There are two ways to ensure locality. The direct way is to invoke the special method x$ensureLocal() on the object. The other way is to modify a field explicitly by x$field <- ... It’s only necessary that one or the other of these happens once for each object, in order to trigger the shallow copy that provides locality for the references. In the example below, we show both mechanisms.

However it’s done, localization must occur before any methods make changes. (Eventually, some use of code tools should at least largely automate this process, although it may be difficult to guarantee success under arbitrary circumstances.)

John Chambers

Examples

```r
## class "myIter" has a BigData field for the real (big) data
## and a "twiddle" field for some parameters that it twiddles
## (for some reason)
myIter <- setRefClass("myIter", contains = "localRefClass",
   fields = list(BigData = "numeric", twiddle = "numeric"))

tw <- rnorm(3)
x1 <- myIter(BigData = rnorm(1000), twiddle = tw) # OK, not REALLY big

x2 <- twiddler(x1, 10)

stopifnot(identical(x1$twiddle, tw), !identical(x1$twiddle, x2$twiddle))
```
makeClassRepresentation

Create a Class Definition

Description

Constructs an object of class `classRepresentation` to describe a particular class. Mostly a utility function, but you can call it to create a class definition without assigning it, as `setClass` would do.

Usage

```
makeClassRepresentation(name, slots=list(), superClasses=character(),
                         prototype=NULL, package, validity, access,
                         version, sealed, virtual=NA, where)
```

Arguments

- **name** character string name for the class
- **slots** named list of slot classes as would be supplied to `setClass`, but without the unnamed arguments for `superClasses` if any.
- **superClasses** what classes does this class extend
- **prototype** an object providing the default data for the class, e.g, the result of a call to `prototype`.
- **package** The character string name for the package in which the class will be stored; see `getPackageName`.
- **validity** Optional validity method. See `validObject`, and the discussion of validity methods in the reference.
- **access** Access information. Not currently used.
- **version** Optional version key for version control. Currently generated, but not used.
- **sealed** Is the class sealed? See `setClass`.
- **virtual** Is this known to be a virtual class?
- **where** The environment from which to look for class definitions needed (e.g., for slots or superclasses). See the discussion of this argument under `GenericFunctions`.

`setClass`
method.skeleton

Create a Skeleton File for a New Method

Description

This function writes a source file containing a call to \texttt{setMethod} to define a method for the generic function and signature supplied. By default the method definition is in line in the call, but can be made an external (previously assigned) function.

Usage

\begin{verbatim}
method.skeleton(generic, signature, file, external = FALSE, where)
\end{verbatim}

Arguments

- \texttt{generic} the character string name of the generic function, or the generic function itself. In the first case, the function need not currently be a generic, as it would not for the resulting call to \texttt{setMethod}.
- \texttt{signature} the method signature, as it would be given to \texttt{setMethod}
- \texttt{file} a character string name for the output file, or a writable connection. By default the generic function name and the classes in the signature are concatenated, with separating underscore characters. The file name should normally end in ".R".
  To write multiple method skeletons to one file, open the file connection first and then pass it to \texttt{method.skeleton()} in multiple calls.
- \texttt{external} flag to control whether the function definition for the method should be a separate external object assigned in the source file, or included in line in the call to \texttt{setMethod}. If supplied as a character string, this will be used as the name for the external function; by default the name concatenates the generic and signature names, with separating underscores.
- \texttt{where} The environment in which to look for the function; by default, the top-level environment of the call to \texttt{method.skeleton}.

Value

The \texttt{file} argument, invisibly, but the function is used for its side effect.

See Also

\texttt{setMethod, package.skeleton}

Examples

\begin{verbatim}
setClass("track", representation(x ="numeric", y="numeric"))
method.skeleton("show", "track")  ## writes show_track.R
method.skeleton("Ops", c("track", "track"))  ## writes "Ops_track_track.R"

## write multiple method skeletons to one file
\end{verbatim}
con <- file("./Math_track.R", "w")
method.skeleton("Math", "track", con)
method.skeleton("exp", "track", con)
method.skeleton("log", "track", con)
close(con)

MethodDefinition-class

Classes to Represent Method Definitions

Description

These classes extend the basic class "function" when functions are to be stored and used as method definitions.

Details

Method definition objects are functions with additional information defining how the function is being used as a method. The target slot is the class signature for which the method will be dispatched, and the defined slot the signature for which the method was originally specified (that is, the one that appeared in some call to setMethod).

Objects from the Class

The action of setting a method by a call to setMethod creates an object of this class. It's unwise to create them directly.

The class "SealedMethodDefinition" is created by a call to setMethod with argument sealed = TRUE. It has the same representation as "MethodDefinition".

Slots

.Data: Object of class "function"; the data part of the definition.

target: Object of class "signature"; the signature for which the method was wanted.

defined: Object of class "signature"; the signature for which a method was found. If the method was inherited, this will not be identical to target.

generic: Object of class "character"; the function for which the method was created.

Extends

Class "function", from data part.
Class "PossibleMethod", directly.
Class "OptionalMethods", by class "function".
Methods

See Also
class MethodsList for the objects defining sets of methods associated with a particular
generic function. The individual method definitions stored in these objects are from class
MethodDefinition, or an extension. Class MethodWithNext for an extension used by
callNextMethod.

Description
This documentation section covers some general topics on how methods work and how the methods
package interacts with the rest of R. The information is usually not needed to get started with
methods and classes, but may be helpful for moderately ambitious projects, or when something
doesn’t work as expected.
The section “How Methods Work” describes the underlying mechanism; “S3 Methods and Generic
Functions” gives the rules applied when S4 classes and methods interact with older S3 methods;
“Method Selection and Dispatch” provides more details on how class definitions determine which
methods are used; “Generic Functions” discusses generic functions as objects. For additional infor-
mation specifically about class definitions, see Classes.

How Methods Work
A generic function has associated with it a collection of other functions (the methods), all of which
have the same formal arguments as the generic. See the “Generic Functions” section below for
more on generic functions themselves.
Each R package will include methods metadata objects corresponding to each generic function for
which methods have been defined in that package. When the package is loaded into an R session,
the methods for each generic function are cached, that is, stored in the environment of the generic
function along with the methods from previously loaded packages. This merged table of methods
is used to dispatch or select methods from the generic, using class inheritance and possibly group
generic functions (see GroupGenericFunctions) to find an applicable method. See the “Method
Selection and Dispatch” section below. The caching computations ensure that only one version of
each generic function is visible globally; although different attached packages may contain a copy
of the generic function, these behave identically with respect to method selection. In contrast, it is
possible for the same function name to refer to more than one generic function, when these have
different package slots. In the latter case, R considers the functions unrelated: A generic function
is defined by the combination of name and package. See the “Generic Functions” section below.
The methods for a generic are stored according to the corresponding signature in the call to
setMethod that defined the method. The signature associates one class name with each of a subset
of the formal arguments to the generic function. Which formal arguments are available, and the
order in which they appear, are determined by the "signature" slot of the generic function itself.
By default, the signature of the generic consists of all the formal arguments except . . . , in the order
they appear in the function definition.
Trailing arguments in the signature of the generic will be inactive if no method has yet been specified
that included those arguments in its signature. Inactive arguments are not needed or used in labeling
the cached methods. (The distinction does not change which methods are dispatched, but ignoring inactive arguments improves the efficiency of dispatch.)

All arguments in the signature of the generic function will be evaluated when the function is called, rather than using the traditional lazy evaluation rules of S. Therefore, it's important to exclude from the signature any arguments that need to be dealt with symbolically (such as the first argument to function substitute). Note that only actual arguments are evaluated, not default expressions. A missing argument enters into the method selection as class "missing".

The cached methods are stored in an environment object. The names used for assignment are a concatenation of the class names for the active arguments in the method signature.

Methods for S3 Generic Functions

S4 methods may be wanted for functions that also have S3 methods, corresponding to classes for the first formal argument of an S3 generic function–either a regular R function in which there is a call to the S3 dispatch function, UseMethod, or one of a fixed set of primitive functions, which are not true functions but go directly to C code. In either case S3 method dispatch looks at the class of the first argument or the class of either argument in a call to one of the primitive binary operators.

S3 methods are ordinary functions with the same arguments as the generic function (for primitives the formal arguments are not actually part of the object, but are simulated when the object is printed or viewed by args()). The “signature” of an S3 method is identified by the name to which the method is assigned, composed of the name of the generic function, followed by ",," , followed by the name of the class. For details, see S3Methods.

To implement a method for one of these functions corresponding to S4 classes, there are two possibilities: either an S4 method or an S3 method with the S4 class name. The S3 method is only possible if the intended signature has the first argument and nothing else. In this case, the recommended approach is to define the S3 method and also supply the identical function as the definition of the S4 method. If the S3 generic function was f3(x, ...) and the S4 class for the new method was "myClass":

f3.myClass <- function(x, ...) { ..... }

setMethod("f3", "myClass", f3.myClass)

The reasons for defining both S3 and S4 methods are as follows:

1. An S4 method alone will not be seen if the S3 generic function is called directly. However, primitive functions and operators are exceptions: The internal C code will look for S4 methods if and only if the object is an S4 object. In the examples, the method for `[` for class "myFrame" will always be called for objects of this class.

For the same reason, an S4 method defined for an S3 class will not be called from internal code for a non-S4 object. (See the example for function Math and class "data.frame" in the examples.)

2. An S3 method alone will not be called if there is any eligible non-default S4 method. (See the example for function f3 and class "classA" in the examples.)

Details of the selection computations are given below.

When an S4 method is defined for an existing function that is not an S4 generic function (whether or not the existing function is an S3 generic), an S4 generic function will be created corresponding to the existing function and the package in which it is found (more precisely, according to the implicit generic function either specified or inferred from the ordinary function; see implicitGeneric). A
message is printed after the initial call to `setMethod`; this is not an error, just a reminder that you have created the generic. Creating the generic explicitly by the call

```
setGeneric("f3")
```

avoids the message, but has the same effect. The existing function becomes the default method for the S4 generic function. Primitive functions work the same way, but the S4 generic function is not explicitly created (as discussed below).

S4 and S3 method selection are designed to follow compatible rules of inheritance, as far as possible. S3 classes can be used for any S4 method selection, provided that the S3 classes have been registered by a call to `setOldClass`, with that call specifying the correct S3 inheritance pattern. S4 classes can be used for any S3 method selection; when an S4 object is detected, S3 method selection uses the contents of `extends(class(x))` as the equivalent of the S3 inheritance (the inheritance is cached after the first call).

An existing S3 method may not behave as desired for an S4 subclass, in which case utilities such as `asS3` and `S3Part` may be useful. If the S3 method fails on the S4 object, `asS3(x)` may be passed instead; if the object returned by the S3 method needs to be incorporated in the S4 object, the replacement function for `S3Part` may be useful, as in the method for class "myFrame" in the examples.

Here are details explaining the reasons for defining both S3 and S4 methods. Calls still accessing the S3 generic function directly will not see S4 methods, except in the case of primitive functions. This means that calls to the generic function from namespaces that import the S3 generic but not the S4 version will only see S3 methods. On the other hand, S3 methods will only be selected from the S4 generic function as part of its default ("ANY") method. If there are inherited S4 non-default methods, these will be chosen in preference to any S3 method.

S3 generic functions implemented as primitive functions (including binary operators) are an exception to recognizing only S3 methods. These functions dispatch both S4 and S3 methods from the internal C code. There is no explicit generic function, either S3 or S4. The internal code looks for S4 methods if the first argument, or either of the arguments in the case of a binary operator, is an S4 object. If no S4 method is found, a search is made for an S3 method.

S4 methods can be defined for an S3 generic function and an S3 class, but if the function is a primitive, such methods will not be selected if the object in question is not an S4 object. In the examples below, for instance, an S4 method for signature "data.frame" for function `f3()` would be called for the S3 object `df1`. A similar S4 method for primitive function `['` would be ignored for that object, but would be called for the S4 object `mydf1` that inherits from "data.frame". Defining both an S3 and S4 method removes this inconsistency.

**Method Selection and Dispatch: Details**

When a call to a generic function is evaluated, a method is selected corresponding to the classes of the actual arguments in the signature. First, the cached methods table is searched for an exact match; that is, a method stored under the signature defined by the string value of `class(x)` for each non-missing argument, and "missing" for each missing argument. If no method is found directly for the actual arguments in a call to a generic function, an attempt is made to match the available methods to the arguments by using the superclass information about the actual classes.

Each class definition may include a list of one or more *superclasses* of the new class. The simplest and most common specification is by the `contains=` argument in the call to `setClass`. Each class named in this argument is a superclass of the new class. Two additional mechanisms for defining
superclasses exist. A call to `setClassUnion` creates a union class that is a superclass of each of the members of the union. A call to `setIs` can create an inheritance relationship that is not the simple one of containing the superclass representation in the new class. Arguments coerce and replace supply methods to convert to the superclass and to replace the part corresponding to the superclass. (In addition, a `test=` argument allows conditional inheritance; conditional inheritance is not recommended and is not used in method selection.) All three mechanisms are treated equivalently for purposes of method selection: they define the *direct* superclasses of a particular class. For more details on the mechanisms, see Classes.

The direct superclasses themselves may have superclasses, defined by any of the same mechanisms, and similarly through further generations. Putting all this information together produces the full list of superclasses for this class. The superclass list is included in the definition of the class that is cached during the R session. Each element of the list describes the nature of the relationship (see `SClassExtension` for details). Included in the element is a distance slot containing the path length for the relationship: 1 for direct superclasses (regardless of which mechanism defined them), then 2 for the direct superclasses of those classes, and so on. In addition, any class implicitly has class "ANY" as a superclass. The distance to "ANY" is treated as larger than the distance to any actual class. The special class "missing" corresponding to missing arguments has only "ANY" as a superclass, while "ANY" has no superclasses.

When a class definition is created or modified, the superclasses are ordered, first by a stable sort of the all superclasses by distance. If the set of superclasses has duplicates (that is, if some class is inherited through more than one relationship), these are removed, if possible, so that the list of superclasses is consistent with the superclasses of all direct superclasses. See the reference on inheritance for details.

The information about superclasses is summarized when a class definition is printed.

When a method is to be selected by inheritance, a search is made in the table for all methods directly corresponding to a combination of either the direct class or one of its superclasses, for each argument in the active signature. For an example, suppose there is only one argument in the signature and that the class of the corresponding object was "dgeMatrix" (from the recommended package Matrix). This class has two direct superclasses and through these 4 additional superclasses. Method selection finds all the methods in the table of directly specified methods labeled by one of these classes, or by "ANY".

When there are multiple arguments in the signature, each argument will generate a similar list of inherited classes. The possible matches are now all the combinations of classes from each argument (think of the function outer generating an array of all possible combinations). The search now finds all the methods matching any of this combination of classes. For each argument, the position in the list of superclasses of that argument’s class defines which method or methods (if the same class appears more than once) match best. When there is only one argument, the best match is unambiguous. With more than one argument, there may be zero or one match that is among the best matches for *all* arguments.

If there is no best match, the selection is ambiguous and a message is printed noting which method was selected (the first method lexicographically in the ordering) and what other methods could have been selected. Since the ambiguity is usually nothing the end user could control, this is not a warning. Package authors should examine their package for possible ambiguous inheritance by calling `testInheritedMethods`.

When the inherited method has been selected, the selection is cached in the generic function so that future calls with the same class will not require repeating the search. Cached inherited selections are
not themselves used in future inheritance searches, since that could result in invalid selections. If you want inheritance computations to be done again (for example, because a newly loaded package has a more direct method than one that has already been used in this session), call `resetGeneric`. Because classes and methods involving them tend to come from the same package, the current implementation does not reset all generics every time a new package is loaded.

Besides being initiated through calls to the generic function, method selection can be done explicitly by calling the function `selectMethod`.

Once a method has been selected, the evaluator creates a new context in which a call to the method is evaluated. The context is initialized with the arguments from the call to the generic function. These arguments are not rematched. All the arguments in the signature of the generic will have been evaluated (including any that are currently inactive); arguments that are not in the signature will obey the usual lazy evaluation rules of the language. If an argument was missing in the call, its default expression if any will *not* have been evaluated, since method dispatch always uses class missing for such arguments.

A call to a generic function therefore has two contexts: one for the function and a second for the method. The argument objects will be copied to the second context, but not any local objects created in a nonstandard generic function. The other important distinction is that the parent ("enclosing") environment of the second context is the environment of the method as a function, so that all \texttt{R} programming techniques using such environments apply to method definitions as ordinary functions.

For further discussion of method selection and dispatch, see the first reference.

**Generic Functions**

In principle, a generic function could be any function that evaluates a call to `standardGeneric()`, the internal function that selects a method and evaluates a call to the selected method. In practice, generic functions are special objects that in addition to being from a subclass of class "function" also extend the class `genericFunction`. Such objects have slots to define information needed to deal with their methods. They also have specialized environments, containing the tables used in method selection.

The slots "generic" and "package" in the object are the character string names of the generic function itself and of the package from which the function is defined. As with classes, generic functions are uniquely defined in \texttt{R} by the combination of the two names. There can be generic functions of the same name associated with different packages (although inevitably keeping such functions cleanly distinguished is not always easy). On the other hand, \texttt{R} will enforce that only one definition of a generic function can be associated with a particular combination of function and package name, in the current session or other active version of \texttt{R}.

Tables of methods for a particular generic function, in this sense, will often be spread over several other packages. The total set of methods for a given generic function may change during a session, as additional packages are loaded. Each table must be consistent in the signature assumed for the generic function.

\texttt{R} distinguishes *standard* and *nonstandard* generic functions, with the former having a function body that does nothing but dispatch a method. For the most part, the distinction is just one of simplicity: knowing that a generic function only dispatches a method call allows some efficiencies and also removes some uncertainties.

In most cases, the generic function is the visible function corresponding to that name, in the corresponding package. There are two exceptions, *implicit* generic functions and the special computations required to deal with \texttt{R}'s *primitive* functions. Packages can contain a table of implicit generic
versions of functions in the package, if the package wishes to leave a function non-generic but to
constrain what the function would be like if it were generic. Such implicit generic functions are
created during the installation of the package, essentially by defining the generic function and pos-
sibly methods for it, and then reverting the function to its non-generic form. (See implicitGeneric
for how this is done.) The mechanism is mainly used for functions in the older packages in R,
which may prefer to ignore S4 methods. Even in this case, the actual mechanism is only needed if
something special has to be specified. All functions have a corresponding implicit generic version
defined automatically (an implicit, implicit generic function one might say). This function is a stan-
dard generic with the same arguments as the non-generic function, with the non-generic version as
the default (and only) method, and with the generic signature being all the formal arguments except
....

The implicit generic mechanism is needed only to override some aspect of the default definition.
One reason to do so would be to remove some arguments from the signature. Arguments that
may need to be interpreted literally, or for which the lazy evaluation mechanism of the language
is needed, must not be included in the signature of the generic function, since all arguments in the
signature will be evaluated in order to select a method. For example, the argument expr to the
function with is treated literally and must therefore be excluded from the signature.

One would also need to define an implicit generic if the existing non-generic function were not
suitable as the default method. Perhaps the function only applies to some classes of objects, and
the package designer prefers to have no general default method. In the other direction, the pack-
age designer might have some ideas about suitable methods for some classes, if the function were
generic. With reasonably modern packages, the simple approach in all these cases is just to define
the function as a generic. The implicit generic mechanism is mainly attractive for older packages
that do not want to require the methods package to be available.

Generic functions will also be defined but not obviously visible for functions implemented as prim-
itive functions in the base package. Primitive functions look like ordinary functions when printed
but are in fact not function objects but objects of two types interpreted by the R evaluator to call
underlying C code directly. Since their entire justification is efficiency, R refuses to hide primitives
behind a generic function object. Methods may be defined for most primitives, and corresponding
metadata objects will be created to store them. Calls to the primitive still go directly to the C code,
which will sometimes check for applicable methods. The definition of “sometimes” is that meth-
ods must have been detected for the function in some package loaded in the session and isS4(x)
is TRUE for the first argument (or for the second argument, in the case of binary operators). You
can test whether methods have been detected by calling isGeneric for the relevant function and
you can examine the generic function by calling getGeneric, whether or not methods have been
detected. For more on generic functions, see the first reference and also section 2 of R Internals.

