1

**Cycles:**

1

**Example**

```
COMF REG1, 0
```

Before Instruction

- REG1 = 0x13

After Instruction

- REG1 = 0x13
- W = 0xEC

### DECF — Decrement f

**Syntax:**

```
[label] DECF f,d
```

**Operands:**

- \( 0 \leq f \leq 127 \)
- \( d \in \{0,1\} \)

**Operation:**

- \( (f) - 1 \rightarrow (\text{dest}) \)

**Status Affected:**

- Z

**Encoding:**

```
00 0111 dfff ffff
```

**Description:**

Decrement register ‘f’. If ‘d’ is 0 the result is stored in the W register. If ‘d’ is 1 the result is stored back in register ‘f’.

**Words:**

1

**Cycles:**

1

**Example**

```
DECF CNT, 1
```

Before Instruction

- CNT = 0x01
- Z = 0

After Instruction

- CNT = 0x00
- Z = 1

### DECFSZ — Decrement f, Skip if 0

**Syntax:**

```
[label] DECFSZ f,d
```

**Operands:**

- \( 0 \leq f \leq 127 \)
- \( d \in \{0,1\} \)

**Operation:**

- \( (f) - 1 \rightarrow (\text{dest}) \); skip if result = 0

**Status Affected:**

None

**Encoding:**

```
00 1011 dfff ffff
```

**Description:**

The contents of register ‘f’ are decremented. If ‘d’ is 0 the result is placed in the W register. If ‘d’ is 1 the result is placed back in register ‘f’.

If the result is 0, the next instruction, which is already fetched, is discarded. A NOP is executed instead making it a two-cycle instruction.

**Words:**

1

**Cycles:**

1(2)

**Example**

```
HERE DECFSZ CNT, 1
GOTO LOOP
CONTINUE • • •
```

Before Instruction

- PC = address HERE

After Instruction

- CNT = CNT - 1
- if CNT = 0, PC = address CONTINUE
- if CNT ≠ 0, PC = address HERE+1
### GOTO Unconditional Branch

**Syntax:** [ label ] GOTO k

**Operands:** 0 ≤ k ≤ 2047

**Operation:**
- k → PC<10:0>
- PCLATH<4:3> → PC<12:11>

**Status Affected:** None

**Encoding:**
- 10 lkkk kkkk kkkk

**Description:**
- GOTO is an unconditional branch. The eleven bit immediate value is loaded into PC bits <10:0>. The upper bits of PC are loaded from PCLATH<4:3>.
- GOTO is a two-cycle instruction.

**Words:** 1

**Cycles:** 2

**Example**

GOTO THERE

After Instruction

PC = Address THERE

---

### INCF Increment f

**Syntax:** [ label ] INCF f,d

**Operands:**
- 0 ≤ f ≤ 127
- d ∈ [0,1]

**Operation:**
- (f) + 1 → (dest)

**Status Affected:** Z

**Encoding:**
- 00 1010 dfff ffff

**Description:**
- The contents of register 'f' are incremented. If 'd' is 0 the result is placed in the W register. If 'd' is 1 the result is placed back in register 'f'.

**Words:** 1

**Cycles:** 1

**Example**

INCF CNT, 1

Before Instruction

<table>
<thead>
<tr>
<th>CNT</th>
<th>Z</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xFF</td>
<td>0</td>
</tr>
</tbody>
</table>

After Instruction

<table>
<thead>
<tr>
<th>CNT</th>
<th>Z</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x00</td>
<td>1</td>
</tr>
</tbody>
</table>

---

### INCFSZ Increment f, Skip if 0

**Syntax:** [ label ] INCFSZ f,d

**Operands:**
- 0 ≤ f ≤ 127
- d ∈ [0,1]

**Operation:**
- (f) + 1 → (dest), skip if result = 0

**Status Affected:** None

**Encoding:**
- 00 l111 dfff ffff

**Description:**
- The contents of register 'f' are incremented. If 'd' is 0 the result is placed in the W register. If 'd' is 1 the result is placed back in register 'f'. If the result is 0, the next instruction, which is already fetched, is discarded. A NOP is executed instead making it a two-cycle instruction.

**Words:** 1

**Cycles:** 1(2)

**Example**

HERE     INCFSZ     CNT, 1
GOTO LOOP
CONTINUE

Before Instruction

<table>
<thead>
<tr>
<th>PC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Address HERE</td>
</tr>
</tbody>
</table>

After Instruction

<table>
<thead>
<tr>
<th>CNT</th>
<th>PC</th>
</tr>
</thead>
<tbody>
<tr>
<td>CNT + 1</td>
<td>Address CONTINUE</td>
</tr>
<tr>
<td>0</td>
<td>Address HERE</td>
</tr>
</tbody>
</table>

---

### IORLW Inclusive OR Literal with W

**Syntax:** [ label ] IORLW k

**Operands:**
- 0 ≤ k ≤ 255

**Operation:**
- (W) .OR. k → (W)

**Status Affected:** Z

**Encoding:**
- 11 1000 kkkk kkkk

**Description:**
- The contents of the W register is OR'ed with the eight bit literal 'k'. The result is placed in the W register.

**Words:** 1

**Cycles:** 1

**Example**

IORLW 0x35

Before Instruction

<table>
<thead>
<tr>
<th>W</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x9A</td>
</tr>
</tbody>
</table>

After Instruction

<table>
<thead>
<tr>
<th>W</th>
<th>Z</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xBF</td>
<td>1</td>
</tr>
</tbody>
</table>
**IORWF**  Inclusive OR W with f

Syntax: \[
[\text{label}] \quad \text{IORWF} \quad f,d
\]

Operands: \[
0 \leq f \leq 127
\]
\[
d \in [0,1]
\]

Operation: \[
(W) .OR. (f) \rightarrow (\text{dest})
\]

Status Affected: \[
Z
\]

Encoding:

| 00 | 0100 | dfff | ffff |

Description: Inclusive OR the W register with register 'f'. If 'd' is 0 the result is placed in the W register. If 'd' is 1 the result is placed back in register 'f'.