Method Definitions

All method definitions are stored as objects from the MethodDefinition class. Like the class
of generic functions, this class extends ordinary R functions with some additional slots: "generic",
containing the name and package of the generic function, and two signature slots, "defined"
and "target", the first being the signature supplied when the method was defined by a call to
setMethod. The "target" slot starts off equal to the "defined" slot. When an inherited method
is cached after being selected, as described above, a copy is made with the appropriate "target"
signature. Output from showMethods, for example, includes both signatures.

Method definitions are required to have the same formal arguments as the generic function, since
the method dispatch mechanism does not rematch arguments, for reasons of both efficiency and consistency.

Examples

## A class that extends a registered S3 class inherits that class' S3
## methods.

setClass("myFrame", contains = "data.frame",
   representation(timestamps = "POSIXt"))

df1 <- data.frame(x = 1:10, y = rnorm(10), z = sample(letters,10))

mydf1 <- new("myFrame", df1, timestamps = Sys.time())

## "myFrame" objects inherit "data.frame" S3 methods; e.g., for '['
mydf1[1:2, ] # a data frame object (with extra attributes)

## a method explicitly for "myFrame" class

setMethod("[",
   signature(x = "myFrame"),
   function (x, i, j, ..., drop = TRUE)
   {
     S3Part(x) <- callNextMethod()
     x@timestamps <- c(Sys.time(), as.POSIXct(x@timestamps))
     x
   }
)

mydf1[1:2, ]

setClass("myDateTime", contains = "POSIXt")

now <- Sys.time() # class(now) is c("POSIXt", "POSIXt")
nowLt <- as.POSIXlt(now)# class(nowLt) is c("POSIXlt", "POSIXt")

mCt <- new("myDateTime", now)
 mLt <- new("myDateTime", nowLt)

### S3 methods for an S4 object will be selected using S4 inheritance
### Objects mCt and mLt have different S3Class() values, but this is
### not used.

f3 <- function(x)UseMethod("f3") # an S3 generic to illustrate inheritance

f3.POSIXct <- function(x) "The POSIXct result"
 f3.POSIXlt <- function(x) "The POSIXlt result"
 f3.POSIXt <- function(x) "The POSIXt result"

stopifnot(identical(f3(mCt), f3.POSIXt(mCt)))
 stopifnot(identical(f3(mLt), f3.POSIXt(mLt)))

### An S4 object selects S3 methods according to its S4 "inheritance"

setClass("classA", contains = "numeric",
 representation(realData = "numeric"))

Math.classA <- function(x) {(getFunction(.Generic))(x@realData)}

setMethod("Math", "classA", Math.classA)

x <- new("classA", log(1:10), realData = 1:10)

stopifnot(identical(abs(x), 1:10))

setClass("classB", contains = "classA")

y <- new("classB", x)

stopifnot(identical(abs(y), 1:10)) # (version 2.9.0 or earlier fails here)

### an S3 generic: just for demonstration purposes
f3 <- function(x, ...) UseMethod("f3")

f3.default <- function(x, ...) "Default f3"

### S3 method (only) for classA
f3.classA <- function(x, ...) "Class classA for f3"

### S3 and S4 method for numeric
f3.numeric <- function(x, ...) "Class numeric for f3"

setMethod("f3", "numeric", f3.numeric)

### The S3 method for classA and the closest inherited S3 method for classB
### are not found.
f3(x); f3(y) # both choose "numeric" method

## to obtain the natural inheritance, set identical S3 and S4 methods
setMethod("f3", "classA", f3.classA)

f3(x); f3(y) # now both choose "classA" method

## Need to define an S3 as well as S4 method to use on an S3 object
## or if called from a package without the S4 generic
MathFun <- function(x) {
  # a smarter "data.frame" method for Math group
  for (i in seq(length = ncol(x))[sapply(x, is.numeric)])
    x[, i] <- (getFunction(.Generic))(x[, i])
  x
}
setMethod("Math", "data.frame", MathFun)

## S4 method works for an S4 class containing data.frame,
## but not for data.frame objects (not S4 objects)
try(logIris <- log(iris)) # gets an error from the old method

## Define an S3 method with the same computation
Math.data.frame <- MathFun

logIris <- log(iris)

MethodsList-class

Class MethodsList, Deprecated Representation of Methods

Description

This class of objects was used in the original implementation of the package to control method dispatch. Its use is now deprecated, but object appear as the default method slot in generic functions. This and any other remaining uses will be removed in the future.

For the modern alternative, see `listOfMethods`.

The details in this documentation are retained to allow analysis of old-style objects.
Details

Suppose a function $f$ has formal arguments $x$ and $y$. The methods list object for that function has the object as \texttt{as.name("x")} as its argument slot. An element of the methods named "track" is selected if the actual argument corresponding to $x$ is an object of class "track". If there is such an element, it can generally be either a function or another methods list object.

In the first case, the function defines the method to use for any call in which $x$ is of class "track". In the second case, the new methods list object defines the available methods depending on the remaining formal arguments, in this example, $y$.

Each method corresponds conceptually to a \textit{signature}; that is a named list of classes, with names corresponding to some or all of the formal arguments. In the previous example, if selecting class "track" for $x$, finding that the selection was another methods list and then selecting class "numeric" for $y$ would produce a method associated with the signature $x = "track", y = "numeric"$.

Slots

\begin{itemize}
  \item \texttt{argument}: Object of class "name". The name of the argument being used for dispatch at this level.
  \item \texttt{methods}: A named list of the methods (and method lists) defined \textit{explicitly} for this argument. The names are the names of classes, and the corresponding element defines the method or methods to be used if the corresponding argument has that class. See the details below.
  \item \texttt{allMethods}: A named list, contains all the directly defined methods from the \texttt{methods} slot, plus any inherited methods. Ignored when methods tables are used for dispatch (see \texttt{Methods}).
\end{itemize}

Extends

Class "OptionalMethods", directly.

MethodWithNext-class  \hspace{1cm} Class MethodWithNext

Description

Class of method definitions set up for callNextMethod

Objects from the Class

Objects from this class are generated as a side-effect of calls to \texttt{callNextMethod}.

Slots

\begin{itemize}
  \item \texttt{.Data}: Object of class "function"; the actual function definition.
  \item \texttt{nextMethod}: Object of class "PossibleMethod" the method to use in response to a \texttt{callNextMethod()} call.
  \item \texttt{excluded}: Object of class "list"; one or more signatures excluded in finding the next method.
  \item \texttt{target}: Object of class "signature", from class "MethodDefinition"
  \item \texttt{defined}: Object of class "signature", from class "MethodDefinition"
  \item \texttt{generic}: Object of class "character"; the function for which the method was created.
\end{itemize}
new

**Extends**

Class "MethodDefinition", directly.
Class "function", from data part.
Class "PossibleMethod", by class "MethodDefinition".
Class "OptionalMethods", by class "MethodDefinition".

**Methods**

- **findNextMethod** signature(method = "MethodWithNext"): used internally by method dispatch.
- **loadMethod** signature(method = "MethodWithNext"): used internally by method dispatch.
- **show** signature(object = "MethodWithNext")

**See Also**

callNextMethod, and class MethodDefinition.

---

new **Generate an Object from a Class**

**Description**

Given the name or the definition of a class, plus optionally data to be included in the object, `new` returns an object from that class.

**Usage**

```
new(Class, ...)
initialize(.Object, ...)
```

**Arguments**

- **Class**
  
either the name of a class, a character string, (the usual case) or the object describing the class (e.g., the value returned by getClass).
- **...**
  
data to include in the new object. Named arguments correspond to slots in the class definition. Unnamed arguments must be objects from classes that this class extends.
- **.Object**
  
An object: see the Details section.
Details

The function `new` begins by copying the prototype object from the class definition. Then information is inserted according to the arguments, if any. As of version 2.4 of R, the type of the prototype object, and therefore of all objects returned by `new()`, is "S4" except for classes that extend one of the basic types, where the prototype has that basic type. User functions that depend on `typeof(object)` should be careful to handle "S4" as a possible type.

Note that the name of the first argument, "Class" entails that "Class" is an undesirable slot name in any formal class: `new("myClass", Class = <value>)` will not work.

The interpretation of the arguments can be specialized to particular classes, if an appropriate method has been defined for the generic function "initialize". The `new` function calls `initialize` with the object generated from the prototype as the .Object argument to `initialize`.

By default, unnamed arguments in the ... are interpreted as objects from a superclass, and named arguments are interpreted as objects to be assigned into the correspondingly named slots. Thus, explicit slots override inherited information for the same slot, regardless of the order in which the arguments appear.

The `initialize` methods do not have to have ... as their second argument (see the examples). Initialize methods are often written when the natural parameters describing the new object are not the names of the slots. If you do define such a method, note the implications for future subclasses of your class. If these have additional slots, and your `initialize` method has ... as a formal argument, then your method should pass such arguments along via `callNextMethod`. If your method does not have this argument, then either a subclass must have its own method or else the added slots must be specified by users in some way other than as arguments to `new`.

For examples of `initialize` methods, see `initialize-methods` for existing methods for classes "traceable" and "environment", among others. See the comments there on subclasses of "environment"; any `initialize` methods for these should be sure to allocate a new environment.

Methods for `initialize` can be inherited only by simple inheritance, since it is a requirement that the method return an object from the target class. See the `simpleInheritanceOnly` argument to `setGeneric` and the discussion in `setIs` for the general concept.

Note that the basic vector classes, "numeric", etc. are implicitly defined, so one can use `new` for these classes.

See Also

`Classes` for an overview of defining class, and `setOldClass` for the relation to S3 classes.

Examples

```r
## using the definition of class "track" from \
link(setClass)
```
## a new object with two slots specified
t1 <- new("track", x = seq_along(ydata), y = ydata)

# a new object including an object from a superclass, plus a slot
t2 <- new("trackCurve", t1, smooth = ysmooth)

### define a method for initialize, to ensure that new objects have
### equal-length x and y slots.

setMethod("initialize", "track",
  function(.Object, x = numeric(0), y = numeric(0)) {
    if(nargs() > 1) {
      if(length(x) != length(y))
        stop("specified x and y of different lengths")
      .Object@x <- x
      .Object@y <- y
    }
    .Object
  })

### the next example will cause an error (x will be numeric(0)),
### because we didn't build in defaults for x,
### although we could with a more elaborate method for initialize

try(new("track", y = sort(stats::rnorm(1))))

## a better way to implement the previous initialize method.
## Why? By using callNextMethod to call the default initialize method
## we don't inhibit classes that extend "track" from using the general
## form of the new() function. In the previous version, they could only
## use x and y as arguments to new, unless they wrote their own
## initialize method.

setMethod("initialize", "track", function(.Object, ...) {
  .Object <- callNextMethod()
  if(length(.Object@x) != length(.Object@y))
    stop("specified x and y of different lengths")
  .Object
})

---

**nonStructure-class** A non-structure S4 Class for basic types

### Description

S4 classes that are defined to extend one of the basic vector classes should contain the class
**structure** if they behave like structures; that is, if they should retain their class behavior under
math functions or operators, so long as their length is unchanged. On the other hand, if their class depends on the values in the object, not just its structure, then they should lose that class under any such transformations. In the latter case, they should be defined to contain nonStructure.

If neither of these strategies applies, the class likely needs some methods of its own for Ops, Math, and/or other generic functions. What is not usually a good idea is to allow such computations to drop down to the default, base code. This is inconsistent with most definitions of such classes.

Methods

Methods are defined for operators and math functions (groups Ops, Math and Math2. In all cases the result is an ordinary vector of the appropriate type.

ObjectsWithPackage-class

*A Vector of Object Names, with associated Package Names*

Description

This class of objects is used to represent ordinary character string object names, extended with a package slot naming the package associated with each object.

Objects from the Class

The function `get Generics` returns an object of this class.

Slots

.Data: Object of class "character": the object names.
.package: Object of class "character" the package names.
promptClass

Extends
Class "character", from data part.
Class "vector", by class "character".

See Also
Methods for general background.

promptClass Generate a Shell for Documentation of a Formal Class

Description
Assembles all relevant slot and method information for a class, with minimal markup for Rd processing; no QC facilities at present.

Usage
promptClass(clName, filename = NULL, type = "class",
keywords = "classes", where = topoenv(parent.frame()),
generatorName = clName)

Arguments
clName a character string naming the class to be documented.
filename usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is the topic name for the class documentation, followed by ".Rd". Can also be NA (see below).
type the documentation type to be declared in the output file.
keywords the keywords to include in the shell of the documentation. The keyword "classes" should be one of them.
where where to look for the definition of the class and of methods that use it.
generatorName the name for a generator function for this class; only required if a generator function was created and saved under a name different from the class name.

Details
The class definition is found on the search list. Using that definition, information about classes extended and slots is determined.
In addition, the currently available generics with methods for this class are found (using getGenerics). Note that these methods need not be in the same environment as the class definition; in particular, this part of the output may depend on which packages are currently in the search list.
As with other prompt-style functions, unless `filename` is `NA`, the documentation shell is written to a file, and a message about this is given. The file will need editing to give information about the *meaning* of the class. The output of `promptClass` can only contain information from the metadata about the formal definition and how it is used.

If `filename` is `NA`, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n"),` where `x` is the list-style representation.

If a generator function is found assigned under the class name or the optional `generatorName`, skeleton documentation for that function is added to the file.

**Value**

If `filename` is `NA`, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

**Author(s)**

VJ Carey `<stvjc@channing.harvard.edu>` and John Chambers

**References**

Chambers, John M. (1998) *Programming with Data* Springer (For the original S4 version.)

**See Also**

`prompt` for documentation of functions, `promptMethods` for documentation of method definitions.

For processing of the edited documentation, either use `R CMD Rdconv`, or include the edited file in the ’man’ subdirectory of a package.

**Examples**

```r
## Not run: > promptClass("track")
A shell of class documentation has been written to the file "track-class.Rd".

## End(Not run)
```

---

**promptMethods**

*Generate a Shell for Documentation of Formal Methods*

**Description**

Generates a shell of documentation for the methods of a generic function.
promptMethods

Usage

promptMethods(f, filename = NULL, methods)

Arguments

- **f**: a character string naming the generic function whose methods are to be documented.
- **filename**: usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to the coded topic name for these methods (currently, f followed by "-methods.Rd"). Can also be FALSE or NA (see below).
- **methods**: Optional methods list object giving the methods to be documented. By default, the first methods object for this generic is used (for example, if the current global environment has some methods for f, these would be documented).
  If this argument is supplied, it is likely to be getMethods(f, where), with where some package containing methods for f.

Details

If filename is FALSE, the text created is returned, presumably to be inserted some other documentation file, such as the documentation of the generic function itself (see prompt).

If filename is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to cat(unlist(x), file = filename, sep = "\n"), where x is the list-style representation.

Otherwise, the documentation shell is written to the file specified by filename.

Value

If filename is FALSE, the text generated; if filename is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

ReferenceClasses  

Objects With Fields Treated by Reference (OOP-style)

Description

The software described here supports reference classes whose objects have fields accessed by reference in the style of “OOP” languages such as Java and C++. Computations with these objects invoke methods on them and extract or set their fields. The field and method computations potentially modify the object. All computations referring to the objects see the modifications, in contrast to the usual functional programming model in R. Reference classes can be used to program in R directly or in combination with an interface to an OOP-style language, allowing R-written methods to extend the interface.

Usage

```r
setRefClass(Class, fields = , contains = , methods =,
    where =, ...)
getRefClass(Class, where =)
```

Arguments

- **Class**
  character string name for the class.
  In the call to `getRefClass()` this argument can also be any object from the relevant class; note also the corresponding reference class methods documented in the section on “Writing Reference Methods”.

- **fields**
  either a character vector of field names or a named list of the fields. The resulting fields will be accessed with reference semantics (see the section on “Reference Objects”). If the argument is a list, the elements of the list can be the character string name of a class, in which case the field must be from that class or a subclass.

  The element in the list can alternatively be an accessor function, a function of one argument that returns the field if called with no argument or sets it to the value of the argument otherwise. Accessor functions are used internally and for inter-system interface applications. Their definition follows the rules for writing methods for the class: they can refer to other fields and can call other methods for this class or its superclasses. See the section on “Implementation” for the internal mechanism used by accessor functions.

  Note that fields are distinct from the slots, if any, in the object. Slots are, as always, handled by standard R object management. It is not generally a good idea to mix slots and fields in the same class; this confuses the distinction in behavior between reference classes and regular S4 classes. See the comments in the “Implementation” section.

- **contains**
  optional vector of superclasses for this class. If a superclass is also a reference class, the fields and class-based methods will be inherited.
ReferenceClasses

Methods

Methods are a named list of function definitions that can be invoked on objects from this class. These can also be created by invoking the $methods method on the generator object returned. See the section on “Writing Reference Methods” for details.

Two optional method names are interpreted specially, initialize and finalize. If an initialize method is defined, it will be invoked when an object is generated from the class. See the discussion of method $new(...) in the section “Reference Object Generators”.

If a finalize method is defined, a function will be registered to invoke it before the environment in the object is discarded by the garbage collector. See the matrix viewer example for both initialize and finalize methods.

Where

The environment in which to store the class definition (or to begin the search for it, in the case of getRefClass()). Defaults to the package namespace or environment for code that is part of an R package, and to the global environment for code sourced directly at the session top level.

Value

setRefClass() returns a generator function suitable for creating objects from the class, invisibly. A call to this function takes any number of arguments, which will be passed on to the initialize method. If no initialize method is defined for the class or one of its superclasses, the default method expects named arguments with the name of one of the fields and unnamed arguments, if any, that are objects from one of the superclasses of this class (but only superclasses that are themselves reference classes have any effect).

The generator function is similar to the S4 generator function returned by setClass. In addition to being a generator function, however, it is also a reference class generator object, with reference class methods for various utilities. See the section on reference class generator objects below.

If the class has a method defined for $initialize(), this method will be called once the reference object has been created. You should write such a method for a class that needs to do some special initialization. In particular, a reference method is recommended rather than a method for the S4 generic function initialize(), because some special initialization is required for reference objects before the initialization of fields. As with S4 classes, methods are written for $initialize() and not for $new(), both for the previous reason and also because $new() is invoked on the generator object and would be a method for that class.

The default method for $initialize() is equivalent to invoking the method $initFields(...). Named arguments assign initial values to the corresponding fields. Unnamed arguments must be objects from this class or a reference superclass of this class. Fields will be initialized to the contents of the fields in such objects, but named arguments override the corresponding inherited fields. Note that fields are simply assigned. If the field is itself a reference object, that object is not copied. The new and previous object will share the reference. Also, a field assigned from an unnamed argument counts as an assignment for locked fields. To override an inherited value for a locked field, the new value must be one of the named arguments in the initializing call. A later assignment of the field will result in an error.

For technical reasons, the default method does not currently appear explicitly, but can be invoked by $callSuper(...) from a method for $initialize(). Initialization methods need some care in design, as they do for S4 classes. In particular, remember that others may subclass your class and pass through field assignments or other arguments. Therefore, your method should normally
Reference Classes

include . . . as an argument, all other arguments should have defaults or check for missingness, and your method should pass all initialized values on via $callSuper() or $initFields() if you know that your superclasses have no initialization methods.

getRefClass() also returns the generator function for the class. Note that the package slot in the value is the correct package from the class definition, regardless of the where argument, which is used only to find the class if necessary.

Reference Objects

Normal objects in R are passed as arguments in function calls consistently with functional programming semantics; that is, changes made to an object passed as an argument are local to the function call. The object that supplied the argument is unchanged.

The functional model (sometimes called pass-by-value, although this is inaccurate for R) is suitable for many statistical computations and is implicit, for example, in the basic R software for fitting statistical models. In some other situations, one would like all the code dealing with an object to see the exact same content, so that changes made in any computation would be reflected everywhere. This is often suitable if the object has some “objective” reality, such as a window in a user interface.

In addition, commonly used languages, including Java, C++ and many others, support a version of classes and methods assuming reference semantics. The corresponding programming mechanism is to invoke a method on an object. In the R syntax we use "$" for this operation; one invokes a method, m1 say, on an object x by the expression x$m1(...).

Methods in this paradigm are associated with the object, or more precisely with the class of the object, as opposed to methods in a function-based class/method system, which are fundamentally associated with the function (in R, for example, a generic function in an R session has a table of all its currently known methods). In this document “methods for a class” as opposed to “methods for a function” will make the distinction.

Objects in this paradigm usually have named fields on which the methods operate. In the R implementation, the fields are defined when the class is created. The field itself can optionally have a specified class, meaning that only objects from this class or one of its subclasses can be assigned to the field. By default, fields have class "ANY". Fields may also be defined by supplying an accessor function which will be called to get or set the field. Accessor functions are likely when reference classes are part of an inter-system interface. The interface will usually supply the accessor functions automatically based on the definition of the corresponding class in the other language.

Fields are accessed by reference. In particular, invoking a method may modify the content of the fields.

Programming for such classes involves writing new methods for a particular class. In the R implementation, these methods are R functions, with zero or more formal arguments. The object on which the methods are invoked is not an explicit argument to the method. Instead, fields and methods for the class can be referred to by name in the method definition. The implementation uses R environments to make fields and methods available by name. Additional special fields allow reference to the complete object and to the definition of the class. See the section on “Writing Reference Methods”.

The goal of the software described here is to provide a uniform programming style in R for software dealing with reference classes, whether implemented directly in R or through an interface to one of the OOP languages.
Writing Reference Methods

Reference methods are functions supplied as elements of a named list, either when invoking \texttt{g$methods()} on a generator object \(g\) or as the argument \texttt{methods} in a call to \texttt{setRefClass}. They are written as ordinary \texttt{R} functions but have some special features and restrictions. The body of the function can contain calls to any other reference method, including those inherited from other reference classes and may refer to fields in the object by name.

Fields may be modified in a method by using the non-local assignment operator, \texttt{<<-}, as in the \$edit and \$undo methods in the example below. Note that non-local assignment is required: a local assignment with the \texttt{<-} operator just creates a local object in the function call, as it would in any \texttt{R} function. When methods are installed, a heuristic check is made for local assignments to field names and a warning issued if any are detected.

Reference methods should be kept simple: if they need to do some specialized \texttt{R} computation, that computation should use a separate \texttt{R} function that is called from the reference method. Specifically, methods can not use special features of the enclosing environment mechanism, since the method’s environment is used to access fields and other methods. In particular, methods should not use non-exported entries in the package’s namespace, because the methods may be inherited by a reference class in another package.

Reference methods can not themselves be generic functions; if you want additional function-based method dispatch, write a separate generic function and call that from the method.

The entire object can be referred to in a method by the reserved name \texttt{.self}, as shown in the \texttt{save} method of the example. The special object \texttt{.refClassDef} contains the definition of the class of the object. These fields are read-only (it makes no sense to modify these references), with one exception. In principal, the \texttt{.self} field can be modified in the \$initialize method, because the object is still being created at this stage. This is definitely not recommended, unless to set some non-reference properties of the object defined for this class, which is itself not recommended if it mixes slots and fields.

The methods available include methods inherited from superclasses, as discussed in the next section.

Only methods actually used will be included in the environment corresponding to an individual object. To declare that a method requires a particular other method, the first method should include a call to \$usingMethods() with the name of the other method as an argument. Declaring the methods this way is essential if the other method is used indirectly (e.g., via \texttt{sapply()} or \texttt{do.call()}). If it is called directly, code analysis will find it. Declaring the method is harmless in any case, however, and may aid readability of the source code.

Documentation for the methods can be obtained by the \$help method for the generator object. Methods for classes are not documented in the \texttt{Rd} format used for \texttt{R} functions. Instead, the \$help method prints the calling sequence of the method, followed by self-documentation from the method definition, in the style of Python. If the first element of the body of the method is a literal character string (possibly multi-line), that string is interpreted as documentation. See the method definitions in the example.

Inheritance

Reference classes inherit from other reference classes by using the standard \texttt{R} inheritance; that is, by including the superclasses in the \texttt{contains=} argument when creating the new class. The names of the reference superclasses are in slot \texttt{refSuperClasses} of the class definition. Reference classes
can inherit from ordinary S4 classes also, but this is usually a bad idea if it mixes reference fields and non-reference slots. See the comments in the section on “Implementation”.

Class fields are inherited. A class definition can override a field of the same name in a superclass only if the overriding class is a subclass of the class of the inherited field. This ensures that a valid object in the field remains valid for the superclass as well.

Inherited methods are installed in the same way as directly specified methods. The code in a method can refer to inherited methods in the same way as directly specified methods.

A method may override a method of the same name in a superclass. The overriding method can call the superclass method by callSuper(...) as described below.

All reference classes inherit from the class "envRefClass", which provides the following methods.

$callSuper(...) Calls the method inherited from a reference superclass. The call is meaningful only from within another method, and will be resolved to call the inherited method of the same name. The arguments to $callSuper are passed to the superclass version. See the matrix viewer class in the example.

Note that the intended arguments for the superclass method must be supplied explicitly: there is no convention for supplying the arguments automatically, in contrast to the similar mechanism for functional methods.

$copy(shallow = FALSE) Creates a copy of the object. With reference classes, unlike ordinary R objects, merely assigning the object with a different name does not create an independent copy. If shallow is FALSE, any field that is itself a reference object will also be copied, and similarly recursively for its fields. Otherwise, while reassigning a field to a new reference object will have no side effect, modifying such a field will still be reflected in both copies of the object. The argument has no effect on non-reference objects in fields. When there are reference objects in some fields but it is asserted that they will not be modified, using shallow = TRUE will save some memory and time.

$field(name, value) With one argument, returns the field of the object with character string name. With two arguments, the corresponding field is assigned value. Assignment checks that name specifies a valid field, but the single-argument version will attempt to get anything of that name from the object’s environment.

The $field() method replaces the direct use of a field name, when the name of the field must be calculated, or for looping over several fields.

$export(Class) Returns the result of coercing the object to Class (typically one of the superclasses of the object’s class). Calling the method has no side effect on the object itself.

$getReference(); $getClass() These return respectively the generator object and the formal class definition for the reference class of this object, efficiently.

$import(value, Class = class(value)) Import the object value into the current object, replacing the corresponding fields in the current object. Object value must come from one of the superclasses of the current object’s class. If argument Class is supplied, value is first coerced to that class.

$initFields(...) Initialize the fields of the object from the supplied arguments. This method is usually only called from a class with a $initialize() method. It corresponds to the default initialization for reference classes. If there are slots and non-reference superclasses, these may be supplied in the ... argument as well.
Typically, a specialized \$initialize() method carries out its own computations, then invokes \$initFields() to perform standard initialization, as shown in the matrixViewer class in the example below.

\$show() This method is called when the object is printed automatically, analogously to the \texttt{show} function. A general method is defined for class "envRefClass". User-defined reference classes will often define their own method: see the Example below.

Note two points in the example. As with any \$show() method, it is a good idea to print the class explicitly to allow for subclasses using the method. Second, to call the \texttt{function} \$show() from the method, as opposed to the \$show() method itself, refer to \texttt{methods::show()} explicitly.

\$trace(what, ...), \$untrace(what) Apply the tracing and debugging facilities of the \texttt{trace} function to the reference method \texttt{what}.

All the arguments of the \texttt{trace} function can be supplied, except for \texttt{signature}, which is not meaningful.

The reference method can be invoked on either an object or the generator for the class. See the section on Debugging below for details.

\$usingMethods(...) Reference methods used by this method are named as the arguments either quoted or unquoted. In the code analysis phase of installing the the present method, the declared methods will be included. It is essential to declare any methods used in a nonstandard way (e.g., via an apply function). Methods called directly do not need to be declared, but it is harmless to do so. \$usingMethods() does nothing at run time.

Objects also inherit two reserved fields:

\texttt{.self} a reference to the entire object;
\texttt{.refClassDef} the class definition.

The defined fields should not override these, and in general it is unwise to define a field whose name begins with ".", since the implementation may use such names for special purposes.

### Reference Class Generators

The call to setRefClass defines the specified class and returns a “generator function” object for that class. This object has class "refObjectGenerator"; it inherits from "function" via "classGeneratorFunction" and can be called to generate new objects from the reference class.

The returned object is also a reference class object, although not of the standard construction. It can be used to invoke reference methods and access fields in the usual way, but instead of being implemented directly as an environment it has a subsidiary generator object as a slot, a standard reference object (of class "refGeneratorSlot"). Note that if one wanted to extend the reference class generator capability with a subclass, this should be done by subclassing "refGeneratorSlot", not "refObjectGenerator".

The fields are \texttt{def}, the class definition, and \texttt{className}, the character string name of the class. Methods generate objects from the class, to access help on reference methods, and to define new reference methods for the class. The currently available methods are:

\$new(...) This method is equivalent to calling the generator function returned by setRefClass.
\$help(topic) Prints brief help on the topic. The topics recognized are reference method names, quoted or not.
The information printed is the calling sequence for the method, plus self-documentation if any. Reference methods can have an initial character string or vector as the first element in the body of the function defining the method. If so, this string is taken as self-documentation for the method (see the section on “Writing Reference Methods” for details).

If no topic is given or if the topic is not a method name, the definition of the class is printed.

$\text{methods}(\ldots)$ With no arguments, returns a list of the reference methods for this class.

Named arguments are method definitions, which will be installed in the class, as if they had been supplied in the methods argument to \text{setRefClass}. Supplying methods in this way, rather than in the call to \text{setRefClass}, is largely for the sake of clearer source code when many or large methods are being defined. All methods for a class should be defined in the source code that defines the class, typically as part of a package. In particular, methods cannot be redefined in a class in an attached package with a namespace: The class method checks for a locked binding of the class definition.

The new methods can refer to any currently defined method by name (including other methods supplied in this call to \text{methods}). Note though that previously defined methods are not re-analyzed meaning that they will not call the new method (unless it redefines an existing method of the same name).

To remove a method, supply \text{NULL} as its new definition.

$\text{fields}()$ Returns a list of the fields, each with its corresponding class. Fields for which an accessor function was supplied in the definition have class "activeBindingFunction".

$\text{lock}(\ldots)$ The fields named in the arguments are locked; specifically, after the lock method is called, the field may be set once. Any further attempt to set it will generate an error. If called with no arguments, the method returns the names of the locked fields.

Fields that are defined by an explicit accessor function can not be locked (on the other hand, the accessor function can be defined to generate an error if called with an argument). All code to lock fields should normally be part of the definition of a class; that is, the read-only nature of the fields is meant to be part of the class definition, not a dynamic property added later. In particular, fields can not be locked in a class in an attached package with a namespace: The class method checks for a locked binding of the class definition. Locked fields can not be subsequently unlocked.

$\text{trace}(\text{what}, \ldots, \text{classMethod} = \text{FALSE})$ Establish a traced version of method \text{what} for objects generated from this class. The generator object tracing works like the \text{\$trace}() method for objects from the class, with two differences. Since it changes the method definition in the class object itself, tracing applies to all objects, not just the one on which the trace method is invoked.

Second, the optional argument \text{classMethod} = \text{TRUE} allows tracing on the methods of the generator object itself. By default, \text{what} is interpreted as the name of a method in the class for which this object is the generator.

$\text{accessors}(\ldots)$ A number of systems using the OOP programming paradigm recommend or enforce \text{getter} and \text{setter} methods corresponding to each field, rather than direct access by name. If you like this style and want to extract a field named \text{abc} by \text{x$getAbc()} and assign it by \text{x$setAbc(value)}, the \text{accessors} method is a convenience function that creates such getter and setter methods for the specified fields. Otherwise there is no reason to use this mechanism. In particular, it has nothing to do with the general ability to define fields by functions as described in the section on “Reference Objects”.

\text{ReferenceClasses}
Implementation

Reference classes are implemented as S4 classes with a data part of type "environment". Fields correspond to named objects in the environment. A field associated with a function is implemented as an active binding. In particular, fields with a specified class are implemented as a special form of active binding to enforce valid assignment to the field. A field, say data, can be accessed generally by an expression of the form x$data for any object from the relevant class. In a method for this class, the field can be accessed by the name data. A field that is not locked can be set by an expression of the form x$data <- value. Inside a method, a field can be assigned by an expression of the form x <<- value. Note the non-local assignment operator. The standard R interpretation of this operator works to assign it in the environment of the object. If the field has an accessor function defined, getting and setting will call that function.

When a method is invoked on an object, the function defining the method is installed in the object’s environment, with the same environment as the environment of the function.

Because of the implementation, new reference classes can inherit from non-reference S4 classes as well as reference classes. This is usually a bad idea, if the slots from the non-reference class are thought of as alternatives to fields. Unless there is some special argument in favor, mixing the functional and reference paradigms for properties of the same object is conceptually unclear. In addition, the initialization method for the class will have to sort out fields from slots, with a good chance of creating anomalous behavior for subclasses of this class. Better in general to define fields analogous to the slots in the S4 class, and to initialize those from an S4 object of that class.

Inter-System Interfaces

A number of languages use a similar reference-based programming model with classes and class-based methods. Aside from differences in choice of terminology and other details, many of these languages are compatible with the programming style described here. R interfaces to the languages exist in a number of packages.

The reference class definitions here provide a hook for classes in the foreign language to be exposed in R. Access to fields and/or methods in the class can be implemented by defining an R reference class corresponding to classes made available through the interface. Typically, the inter-system interface will take care of the details of creating the R class, given a description of the foreign class (what fields and methods it has, the classes for the fields, whether any are read-only, etc.) The specifics for the fields and methods can be implemented via reference methods for the R class. In particular, the use of active bindings allows field access for getting and setting, with actual access handled by the inter-system interface.

R methods and/or fields can be included in the class definition as for any reference class. The methods can use or set fields and can call other methods transparently whether the field or method comes from the interface or is defined directly in R.

For an inter-system interface using this approach, see the code for package Rcpp, version 0.8.7 or later.

Debugging

The standard R debugging and tracing facilities can be applied to reference methods. Reference methods can be passed to debug and its relatives from an object to debug further method invocations on that object; for example, debug(xx$edit).
Somewhat more flexible use is available for a reference method version of the \texttt{trace} function. A corresponding \$\texttt{trace()} reference method is available for either an object or for the reference class generator (\texttt{xx$trace()} or \texttt{mEdit$trace()} in the example below). Using \$\texttt{trace()} on an object sets up a tracing version for future invocations of the specified method for that object. Using \$\texttt{trace()} on the generator for the class sets up a tracing version for all future objects from that class (and sometimes for existing objects from the class if the method is not declared or previously invoked).

In either case, all the arguments to the standard \texttt{trace} function are available, except for \texttt{signature=} which is meaningless since reference methods cannot be S4 generic functions. This includes the typical style \texttt{trace(what, browser)} for interactive debugging and \texttt{trace(what, edit = TRUE)} to edit the reference method interactively.

\textbf{Author(s)}

John Chambers

\textbf{Examples}

\begin{verbatim}
## a simple editor for matrix objects. Method \$\texttt{edit()} changes some
## range of values; method \$\texttt{undo()} undoes the last edit.
mEdit <- setRefClass("mEdit",
  fields = list( data = "matrix",
                  edits = "list"),
  methods = list(
    edit = function(i, j, value) {
      ## the following string documents the edit method
      'Replaces the range [i, j] of the
      object by value.'
      
      backup <-
        list(i, j, data[i,j])
      data[i,j] <<- value
      edits <<- c(edits, list(backup))
      invisible(value)
    },
    undo = function() {
      'Undoes the last edit() operation
      and update the edits field accordingly.'
      
      prev <- edits
      if(length(prev)) prev <- prev[length(prev)]
      else stop("No more edits to undo")
      edit(prev[[1]], prev[[2]], prev[[3]])
    },
    show = function() {
      'Method for automatically printing matrix editors'
      cat("Reference matrix editor object of class",
           classLabel(class(.self)), "\n")
    }
  )
)
\end{verbatim}
cat("Data: \\
")
methods::show(data)
  cat("Undo list is of length", length(edits), \\
} \\
))

xMat <- matrix(1:12, 4, 3)
xx <- mEdit(data = xMat)
xx$edit(2, 2, /zero.noslash)
xx
xx$undo()
mEdit$help("undo")
stopifnot(all.equal(xx$data, xMat))

utils::str(xx) # show fields and names of non-trivial methods

## add a method to save the object
mEdit$methods(
  save = function(file) {
    'Save the current object on the file 
    in R external object format.
    ,
    base::save(.self, file = file)
  }
)

tf <- tempfile()
xx$save(tf)

## Not run:
## Inheriting a reference class: a matrix viewer
mv <- setRefClass("matrixViewer",
  fields = c("viewerDevice", "viewerFile"),
  contains = "mEdit",
  methods = list(view = function() {
    dd <- dev.cur(); dev.set(viewerDevice)
    devAskNewPage(FALSE)
    matplot(data, main = paste("After",length(edits),"edits"))
    dev.set(dd)),
    edit = # invoke previous method, then replot
    function(i, j, value) {
      callSuper(i, j, value)
      view()
    })
  })))

## initialize and finalize methods
mv$methods(initialize =
  function(file = ".matrixView.pdf", ...) {
    viewerFile <<- file
    pdf(viewerFile)
    viewerDevice <<- dev.cur()
    dev.set(dev.prev())
  })
representation

Construct a Representation or a Prototype for a Class Definition

Description

In calls to `setClass`, these two functions construct, respectively, the representation and prototype arguments. They do various checks and handle special cases. You’re encouraged to use them when defining classes that, for example, extend other classes as a data part or have multiple superclasses, or that combine extending a class and slots.