Words: 1
Cycles: 1

Example:

```
IORWF RESULT, 0
```

Before Instruction

\[
\begin{align*}
\text{RESULT} &= \text{0x13} \\
W &= \text{0x91}
\end{align*}
\]

After Instruction

\[
\begin{align*}
\text{RESULT} &= \text{0x13} \\
W &= \text{0x93} \\
Z &= 1
\end{align*}
\]

**MOVF**  Move f

Syntax: \[
[\text{label}] \quad \text{MOVF} \quad f,d
\]

Operands: \[
0 \leq f \leq 127
\]
\[
d \in [0,1]
\]

Operation: \[
(f) \rightarrow (\text{dest})
\]

Status Affected: \[
Z
\]

Encoding:

| 00 | 1000 | dfff | ffff |

Description: The contents of register f is moved to a destination dependent upon the status of d. If d = 0, destination is W register. If d = 1, the destination is file register f itself. d = 1 is useful to test a file register since status flag Z is affected.

Words: 1
Cycles: 1

Example:

```
MOVF FSR, 0
```

After Instruction

\[
\begin{align*}
W &= \text{value in FSR register} \\
Z &= 1
\end{align*}
\]

**MOVLW**  Move Literal to W

Syntax: \[
[\text{label}] \quad \text{MOVLW} \quad k
\]

Operands: \[
0 \leq k \leq 255
\]

Operation: \[
k \rightarrow (W)
\]

Status Affected: None

Encoding:

| 11 | 00xx | kkkk | kkkk |

Description: The eight bit literal 'k' is loaded into W register. The don't cares will assemble as 0's.

Words: 1
Cycles: 1

Example:

```
MOVLW 0x5A
```

After Instruction

\[
\begin{align*}
W &= \text{0x5A}
\end{align*}
\]

**MOVWF**  Move W to f

Syntax: \[
[\text{label}] \quad \text{MOVWF} \quad f
\]

Operands: \[
0 \leq f \leq 127
\]

Operation: \[
(W) \rightarrow (f)
\]

Status Affected: None

Encoding:

| 00 | 0000 | lfff | ffff |

Description: Move data from W register to register 'f'.

Words: 1
Cycles: 1

Example:

```
MOVWF OPTION
```

Before Instruction

\[
\begin{align*}
\text{OPTION} &= \text{0xFF} \\
W &= \text{0x4F}
\end{align*}
\]

After Instruction

\[
\begin{align*}
\text{OPTION} &= \text{0x4F} \\
W &= \text{0x4F}
\end{align*}
\]
### NOP
No Operation

<table>
<thead>
<tr>
<th>Syntax:</th>
<th>[ label ]    NOP</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operands:</td>
<td>None</td>
</tr>
<tr>
<td>Operation:</td>
<td>No operation</td>
</tr>
<tr>
<td>Status Affected:</td>
<td>None</td>
</tr>
<tr>
<td>Encoding:</td>
<td>00 0000 0xx0 0000</td>
</tr>
<tr>
<td>Description:</td>
<td>No operation.</td>
</tr>
<tr>
<td>Words:</td>
<td>1</td>
</tr>
<tr>
<td>Cycles:</td>
<td>1</td>
</tr>
<tr>
<td>Example:</td>
<td>NOP</td>
</tr>
</tbody>
</table>

### RETFIE
Return from Interrupt

<table>
<thead>
<tr>
<th>Syntax:</th>
<th>[ label ]    RETFIE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operands:</td>
<td>None</td>
</tr>
<tr>
<td>Operation:</td>
<td>TOS → PC, 1 → GIE</td>
</tr>
<tr>
<td>Status Affected:</td>
<td>None</td>
</tr>
<tr>
<td>Encoding:</td>
<td>00 0000 0000 1001</td>
</tr>
<tr>
<td>Description:</td>
<td>Return from Interrupt. Stack is POPed and Top of Stack (TOS) is loaded in the PC. Interrupts are enabled by setting Global Interrupt Enable bit, GIE (INTCON&lt;7&gt;). This is a two-cycle instruction.</td>
</tr>
<tr>
<td>Words:</td>
<td>1</td>
</tr>
<tr>
<td>Cycles:</td>
<td>2</td>
</tr>
<tr>
<td>Example:</td>
<td>RETFIE</td>
</tr>
</tbody>
</table>

### OPTION
Load Option Register

<table>
<thead>
<tr>
<th>Syntax:</th>
<th>[ label ]    OPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operands:</td>
<td>None</td>
</tr>
<tr>
<td>Operation:</td>
<td>(W) → OPTION</td>
</tr>
<tr>
<td>Status Affected:</td>
<td>None</td>
</tr>
<tr>
<td>Encoding:</td>
<td>00 0000 0110 0010</td>
</tr>
<tr>
<td>Description:</td>
<td>The contents of the W register are loaded in the OPTION register. This instruction is supported for code compatibility with PIC16C5X products. Since OPTION is a readable/writable register, the user can directly address it.</td>
</tr>
<tr>
<td>Words:</td>
<td>1</td>
</tr>
<tr>
<td>Cycles:</td>
<td>1</td>
</tr>
<tr>
<td>Example:</td>
<td>To maintain upward compatibility with future PICmicro® products, do not use this instruction.</td>
</tr>
</tbody>
</table>

### RETLW
Return with Literal in W

<table>
<thead>
<tr>
<th>Syntax:</th>
<th>[ label ]    RETLW   k</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operands:</td>
<td>0 ≤ k ≤ 255</td>
</tr>
<tr>
<td>Operation:</td>
<td>k → (W); TOS → PC</td>
</tr>
<tr>
<td>Status Affected:</td>
<td>None</td>
</tr>
<tr>
<td>Encoding:</td>
<td>11 01xx kkkk kkkk</td>
</tr>
<tr>
<td>Description:</td>
<td>The W register is loaded with the eight bit literal 'k'. The program counter is loaded from the top of the stack (the return address). This is a two-cycle instruction.</td>
</tr>
<tr>
<td>Words:</td>
<td>1</td>
</tr>
<tr>
<td>Cycles:</td>
<td>2</td>
</tr>
<tr>
<td>Example:</td>
<td>CALL TABLE ;W contains table</td>
</tr>
<tr>
<td></td>
<td>;offset value</td>
</tr>
<tr>
<td></td>
<td>;W now has table value</td>
</tr>
<tr>
<td></td>
<td>TABLE</td>
</tr>
<tr>
<td></td>
<td>ADDWF PC ;W = offset</td>
</tr>
<tr>
<td></td>
<td>RETLW k1 ;Begin table</td>
</tr>
<tr>
<td></td>
<td>RETLW k2 ;</td>
</tr>
<tr>
<td></td>
<td>·</td>
</tr>
<tr>
<td></td>
<td>·</td>
</tr>
<tr>
<td></td>
<td>·</td>
</tr>
<tr>
<td></td>
<td>RETLW kn ; End of table</td>
</tr>
<tr>
<td>Before Instruction</td>
<td>W = 0x07</td>
</tr>
<tr>
<td>After Instruction</td>
<td>W = value of k8</td>
</tr>
</tbody>
</table>
**RETURN**