Usage

```r
representation(...) prototype(...)```

Arguments

... The call to representation takes arguments that are single character strings. Unnamed arguments are classes that a newly defined class extends; named arguments name the explicit slots in the new class, and specify what class each slot should have.

In the call to prototype, if an unnamed argument is supplied, it unconditionally forms the basis for the prototype object. Remaining arguments are taken to correspond to slots of this object. It is an error to supply more than one unnamed argument.

Details

The representation function applies tests for the validity of the arguments. Each must specify the name of a class.

The classes named don’t have to exist when representation is called, but if they do, then the function will check for any duplicate slot names introduced by each of the inherited classes.
The arguments to prototype are usually named initial values for slots, plus an optional first argument that gives the object itself. The unnamed argument is typically useful if there is a data part to the definition (see the examples below).

Value

The value of representation is just the list of arguments, after these have been checked for validity.

The value of prototype is the object to be used as the prototype. Slots will have been set consistently with the arguments, but the construction does *not* use the class definition to test validity of the contents (it hardly can, since the prototype object is usually supplied to create the definition).

`setClass`

Examples

```r
## representation for a new class with a directly define slot "smooth"
## which should be a "numeric" object, and extending class "track"
representation("track", smooth = "numeric")

setClass("Character", representation("character"))
setClass("TypedCharacter", representation("Character", type = "character"),
    prototype(character(0), type = "plain"))
ttt <- new("TypedCharacter", "foo", type = "character")

setClass("num1", representation(comment = "character"),
    contains = "numeric",
    prototype = prototype(pi, comment = "Start with pi"))
```
Description

Old-style (S3) classes may be registered as S4 classes (by calling `set0ldClass`, and many have been. These classes can then be contained in (that is, superclasses of) regular S4 classes, allowing formal methods and slots to be added to the S3 behavior. The function `S3Part` extracts or replaces the S3 part of such an object. `S3Class` extracts or replaces the S3-style class. `S3Class` also applies to object from an S4 class with S3methods=TRUE in the call to `setClass`.

See the details below. Also discussed are S3 <-> S4 coercion; see the section “S3 and S4 objects”

Usage

```r
S3Part(object, strictS3 = FALSE, S3Class)
S3Part(object, strictS3 = FALSE, needClass = ) <- value
S3Class(object)
S3Class(object) <- value
isXS3Class(classDef)
slotsFromS3(object)
```

Arguments

- **object**: An object from some class that extends a registered S3 class, usually because the class has as one of its superclasses an S3 class registered by a call to `set0ldClass`, or from a class that extends a basic vector, matrix or array object type. See the details.
  - For most of the functions, an S3 object can also be supplied, with the interpretation that it is its own S3 part.

- **strictS3**: If TRUE, the value returned by `S3Part` will be an S3 object, with all the S4 slots removed. Otherwise, an S4 object will always be returned; for example, from the S4 class created by `set0ldClass` as a proxy for an S3 class, rather than the underlying S3 object.

- **S3Class**: The character vector to be stored as the S3 class slot in the object. Usually, and by default, retains the slot from `object`.

- **needClass**: Require that the replacement value be this class or a subclass of it.

- **value**: For `S3Part<-`, the replacement value for the S3 part of the object. This does not need to be an S4 object; in fact, the usual way to create objects from these classes is by giving an S3 object of the right class as an argument to `new`.
  - For `S3Class<-`, the character vector that will be used as a proxy for `class(x)` in S3 method dispatch. This replacement function can be used to control S3 per-object method selection.

- **classDef**: A class definition object, as returned by `getClass`.
Details

Classes that register S3 classes by a call to `setOldClass` have slot ".S3Class" to hold the corresponding S3 vector of class strings. The prototype of such a class has the value for this slot determined by the argument to `setOldClass`. Other S4 classes will have the same slot if the argument `S3methods = TRUE` is supplied to `setClass`; in this case, the slot is set to the S4 inheritance of the class.

New S4 classes that extend (contain) such classes also have the same slot, and by default the prototype has the value determined by the `contains=` argument to `setClass`. Individual objects from the S4 class may have an S3 class corresponding to the value in the prototype or to an (S3) subclass of that value. See the examples below.

`S3Part()` with `strictS3 = TRUE` constructs the underlying S3 object by eliminating all the formally defined slots and turning off the S4 bit of the object. With `strictS3 = FALSE` the object returned is from the corresponding S4 class. For consistency and generality, `S3Part()` works also for classes that extend the basic vector, matrix and array classes. Since R is somewhat arbitrary about what it treats as an S3 class ("ts" is, but "matrix" is not), `S3Part()` tries to return an S3 (that is, non-S4) object whenever the S4 class has a suitable superclass, of either S3 or basic object type.

One general application that relies on this generality is to use `S3Part()` to get a superclass object that is guaranteed not to be an S4 object. If you are calling some function that checks for S4 objects, you need to be careful not to end up in a closed loop (fooS4 calls fooS3, which checks for an S4 object and calls fooS4 again, maybe indirectly). Using `S3Part()` with `strictS3 = TRUE` is a mechanism to avoid such loops.

Because the contents of S3 class objects have no definition or guarantee, the computations involving S3 parts do not check for slot validity. Slots are implemented internally in R as attributes, which are copied when present in the S3 part. Grave problems can occur if an S4 class extending an S3 class uses the name of an S3 attribute as the name of an S4 slot, and S3 code sets the attribute to an object from an invalid class according to the S4 definition.

Frequently, `S3Part` can and should be avoided by simply coercing objects to the desired class; methods are automatically defined to deal correctly with the slots when `as` is called to extract or replace superclass objects.

The function `slotsFromS3()` is a generic function used internally to access the slots associated with the S3 part of the object. Methods for this function are created automatically when `setOldClass` is called with the `S4Class` argument. Usually, there is only one S3 slot, containing the S3 class, but the `S4Class` argument may provide additional slots, in the case that the S3 class has some guaranteed attributes that can be used as formal S4 slots. See the corresponding section in the documentation of `setOldClass`.

Value

`S3Part`:
Returns or sets the S3 information (and possibly some S4 slots as well, depending on arguments `S3Class` and `keepSlots`). See the discussion of argument `strict` above. If it is `TRUE` the value returned is an S3 object.

`S3Class`:
Returns or sets the character vector of S3 class(es) stored in the object, if the class has the corresponding .S3Class slot. Currently, the function defaults to `class` otherwise.

`isXS3Class`:
Returns `TRUE` or `FALSE` according to whether the class defined by `ClassDef` extends S3 classes (specifically, whether it has the slot for holding the S3 class).
slotsFromS3: returns a list of the relevant slot classes, or an empty list for any other object.

S3 and S4 Objects: Conversion Mechanisms

Objects in R have an internal bit that indicates whether or not to treat the object as coming from an S4 class. This bit is tested by `isS4` and can be set on or off by `asS4`. The latter function, however, does no checking or interpretation; you should only use it if you are very certain every detail has been handled correctly.

As a friendlier alternative, methods have been defined for coercing to the virtual classes "S3" and "S4". The expressions `as(object, "S3")` and `as(object, "S4")` return S3 and S4 objects, respectively. In addition, they attempt to do conversions in a valid way, and also check validity when coercing to S4.

The expression `as(object, "S3")` can be used in two ways. For objects from one of the registered S3 classes, the expression will ensure that the class attribute is the full multi-string S3 class implied by `class(object)`. If the registered class has known attribute/slots, these will also be provided.

Another use of `as(object, "S3")` is to take an S4 object and turn it into an S3 object with corresponding attributes. This is only meaningful with S4 classes that have a data part. If you want to operate on the object without invoking S4 methods, this conversion is usually the safest way.

The expression `as(object, "S4")` will use the attributes in the object to create an object from the S4 definition of `class(object)`. This is a general mechanism to create partially defined version of S4 objects via S3 computations (not much different from invoking `new` with corresponding arguments, but usable in this form even if the S4 object has an initialize method with different arguments).

`setOldClass`

Examples

```r
## two examples extending S3 class "lm", class "xlm" directly
## and "ylm" indirectly
setClass("xlm", representation(eps = "numeric"), contains = "lm")
setClass("ylm", representation(header = "character"), contains = "xlm")

## lm.D9 is as computed in the example for stats::lm
y1 = new("ylm", lm.D9, header = "test", eps = .1)
x2 = new("xlm", lm.D9, eps = .1)
y2 = new("ylm", xx, header = "test")
stopifnot(inherits(y2, "lm"))
stopifnot(identical(y1, y2))
stopifnot(identical(S3Part(y1, strict = TRUE), lm.D9))
```
## note the these classes can insert an S3 subclass of "lm" as the S3 part:
myData <- data.frame(time = 1:10, y = (1:10)^.5)
myLm <- lm(cbind(y, y^3) ~ time, myData) # S3 class: c("mlm", "lm")
ym1 = new("ylm", myLm, header = "Example", eps = 0.)

## similar classes to "xlm" and "ylm", but extending S3 class c("mlm", "lm")
setClass("xmm", representation(eps = "numeric"), contains = "mlm")
setClass("ymm", representation(header="character"), contains = "xmm")

ym2 <- new("ymm", myLm, header = "Example2", eps = .001)

# but for class "ymm", an S3 part of class "lm" is an error:
try(new("ymm", lm.D9, header = "Example2", eps = .001))

setClass("dataFrameD", representation(date = "Date"),
         contains = "data.frame")
myDD <- new("dataFrameD", myData, date = Sys.Date())

## S3Part() applied to classes with a data part (.Data slot)
setClass("NumX", contains="numeric", representation(id="character"))
nn = new("NumX", 1:10, id="test")
stopifnot(identical(1:10, S3Part(nn, strict = TRUE)))

m1 = cbind(group, weight)
setClass("MatX", contains = "matrix", representation(date = "Date"))
mx1 = new("MatX", m1, date = Sys.Date())
stopifnot(identical(m1, S3Part(mx1, strict = TRUE)))

---

### Description

Methods can be defined for *group generic functions*. Each group generic function has a number of *member* generic functions associated with it.

Methods defined for a group generic function cause the same method to be defined for each member of the group, but a method explicitly defined for a member of the group takes precedence over a method defined, with the same signature, for the group generic.

The functions shown in this documentation page all reside in the `methods` package, but the mechanism is available to any programmer, by calling `setGroupGeneric` (provided package `methods` is attached).

### Usage

```r
## S4 group generics:
Arith(e1, e2)
```
S4groupGeneric

Compare(e1, e2)
Ops(e1, e2)
Logic(e1, e2)
Math(x)
Math2(x, digits)
Summary(x, ..., na.rm = FALSE)
Complex(z)

Arguments

x, z, e1, e2  objects.
digits  number of digits to be used in round or signif.
...  further arguments passed to or from methods.
na.rm  logical: should missing values be removed?

Details

Methods can be defined for the group generic functions by calls to setMethod in the usual way. Note that the group generic functions should never be called directly – a suitable error message will result if they are. When metadata for a group generic is loaded, the methods defined become methods for the members of the group, but only if no method has been specified directly for the member function for the same signature. The effect is that group generic definitions are selected before inherited methods but after directly specified methods. For more on method selection, see Methods.

There are also S3 groups Math, Ops, Summary and Complex, see ?S3groupGeneric, with no corresponding R objects, but these are irrelevant for S4 group generic functions.

The members of the group defined by a particular generic can be obtained by calling getGroupMembers. For the group generic functions currently defined in this package the members are as follows:

Arith "+", "-", ",", ",%", ",%/", "/"

Compare ":", ">", ":", ":=", ":="

Logic ":&", ":|

Ops "Arith", "Compare", "Logic"

Math2 "round", "signif"

Summary "max", "min", "range", "prod", "sum", "any", "all"

Complex "Arg", "Conj", "Im", "Mod", "Re"

Note that Ops merely consists of three sub groups.

All the functions in these groups (other than the group generics themselves) are basic functions in R. They are not by default S4 generic functions, and many of them are defined as primitives. However, you can still define formal methods for them, both individually and via the group generics. It all
works more or less as you might expect, admittedly via a bit of trickery in the background. See Methods for details.

Note that two members of the Math group, `log` and `trunc`, have ... as an extra formal argument. Since methods for Math will have only one formal argument, you must set a specific method for these functions in order to call them with the extra argument(s).

For further details about group generic functions see section 10.5 of Software for Data Analysis.

References

See Also

The function `callGeneric` is nearly always relevant when writing a method for a group generic. See the examples below and in section 10.5 of Software for Data Analysis.

See `S3groupGeneric` for S3 group generics.

Examples

```r
setClass("testComplex", representation(zz = "complex"))
## method for whole group "Complex"
setMethod("Complex", "testComplex",
    function(z) c("groupMethod", callGeneric(z@zz)))
## exception for Arg()
setMethod("Arg", "testComplex",
    function(z) c("ArgMethod", Arg(z@zz)))
z1 <- 1+2i
z2 <- new("testComplex", zz = z1)
stopifnot(identical(Mod(z2), c("groupMethod", Mod(z1))))
stopifnot(identical(Arg(z2), c("ArgMethod", Arg(z1))))
```

SClassExtension-class  Class to Represent Inheritance (Extension) Relations

Description

An object from this class represents a single ‘is’ relationship; lists of these objects are used to represent all the extensions (superclasses) and subclasses for a given class. The object contains information about how the relation is defined and methods to coerce, test, and replace correspondingly.

Objects from the Class

Objects from this class are generated by `set1s`, from direct calls and from the contains= information in a call to `setClass`, and from class unions created by `setClassUnion`. In the last case, the information is stored in defining the subclasses of the union class (allowing unions to contain sealed classes).
Slots

subClass, superClass: The classes being extended: corresponding to the from, and to arguments to setIs.

package: The package to which that class belongs.

coerce: A function to carry out the as() computation implied by the relation. Note that these functions should not be used directly. They only deal with the strict=TRUE calls to the as function, with the full method constructed from this mechanically.

test: The function that would test whether the relation holds. Except for explicitly specified test arguments to setIs, this function is trivial.

replace: The method used to implement as(x,  Class) <- value.

simple: A "logical" flag, TRUE if this is a simple relation, either because one class is contained in the definition of another, or because a class has been explicitly stated to extend a virtual class. For simple extensions, the three methods are generated automatically.

by: If this relation has been constructed transitively, the first intermediate class from the subclass.

dataPart: A "logical" flag, TRUE if the extended class is in fact the data part of the subclass. In this case the extended class is a basic class (i.e., a type).

distance: The distance between the two classes, 1 for directly contained classes, plus the number of generations between otherwise.

Methods

No methods defined with class "SClassExtension" in the signature.

See Also

is, as, and the classRepresentation class.

selectSuperClasses  Super Classes (of Specific Kinds) of a Class

Description

Return superclasses of ClassDef, possibly only non-virtual or direct or simple ones.

These functions are designed to be fast, and consequently only work with the contains slot of the corresponding class definitions.

Usage

```r
selectSuperClasses(Class, dropVirtual = FALSE, namesOnly = TRUE, 
directOnly = TRUE, simpleOnly = directOnly, 
where = topenv(parent.frame()))
```

```r
.selectSuperClasses(ext, dropVirtual = FALSE, namesOnly = TRUE, 
directOnly = TRUE, simpleOnly = directOnly)
```
Arguments

Class name of the class or (more efficiently) the class definition object (see getClass).

dropVirtual logical indicating if only non-virtual superclasses should be returned.

namesOnly logical indicating if only a vector names instead of a named list class-extensions should be returned.

directOnly logical indicating if only a direct super classes should be returned.

simpleOnly logical indicating if only simple class extensions should be returned.

where (only used when Class is not a class definition) environment where the class definition of Class is found.

ext for .selectSuperClasses() only, a list of class extensions, typically getClassDef(../)@contains.

Value

a character vector (if namesOnly is true, as per default) or a list of class extensions (as the contains slot in the result of getClass).

Note

The typical user level function is selectSuperClasses() which calls .selectSuperClasses(); i.e., the latter should only be used for efficiency reasons by experienced useRs.

See Also

is, getClass; further, the more technical class classRepresentation documentation.

Examples

```r
setClass("Root")
setClass("Base", contains = "Root", representation(length = "integer"))
setClass("A", contains = "Base", representation(x = "numeric"))
setClass("B", contains = "Base", representation(y = "character"))
setClass("C", contains = c("A", "B"))

extends("C") #--> "C" "A" "B" "Base" "Root"
selectSuperClasses("C") # "A" "B" 
selectSuperClasses("C", direct=FALSE) # "A" "B" "Base" "Root"
selectSuperClasses("C", dropVirt = TRUE, direct=FALSE)# ditto w/o "Root"
```
setClass

Create a Class Definition

Description

Create a class definition, specifying the representation (the slots) and/or the classes contained in this one (the superclasses), plus other optional details. As a side effect, the class definition is stored in the specified environment. A generator function is returned as the value of setClass(), suitable for creating objects from the class if the class is not virtual. Of the many arguments to the function only Class, representation and contains are usually needed.

Usage

setClass(Class, representation, prototype, contains=character(),
    validity, access, where, version, sealed, package,
    S3methods = FALSE, slots)

Arguments

Class character string name for the class.
slots a named list or named character vector. The names are the names of the slots in the new class and the elements are the character string names of the corresponding classes.
   In rare cases where there is ambiguity about the class of a slot, because two classes of the same name are imported from different packages, the corresponding element of the argument must have a "package" attribute to disambiguate the choice.
   It is allowed to provide an unnamed character vector as a limiting case, with the elements taken as slot names and all slots having the unrestricted class "ANY".
contains the names (and optionally package slots) for the superclasses of this class. The special superclass "VIRTUAL" causes the new class to be created as a virtual class; see the section on virtual classes in Classes.
prototype an object providing the default data for the slots in this class. By default, each will be the prototype object for the superclass. If provided, using a call to prototype will carry out some checks.
where the environment in which to store the definition. Should not be supplied in standard use. For calls to setClass() appearing in the source code for a package, will default to the namespace of the package. For calls typed or sourced at the top level in a session, will default to the global environment.
validity if supplied, should be a validity-checking method for objects from this class (a function that returns TRUE if its argument is a valid object of this class and one or more strings describing the failures otherwise). See validObject for details.
S3methods, representation, access, version
   All these arguments are deprecated from version 3.0.0 of R and should be avoided.
S3methods is a flag indicating that old-style methods will be written involving this class. Modern versions of R attempt to match formal and old-style methods consistently, so this argument is largely irrelevant.

representation is an argument inherited from S that included both slots and contains, but the use of the latter two arguments is clearer and recommended.

access and version are included for historical compatibility with S-Plus, but ignored.

sealed if TRUE, the class definition will be sealed, so that another call to setClass will fail on this class name.

package an optional package name for the class. Should very rarely be used. By default the name of the package in which the class definition is assigned.

Value

A generator function suitable for creating objects from the class is returned, invisibly. A call to this function generates a call to new for the class. The call takes any number of arguments, which will be passed on to the initialize method. If no initialize method is defined for the class or one of its superclasses, the default method expects named arguments with the name of one of the slots.

Typically the generator function is assigned the name of the class, for programming clarity. This is not a requirement and objects from the class can also be generated directly from new. The advantages of the generator function are a slightly simpler and clearer call, and that the call will contain the package name of the class (eliminating any ambiguity if two classes from different packages have the same name).

If the class is virtual, an attempt to generate an object from either the generator or new() will result in an error.

Basic Use: Slots and Inheritance

The two essential arguments other than the class name are slots and contains, defining the explicit slots and the inheritance (superclasses). Together, these arguments define all the information in an object from this class; that is, the names of all the slots and the classes required for each of them.

The name of the class determines which methods apply directly to objects from this class. The inheritance information specifies which methods apply indirectly, through inheritance. See Methods.

The slots in a class definition will be the union of all the slots specified directly by slots and all the slots in all the contained classes. There can only be one slot with a given name; specifically, the direct and inherited slot names must be unique. That does not, however, prevent the same class from being inherited via more than one path.

One kind of element in the contains= argument is special, specifying one of the R object types or one of a few other special R types (matrix and array). See the section on inheriting from object types, below.

Slot names "class" and "Class" are not allowed. There are other slot names with a special meaning; these names start with the "." character. To be safe, you should define all of your own slots with names starting with an alphabetic character.
Inheriting from Object Types

In addition to containing other S4 classes, a class definition can contain either an S3 class (see the next section) or a built-in R pseudo-class—one of the R object types or one of the special R pseudo-classes "matrix" and "array". A class can contain at most one of the object types, directly or indirectly. When it does, that contained class determines the “data part” of the class.

Objects from the new class try to inherit the built in behavior of the contained type. In the case of normal R data types, including vectors, functions and expressions, the implementation is relatively straightforward. For any object \( x \) from the class, \( \text{typeof}(x) \) will be the contained basic type; and a special pseudo-slot, .\( \text{Data} \), will be shown with the corresponding class. See the "numWithId" example below.

Classes may also inherit from "vector", "matrix" or "array". The data part of these objects can be any vector data type.

For an object from any class that does not contain one of these types or classes, \( \text{typeof}(x) \) will be "S4".

Some R data types do not behave normally, in the sense that they are non-local references or other objects that are not duplicated. Examples include those corresponding to classes "environment", "externalPtr", and "name". These cannot be the types for objects with user-defined classes (either S4 or S3) because setting an attribute overwrites the object in all contexts. It is possible to define a class that inherits from such types, through an indirect mechanism that stores the inherited object in a reserved slot. See the example for class "stampedEnv" below. S3 method dispatch and the relevant \( \text{as.type}() \) functions should behave correctly, but code that uses the type of the object directly will not.

Also, keep in mind that the object passed to low-level computations will be the underlying object type, without any of the slots defined in the class. To return the full information, you will usually have to define a method that sets the data part.

Inheriting from S3 Classes

Old-style S3 classes have no formal definition. Objects are “from” the class when their class attribute contains the character string considered to be the class name.

Using such classes with formal classes and methods is necessarily a risky business, since there are no guarantees about the content of the objects or about consistency of inherited methods. Given that, it is still possible to define a class that inherits from such types, through an indirect mechanism that stores the inherited object in a reserved slot. See the example for class "stampedEnv" below. S3 method dispatch and the relevant \( \text{as.type}() \) functions should behave correctly, but code that uses the type of the object directly will not.

Also, keep in mind that the object passed to low-level computations will be the underlying object type, without any of the slots defined in the class. To return the full information, you will usually have to define a method that sets the data part.

Classes and Packages

Class definitions normally belong to packages (but can be defined in the global environment as well, by evaluating the expression on the command line or in a file sourced from the command line). The corresponding package name is part of the class definition; that is, part of the \( \text{classRepresentation} \) object holding that definition. Thus, two classes with the same name can exist in different packages, for most purposes.
When a class name is supplied for a slot or a superclass in a call to `setClass`, a corresponding class definition will be found, looking from the namespace of the current package, assuming the call in question appears directly in the source for the package, as it should to avoid ambiguity. The class definition must be found in the namespace of the current package, in the imports for that namespace or in the basic classes defined by the methods package. (The methods package must be included in the Depends directive of the package’s "DESCRIPTION" file in order for the "CMD check" utility to find these classes.)

When this rule does not identify a class uniquely (because it appears in more than one imported package) then the `packageSlot` of the character string name needs to be supplied with the name. This should be a rare occurrence.

*Classes* for a general discussion of classes, *Methods* for an analogous discussion of methods, *makeClassRepresentation*

**Examples**