Return from Subroutine

**Syntax:**

```
[label]  RETURN
```

**Operands:**

None

**Operation:**

TOS → PC

**Status Affected:**

None

**Encoding:**

```
00 0000 0000 1000
```

**Description:**

Return from subroutine. The stack is POPed and the top of the stack (TOS) is loaded into the program counter. This is a two cycle instruction.

**Words:**

1

**Cycles:**

2

**Example**

RETURN

After Interrupt

PC = TOS

---

**RLF**

Rotate Left f through Carry

**Syntax:**

```
[label]  RLF  f,d
```

**Operands:**

0 ≤ f ≤ 127

d ∈ [0,1]

**Operation:**

See description below

**Status Affected:**

C

**Encoding:**

```
00 1101 dfff ffff
```

**Description:**

The contents of register 'f' are rotated one bit to the left through the Carry Flag. If 'd' is 0 the result is placed in the W register. If 'd' is 1 the result is stored back in register 'f'.

**Words:**

1

**Cycles:**

1

**Example**

RLF REG1,0

Before Instruction

REG1 = 1110 0110
C = 0

After Instruction

REG1 = 1110 0110
W = 0111 0011
C = 0

---

**RRF**

Rotate Right f through Carry

**Syntax:**

```
[label]  RRF  f,d
```

**Operands:**

0 ≤ f ≤ 127

d ∈ [0,1]

**Operation:**

See description below

**Status Affected:**

C

**Encoding:**

```
00 1100 dfff ffff
```

**Description:**

The contents of register 'f' are rotated one bit to the right through the Carry Flag. If 'd' is 0 the result is placed back in register 'f'.

**Words:**

1

**Cycles:**

1

**Example**

RRF REG1,0

Before Instruction

REG1 = 1110 0110
C = 0

After Instruction

REG1 = 1110 0110
W = 0111 0011
C = 0

---

**SLEEP**

**Syntax:**

```
[label]  SLEEP
```

**Operands:**

None

**Operation:**

00h → WDT,

0 → WDT prescaler,

1 → TO,

0 → PD

**Status Affected:**

TO, PD

**Encoding:**

```
00 0000 0110 0011
```

**Description:**

The power-down status bit, PD is cleared. Time-out status bit, TO is set. Watchdog Timer and its prescaler are cleared. The processor is put into SLEEP mode with the oscillator stopped. See Section 14.9 for more details.

**Words:**

1

**Cycles:**

1

**Example**

SLEEP

---
### SUBLW

**Subtract W from Literal**

- **Syntax:** `[ label ] SUBLW k
- **Operands:** 0 ≤ k ≤ 255
- **Operation:** k - (W) → (W)
- **Status Affected:** C, DC, Z
- **Encoding:** 11 110x kkkk kkkk
- **Description:** The W register is subtracted (2's complement method) from the eight bit literal 'k'. The result is placed in the W register.

<table>
<thead>
<tr>
<th>Words:</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cycles:</td>
<td>1</td>
</tr>
</tbody>
</table>

**Example 1:**

**Before Instruction**

- W = 1
- C = ?

**After Instruction**

- W = 1
- C = 1; result is positive

**Example 2:**

**Before Instruction**

- W = 2
- C = ?

**After Instruction**

- W = 0
- C = 1; result is zero

**Example 3:**

**Before Instruction**

- W = 3
- C = ?

**After Instruction**

- W = 0xFF
- C = 0; result is negative

---

### SUBWF

**Subtract W from f**

- **Syntax:** `[ label ] SUBWF f,d
- **Operands:** 0 ≤ f ≤ 127
d ∈ [0,1]
- **Operation:** (f) - (W) → (dest)
- **Status Affected:** C, DC, Z
- **Encoding:** 00 0010 dfff ffff
- **Description:** Subtract (2's complement method) W register from register 'f'. If 'd' is 0 the result is stored in the W register. If 'd' is 1 the result is stored back in register 'f'.

<table>
<thead>
<tr>
<th>Words:</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cycles:</td>
<td>1</td>
</tr>
</tbody>
</table>

**Example 1:**

**Before Instruction**

- REG1 = 3
- W = 2
- C = ?

**After Instruction**

- REG1 = 1
- W = 2
- C = 1; result is positive

**Example 2:**

**Before Instruction**

- REG1 = 2
- W = 2
- C = ?

**After Instruction**

- REG1 = 0
- W = 2
- C = 1; result is zero

**Example 3:**

**Before Instruction**

- REG1 = 1
- W = 2
- C = ?

**After Instruction**

- REG1 = 0xFF
- W = 2
- C = 0; result is negative
**SWAPF**

Swap Nibbles in f

Syntax:  
\[
\text{[ label]} \text{ SWAPF } f,d
\]

Operands:  
\[
0 \leq f \leq 127  \\
\text{d} \in [0,1]
\]

Operation:  
\[
(f<3:0>) \rightarrow (\text{dest}<7:4>)  \\
(f<7:4>) \rightarrow (\text{dest}<3:0>)
\]

Status Affected: None

Encoding:  
\[
00 1110 \text{ dfff ffff}
\]

Description: The upper and lower nibbles of register 'f' are exchanged. If 'd' is 0 the result is placed in W register. If 'd' is 1 the result is placed in register 'f'.

Words: 1  
Cycles: 1

Example:  
\[
\text{SWAPF REG, 0}
\]

Before Instruction
\[
\text{REG}1 = 0xA5
\]

After Instruction
\[
\text{REG}1 = 0xA5  \\
\text{W} = 0x5A
\]

---

**TRIS**

Load TRIS Register

Syntax:  
\[
\text{[ label]} \text{ TRIS } f
\]

Operands:  
\[
5 \leq f \leq 7
\]

Operation:  
\[
(W) \rightarrow \text{TRIS register } f;
\]

Status Affected: None

Encoding:  
\[
00 0000 0110 0fff
\]

Description: The instruction is supported for code compatibility with the PIC16C5X products. Since TRIS registers are readable and writable, the user can directly address them.

Words: 1  
Cycles: 1

Example:  
To maintain upward compatibility with future PICmicro® products, do not use this instruction.

---

**SWAPF**

**XORLW**

Exclusive OR Literal with W

Syntax:  
\[
\text{[ label]} \text{ XORLW } k
\]

Operands:  
\[
0 \leq k \leq 255
\]

Operation:  
\[
(W) .XOR. k \rightarrow (W)
\]

Status Affected: Z

Encoding:  
\[
11 1010 \text{ kkkk kkkk}
\]

Description: The contents of the W register are XOR'ed with the eight bit literal 'k'. The result is placed in the W register.

Words: 1  
Cycles: 1

Example:  
\[
\text{XORLW 0xAF}
\]

Before Instruction
\[
\text{W} = 0xB5
\]

After Instruction
\[
\text{W} = 0x1A
\]

---

**SWAPF**

**XORWF**

Exclusive OR W with f

Syntax:  
\[
\text{[ label]} \text{ XORWF } f,d
\]

Operands:  
\[
0 \leq f \leq 127  \\
\text{d} \in [0,1]
\]

Operation:  
\[
(W) .XOR. (f) \rightarrow (\text{dest})
\]

Status Affected: Z

Encoding:  
\[
00 0110 \text{ dfff ffff}
\]

Description: Exclusive OR the contents of the W register with register 'f'. If 'd' is 0 the result is stored in the W register. If 'd' is 1 the result is stored back in register 'f'.

Words: 1  
Cycles: 1

Example:  
\[
\text{XORWF REG 1}
\]

Before Instruction
\[
\text{REG} = 0xAF  \\
\text{W} = 0xB5
\]

After Instruction
\[
\text{REG} = 0x1A  \\
\text{W} = 0xB5
\]
16.0 DEVELOPMENT SUPPORT

The PICmicro® microcontrollers are supported with a full range of hardware and software development tools:

- Integrated Development Environment
  - MPLAB™ IDE Software
- Assemblers/ Compilers/ Linkers
  - MPASM Assembler
  - MPLAB-C17 and MPLAB-C18 C Compilers
  - MPLINK/MPLIB Linker/Librarian
- Simulators
  - MPLAB-SIM Software Simulator
- Emulators
  - MPLAB-ICE Real-Time In-Circuit Emulator
  - PICMASTER®/PICMASTER-CE In-Circuit Emulator
  - ICEPIC™
- In-Circuit Debugger
  - MPLAB-ICD for PIC16F877
- Device Programmers
  - PRO MATE® II Universal Programmer
  - PICSTART® Plus Entry-Level Prototype Programmer
- Low-Cost Demonstration Boards
  - Simice
  - PICDEM-1
  - PICDEM-2
  - PICDEM-3
  - PICDEM-17
  - SEEVAL®
  - KEELQ®

16.1 MPLAB Integrated Development Environment Software

- The MPLAB IDE software brings an ease of software development previously unseen in the 8-bit microcontroller market. MPLAB is a Windows®-based application which contains:
  - Multiple functionality
    - editor
    - simulator
    - programmer (sold separately)
    - emulator (sold separately)
  - A full featured editor
  - A project manager
  - Customizable tool bar and key mapping
  - A status bar
  - On-line help

MPLAB allows you to:

- Edit your source files (either assembly or ‘C’)
- One touch assemble (or compile) and download to PICmicro tools (automatically updates all project information)
- Debug using:
  - source files
  - absolute listing file
  - object code

The ability to use MPLAB with Microchip’s simulator, MPLAB-SIM, allows a consistent platform and the ability to easily switch from the cost-effective simulator to the full featured emulator with minimal retraining.

16.2 MPASM Assembler

MPASM is a full featured universal macro assembler for all PICmicro MCU’s. It can produce absolute code directly in the form of HEX files for device programmers, or it can generate relocatable objects for MPLINK.

MPASM has a command line interface and a Windows shell and can be used as a standalone application on a Windows 3.x or greater system. MPASM generates relocatable object files, Intel standard HEX files, MAP files to detail memory usage and symbol reference, an absolute LST file which contains source lines and generated machine code, and a COD file for MPLAB debugging.

MPASM features include:

- MPASM and MPLINK are integrated into MPLAB projects.
- MPASM allows user defined macros to be created for streamlined assembly.
- MPASM allows conditional assembly for multi purpose source files.
- MPASM directives allow complete control over the assembly process.

16.3 MPLAB-C17 and MPLAB-C18 C Compilers

The MPLAB-C17 and MPLAB-C18 Code Development Systems are complete ANSI ‘C’ compilers and integrated development environments for Microchip’s PIC17CXXX and PIC18CXXX family of microcontrollers, respectively. These compilers provide powerful integration capabilities and ease of use not found with other compilers.

For easier source level debugging, the compilers provide symbol information that is compatible with the MPLAB IDE memory display.
16.4 MPLINK/MPLIB Linker/Librarian

MPLINK is a relocatable linker for MPASM and MPLAB-C17 and MPLAB-C18. It can link relocatable objects from assembly or C source files along with pre-compiled libraries using directives from a linker script. MPLIB is a librarian for pre-compiled code to be used with MPLINK. When a routine from a library is called from another source file, only the modules that contains that routine will be linked in with the application. This allows large libraries to be used efficiently in many different applications. MPLIB manages the creation and modification of library files.

MPLINK features include:
• MPLINK works with MPASM and MPLAB-C17 and MPLAB-C18.
• MPLINK allows all memory areas to be defined as sections to provide link-time flexibility.

MPLIB features include:
• MPLIB makes linking easier because single libraries can be included instead of many smaller files.
• MPLIB helps keep code maintainable by grouping related modules together.
• MPLIB commands allow libraries to be created and modules to be added, listed, replaced, deleted, or extracted.