```r
## A simple class with two slots
track <- setClass("track",
    slots = c(x="numeric", y="numeric"))
## an object from the class
t1 <- track(x = 1:10, y = 1:10 + rnorm(10))

## A class extending the previous, adding one more slot
trackCurve <- setClass("trackCurve",
    slots = c(smooth = "numeric"),
    contains = "track")

## an object containing a superclass object
t1s <- trackCurve(t1, smooth = 1:10)

## A class similar to "trackCurve", but with different structure
## allowing matrices for the "y" and "smooth" slots
setClass("trackMultiCurve",
    slots = c(x="numeric", y="matrix", smooth="matrix"),
    prototype = list(x=numeric(), y=matrix(0,0,0),
                     smooth= matrix(0,0,0)))
## See ?setIs for further examples using these classes

## A class that extends the built-in data type "numeric"
numWithId <- setClass("numWithId", slots = c(id = "character"),
                     contains = "numeric")
```
numWithId(1:3, id = "An Example")

## inherit from reference object of type "environment"
setClass(stampedEnv, contains = "environment",
slots = c(update = "POSIXct"))
setMethod("[[-", c("stampedEnv", "character", "missing"),
  function(x, i, j, ..., value) {
    ev <- as(x, "environment")
    ev[[i]] <- value  # update the object in the environment
    x$update <- Sys.time()  # and the update time
  })

e1 <- stampedEnv(update = Sys.time())
e1[["noise"]]<- rnorm(10)

---

### setClassUnion

#### Classes Defined as the Union of Other Classes

**Description**

A class may be defined as the *union* of other classes; that is, as a virtual class defined as a superclass of several other classes. Class unions are useful in method signatures or as slots in other classes, when we want to allow one of several classes to be supplied.

**Usage**

```r
setClassUnion(name, members, where)
```

**Arguments**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>the name for the new union class.</td>
</tr>
<tr>
<td>members</td>
<td>the classes that should be members of this union.</td>
</tr>
<tr>
<td>where</td>
<td>where to save the new class definition; by default, the environment of the package in which the <code>setClassUnion</code> call appears, or the global environment if called outside of the source of a package.</td>
</tr>
</tbody>
</table>

**Class**

the name or definition of a class.

**Details**

The classes in `members` must be defined before creating the union. However, members can be added later on to an existing union, as shown in the example below. Class unions can be members of other class unions.
The prototype object in the class union definition will be NULL if class "NULL" is a member of the union and the prototype object of the first member class otherwise (as of version 2.15.0 of R; earlier versions had a NULL prototype even if that was not valid).

Class unions are the only way to create a class that is extended by a class whose definition is sealed (for example, the basic datatypes or other classes defined in the base or methods package in R are sealed). You cannot say setIs("function", "other") unless "other" is a class union. In general, a setIs call of this form changes the definition of the first class mentioned (adding "other" to the list of superclasses contained in the definition of "function").

Class unions get around this by not modifying the first class definition, relying instead on storing information in the subclasses slot of the class union. In order for this technique to work, the internal computations for expressions such as extends(class1, class2) work differently for class unions than for regular classes; specifically, they test whether any class is in common between the superclasses of class1 and the subclasses of class2.

The different behavior for class unions is made possible because the class definition object for class unions has itself a special class, "ClassUnionRepresentation", an extension of class classRepresentation.

References

Chambers, John M. (1998) Programming with Data Springer (For the original S4 version.)

Examples

```r
## a class for either numeric or logical data
setClassUnion("maybeNumber", c("numeric", "logical"))

## use the union as the data part of another class
setClass("withId", representation("maybeNumber", id = "character"))

w1 <- new("withId", 1:10, id = "test 1")
w2 <- new("withId", sqrt(w1)%%1 < .01, id = "Perfect squares")

## add class "complex" to the union "maybeNumber"
setIs("complex", "maybeNumber")

w3 <- new("withId", complex(real = 1:10, imaginary = sqrt(1:10)))

## a class union containing the existing class union "OptionalFunction"
setClassUnion("maybeCode",
  c("expression", "language", "OptionalFunction"))

is(quote(sqrt(1:10)), "maybeCode")  ## TRUE
```
Define a New Generic Function

Description

Create a new generic function of the given name, that is, a function that dispatches methods according to the classes of the arguments, from among the formal methods defined for this function.

Usage

```r
setGeneric(name, def=, group=list(), valueClass=character(), 
where=, package=, signature=, useAsDefault=, 
genericFunction=, simpleInheritanceOnly = )
```

```r
setGroupGeneric(name, def=, group=list(), valueClass=character(), 
knownMembers=list(), package=, where= )
```

Arguments

- **name**
  The character string name of the generic function. The simplest (and recommended) call, `setGeneric(name)`, looks for a function with this name and creates a corresponding generic function, if the function found was not generic. In the latter case, the existing function becomes the default method.

- **def**
  An optional function object, defining the generic. Don’t supply this argument if you want to turn an existing non-generic function into a generic. In this case, you usually want to use the simple call with one argument. Do supply `def` if there is no current function of this name or for some reason you do not want to use that function to define the generic. In that case, the formal arguments and default values for the generic are taken from `def`. In most cases, the body of `def` will then define the default method, as the existing function did in the one-argument call.

  If you want to create a new generic function with no default method, then `def` should be only a call to `standardGeneric` with the same character string as `name`.

- **group**
  Optionally, a character string giving the name of the group generic function to which this function belongs. See `Methods` for details of group generic functions in method selection.

- **valueClass**
  An optional character vector of one or more class names. The value returned by the generic function must have (or extend) this class, or one of the classes; otherwise, an error is generated.

- **package**
  The name of the package with which this function is associated. Usually determined automatically (as the package containing the non-generic version if there is one, or else the package where this generic is to be saved).

- **where**
  Where to store the resulting initial methods definition, and possibly the generic function; by default, stored into the top-level environment.
signature

Optionally, the vector of names, from among the formal arguments to the function, that can appear in the signature of methods for this function, in calls to `setMethod`. If ... is one of the formal arguments, it is treated specially. Starting with version 2.8.0 of R, ... may be signature of the generic function. Methods will then be selected if their signature matches all the ... arguments. See the documentation for topic `dotsMethods` for details. In the present version, it is not possible to mix ... and other arguments in the signature (this restriction may be lifted in later versions).

By default, the signature is inferred from the implicit generic function corresponding to a non-generic function. If no implicit generic function has been defined, the default is all the formal arguments except ..., in the order they appear in the function definition. In the case that ... is the only formal argument, that is also the default signature. To use ... as the signature in a function that has any other arguments, you must supply the signature argument explicitly. See the “Implicit Generic” section below for more details.

useAsDefault

Override the usual choice of default argument. Argument `useAsDefault` can be supplied, either as a function to use for the default, or as a logical value. This argument is now rarely needed. See the section on details.

simpleInheritanceOnly

Supply this argument as `TRUE` to require that methods selected be inherited through simple inheritance only; that is, from superclasses specified in the `contains=` argument to `setClass`, or by simple inheritance to a class union or other virtual class. Generic functions should require simple inheritance if they need to be assured that they get the complete original object, not one that has been transformed. Examples of functions requiring simple inheritance are `initialize`, because by definition it must return an object from the same class as its argument, and `show`, because it claims to give a full description of the object provided as its argument.

genericFunction

Don’t use; for (possible) internal use only.

knownMembers

(For `setGroupGeneric` only.) The names of functions that are known to be members of this group. This information is used to reset cached definitions of the member generics when information about the group generic is changed.

Value

The `setGeneric` function exists for its side effect: saving the generic function to allow methods to be specified later. It returns `name`.

Basic Use

The `setGeneric` function is called to initialize a generic function as preparation for defining some methods for that function.

The simplest and most common situation is that `name` is already an ordinary non-generic non-primitive function, and you now want to turn this function into a generic. In this case you will most often supply only `name`, for example:

`setGeneric("colSums")`
There must be an existing function of this name, on some attached package (in this case package "base"). A generic version of this function will be created in the current package (or in the global environment if the call to `setGeneric()` is from an ordinary source file or is entered on the command line). The existing function becomes the default method, and the package slot of the new generic function is set to the location of the original function ("base" in the example). It's an important feature that the same generic function definition is created each time, depending in the example only on the definition of `print` and where it is found. The signature of the generic function, defining which of the formal arguments can be used in specifying methods, is set by default to all the formal arguments except ....

Note that calling `setGeneric()` in this form is not strictly necessary before calling `setMethod()` for the same function. If the function specified in the call to `setMethod` is not generic, `setMethod` will execute the call to `setGeneric` itself. Declaring explicitly that you want the function to be generic can be considered better programming style; the only difference in the result, however, is that not doing so produces a message noting the creation of the generic function.

You cannot (and never need to) create an explicit generic version of the primitive functions in the base package. Those which can be treated as generic functions have methods selected and dispatched from the internal C code, to satisfy concerns for efficiency, and the others cannot be made generic. See the section on Primitive Functions below.

The description above is the effect when the package that owns the non-generic function has not created an implicit generic version. Otherwise, it is this implicit generic function that is used. See the section on Implicit Generic Functions below. Either way, the essential result is that the same version of the generic function will be created each time.

The second common use of `setGeneric()` is to create a new generic function, unrelated to any existing function, and frequently having no default method. In this case, you need to supply a skeleton of the function definition, to define the arguments for the function. The body of a generic function is usually a standard form, `standardGeneric(name)` where name is the quoted name of the generic function. When calling `setGeneric` in this form, you would normally supply the `def` argument as a function of this form. See the second and third examples below.

The `useAsDefault` argument controls the default method for the new generic. If not told otherwise, `setGeneric` will try to find a non-generic version of the function to use as a default. So, if you do have a suitable default method, it is often simpler to first set this up as a non-generic function, and then use the one-argument call to `setGeneric` at the beginning of this section. See the first example in the Examples section below.

If you don't want the existing function to be taken as default, supply the argument `useAsDefault`. That argument can be the function you want to be the default method, or `FALSE` to force no default (i.e., to cause an error if there is no direct or inherited method selected for a call to the function).

Details

The great majority of calls to `setGeneric()` should either have one argument to ensure that an existing function can have methods, or arguments `name` and `def` to create a new generic function and optionally a default method. If that's not what you plan to do, read on.

If you want to change the behavior of an existing function (typically, one in another package) when you create a generic version, you must supply arguments to `setGeneric` correspondingly. Whatever changes are made, the new generic function will be assigned with a package slot set to the current package, not the one in which the non-generic version of the function is found. This step is required because the version you are creating is no longer the same as that implied by the function in the
other package. A message will be printed to indicate that this has taken place and noting one of the
differences between the two functions. It tends to be a bad idea, because the two versions are now
competing for methods, with many chances for mistakes in programming.

The body of a generic function usually does nothing except for dispatching methods by a call to
standardGeneric. Under some circumstances you might just want to do some additional computa-
tion in the generic function itself. As long as your function eventually calls standardGeneric
that is permissible (though perhaps not a good idea, in that it may make the behavior of your
function less easy to understand). If your explicit definition of the generic function does not call
standardGeneric you are in trouble, because none of the methods for the function will ever be
dispatched.

By default, the generic function can return any object. If valueClass is supplied, it should be a vec-
tor of class names; the value returned by a method is then required to satisfy is(object, Class)
for one of the specified classes. An empty (i.e., zero length) vector of classes means anything is
allowed. Note that more complicated requirements on the result can be specified explicitly, by
defining a non-standard generic function.

The setGroupGeneric function behaves like setGeneric except that it constructs a group generic
function, differing in two ways from an ordinary generic function. First, this function cannot be
called directly, and the body of the function created will contain a stop call with this information.
Second, the group generic function contains information about the known members of the group,
used to keep the members up to date when the group definition changes, through changes in the
search list or direct specification of methods, etc.

Implicit Generic Functions

Saying that a non-generic function “is converted to a generic” is more precisely state that the func-
tion is converted to the corresponding implicit generic function. If no special action has been taken,
your function corresponds implicitly to a generic function with the same arguments, in which all
arguments other than . . . can be used. The signature of this generic function is the vector of formal
arguments, in order, except for . . .

The source code for a package can define an implicit generic function version of any function in
that package (see implicitGeneric for the mechanism). You can not, generally, define an implicit
generic function in someone else’s package. The usual reason for defining an implicit generic is
to prevent certain arguments from appearing in the signature, which you must do if you want
the arguments to be used literally or if you want to enforce lazy evaluation for any reason. An implicit
generic can also contain some methods that you want to be predefined; in fact, the implicit generic
can be any generic version of the non-generic function. The implicit generic mechanism can also
be used to prohibit a generic version (see prohibitGeneric).

Whether defined or inferred automatically, the implicit generic will be compared with the generic
function that setGeneric creates, when the implicit generic is in another package. If the two
functions are identical, then the package slot of the created generic will have the name of the
package containing the implicit generic. Otherwise, the slot will be the name of the package in
which the generic is assigned.

The purpose of this rule is to ensure that all methods defined for a particular combination of generic
function and package names correspond to a single, consistent version of the generic function.
Calling setGeneric with only name and possibly package as arguments guarantees getting the
implicit generic version, if one exists.
Including any of the other arguments can force a new, local version of the generic function. If you don’t want to create a new version, don’t use the extra arguments.

**Generic Functions and Primitive Functions**

A number of the basic R functions are specially implemented as primitive functions, to be evaluated directly in the underlying C code rather than by evaluating an R language definition. Most have implicit generics (see `implicitGeneric`), and become generic as soon as methods (including group methods) are defined on them. Others cannot be made generic.

Even when methods are defined for such functions, the generic version is not visible on the search list, in order that the C version continues to be called. Method selection will be initiated in the C code. Note, however, that the result is to restrict methods for primitive functions to signatures in which at least one of the classes in the signature is a formal S4 class.

To see the generic version of a primitive function, use `getGeneric(name)`. The function `isGeneric` will tell you whether methods are defined for the function in the current session.

Note that S4 methods can only be set on those primitives which are ‘internal generic’, plus `%*%`.

**See Also**

`Methods` and the links there for a general discussion, `dotsMethods` for methods that dispatch on “...”, and `setMethod` for method definitions.

**Examples**

```r
## create a new generic function, with a default method
setGeneric("props", function(object) attributes(object))

## A new generic function with no default method
setGeneric("increment",
  function(object, step, ...)
  standardGeneric("increment")
)

### A non-standard generic function. It insists that the methods
### return a non-empty character vector (a stronger requirement than
### valueClass = "character" in the call to setGeneric)
setGeneric("authorNames",
  function(text) {
    value <- standardGeneric("authorNames")
    if(!(is(value, "character") && any(nchar(value)>0)))
      stop("authorNames methods must return non-empty strings")
```
### An example of group generic methods, using the class
### "track"; see the documentation of 
### \link{setClass} for its definition

## define a method for the Arith group

```r
define a method for the Arith group

setMethod("Arith", c("track", "numeric"),
  function(e1, e2) {
    e1@y <- callGeneric(e1@y , e2)
    e1
  })

setMethod("Arith", c("numeric", "track"),
  function(e1, e2) {
    e2@y <- callGeneric(e1, e2@y)
    e2
  })
```

## now arithmetic operators will dispatch methods:

```r
setMethod("Arith", c("numeric", "track"),
  function(e1, e2) {
    e2@y <- callGeneric(e1, e2@y)
    e2
  })
```

```r
t1 <- new("track", x=1:10, y=sort(stats::rnorm(10)))

t1 - 1/zero.noslash/zero.noslash
1/t1
```

---

## Description

These functions provide a mechanism for packages to specify computations to be done during the
loading of the package namespace. Such actions are a flexible way to provide information only
available at load time (such as locations in a dynamically linked library).

A call to `setLoadAction()` or `setLoadActions()` specifies one or more functions to be called
when the corresponding package is loaded, with the ...argument names being used as identifying
names for the actions.

`getLoadActions` reports the currently defined load actions, given a package's namespace as its
argument.

`hasLoadAction` returns TRUE if a load action corresponding to the given name has previously been
set for the where namespace.

`evalOnLoad()` and `evalqOnLoad()` schedule a specific expression for evaluation at load time.
setLoadActions

Usage

setLoadAction(action, aname=, where=)

setLoadActions(..., .where=)

getLoadActions(where=)

hasLoadAction(aname, where=)

evalOnLoad(expr, where=, aname=)

evalqOnLoad(expr, where=, aname=)

Arguments

action, ... functions of one or more arguments, to be called when this package is loaded. The functions will be called with one argument (the package namespace) so all following arguments must have default values.

If the elements of ... are named, these names will be used for the corresponding load metadata.

where, .where the namespace of the package for which the list of load actions are defined. This argument is normally omitted if the call comes from the source code for the package itself, but will be needed if a package supplies load actions for another package.

aname the name for the action. If an action is set without supplying a name, the default uses the position in the sequence of actions specified (".1", etc.).

expr an expression to be evaluated in a load action in environment where. In the case of evalqOnLoad(), the expression is interpreted literally, in that of evalOnLoad() it must be precomputed, typically as an object of type "language".

Details

The evalOnLoad() and evalqOnLoad() functions are for convenience. They construct a function to evaluate the expression and call setLoadAction() to schedule a call to that function.

Each of the functions supplied as an argument to setLoadAction() or setLoadActions() is saved as metadata in the namespace, typically that of the package containing the call to setLoadActions(). When this package’s namespace is loaded, each of these functions will be called. Action functions are called in the order they are supplied to setLoadActions(). The objects assigned have metadata names constructed from the names supplied in the call; unnamed arguments are taken to be named by their position in the list of actions (".1", etc.).

Multiple calls to setLoadAction() or setLoadActions() can be used in a package’s code; the actions will be scheduled after any previously specified, except if the name given to setLoadAction() is that of an existing action. In typical applications, setLoadActions() is more convenient when calling from the package’s own code to set several actions. Calls to setLoadAction() are more
convenient if the action name is to be constructed, which is more typical when one package constructs load actions for another package.

Actions can be revised by assigning with the same name, actual or constructed, in a subsequent call. The replacement must still be a valid function, but can of course do nothing if the intention was to remove a previously specified action.

The functions must have at least one argument. They will be called with one argument, the namespace of the package. The functions will be called at the end of processing of S4 metadata, after dynamically linking any libraries, the call to `.onLoad()`, if any, and caching method and class definitions, but before the namespace is sealed.

Functions may therefore assign or modify objects in the namespace supplied as the argument in the call. The mechanism allows packages to save information not available until load time, such as values obtained from a dynamically linked library.

Load actions should be contrasted with user load hooks supplied by `setHook()`. User hooks are generally provided from outside the package and are run after the namespace has been sealed. Load actions are part of the package code, and the list of actions is normally established when the package is installed.

Load actions can be supplied directly in the source code for a package. It is also possible and useful to provide facilities in one package to create load actions in another package. The software needs to be careful to assign the action functions in the correct environment, namely the namespace of the target package.

Value

`setLoadAction()` and `setLoadActions()` are called for their side effect and return no useful value.

`getLoadActions()` returns a named list of the actions in the supplied namespace.

`hasLoadAction()` returns `TRUE` if the specified action name appears in the actions for this package.

Examples

```r
## Not run:
## in the code for some package

## ... somewhere else
setLoadActions(function(attach)
  cat(c("Loaded", "Unloaded")[attach], "at", Sys.time(), "\n"),
  setCount = function(ns) assign("myCount", 1, envir = ns),
  function(ns) assign("myPointer", getMyExternalPointer(), envir = ns))
  ...
  somewhere later
if(countShouldBeZero)
  setLoadAction(function(ns) assign("myCount", 0, envir = ns), "setCount")

## End(Not run)
```
setMethod

Create and Save a Method

Description
Create and save a formal method for a given function and list of classes.

Usage
setMethod(f, signature=character(), definition, where = topenv(parent.frame()), valueClass = NULL, sealed = FALSE)
removeMethod(f, signature, where)

Arguments
- **f**: A generic function or the character-string name of the function.
- **signature**: A match of formal argument names for *f* with the character-string names of corresponding classes. See the details below; however, if the signature is not trivial, you should use `method.skeleton` to generate a valid call to `setMethod`.
- **definition**: A function definition, which will become the method called when the arguments in a call to *f* match the classes in signature, directly or through inheritance.
- **where**: the environment in which to store the definition of the method. For `setMethod`, it is recommended to omit this argument and to include the call in source code that is evaluated at the top level; that is, either in an R session by something equivalent to a call to `source`, or as part of the R source code for a package. For `removeMethod`, the default is the location of the (first) instance of the method for this signature.
- **valueClass**: Obsolete and unused, but see the same argument for `setGeneric`.
- **sealed**: If TRUE, the method so defined cannot be redefined by another call to `setMethod` (although it can be removed and then re-assigned).

Details
The call to `setMethod` stores the supplied method definition in the metadata table for this generic function in the environment, typically the global environment or the namespace of a package. In the case of a package, the table object becomes part of the namespace or environment of the package. When the package is loaded into a later session, the methods will be merged into the table of methods in the corresponding generic function object.

Generic functions are referenced by the combination of the function name and the package name; for example, the function "show" from the package "methods". Metadata for methods is identified by the two strings; in particular, the generic function object itself has slots containing its name and its package name. The package name of a generic is set according to the package from which it originally comes; in particular, and frequently, the package where a non-generic version of the
function originated. For example, generic functions for all the functions in package base will have "base" as the package name, although none of them is an S4 generic on that package. These include most of the base functions that are primitives, rather than true functions; see the section on primitive functions in the documentation for setGeneric for details.

Multiple packages can have methods for the same generic function; that is, for the same combination of generic function name and package name. Even though the methods are stored in separate tables in separate environments, loading the corresponding packages adds the methods to the table in the generic function itself, for the duration of the session.

The class names in the signature can be any formal class, including basic classes such as "numeric", "character", and "matrix". Two additional special class names can appear: "ANY", meaning that this argument can have any class at all; and "missing", meaning that this argument must not appear in the call in order to match this signature. Don’t confuse these two: if an argument isn’t mentioned in a signature, it corresponds implicitly to class "ANY", not to "missing". See the example below.

Old-style (‘S3’) classes can also be used, if you need compatibility with these, but you should definitely declare these classes by calling setOldClass if you want S3-style inheritance to work.

Method definitions can have default expressions for arguments, but a current limitation is that the generic function must have some default expression for the same argument in order for the method’s defaults to be used. If so, and if the corresponding argument is missing in the call to the generic function, the default expression in the method is used. If the method definition has no default for the argument, then the expression supplied in the definition of the generic function itself is used, but note that this expression will be evaluated using the enclosing environment of the method, not of the generic function. Note also that specifying class "missing" in the signature does not require any default expressions, and method selection does not evaluate default expressions. All actual (non-missing) arguments in the signature of the generic function will be evaluated when a method is selected—when the call to standardGeneric(f) occurs.

It is possible to have some differences between the formal arguments to a method supplied to setMethod and those of the generic. Roughly, if the generic has ... as one of its arguments, then the method may have extra formal arguments, which will be matched from the arguments matching ... in the call to f. (What actually happens is that a local function is created inside the method, with the modified formal arguments, and the method is re-defined to call that local function.)

Method dispatch tries to match the class of the actual arguments in a call to the available methods collected for f. If there is a method defined for the exact same classes as in this call, that method is used. Otherwise, all possible signatures are considered corresponding to the actual classes or to superclasses of the actual classes (including "ANY"). The method having the least distance from the actual classes is chosen; if more than one method has minimal distance, one is chosen (the lexicographically first in terms of superclasses) but a warning is issued. All inherited methods chosen are stored in another table, so that the inheritance calculations only need to be done once per session per sequence of actual classes. See Methods for more details.

The function removeMethod removes the specified method from the metadata table in the corresponding environment. It’s not a function that is used much, since one normally wants to redefine a method rather than leave no definition.

**Value**

These functions exist for their side-effect, in setting or removing a method in the object defining methods for the specified generic.

The value returned by removeMethod is TRUE if a method was found to be removed.

Examples

```r
require(graphics)

## methods for plotting track objects (see the example for \link{setClass})
## First, with only one object as argument:
setMethod("plot", signature(x="track", y="missing"),
  function(x, y, ...) plot(slot(x, "x"), slot(x, "y"), ...)
)
## Second, plot the data from the track on the y-axis against anything
## as the x data.
setMethod("plot", signature(y = "track"),
  function(x, y, ...) plot(x, slot(y, "y"), ...)
)
## and similarly with the track on the x-axis (using the short form of
## specification for signatures)
setMethod("plot", "track",
  function(x, y, ...) plot(slot(x, "y"), y, ...)
)
```

```r
t1 <- new("track", x=1:2/zero.noslash, y=(1:2/zero.noslash)^2)
tc1 <- new("trackCurve", t1)
slot(tc1, "smooth") <- smooth.spline(slot(tc1, "x"), slot(tc1, "y"))$y
plot(t1)
plot(qnorm(ppoints(2/zero.noslash)), t1)
```

```r
## An example of inherited methods, and of conforming method arguments
## (note the dotCurve argument in the method, which will be pulled out
## of ... in the generic.
setMethod("plot", c("trackCurve", "missing"),
  function(x, y, dotCurve = FALSE, ...)
  {
    plot(as(x, "track"))
    if(length(slot(x, "smooth") > 0))
      lines(slot(x, "x"), slot(x, "smooth"),
      lty = if(dotCurve) 2 else 1)
  }
)
## the plot of tc1 alone has an added curve; other uses of tc1
## are treated as if it were a "track" object.
plot(tc1, dotCurve = TRUE)
```

setMethod
plot(qnorm(ppoints(20)), tc1)

## defining methods for a special function.  
## Although "[" and "length" are not ordinary functions  
## methods can be defined for them.
setMethod("[", "track", 
    function(x, i, j, ..., drop) {
      x@x <- x@x[i]; x@y <- x@y[i]
      x
    })
plot(t1[1:15])

setMethod("length", "track", function(x)length(x@y))
length(t1)

## methods can be defined for missing arguments as well
setGeneric("summary") ## make the function into a generic

## A method for summary()
## The method definition can include the arguments, but  
## if they're omitted, class "missing" is assumed.
setMethod("summary", "missing", function() "<No Object>")

---

**setOldClass**

Register Old-Style (S3) Classes and Inheritance

**Description**

Register an old-style (a.k.a. ‘S3’) class as a formally defined class. The Classes argument is the character vector used as the class attribute; in particular, if there is more than one string, old-style class inheritance is mimicked. Registering via setOldClass allows S3 classes to appear in method signatures, as a slot in an S4 class, or as a superclass of an S4 class.

**Usage**

`setOldClass(Classes, prototype, where, test = FALSE, S4Class)`

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Classes</td>
<td>A character vector, giving the names for S3 classes, as they would appear on the right side of an assignment of the class attribute in S3 computations. In addition to S3 classes, an object type or other valid data part can be specified, if the S3 class is known to require its data to be of that form.</td>
</tr>
<tr>
<td>prototype</td>
<td>An optional object to use as the prototype. This should be provided as the default S3 object for the class. If omitted, the S4 class created to register the S3 class is VIRTUAL. See the details.</td>
</tr>
</tbody>
</table>
where

Where to store the class definitions, the global or top-level environment by default. (When either function is called in the source for a package, the class definitions will be included in the package's environment by default.)

test

flag, if TRUE, arrange to test inheritance explicitly for each object, needed if the S3 class can have a different set of class strings, with the same first string. This is a different mechanism in implementation and should be specified separately for each pair of classes that have an optional inheritance. See the 'Details'.

S4Class

optionally, the class definition or the class name of an S4 class. The new class will have all the slots and other properties of this class, plus its S3 inheritance as defined by the Classes argument. Arguments prototype and test must not be supplied in this case. See the section on “S3 classes with known attributes” below.

Details

Each of the names will be defined as an S4 class, extending the remaining classes in Classes, and the class oldClass, which is the ‘root’ of all old-style classes. S3 classes have no formal definition, and therefore no formally defined slots. If a prototype argument is supplied in the call to setOldClass(), objects from the class can be generated, by a call to new; however, this usually not as relevant as generating objects from subclasses (see the section on extending S3 classes below). If a prototype is not provided, the class will be created as a virtual S4 class. The main disadvantage is that the prototype object in an S4 class that uses this class as a slot will have a NULL object in that slot, which can sometimes lead to confusion.

Beginning with version 2.8.0 of R, support is provided for using a (registered) S3 class as a superclass of a new S4 class. See the section on extending S3 classes below, and the examples.

See Methods for the details of method dispatch and inheritance.

Some S3 classes cannot be represented as an ordinary combination of S4 classes and superclasses, because objects from the S3 class can have a variable set of strings in the class. It is still possible to register such classes as S4 classes, but now the inheritance has to be verified for each object, and you must call setOldClass with argument test=TRUE once for each superclass.

For example, ordered factors always have the S3 class c("ordered", "factor"). This is proper behavior, and maps simply into two S4 classes, with "ordered" extending "factor".

But objects whose class attribute has "POSIXt" as the first string may have either (or neither) of "POSIXct" or "POSIXlt" as the second string. This behavior can be mapped into S4 classes but now to evaluate is(x, "POSIXlt"), for example, requires checking the S3 class attribute on each object. Supplying the test=TRUE argument to setOldClass causes an explicit test to be included in the class definitions. It's never wrong to have this test, but since it adds significant overhead to methods defined for the inherited classes, you should only supply this argument if it's known that object-specific tests are needed.

The list .OldClassesList contains the old-style classes that are defined by the methods package. Each element of the list is a character vector, with multiple strings if inheritance is included. Each element of the list was passed to setOldClass when creating the methods package; therefore, these classes can be used in setMethod calls, with the inheritance as implied by the list.
Extending S3 classes

A call to `setOldClass` creates formal classes corresponding to S3 classes, allows these to be used as slots in other classes or in a signature in `setMethod`, and mimics the S3 inheritance.

In documentation for the initial implementation of S4 classes in R, users were warned against defining S4 classes that contained S3 classes, even if those had been registered. The warning was based mainly on two points. 1: The S3 behavior of the objects would fail because the S3 class would not be visible, for example, when S3 methods are dispatched. 2: Because S3 classes have no formal definition, nothing can be asserted in general about the S3 part of an object from such a class. (The warning was repeated as recently as the first reference below.)

Nevertheless, defining S4 classes to contain an S3 class and extend its behavior is attractive in many applications. The alternative is to be stuck with S3 programming, without the flexibility and security of formal class and method definitions.

Beginning with version 2.8.0, R provides support for extending registered S3 classes; that is, for new classes defined by a call to `setClass` in which the `contains` argument includes an S3 class. See the examples below. The support is aimed primarily at providing the S3 class information for all classes that extend class `oldClass`, in particular by ensuring that all objects from such classes contain the S3 class in a special slot.

There are three different ways to indicate an extension to an existing S3 class: `setOldClass()`, `setClass()` and `setIs()`. In most cases, calling `setOldClass` is the best approach, but the alternatives may be preferred in the special circumstances described below.

Suppose "A" is any class extending "oldClass". then

```r
class(c("B", "A"))
```

creates a new class "B" whose S3 class concatenates "B" with `S3Class("A")`. The new class is a virtual class. If "A" was defined with known attribute/slots, then "B" has these slots also; therefore, you must believe that the corresponding S3 objects from class "B" do indeed have the claimed attributes. Notice that you can supply an S4 definition for the new class to specify additional attributes (as described in the next section.) The first alternative call produces a non-virtual class.

```r
setClass("B", contains = "A")
```

This creates a non-virtual class with the same slots and superclasses as class "A". However, class "B" is not included in the S3 class slot of the new class, unless you provide it explicitly in the prototype.

```r
setClass("B"); setIs("B", "A", .....)
```

This creates a virtual class that extends "A", but does not contain the slots of "A". The additional arguments to `setIs` should provide a coerce and replacement method. In order for the new class to inherit S3 methods, the coerce method must ensure that the class "A" object produced has a suitable S3 class. The only likely reason to prefer this third approach is that class "B" is not consistent with known attributes in class "A".

Beginning with version 2.9.0 of R, objects from a class extending an S3 class will be converted to the corresponding S3 class when being passed to an S3 method defined for that class (that is, for one of the strings in the S3 class attribute). This is intended to ensure, as far as possible, that such methods will work if they work for ordinary S3 objects. See `Classes` for details.
S3 Classes with known attributes

A further specification of an S3 class can be made if the class is guaranteed to have some attributes of known class (where as with slots, “known” means that the attribute is an object of a specified class, or a subclass of that class).

In this case, the call to `setOldClass()` can supply an S4 class definition representing the known structure. Since S4 slots are implemented as attributes (largely for just this reason), the known attributes can be specified in the representation of the S4 class. The usual technique will be to create an S4 class with the desired structure, and then supply the class name or definition as the argument `S4Class` to `setOldClass()`.

See the definition of class "ts" in the examples below. The call to `setClass` to create the S4 class can use the same class name, as here, so long as the class definition is not sealed. In the example, we define "ts" as a vector structure with a numeric slot for "tsp". The validity of this definition relies on an assertion that all the S3 code for this class is consistent with that definition; specifically, that all "ts" objects will behave as vector structures and will have a numeric "tsp" attribute. We believe this to be true of all the base code in R, but as always with S3 classes, no guarantee is possible.

The S4 class definition can have virtual superclasses (as in the "ts" case) if the S3 class is asserted to behave consistently with these (in the example, time-series objects are asserted to be consistent with the `structure` class).

For another example, look at the S4 class definition for "data.frame".

Be warned that failures of the S3 class to live up to its asserted behavior will usually go uncorrected, since S3 classes inherently have no definition, and the resulting invalid S4 objects can cause all sorts of grief. Many S3 classes are not candidates for known slots, either because the presence or class of the attributes are not guaranteed (e.g., `dimnames` in arrays, although these are not even S3 classes), or because the class uses named components of a list rather than attributes (e.g., "lm"). An attribute that is sometimes missing cannot be represented as a slot, not even by pretending that it is present with class "NULL", because attributes unlike slots can not have value NULL.

One irregularity that is usually tolerated, however, is to optionally add other attributes to those guaranteed to exist (for example, "terms" in "data.frame" objects returned by `model.frame`). As of version 2.8.0, validity checks by `validObject` ignore extra attributes; even if this check is tightened in the future, classes extending S3 classes would likely be exempted because extra attributes are so common.

Examples

```r
require(stats)
```
setOldClass(c("mlm", "lm"))
setGeneric("dfResidual", function(model)standardGeneric("dfResidual"))
setMethod("dfResidual", "lm", function(model)model$df.residual)

## dfResidual will work on mlm objects as well as lm objects
myData <- data.frame(time = 1:10, y = (1:10)^.5)
myLm <- lm(cbind(y, y^3) ~ time, myData)

showClass("data.frame")# to see the predefined S4 "oldClass"

## two examples extending S3 class "lm", class "xlm" directly
## and "ylm" indirectly
setClass("xlm", representation(eps = "numeric"), contains = "lm")
setClass("ylm", representation(header = "character"), contains = "xlm")
yml1 = new("ylm", myLm, header = "Example", eps = 0.)
## for more examples, see ?\link{S3Class}.

utils::str(.OldClassesList)

## Examples of S3 classes with guaranteed attributes
## an S3 class "stamped" with a vector and a "date" attribute
## Here is a generator function and an S3 print method.
## NOTE: it's essential that the generator checks the attribute classes
stamped <- function(x, date = Sys.time()) {
  if(!inherits(date, "POSIXt"))
    stop("bad date argument")
  if(!is.vector(x))
    stop("x must be a vector")
  attr(x, "date") <- date
  class(x) <- "stamped"
  x
}

print.stamped <- function(x, ...) {
  print(as.vector(x))
  cat("Date: ", format(attr(x,"date")), "\n")
}

## Now, an S4 class with the same structure:
setClass("stamped4", contains = "vector", representation(date = "POSIXt"))

## We can use the S4 class to register "stamped", with its attributes:
setOldClass("stamped", S4Class = "stamped4")
selectMethod("show", "stamped")
## and then remove "stamped4" to clean up
removeClass("stamped4")

someLetters <- stamped(sample(letters, 10),
                       ISOdatetime(2008, 10, 15, 12, 0, 0))

st <- new("stamped", someLetters)
show

# show() method prints the object's class, then calls the S3 print method.

stopifnot(identical(S3Part(st, TRUE), someLetters))

# creating the S4 object directly from its data part and slots
new("stamped", 1:10, date = ISOdatetime(1976, 5, 5, 15, 1/zero.noslash, /zero.noslash))

## Not run:
## The code in R that defines "ts" as an S4 class
setClass("ts", contains = "structure",
    representation(tsp = "numeric"),
    prototype(NA, tsp = rep(1,3)))

## and now registers it as an S3 class
setOldClass("ts", S4Class = "ts", where = envir)

## End(Not run)

---

show  

**Show an Object**

**Description**

Display the object, by printing, plotting or whatever suits its class. This function exists to be specialized by methods. The default method calls `showDefault`.

Formal methods for `show` will usually be invoked for automatic printing (see the details).

**Usage**

`show(object)`

**Arguments**

object  
Any R object

**Details**

Objects from an S4 class (a class defined by a call to `setClass`) will be displayed automatically if by a call to `show`. S4 objects that occur as attributes of S3 objects will also be displayed in this form; conversely, S3 objects encountered as slots in S4 objects will be printed using the S3 convention, as if by a call to `print`.

Methods defined for `show` will only be inherited by simple inheritance, since otherwise the method would not receive the complete, original object, with misleading results. See the `simpleInheritanceOnly` argument to `setGeneric` and the discussion in `setIs` for the general concept.
Value

show returns an invisible NULL.

See Also

showMethods prints all the methods for one or more functions.

Examples

## following the example shown in the setMethod documentation ...
setClass("track",
  representation(x="numeric", y="numeric"))
setClass("trackCurve",
  representation("track", smooth = "numeric"))

t1 <- new("track", x=1:20, y=(1:20)^2)
tc1 <- new("trackCurve", t1)

setMethod("show", "track",
  function(object)print(rbind(x = object@x, y=object@y))
)
## The method will now be used for automatic printing of t1

t1

x  1  2  3  4  5  6  7  8  9 10 11 12 13 14 15 16 17 18 19 20
y  1  4  9 16 25 36 49 64 81 100 121 144 169 196 225 256 289 324 361 400

## End(Not run)

## and also for tc1, an object of a class that extends "track"
tc1

x  1  2  3  4  5  6  7  8  9 10 11 12 13 14 15 16 17 18 19 20
y  1  4  9 16 25 36 49 64 81 100 121 144 169 196 225 256 289 324 361 400

## End(Not run)
Description

Show a summary of the methods for one or more generic functions, possibly restricted to those involving specified classes.

Usage

showMethods(f = character(), where = topenv(parent.frame()),
classes = NULL, includeDefs = FALSE,
inherited = !includeDefs,
showEmpty, printTo = stdout(), fdef)

Arguments

f one or more function names. If omitted, all functions will be shown that match the other arguments.
The argument can also be an expression that evaluates to a single generic function, in which case argument fdef is ignored. Providing an expression for the function allows examination of hidden or anonymous functions; see the example for isDiagonal().

where Where to find the generic function, if not supplied as an argument. When f is missing, or length 0, this also determines which generic functions to examine. If where is supplied, only the generic functions returned by getGenerics(where) are eligible for printing. If where is also missing, all the cached generic functions are considered.

classes If argument classes is supplied, it is a vector of class names that restricts the displayed results to those methods whose signatures include one or more of those classes.

includeDefs If includeDefs is TRUE, include the definitions of the individual methods in the printout.

inherited logical indicating if methods that have been found by inheritance, so far in the session, will be included and marked as inherited. Note that an inherited method will not usually appear until it has been used in this session. See selectMethod if you want to know what method would be dispatched for particular classes of arguments.

showEmpty logical indicating whether methods with no defined methods matching the other criteria should be shown at all. By default, TRUE if and only if argument f is not missing.

printTo The connection on which the information will be shown; by default, on standard output.

fdef Optionally, the generic function definition to use; if missing, one is found, looking in where if that is specified. See also comment in ‘Details’.

Details

The name and package of the generic are followed by the list of signatures for which methods are currently defined, according to the criteria determined by the various arguments. Note that the
package refers to the source of the generic function. Individual methods for that generic can come from other packages as well.

When more than one generic function is involved, either as specified or because f was missing, the functions are found and `showMethods` is recalled for each, including the generic as the argument `fdef`. In complicated situations, this can avoid some anomalous results.

**Value**

If `printTo` is `FALSE`, the character vector that would have been printed is returned; otherwise the value is the connection or filename, via `invisible`.

**References**

Chambers, John M. (1998) *Programming with Data* Springer (For the original S4 version.)

**See Also**

`setMethod`, and *GenericFunctions* for other tools involving methods; `selectMethod` will show you the method dispatched for a particular function and signature of classes for the arguments.

**Examples**