16.5 MPLAB-SIM Software Simulator

The MPLAB-SIM Software Simulator allows code development in a PC host environment by simulating the PICmicro series microcontrollers on an instruction level. On any given instruction, the data areas can be examined or modified and stimuli can be applied from a file or user-defined key press to any of the pins. The execution can be performed in single step, execute until break, or trace mode.

MPLAB-SIM fully supports symbolic debugging using MPLAB-C17 and MPLAB-C18 and MPASM. The Software Simulator offers the flexibility to develop and debug code outside of the laboratory environment making it an excellent multi-project software development tool.

16.6 MPLAB-ICE High Performance Universal In-Circuit Emulator with MPLAB IDE

The MPLAB-ICE Universal In-Circuit Emulator is intended to provide the product development engineer with a complete microcontroller design tool set for PICmicro microcontrollers (MCUs). Software control of MPLAB-ICE is provided by the MPLAB Integrated Development Environment (IDE), which allows editing, “make” and download, and source debugging from a single environment.

Interchangeable processor modules allow the system to be easily reconfigured for emulation of different processors. The universal architecture of the MPLAB-ICE allows expansion to support new PICmicro microcontrollers.

The MPLAB-ICE Emulator System has been designed as a real-time emulation system with advanced features that are generally found on more expensive development tools. The PC platform and Microsoft® Windows 3.x/95/98 environment were chosen to best make these features available to you, the end user.

MPLAB-ICE 2000 is a full-featured emulator system with enhanced trace, trigger, and data monitoring features. Both systems use the same processor modules and will operate across the full operating speed range of the PICmicro MCU.

16.7 PICMASTER/PICMASTER CE

The PICMASTER system from Microchip Technology is a full-featured, professional quality emulator system. This flexible in-circuit emulator provides a high-quality, universal platform for emulating Microchip 8-bit PICmicro microcontrollers (MCUs). PICMASTER systems are sold worldwide, with a CE compliant model available for European Union (EU) countries.

16.8 ICEPIC

ICEPIC is a low-cost in-circuit emulation solution for the Microchip Technology PIC16C5X, PIC16C6X, PIC16C7X, and PIC16CXXX families of 8-bit one-time-programmable (OTP) microcontrollers. The modular system can support different subsets of PIC16C5X or PIC16CXXX products through the use of interchangeable personality modules or daughter boards. The emulator is capable of emulating without target application circuitry being present.

16.9 MPLAB-ICD In-Circuit Debugger

Microchip's In-Circuit Debugger, MPLAB-ICD, is a powerful, low-cost run-time development tool. This tool is based on the flash PIC16F877 and can be used to develop for this and other PICmicro microcontrollers from the PIC16CXXX family. MPLAB-ICD utilizes the In-Circuit Debugging capability built into the PIC16F87X. This feature, along with Microchip's In-Circuit Serial Programming protocol, offers cost-effective in-circuit flash programming and debugging from the graphical user interface of the MPLAB Integrated Development Environment. This enables a designer to develop and debug source code by watching variables, single-stepping and setting break points. Running at full speed enables testing hardware in real-time. The MPLAB-ICD is also a programmer for the flash PIC16F87X family.
16.10 **PRO MATE II Universal Programmer**

The PRO MATE II Universal Programmer is a full-featured programmer capable of operating in stand-alone mode as well as PC-hosted mode. PRO MATE II is CE compliant.

The PRO MATE II has programmable Vdd and VPP supplies which allows it to verify programmed memory at Vdd min and Vdd max for maximum reliability. It has an LCD display for instructions and error messages, keys to enter commands and a modular detachable socket assembly to support various package types. In stand-alone mode the PRO MATE II can read, verify or program PICmicro devices. It can also set code-protect bits in this mode.

16.11 **PICSTART Plus Entry Level Development System**

The PICSTART programmer is an easy-to-use, low-cost prototype programmer. It connects to the PC via one of the COM (RS-232) ports. MPLAB Integrated Development Environment software makes using the programmer simple and efficient.

PICSTART Plus supports all PICmicro devices with up to 40 pins. Larger pin count devices such as the PIC16C92X, and PIC17C76X may be supported with an adapter socket. PICSTART Plus is CE compliant.

16.12 **SIMICE Entry-Level Hardware Simulator**

SIMICE is an entry-level hardware development system designed to operate in a PC-based environment with Microchip’s simulator MPLAB-SIM. Both SIMICE and MPLAB-SIM run under Microchip Technology’s MPLAB Integrated Development Environment (IDE) software. Specifically, SIMICE provides hardware simulation for Microchip’s PIC12C5XX, PIC12C65XX, and PIC16C5X families of PICmicro 8-bit microcontrollers.

SIMICE works in conjunction with MPLAB-SIM to provide non-real-time I/O port emulation. SIMICE enables a developer to run simulator code for driving the target system. In addition, the target system can provide input to the simulator code. This capability allows for simple and interactive debugging without having to manually generate MPLAB-SIM stimulus files. SIMICE is a valuable debugging tool for entry-level system development.

16.13 **PICDEM-1 Low-Cost PICmicro Demonstration Board**

The PICDEM-1 is a simple board which demonstrates the capabilities of several of Microchip’s microcontrollers. The microcontrollers supported are: PIC16C5X (PIC16C54 to PIC16C58A), PIC16C61, PIC16C62X, PIC16C71, PIC16C8X, PIC17C42, PIC17C43 and PIC17C44. All necessary hardware and software is included to run basic demo programs. The users can program the sample microcontrollers provided with the PICDEM-1 board, on a PRO MATE II or PICSTART-Plus programmer, and easily test firmware. The user can also connect the PICDEM-1 board to the MPLAB-ICE emulator and download the firmware to the emulator for testing. Additional prototype area is available for the user to build some additional hardware and connect it to the microcontroller socket(s). Some of the features include an RS-232 interface, a potentiometer for simulated analog input, push-button switches and eight LEDs connected to PORTB.

16.14 **PICDEM-2 Low-Cost PIC16CXX Demonstration Board**

The PICDEM-2 is a simple demonstration board that supports the PIC16C62, PIC16C64, PIC16C65, PIC16C73 and PIC16C74 microcontrollers. All the necessary hardware and software is included to run the basic demonstration programs. The user can program the sample microcontrollers provided with the PICDEM-2 board, on a PRO MATE II programmer or PICSTART-Plus, and easily test firmware. The MPLAB-ICE emulator may also be used with the PICDEM-2 board to test firmware. Additional prototype area has been provided to the user for adding additional hardware and connecting it to the microcontroller socket(s). Some of the features include a RS-232 interface, push-button switches, a potentiometer for simulated analog input, a Serial EEPROM to demonstrate usage of the I²C bus and separate headers for connection to an LCD module and a keypad.

16.15 **PICDEM-3 Low-Cost PIC16CXXX Demonstration Board**

The PICDEM-3 is a simple demonstration board that supports the PIC16C923 and PIC16C924 in the PLCC package. It will also support future 44-pin PLCC microcontrollers with a LCD module. All the necessary hardware and software is included to run the basic demonstration programs. The user can program the sample microcontrollers provided with the PICDEM-3 board, on a PRO MATE II programmer or PICSTART Plus with an adapter socket, and easily test firmware. The MPLAB-ICE emulator may also be used with the PICDEM-3 board to test firmware. Additional prototype area has been provided to the user for adding hardware and connecting it to the microcontroller socket(s). Some of the features include an RS-232 interface, push-button switches, a potentiometer for simulated analog input, a thermistor and separate headers for connection to an external LCD module and a keypad. Also provided on the PICDEM-3 board is an LCD panel, with 4 commons and 12 segments, that is capable of displaying time, temperature and day of the week. The PICDEM-3 provides an additional RS-232 interface and Windows 3.1 software for showing the demultiplexed LCD signals on a PC. A simple serial interface allows the user to construct a hardware demultiplexer for the LCD signals.
16.16 PICDEM-17

The PICDEM-17 is an evaluation board that demonstrates the capabilities of several Microchip microcontrollers, including PIC17C752, PIC17C756, PIC17C762, and PIC17C766. All necessary hardware is included to run basic demo programs, which are supplied on a 3.5-inch disk. A programmed sample is included, and the user may erase it and program it with the other sample programs using the PRO MATE II or PICSTART Plus device programmers and easily debug and test the sample code. In addition, PICDEM-17 supports down-loading of programs to and executing out of external FLASH memory on board. The PICDEM-17 is also usable with the MPLAB-ICE or PICMASTER emulator, and all of the sample programs can be run and modified using either emulator. Additionally, a generous prototype area is available for user hardware.

16.17 SEEVAL Evaluation and Programming System

The SEEVAL SEEPROM Designer's Kit supports all Microchip 2-wire and 3-wire Serial EEPROMs. The kit includes everything necessary to read, write, erase or program special features of any Microchip SEEPROM product including Smart Serials™ and secure serials. The Total Endurance™ Disk is included to aid in trade-off analysis and reliability calculations. The total kit can significantly reduce time-to-market and result in an optimized system.

16.18 KeeLOO Evaluation and Programming Tools

KeeLOO evaluation and programming tools support Microchips HCS Secure Data Products. The HCS evaluation kit includes an LCD display to show changing codes, a decoder to decode transmissions, and a programming interface to program test transmitters.

17.0 ELECTRICAL SPECIFICATIONS

Absolute Maximum Ratings †
Ambient temperature under bias.................................................................................................................. -40 to +125°C
Storage temperature ........................................................................................................................................... -65°C to +150°C
Voltage on VDD with respect to VSS ........................................................................................................... -0.3 to +6.5V
Voltage on MCLR and RA4 with respect to VSS .................................................................................. -0.3 to +14V
Voltage on all other pins with respect to VSS ..................................................................................... -0.3V to VDD + 0.3V
Total power dissipation (Note 1) ........................................................................................................ 800 mW
Maximum current out of VSS pin ............................................................................................................. 300 mA
Maximum current into VDD pin .............................................................................................................. 250 mA
Input clamp current, IIL (VI < 0 or VI > VDD) .......................................................................................... ± 20 mA
Output clamp current, IOL (VO < 0 or VO > VDD) .................................................................................... ± 20 mA
Maximum output current sunk by any I/O pin .................................................................................... 25 mA
Maximum output current sourced by any I/O pin .................................................................................. 25 mA
Maximum current sunk by PORTA and PORTB .................................................................................... 200 mA
Maximum current sourced by PORTA and PORTB ............................................................................... 200 mA

Note 1: Power dissipation is calculated as follows: Pdis = VDD x (IDD - Σ IOH) + Σ ((VDD-VOH) x IOH) + Σ (VOH x IOL)

† NOTICE: Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at those or any other conditions above those indicated in the operation listings of this specification is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.

Note: Voltage spikes below VSS at the MCLR pin, inducing currents greater than 80 mA, may cause latch-up. Thus, a series resistor of 50-100Ω should be used when applying a "low" level to the MCLR pin rather than pulling this pin directly to Vss.

* These parameters are characterized but not tested.
† Data in “Typ” column is at 5.0V, 25°C, unless otherwise stated. These parameters are for design guidance only and are not tested.

**Note 1:** This is the limit to which VDD can be lowered in SLEEP mode without losing RAM data.

**Note 2:** The supply current is mainly a function of the operating voltage and frequency. Other factors such as I/O pin loading and switching rate, oscillator type, internal code execution pattern, and temperature also have an impact on the current consumption.

The test conditions for all Idd measurements in active operation mode are:

- OSC1 = external square wave, from rail to rail; all I/O pins tri-stated, pulled to Vdd,
- MCLR = Vdd; WDT enabled/disabled as specified.

**Note 3:** The power down current in SLEEP mode does not depend on the oscillator type. Power down current is measured with the part in SLEEP mode, with all I/O pins in hi-impedance state and tied to VDD or VSS.

**Note 4:** The Δ current is the additional current consumed when this peripheral is enabled. This current should be added to the base Idd or IPD measurement.