```r
require(graphics)

## Assuming the methods for plot
## are set up as in the example of help(setMethod),
## print (without definitions) the methods that involve class "track":
showMethods("plot", classes = "track")
## Not run:
# Function "plot":
# x = ANY, y = track
# x = track, y = missing
# x = track, y = ANY

require("Matrix")
showMethods("%*%")# many!
  methods(class = "Matrix")# nothing
showMethods(class = "Matrix")# everything
showMethods(Matrix:::isDiagonal) # a non-exported generic

## End(Not run)

not.there <- !any("package:stats4" == search())
if(not.there) library(stats4)
showMethods(classes = "mle")
if(not.there) detach("package:stats4")
```
signature-class

Class "signature" For Method Definitions

Description

This class represents the mapping of some of the formal arguments of a function onto the corresponding classes. It is used for two slots in the MethodDefinition class.

Objects from the Class

Objects can be created by calls of the form new("signature", functionDef, ...). The functionDef argument, if it is supplied as a function object, defines the formal names. The other arguments define the classes. More typically, the objects are created as side effects of defining methods. Either way, note that the classes are expected to be well defined, usually because the corresponding class definitions exist. See the comment on the package slot.

Slots

.Data: Object of class "character" the class names.

names: Object of class "character" the corresponding argument names.

package: Object of class "character" the names of the packages corresponding to the class names. The combination of class name and package uniquely defines the class. In principle, the same class name could appear in more than one package, in which case the package information is required for the signature to be well defined.

Extends

Class "character", from data part. Class "vector", by class "character".

Methods

initialize signature(object = "signature"): see the discussion of objects from the class, above.

See Also

class MethodDefinition for the use of this class.
The Slots in an Object from a Formal Class

Description

These functions return or set information about the individual slots in an object.

Usage

object@name
object@name <- value

slot(object, name)
slot(object, name, check = TRUE) <- value
_hasSlot(object, name)

slotNames(x)
getSlots(x)

Arguments

object An object from a formally defined class.
name The name of the slot. The operator takes a fixed name, which can be unquoted if it is syntactically a name in the language. A slot name can be any non-empty string, but if the name is not made up of letters, numbers, and ., it needs to be quoted (by backticks or single or double quotes).
value A new value for the named slot. The value must be valid for this slot in this object’s class.
check In the replacement version of slot, a flag. If TRUE, check the assigned value for validity as the value of this slot. User’s coded should not set this to FALSE in normal use, since the resulting object can be invalid.
x either the name of a class (as character string), or a class definition. If given an argument that is neither a character string nor a class definition, slotNames (only) uses class(x) instead.

Details

The definition of the class specifies all slots directly and indirectly defined for that class. Each slot has a name and an associated class. Extracting a slot returns an object from that class. Setting a slot first coerces the value to the specified slot and then stores it.

Unlike general attributes, slots are not partially matched, and asking for (or trying to set) a slot with an invalid name for that class generates an error.
The @ extraction operator and slot function themselves do no checking against the class definition, simply matching the name in the object itself. The replacement forms do check (except for slot in the case check=FALSE). So long as slots are set without cheating, the extracted slots will be valid.

Be aware that there are two ways to cheat, both to be avoided but with no guarantees. The obvious way is to assign a slot with check=FALSE. Also, slots in R are implemented as attributes, for the sake of some back compatibility. The current implementation does not prevent attributes being assigned, via attr<-, and such assignments are not checked for legitimate slot names.

Note that the "@" operators for extraction and (since R 3.0.0) replacement are primitive and actually reside in the base package.

The replacement versions of "@" and slot() differ in the computations done to coerce the right side of the assignment to the declared class of the slot. Both verify that the value provided is from a subclass of the declared slot class. The slot() version will go on to call the coerce method if there is one, in effect doing the computation as(value, slotClass, strict = FALSE). The "@" version just verifies the relation, leaving any coerce to be done later (e.g., when a relevant method is dispatched).

In most uses the result is equivalent, and the "@" version saves an extra function call, but if empirical evidence shows that a conversion is needed, either call as() before the replacement or use the replacement version of slot().

Value

The "@" operator and the slot function extract or replace the formally defined slots for the object. Functions slotNames and getSlots return respectively the names of the slots and the classes associated with the slots in the specified class definition. Except for its extended interpretation of x (above), slotNames(x) is just names(getSlots(x)).

myTrack <- new("track", x = -4:4, y = exp(-4:4))
slot(myTrack, "x")
slot(myTrack, "y") <- log(slot(myTrack, "y"))
utils::str(myTrack) # or
getSlots(getClass("track"))
slotNames(class(myTrack)) # is the same as
Description

The virtual class `structure` and classes that extend it are formal classes analogous to S language structures such as arrays and time-series.

Usage

```r
## The following class names can appear in method signatures,
## as the class in as() and is() expressions, and, except for
## the classes commented as VIRTUAL, in calls to new()

"matrix"
"array"
"ts"

"structure" ## VIRTUAL
```

Objects from the Classes

Objects can be created by calls of the form `new(Class, ...)`, where `Class` is the quoted name of the specific class (e.g., "matrix"), and the other arguments, if any, are interpreted as arguments to the corresponding function, e.g., to function `matrix()`. There is no particular advantage over calling those functions directly, unless you are writing software designed to work for multiple classes, perhaps with the class name and the arguments passed in.

Objects created from the classes "matrix" and "array" are unusual, to put it mildly, and have been for some time. Although they may appear to be objects from these classes, they do not have the internal structure of either an S3 or S4 class object. In particular, they have no "class" attribute and are not recognized as objects with classes (that is, both `is.object` and `isS4` will return `FALSE` for such objects). However, methods (both S4 and S3) can be defined for these pseudo-classes and new classes (both S4 and S3) can inherit from them.

That the objects still behave as if they came from the corresponding class (most of the time, anyway) results from special code recognizing such objects being built into the base code of R. For most purposes, treating the classes in the usual way will work, fortunately. One consequence of the special treatment is that these two classes `matrix` and `array` may be used as the data part of an S4 class; for example, you can get away with `contains = "matrix"` in a call to `setGeneric` to create an S4 class that is a subclass of "matrix". There is no guarantee that everything will work perfectly, but a number of classes have been written in this form successfully.

Note that a class containing "matrix" or "array" will have a `.Data` slot with that class. This is the only use of `.Data` other than as a pseudo-class indicating the type of the object. In this case
the type of the object will be the type of the contained matrix or array. See Classes for a general discussion.

The class "ts" is basically an S3 class that has been registered with S4, using the setOldClass mechanism. Versions of R through 2.7.0 treated this class as a pure S4 class, which was in principal a good idea, but in practice did not allow subclasses to be defined and had other intrinsic problems. (For example, setting the "tsp" parameters as a slot often fails because the built-in implementation does not allow the slot to be temporarily inconsistent with the length of the data. Also, the S4 class prevented the correct specification of the S3 inheritance for class "mts".)

Time-series objects, in contrast to matrices and arrays, have a valid S3 class, "ts", registered using an S4-style definition (see the documentation for setOldClass in the examples section for an abbreviated listing of how this is done. The S3 inheritance of "mts" in package stats is also registered. These classes, as well as "matrix" and "array" should be valid in most examples as superclasses for new S4 class definitions.

All of these classes have special S4 methods for initialize that accept the same arguments as the basic generator functions, matrix, array, and ts, in so far as possible. The limitation is that a class that has more than one non-virtual superclass must accept objects from that superclass in the call to new; therefore, a such a class (what is called a "mixin" in some languages) uses the default method for initialize, with no special arguments.

Extends

The specific classes all extend class "structure", directly, and class "vector", by class "structure".

Methods

coerce  Methods are defined to coerce arbitrary objects to these classes, by calling the corresponding basic function, for example, as(x, "matrix") calls as.matrix(x). If strict = TRUE in the call to as(), the method goes on to delete all other slots and attributes other than the dim and dimnames.

Ops  Group methods (see, e.g., S4groupGeneric) are defined for combinations of structures and vectors (including special cases for array and matrix), implementing the concept of vector structures as in the reference. Essentially, structures combined with vectors retain the structure as long as the resulting object has the same length. Structures combined with other structures remove the structure, since there is no automatic way to determine what should happen to the slots defining the structure.

Note that these methods will be activated when a package is loaded containing a class that inherits from any of the structure classes or class "vector".

testInheritedMethods

See Also

Class nonStructure, which enforces the alternative model, in which all slots are dropped if any math transformation or operation is applied to an object from a class extending one of the basic classes.

Examples

```
showClass("structure")

## explore a bit :
showClass("ts")
(ts0 <- new("ts"))
str(ts0)

showMethods("Ops") # six methods from these classes, but maybe many more
```

testInheritedMethods  Test for and Report about Selection of Inherited Methods

Description

A set of distinct inherited signatures is generated to test inheritance for all the methods of a specified generic function. If method selection is ambiguous for some of these, a summary of the ambiguities is attached to the returned object. This test should be performed by package authors before releasing a package.

Usage

```
testInheritedMethods(f, signatures, test = TRUE, virtual = FALSE,
                    groupMethods = TRUE, where = .GlobalEnv)
```

Arguments

- `f` a generic function or the character string name of one. By default, all currently defined subclasses of all the method signatures for this generic will be examined. The other arguments are mainly options to modify which inheritance patterns will be examined.

- `signatures` An optional set of subclass signatures to use instead of the relevant subclasses computed by testInheritedMethods. See the Details for how this is done. This argument might be supplied after a call with test = FALSE, to test selection in batches.

- `test` optional flag to control whether method selection is actually tested. If FALSE, returns just the list of relevant signatures for subclasses, without calling selectMethod for each signature. If there are a very large number of signatures, you may want to collect the full list and then test them in batches.
should virtual classes be included in the relevant subclasses. Normally not, since
only the classes of actual arguments will trigger the inheritance calculation in a
call to the generic function. Including virtual classes may be useful if the class
has no current non-virtual subclasses but you anticipate your users may define
such classes in the future.

should methods for the group generic function be included?

the environment in which to look for class definitions. Nearly always, use the
default global environment after attaching all the packages with relevant meth-
ods and/or class definitions.

The following description applies when the optional arguments are omitted, the usual case. First,
the defining signatures for all methods are computed by calls to findMethodSignatures. From
these all the known non-virtual subclasses are found for each class that appears in the signature of
some method. These subclasses are split into groups according to which class they inherit from,
and only one subclass from each group is retained (for each argument in the generic signature).
So if a method was defined with class "vector" for some argument, one actual vector class is
chosen arbitrarily. The case of "ANY" is dealt with specially, since all classes extend it. A dummy,
nonvirtual class, ".Other", is used to correspond to all classes that have no superclasses among
those being tested.

All combinations of retained subclasses for the arguments in the generic signature are then com-
puted. Each row of the resulting matrix is a signature to be tested by a call to selectMethod. To
collect information on ambiguous selections, testInheritedMethods establishes a calling handler
for the special signal "ambiguousMethodSelection", by setting the corresponding option.

An object of class "methodSelectionReport". The details of this class are currently subject to
change. It has slots "target", "selected", "candidates", and "note", all referring to the am-
biguous cases (and so of length 0 if there were none). These slots are intended to be examined
by the programmer to detect and preferably fix ambiguous method selections. The object contains
in addition slots "generic", the name of the generic function, and "allSelections", giving the
vector of labels for all the signatures tested.

10.6 for basics of method selection.)

## if no other attached packages have methods for `+` or its group
## generic functions, this returns a 16 by 2 matrix of selection
## patterns (in R 2.9.0)
testInheritedMethods("+")
**Description**

The classes described here are used by the R function `trace` to create versions of functions and methods including browser calls, etc., and also to `untrace` the same objects.

**Usage**

```r
### Objects from the following classes are generated
### by calling `trace()` on an object from the corresponding
### class without the "WithTrace" in the name.

"functionWithTrace"
"MethodDefinitionWithTrace"
"MethodWithNextWithTrace"
"genericFunctionWithTrace"
"groupGenericFunctionWithTrace"

### the following is a virtual class extended by each of the
### classes above

"traceable"
```

**Objects from the Class**

Objects will be created from these classes by calls to `trace`. (There is an `initialize` method for class "traceable", but you are unlikely to need it directly.)

**Slots**

- `.Data`: The data part, which will be "function" for class "functionWithTrace", and similarly for the other classes.
- `original`: Object of the original class; e.g., "function" for class "functionWithTrace".

**Extends**

Each of the classes extends the corresponding untraced class, from the data part; e.g., "functionWithTrace" extends "function". Each of the specific classes extends "traceable", directly, and class "VIRTUAL", by class "traceable".

**Methods**

The point of the specific classes is that objects generated from them, by function `trace()`, remain callable or dispatchable, in addition to their new trace information.
validObject

Test the Validity of an Object

Description

The validity of object related to its class definition is tested. If the object is valid, TRUE is returned; otherwise, either a vector of strings describing validity failures is returned, or an error is generated (according to whether test is TRUE). Optionally, all slots in the object can also be validated.

The function setValidity sets the validity method of a class (but more normally, this method will be supplied as the validity argument to setClass). The method should be a function of one object that returns TRUE or a description of the non-validity.

Usage

validObject(object, test = FALSE, complete = FALSE)

setValidity(Class, method, where = topoenv(parent.frame()) )

getValidity(ClassDef)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object</td>
<td>any object, but not much will happen unless the object’s class has a formal definition.</td>
</tr>
<tr>
<td>test</td>
<td>logical; if TRUE and validity fails, the function returns a vector of strings describing the problems. If test is FALSE (the default) validity failure generates an error.</td>
</tr>
<tr>
<td>complete</td>
<td>logical; if TRUE, validity methods will be applied recursively to any of the slots that have such methods.</td>
</tr>
<tr>
<td>Class</td>
<td>the name or class definition of the class whose validity method is to be set.</td>
</tr>
<tr>
<td>ClassDef</td>
<td>a class definition object, as from getClassDef.</td>
</tr>
<tr>
<td>method</td>
<td>a validity method; that is, either NULL or a function of one argument (object). Like validObject, the function should return TRUE if the object is valid, and one or more descriptive strings if any problems are found. Unlike validObject, it should never generate an error.</td>
</tr>
<tr>
<td>where</td>
<td>the modified class definition will be stored in this environment.</td>
</tr>
</tbody>
</table>

Note that validity methods do not have to check validity of superclasses: the logic of validObject ensures these tests are done once only. As a consequence, if one validity method wants to use another, it should extract and call the method from the other definition of the other class by calling getValidity(): it should not call validObject.

See Also

function trace
Details

Validity testing takes place 'bottom up': Optionally, if complete=TRUE, the validity of the object's slots, if any, is tested. Then, in all cases, for each of the classes that this class extends (the 'superclasses'), the explicit validity method of that class is called, if one exists. Finally, the validity method of object's class is called, if there is one.

Testing generally stops at the first stage of finding an error, except that all the slots will be examined even if a slot has failed its validity test.

The standard validity test (with complete=FALSE) is applied when an object is created via new with any optional arguments (without the extra arguments the result is just the class prototype object).

An attempt is made to fix up the definition of a validity method if its argument is not object.

Value

validObject returns TRUE if the object is valid. Otherwise a vector of strings describing problems found, except that if test is FALSE, validity failure generates an error, with the corresponding strings in the error message.

setClass; class classRepresentation.

Examples

setClass("track",
    representation(x="numeric", y = "numeric"))
t1 <- new("track", x=1:10, y=sort(stats::rnorm(10)))
## A valid "track" object has the same number of x, y values
validTrackObject <- function(object) {
    if(length(object@x) == length(object@y)) TRUE
    else paste("Unequal x,y lengths: ", length(object@x), ", ", 
             length(object@y), sep="")
}
## assign the function as the validity method for the class
setValidity("track", validtrackObject)
## t1 should be a valid "track" object
validObject(t1)
## Now we do something bad

## This should generate an error
## Not run: try(validObject(t2))
setClass("trackCurve",
    representation("track", smooth = "numeric"))

## all superclass validity methods are used when validObject
## is called from initialize() with arguments, so this fails
## Not run: trynew("trackCurve", t2)

setClass("twoTrack", representation(tr1 = "track", tr2 = "track"))

## validity tests are not applied recursively by default,
## so this object is created (invalidly)
tT <- new("twoTrack", tr2 = t2)

## A stricter test detects the problem
## Not run: try(validObject(tT, complete = TRUE))
Chapter 8

The parallel package

parallel-package     Support for Parallel Computation

Description

Support for parallel computation, including random-number generation.

Details

This package is under development: a first version was released with R 2.14.0.

There is support for multiple RNG streams with the ‘“L’Ecuyer-CMRG”’ RNG: see nextRNGStream.

It contains functionality derived from and pretty much equivalent to that contained in packages multicore (with some low-level functions renamed and not exported) and snow (for socket clusters only, but MPI and NWS clusters generated by snow are also supported). This package also provides makeForkCluster.

For a complete list of exported functions, use library(help = "parallel").

Author(s)

Brian Ripley, Luke Tierney and Simon Urbanek

Maintainer: R Core Team <R-core@r-project.org>

See Also

Parallel computation involves launching worker processes: functions psnice and pskill in package tools provide means to manage such processes.
clusterApply  

Apply Operations using Clusters

Description

These functions provide several ways to parallelize computations using a cluster.

Usage

clusterCall(cl = NULL, fun, ...)
clusterApply(cl = NULL, x, fun, ...) 
clusterApplyLB(cl = NULL, x, fun, ...) 
clusterEvalQ(cl = NULL, expr) 
clusterExport(cl = NULL, varlist, envir = .GlobalEnv) 
clusterMap(cl = NULL, fun, ..., MoreArgs = NULL, RECYCLE = TRUE, SIMPLIFY = FALSE, USE.NAMES = TRUE, .scheduling = c("static", "dynamic")) 
clusterSplit(cl = NULL, seq)

parLapply(cl = NULL, X, fun, ...) 
parSapply(cl = NULL, X, FUN, ..., simplify = TRUE, USE.NAMES = TRUE) 
parApply(cl = NULL, X, MARGIN, FUN, ...) 
parRapply(cl = NULL, x, FUN, ...) 
parCapply(cl = NULL, x, FUN, ...) 

parLapplyLB(cl = NULL, X, fun, ...) 
parSapplyLB(cl = NULL, X, FUN, ..., simplify = TRUE, USE.NAMES = TRUE)

Arguments

cl  a cluster object, created by this package or by package snow. If NULL, use the registered default cluster.
fun, FUN  function or character string naming a function.
expr  expression to evaluate.
seq  vector to split.
varlist  character vector of names of objects to export.
envir  environment from which t export variables
x  a vector for clusterApply and clusterApplyLB, a matrix for parRapply and parCapply.
...  additional arguments to pass to fun or FUN: beware of partial matching to earlier arguments.
MoreArgs  additional arguments for fun.
Details

clusterCall calls a function fun with identical arguments … on each node.

clusterEvalQ evaluates a literal expression on each cluster node. It is a parallel version of evalq, and is a convenience function invoking clusterCall.

clusterApply calls fun on the first node with arguments seq[[1]] and …, on the second node with seq[[2]] and …, and so on, recycling nodes as needed.

clusterApplyLB is a load balancing version of clusterApply. If the length p of seq is not greater than the number of nodes n, then a job is sent to p nodes. Otherwise the first n jobs are placed in order on the n nodes. When the first job completes, the next job is placed on the node that has become free; this continues until all jobs are complete. Using clusterApplyLB can result in better cluster utilization than using clusterApply, but increased communication can reduce performance. Furthermore, the node that executes a particular job is non-deterministic.

clusterMap is a multi-argument version of clusterApply, analogous to mapply and Map. If RECYCLE is true shorter arguments are recycled (and either none or all must be of length zero); otherwise, the result length is the length of the shortest argument. Nodes are recycled if the length of the result is greater than the number of nodes. (mapply always uses RECYCLE = TRUE, and has argument SIMPLIFY = TRUE. Map always uses RECYCLE = TRUE.)

clusterExport assigns the values on the master R process of the variables named in varlist to variables of the same names in the global environment (aka ‘workspace’) of each node. The environment on the master from which variables are exported defaults to the global environment.

clusterSplit splits seq into a consecutive piece for each cluster and returns the result as a list with length equal to the number of nodes. Currently the pieces are chosen to be close to equal in length: the computation is done on the master.

parLapply, parSapply, and parApply are parallel versions of lapply, sapply and apply. parLapplyLB, parSapplyLB are load-balancing versions, intended for use when applying FUN to different elements of X takes quite variable amounts of time, and either the function is deterministic or reproducible results are not required.

parRapply and parCapply are parallel row and column apply functions for a matrix x; they may be slightly more efficient than parApply but do less post-processing of the result.

Value

For clusterCall, clusterEvalQ and clusterSplit, a list with one element per node.
For clusterApply and clusterApplyLB, a list the same length as seq.
clusterMap follows mapply.
clusterExport returns nothing.
parLapply returns a list the length of \( X \).
parSapply and parApply follow \texttt{sapply} and \texttt{apply} respectively.
parRapply and parCapply always return a vector. If \texttt{FUN} always returns a scalar result this will be of length the number of rows or columns: otherwise it will be the concatenation of the returned values.
An error is signalled on the master if any of the workers produces an error.

\textbf{Note}

These functions are almost identical to those in package \texttt{snow}.
Two exceptions: \texttt{parLapply} has argument \( X \) not \( x \) for consistency with \texttt{lapply}, and \texttt{parSapply} has been updated to match \texttt{sapply}.

\textbf{Author(s)}

Luke Tierney and R Core.
Derived from the \texttt{snow} package.

\textbf{Examples}