**Note 5:** For RC osc configuration, current through Rext is not included. The current through the resistor can be estimated by the formula Ir = Vdd/2Rext (mA) with Rext in kΩ.
### 17.2 DC CHARACTERISTICS: PIC16LF62X-04 (Commercial, Industrial, Extended)

**Standard Operating Conditions (unless otherwise stated)**
- Operating temperature: $-40°C \leq T_A \leq +85°C$ for industrial and $0°C \leq T_A \leq +70°C$ for commercial and $-40°C \leq T_A \leq +125°C$ for extended
- Operating voltage $V_{DD}$ range as described in DC spec Table 17.1 and Table 12-2

* These parameters are characterized but not tested.
† Data in “Typ” column is at 5.0V, 25°C, unless otherwise stated. These parameters are for design guidance only and are not tested.

**Note 1:**
This is the limit to which $V_{DD}$ can be lowered in SLEEP mode without losing RAM data.

**Note 2:**
The supply current is mainly a function of the operating voltage and frequency. Other factors such as I/O pin loading and switching rate, oscillator type, internal code execution pattern, and temperature also have an impact on the current consumption.

The test conditions for all IDD measurements in active operation mode are:
- OSC1 = external square wave, from rail to rail; all I/O pins tristated, pulled to $V_{DD}$;
- MCLR = $V_{DD}$; WDT enabled/disabled as specified.

**Note 3:**
The power down current in SLEEP mode does not depend on the oscillator type. Power down current is measured with the part in SLEEP mode, with all I/O pins in hi-impedance state and tied to $V_{DD}$ or Vss.

**Note 4:**
The $\Delta I$ current is the additional current consumed when this peripheral is enabled. This current should be added to the base $I_{DD}$ or $I_{PD}$ measurement.

**Note 5:**
For RC osc configuration, current through $R_{ext}$ is not included. The current through the resistor can be estimated by the formula $I_r = V_{DD}/2R_{ext}$ (mA) with $R_{ext}$ in kΩ.
### DC CHARACTERISTICS: PIC16F62X (Commercial, Industrial, Extended) PIC16LF62X (Commercial, Industrial, Extended)

- **Standard Operating Conditions (unless otherwise stated):**
  - Operating temperature: $-40°C \leq TA \leq +85°C$ for industrial and $0°C \leq TA \leq +70°C$ for commercial and $-40°C \leq TA \leq +125°C$ for extended.
  - Operating voltage $V_{DD}$ range as described in DC specs Table 17.1 and Table 12-2.

#### Param. No. | Sym | Characteristic | Min | Typ† | Max | Unit | Conditions
--- | --- | --- | --- | --- | --- | --- | ---
| | | | | | | | |
| VIL | Input Low Voltage | I/O ports | Vss | - | 0.8V | V | $V_{DD} = 4.5V$ to $5.5V$ |
| | | with TTL buffer | | | 0.15V$DD$ | | otherwise |
| | | with Schmitt Trigger input | Vss | | 0.2V$DD$ | V | |
| | | MCLR, RA4/T0CKI, OSC1 (in ER mode) | Vss | | - | 0.2V$DD$ | V | Note1 |
| | | OSC1 (in XT and HS) | Vss | | - | 0.3V$DD$ | V | |
| | | OSC1 (in LP) | Vss | | - | 0.6V$DD$-1.0V | V | |
| VH | Input High Voltage | I/O ports | 2.0V | - | V$DD$ | V | $V_{DD} = 4.5V$ to $5.5V$ |
| | | with TTL buffer | | | 0.25V$DD$ + 0.8V | V$DD$ | otherwise |
| | | with Schmitt Trigger input | 0.8V$DD$ | - | V$DD$ | V$DD$ | |
| | | MCLR RA4/T0CKI | 0.8V$DD$ | - | V$DD$ | V$DD$ | |
| | | OSC1 (XT, HS and LP) | 0.7V$DD$ | - | V$DD$ | V$DD$ | |
| | | OSC1 (in ER mode) | 0.9V$DD$ | - | V$DD$ | V$DD$ | |
| | | Note1 | | | | | |
| D070 | IPURB | PORTB weak pull-up current | 50 | 200 | 400 | µA | $V_{DD} = 5.0V$, $V_{PIN} = V_{SS}$ |
| IIL | Input Leakage Current | I/O ports (Except PORTA) | | | ±1.0 | µA | $V_{SS} \leq V_{PIN} \leq V_{DD}$, pin at hi-impedance |
| | | PORTA | | | ±0.5 | µA | $V_{SS} \leq V_{PIN} \leq V_{DD}$, pin at hi-impedance |
| | | RA4/T0CKI | | | ±1.0 | µA | $V_{SS} \leq V_{PIN} \leq V_{DD}$ |
| | | OSC1, MCLR | | | ±5.0 | µA | $V_{SS} \leq V_{PIN} \leq V_{DD}$, XT, HS and LP osc configuration |
| VOL | Output Low Voltage | I/O ports | - | - | 0.6 | V | $I_{OL}=8.5\ mA$, $V_{DD}=4.5V$, $-40^\circ$ to $+85^\circ$C |
| | | OSC2/CLKOUT (ER only) | - | - | 0.6 | V | $I_{OL}=7.0\ mA$, $V_{DD}=4.5V$, $+125^\circ$C |
| VOH | Output High Voltage (Note 3) | I/O ports (Except RA4) | V$DD$-0.7 | - | - | V | $I_{OH}=3.0\ mA$, $V_{DD}=4.5V$, $-40^\circ$ to $+85^\circ$C |
| | | OSC2/CLKOUT (ER only) | V$DD$-0.7 | - | - | V | $I_{OH}=2.5\ mA$, $V_{DD}=4.5V$, $+125^\circ$C |
| | | Note1 | | | | | |
| *D150 | VOD | Open-Drain High Voltage | - | | 8.5* | V | RA4 pin PIC16F62X, PIC16LF62X |
| | | Capacitive Loading Specs on Output Pins | | | | | |
| | | OSC2 pin | - | 15 | pF | | In XT, HS and LP modes when external clock used to drive OSC1 |
| | | All I/O pins/OSC2 (in ER mode) | - | 50 | pF | | |

* These parameters are characterized but not tested.
† Data in "Typ" column is at $5.0V$, $25^\circ$C unless otherwise stated. These parameters are for design guidance only and are not tested.

**Note 1:** In ER oscillator configuration, the OSC1 pin is a Schmitt Trigger input. It is not recommended that the PIC16F62X be driven with external clock in ER mode.

**Note 2:** The leakage current on the MCLR pin is strongly dependent on applied voltage level. The specified levels represent normal operating conditions. Higher leakage current may be measured at different input voltages.

**Note 3:** Negative current is defined as coming out of the pin.

<td>PIC16F627-04I / 218 9951 CBP</td>
</tr>
</tbody>
</table>

**Legend:**
- MM...M: Microchip part number information
- XX...X: Customer specific information*
- AA: Year code (last 2 digits of calendar year)
- BB: Week code (week of January 1 is week '01')
- C: Facility code of the plant at which wafer is manufactured
  - O = Outside Vendor
  - C = 5" Line
  - S = 6" Line
  - H = 8" Line
- D: Mask revision number
- E: Assembly code of the plant or country of origin in which part was assembled

**Note:** In the event the full Microchip part number cannot be marked on one line, it will be carried over to the next line thus limiting the number of available characters for customer specific information.

*Standard OTP marking consists of Microchip part number, year code, week code, facility code, mask rev#, and assembly code. For OTP marking beyond this, certain price adders apply. Please check with your Microchip Sales Office. For QTP devices, any special marking adders are included in QTP price.
**Package Type:** K04-007 18-Lead Plastic Dual In-line (P) – 300 mil

ON-LINE SUPPORT

Microchip provides on-line support on the Microchip World Wide Web (WWW) site.
The web site is used by Microchip as a means to make files and information easily available to customers. To view the site, the user must have access to the Internet and a web browser, such as Netscape or Microsoft Explorer. Files are also available for FTP download from our FTP site.

Connecting to the Microchip Internet Web Site

The Microchip web site is available by using your favorite Internet browser to attach to:

www.microchip.com

The file transfer site is available by using an FTP service to connect to:

ftp://ftp.microchip.com

The web site and file transfer site provide a variety of services. Users may download files for the latest Development Tools, Data Sheets, Application Notes, User’s Guides, Articles and Sample Programs. A variety of Microchip specific business information is also available, including listings of Microchip sales offices, distributors and factory representatives. Other data available for consideration is:

• Latest Microchip Press Releases
• Technical Support Section with Frequently Asked Questions
• Design Tips
• Device Errata
• Job Postings
• Microchip Consultant Program Member Listing
• Links to other useful web sites related to Microchip Products
• Conferences for products, Development Systems, technical information and more
• Listing of seminars and events

Systems Information and Upgrade Hot Line

The Systems Information and Upgrade Line provides system users a listing of the latest versions of all of Microchip’s development systems software products. Plus, this line provides information on how customers can receive any currently available upgrade kits. The Hot Line Numbers are:
1-800-755-2345 for U.S. and most of Canada, and
1-602-786-7302 for the rest of the world.

Trademarks: The Microchip name, logo, PIC, PICmicro, PICSTART, PICMASTER and PRO MATE are registered trademarks of Microchip Technology Incorporated in the U.S.A. and other countries. FlexROM, MPLAB and fuzzy-LAB are trademarks and SQTP is a service mark of Microchip in the U.S.A.

All other trademarks mentioned herein are the property of their respective companies.
READER RESPONSE

It is our intention to provide you with the best documentation possible to ensure successful use of your Microchip product. If you wish to provide your comments on organization, clarity, subject matter, and ways in which our documentation can better serve you, please FAX your comments to the Technical Publications Manager at (602) 786-7578.

Please list the following information, and use this outline to provide us with your comments about this Data Sheet.

To: Technical Publications Manager  Total Pages Sent
RE: Reader Response
From: Name ________________________________________________
Company ________________________________________________
Address ________________________________________________
City / State / ZIP / Country _________________________________
Telephone: (______) _________ - _________  FAX: (_____ ) _________ - _________

Application (optional):

Would you like a reply?  ____ Y ____ N

Device: PIC16F62X  Literature Number: DS40300B

Questions:

1. What are the best features of this document?
   _________________________________________________________

2. How does this document meet your hardware and software development needs?
   _________________________________________________________

3. Do you find the organization of this data sheet easy to follow? If not, why?
   _________________________________________________________

4. What additions to the data sheet do you think would enhance the structure and subject?
   _________________________________________________________

5. What deletions from the data sheet could be made without affecting the overall usefulness?
   _________________________________________________________

6. Is there any incorrect or misleading information (what and where)?
   _________________________________________________________

7. How would you improve this document?
   _________________________________________________________

8. How would you improve our software, systems, and silicon products?
   _________________________________________________________
## PIC16F62X PRODUCT IDENTIFICATION SYSTEM

To order or to obtain information, e.g., on pricing or delivery, please use the listed part numbers, and refer to the factory or the listed sales offices.

### Examples:
- g) PIC16F627 - 04/P 301 = Commercial temp., PDIP package, 4 MHz, normal VDD limits, QTP pattern #301.
- h) PIC16LF627- 04/SO = Industrial temp., SOIC package, 200kHz, extended VDD limits.

### Sales and Support

**Data Sheets**

Products supported by a preliminary Data Sheet may have an errata sheet describing minor operational differences and recommended workarounds. To determine if an errata sheet exists for a particular device, please contact one of the following:

1. Your local Microchip sales office
2. The Microchip Corporate Literature Center U.S. FAX: (602) 786-7277
3. The Microchip Worldwide Site (www.microchip.com)

Please specify which device, revision of silicon and Data Sheet (include Literature #) you are using.

**New Customer Notification System**

Register on our web site (www.microchip.com/cn) to receive the most current information on our products.
Note the following details of the code protection feature on PICmicro® MCUs.

- The PICmicro family meets the specifications contained in the Microchip Data Sheet.
- Microchip believes that its family of PICmicro microcontrollers is one of the most secure products of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the PICmicro microcontroller in a manner outside the operating specifications contained in the data sheet. The person doing so may be engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as "unbreakable".
- Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our product.

If you have any further questions about this matter, please contact the local sales office nearest to you.

Information contained in this publication regarding device applications and the like is intended through suggestion only and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. No representation or warranty is given and no liability is assumed by Microchip Technology Incorporated with respect to the accuracy or use of such information, or infringement of patents or other intellectual property rights arising from such use or otherwise. Use of Microchip’s products as critical components in life support systems is not authorized except with express written approval by Microchip. No licenses are conveyed, implicitly or otherwise, under any intellectual property rights.

Trademarks