```r
## Use option cl.cores to choose an appropriate cluster size.
cl <- makeCluster(getOption("cl.cores", 2))

clusterApply(cl, 1:2, get("+"), 3)
x <- 1
clusterExport(cl, "xx")
clusterCall(cl, function(y) xx + y, 2)

## Use clusterMap like an mapply example
clusterMap(cl, function(x, y) seq_len(x) + y,
          c(a = 1, b = 2, c = 3), c(A = 1/zero.noslash, B = /zero.noslash, C = -1/zero.noslash))

parSapply(cl, 1:2/zero.noslash, get("+"), 3)

## A bootstrapping example, which can be done in many ways:
clusterEvalQ(cl, {
  ## set up each worker. Could also use clusterExport()
  library(boot)
  cd4.rg <- function(data, mle) MASS::mvrnorm(nrow(data), mle$m, mle$v)
  cd4.mle <- list(m = colMeans(cd4), v = var(cd4))
  NULL
})
res <- clusterEvalQ(cl, boot(cd4, corr, R = 1/zero.noslash/zero.noslash,
                           sim = "parametric", ran.gen = cd4.rg, mle = cd4.mle))
library(boot)

# (Rest of the example continues here)
stopCluster(cl)

## or
library(boot)
run1 <- function(...) {
  library(boot)
  cd4.rg <- function(data, mle) MASS::mvrnorm(nrow(data), mle$m, mle$v)
  cd4.mle <- list(m = colMeans(cd4), v = var(cd4))
  boot(cd4, corr, R = 500, sim = "parametric",
       ran.gen = cd4.rg, mle = cd4.mle)
}
cl <- makeCluster(mc <- getOption("cl.cores", 2))
## to make this reproducible
clusterSetRNGStream(cl, 123)
cd4.boot <- do.call(c, parLapply(cl, seq_len(mc), run1))
boot.ci(cd4.boot, type = c("norm", "basic", "perc"),
         conf = 0.9, h = atanh, hinv = tanh)
stopCluster(cl)

detectCores

---

**Detect the Number of CPU Cores**

**Description**

Attempt to detect the number of CPU cores on the current host.

**Usage**

detectCores(all.tests = FALSE, logical = FALSE)

**Arguments**

- `all.tests` Logical: if true apply all known tests.
- `logical` Logical: if possible, use the number of physical CPUs/cores (if FALSE) or logical CPUs (if TRUE).

**Details**

This attempts to detect the number of CPU cores in the current machine.

It has methods to do so for Linux, OS X, FreeBSD, Solaris, Irix and Windows. `detectCores(TRUE)` could be tried on other Unix-alike systems.

**Value**

An integer, NA if the answer is unknown.

Exactly what this represents is OS-dependent: where possible by default it represents physical cores and not logical (e.g. hyperthreaded) CPUs.

On Windows the default is the number of logical CPUs.
Currently logical makes a difference on Sparc Solaris: there logical = FALSE returns the number of physical cores and logical = TRUE returns the number of available hardware threads. (Some Sparc CPUs which do have multiple cores per CPU, others have multiple threads per core and some have both.) For example, the UltraSparc T2 CPU in the CRAN check server is a single physical CPU with 8 cores, and each core supports 8 hardware threads. So detectCores(logical = FALSE) returns 8, and detectCores(logical = TRUE) returns 64.

Where virtual machines are in use, one would hope that the result represents the number of CPUs available (or potentially available) to that particular VM.

Author(s)
Simon Urbanek and Brian Ripley

Examples

detectCores()
detectCores(logical = TRUE)

makeCluster

Create a Parallel Socket Cluster

Description

Creates a set of copies of R running in parallel and communicating over sockets.

Usage

makeCluster(spec, type, ...)  
makePSOCKcluster(names, ...)  
makeForkCluster(nnodes = getOption("mc.cores", 2L), ...)  

stopCluster(cl = NULL)  
setDefaultCluster(cl = NULL)

Arguments

spec  
A specification appropriate to the type of cluster.

names  
Either a character vector of host names on which to run the worker copies of R, or a positive integer (in which case that number of copies is run on ‘localhost’).

nnodes  
The number of nodes to be forked.

tyype  
One of the supported types: see ‘Details’.

...  
Options to be passed to the function spawning the workers. See ‘Details’.

c1  
an object of class "cluster".
makeCluster creates a cluster of one of the supported types. The default type, "PSOCK", calls makePSOCKcluster. Type "FORK" calls makeForkCluster. Other types are passed to package snow.

makePSOCKcluster is very similar to makeSOCKcluster in package snow. It runs Rscript on the specified host(s) to set up a worker process which listens on a socket for expressions to evaluate, and returns the results (as serialized objects).

makeForkCluster is merely a stub on Windows. On Unix-alike platforms it creates the worker process by forking.

The workers are most often running on the same host as the master, when no options need be set. Several options are supported (mainly for makePSOCKcluster):

- **master** The host name of the master, as known to the workers. This may not be the same as it is known to the master, and on private subnets it may be necessary to specify this as a numeric IP address. For example, OS X is likely to detect a machine as 'somename.local', a name known only to itself.
- **port** The port number for the socket connection, default taken from the environment variable R_PARALLEL_PORT, then a randomly chosen port in the range 11000:11999.
- **timeout** The timeout in seconds for that port. Default 30 days (and the POSIX standard only requires values up to 31 days to be supported).
- **outfile** Where to direct the stdout and stderr connection output from the workers. "" indicates no redirection (which may only be useful for workers on the local machines). Defaults to '/dev/null' ('nul:' on Windows). The other possibility is a file path on the worker's host. Files will be opened in append mode, as all workers log to the same file.
- **homogeneous** Logical. Are all the hosts running identical setups, so Rscript can be launched using its full path on the master? Otherwise it has to be in the default path on the other hosts.
- **rscript** The path to Rscript on the workers. Defaults to the full path on the master.
- **renice** A numerical 'niceness' to set for the worker processes, e.g. 15 for a low priority. OS-dependent: see psnice for details.
- **rshcmd** The command to be run on the master to launch a process on another host. Defaults to ssh.
- **user** The user name to be used when communicating with another host.
- **methods** Logical. If true (default) the workers will load the methods package: not loading it saves ca 30% of the startup time of the cluster.
- **useXDR** Logical. If true (default) serialization will use XDR: where large amounts of data are to be transferred and all the nodes are little-endian, communication may be substantially fast if this is set to false.

Function makeForkCluster creates a socket cluster by forking (and hence is not available on Windows). It supports options port, timeout and outfile, and always uses useXDR = FALSE.

It is good practice to shut down the workers by calling stopCluster: however the workers will terminate themselves once the socket on which they are listening for commands becomes unavailable, which it should if the master R session is completed (or its process dies).

Function setDefaultCluster registers a cluster as the default one for the current session. Using setDefaultCluster(NULL) removes the registered cluster, as does stopping that cluster.
Value

An object of class c("SOCKcluster", "cluster").

Author(s)

Luke Tierney and R Core.
Derived from the snow package.

mcaffinity
Get or Set CPU Affinity Mask of the Current Process

Description

mcaffinity retrieves or sets the CPU affinity mask of the current process, i.e., the set of CPUs
the process is allowed to be run on. (CPU here means logical CPU which can be CPU, core or
hyperthread unit.)

Usage

mcaffinity(affinity = NULL)

Arguments

affinity specification of the CPUs to lock this process to (numeric vector) or NULL if no
change is requested

Details

mcaffinity can be used to obtain (affinity = NULL) or set the CPU affinity mask of the current
process. The affinity mask is a list of integer CPU identifiers (starting from 1) that this process is
allowed to run on. Not all systems provide user access to the process CPU affinity, in cases where
no support is present at all mcaffinity() will return NULL. Some systems may take into account
only the number of CPUs present in the mask.

Typically, it is legal to specify larger set than the number of logical CPUs (but at most as many as
the OS can handle) and the system will return back the actually present set.

Value

NULL if CPU affinity is not supported by the system or an integer vector with the set of CPUs in the
active affinity mask for this process (this may be different than affinity).

mcparallel
Description

These are low-level support functions for the forking approach.

They are not available on Windows, and not exported from the namespace.

Usage

children(select)
readChild(child)
readChildren(timeout = 0)
selectChildren(children = NULL, timeout = 0)
sendChildStdin(child, what)
sendMaster(what)
mckill(process, signal = 2L)

Arguments

select if omitted, all active children are returned, otherwise select should be a list of processes and only those from the list that are active will be returned.
child child process (object of the class "childProcess") or a process ID (pid). See also 'Details'.
timeout timeout (in seconds, fractions supported) to wait for a response before giving up.
children list of child processes or a single child process object or a vector of process IDs or NULL. If NULL behaves as if all currently known children were supplied.
what For sendChildStdin:
Character or raw vector. In the former case elements are collapsed using the newline character. (But no trailing newline is added at the end!)
For sendMaster:
Data to send to the master process. If what is not a raw vector, it will be serialized into a raw vector. Do NOT send an empty raw vector – that is reserved for internal use.
process process (object of the class process) or a process ID (pid)
signal integer: signal to send. Values of 2 (SIGINT), 9 (SIGKILL) and 15 (SIGTERM) are pretty much portable, but for maximal portability use tools::SIGTERM and so on.
mcchildren

Details

children returns currently active children.
readChild reads data from a given child process.
selectChildren checks children for available data.
readChildren checks all children for available data and reads from the first child that has available data.

sendChildStdin sends a string (or data) to one or more child’s standard input. Note that if the master session was interactive, it will also be echoed on the standard output of the master process (unless disabled). The function is vector-compatible, so you can specify child as a list or a vector of process IDs.

sendMaster sends data from the child to the master process.
mckill sends a signal to a child process: it is equivalent to pskill in package tools.

Value

children returns a (possibly empty) list of objects of class "process", the process ID.
readChild and readChildren return a raw vector with a "pid" attribute if data were available, an integer vector of length one with the process ID if a child terminated or NULL if the child no longer exists (no children at all for readChildren).
selectChildren returns TRUE is the timeout was reached, FALSE if an error occurred (e.g. if the master process was interrupted) or an integer vector of process IDs with children that have data available, or NULL if there are no children.
sendChildStdin returns a vector of TRUE values (one for each member of child) or throws an error.
sendMaster returns TRUE or throws an error.
mckill returns TRUE.

Warning

This is a very low-level API for expert use only.

## End(Not run)
```

### mcfork

Fork a Copy of the Current R Process

**Description**

These are low-level functions, not available on Windows, and not exported from the namespace. `mcfork` creates a new child process as a copy of the current R process. `mcexit` closes the current child process, informing the master process as necessary.

**Usage**

```r
mcfork()
mcheck(exit.code = 0L, send = NULL)
```

**Arguments**

- `exit.code` (process exit code. By convention 0L signifies a clean exit, 1L an error.
- `send` if not NULL send this data before exiting (equivalent to using `sendMaster`).

**Details**

The `mcfork` function provides an interface to the `fork` system call. In addition it sets up a pipe between the master and child process that can be used to send data from the child process to the master (see `sendMaster`) and child's `stdin` is re-mapped to another pipe held by the master process (see `sendChildStdin`).

If you are not familiar with the `fork` system call, do not use this function directly as it leads to very complex inter-process interactions amongst the R processes involved.

In a nutshell `fork` spawns a copy (child) of the current process, that can work in parallel to the master (parent) process. At the point of forking both processes share exactly the same state including the workspace, global options, loaded packages etc. Forking is relatively cheap in modern operating systems and no real copy of the used memory is created, instead both processes share the same memory and only modified parts are copied. This makes `mcfork` an ideal tool for parallel processing since there is no need to setup the parallel working environment, data and code is shared automatically from the start.

`mcexit` is to be run in the child process. It sends send to the master (unless NULL) and then shuts down the child process. The child can also be shut down by sending it the signal SIGUSR1, as is done by the unexported function `parallel:::rmChild`. 

Value

mcfork returns an object of the class "childProcess" to the master and of class "masterProcess" to the child: both the classes inherit from class "process". These are lists with components pid (the process id of the other process) and a vector fd of the two file descriptor numbers for ends in the current process of the inter-process pipes.

mcexit never returns.

GUI/embedded environments

It is strongly discouraged to use mcfork and the higher-level functions which rely on it (e.g., mcparallel, mcallapply and pvec) in GUI or embedded environments, because it leads to several processes sharing the same GUI which will likely cause chaos (and possibly crashes). Child processes should never use on-screen graphics devices. Some precautions have been taken to make this usable in R.app on OS X, but users of third-party front-ends should consult their documentation.

This can also apply to other connections, e.g. to an X server, created before forking.

Note that tcltk counts as a GUI for these purposes since Tcl runs an event loop. As from R 2.15.3 that event loop is inhibited in a child process but there could still be problems with Tk graphical connections.

Warning

This is a very low-level API for expert use only.

mcparallel, sendMaster

Examples

```r
## This will work when run as an example, but not when pasted in.
p <- mcfork()
if (inherits(p, "masterProcess")) {
  cat("I'm a child! ", Sys.getpid(), "\n")
  mcexit("I was a child")
}
cat("I'm the master\n")
unserialize(readChildren(1.5))
```
**Description**

mclapply is a parallelized version of `lapply`, it returns a list of the same length as `X`, each element of which is the result of applying `FUN` to the corresponding element of `X`.

It relies on forking and hence is not available on Windows unless `mc.cores = 1`.

**Usage**

```r
mclapply(X, FUN, ..., 
   mc.preschedule = TRUE, mc.set.seed = TRUE, 
   mc.silent = FALSE, mc.cores = getOption("mc.cores", 2L), 
   mc.cleanup = TRUE, mc.allow.recursive = TRUE)
```

```r
mcmapply(FUN, ..., 
   MoreArgs = NULL, SIMPLIFY = TRUE, USE.NAMES = TRUE, 
   mc.preschedule = TRUE, mc.set.seed = TRUE, 
   mc.silent = FALSE, mc.cores = getOption("mc.cores", 2L), 
   mc.cleanup = TRUE)
```

```r
mcMap(f, ...)
```

**Arguments**

- **X**
  a vector (atomic or list) or an expressions vector. Other objects (including classed objects) will be coerced by `as.list`.

- **FUN**
  the function to be applied to (mclapply) each element of `X` or (mcmapply) in parallel to `...`

- **f**
  the function to be applied in parallel to `...`

- **...**
  For mclapply, optional arguments to `FUN`. For mcmapply and mcMap, vector or list inputs: see `mapply`.

- **MoreArgs**, **SIMPLIFY**, **USE.NAMES**
  see `mapply`.

- **mc.preschedule**
  if set to `TRUE` then the computation is first divided to (at most) as many jobs are there are cores and then the jobs are started, each job possibly covering more than one value. If set to `FALSE` then one job is forked for each value of `X`. The former is better for short computations or large number of values in `X`, the latter is better for jobs that have high variance of completion time and not too many values of `X` compared to `mc.cores`.

- **mc.set.seed**
  See `mcparallel`.

- **mc.silent**
  if set to `TRUE` then all output on `stdout` will be suppressed for all parallel processes forked (`stderr` is not affected).
mc.cores  The number of cores to use, i.e. at most how many child processes will be run simultaneously. The option is initialized from environment variable MC_CORES if set. Must be at least one, and parallelization requires at least two cores.

mc.cleanup  if set to TRUE then all children that have been forked by this function will be killed (by sending SIGTERM) before this function returns. Under normal circumstances mclapply waits for the children to deliver results, so this option usually has only effect when mclapply is interrupted. If set to FALSE then child processes are collected, but not forcefully terminated. As a special case this argument can be set to the number of the signal that should be used to kill the children instead of SIGTERM.

mc.allow.recursive  Unless true, calling mclapply in a child process will use the child and not fork again.

Details

mclapply is a parallelized version of lapply, provided mc.cores > 1: for mc.cores == 1 it simply calls lapply.

By default (mc.preschedule = TRUE) the input X is split into as many parts as there are cores (currently the values are spread across the cores sequentially, i.e. first value to core 1, second to core 2, ... (core + 1)-th value to core 1 etc.) and then one process is forked to each core and the results are collected.

Without prescheduling, a separate job is forked for each value of X. To ensure that no more than mc.cores jobs are running at once, once that number has been forked the master process waits for a child to complete before the next fork.

Due to the parallel nature of the execution random numbers are not sequential (in the random number sequence) as they would be when using lapply. They are sequential for each forked process, but not all jobs as a whole. See mcparallel or the package’s vignette for ways to make the results reproducible with mc.preschedule = TRUE.

Note: the number of file descriptors (and processes) is usually limited by the operating system, so you may have trouble using more than 100 cores or so (see ulimit -n or similar in your OS documentation) unless you raise the limit of permissible open file descriptors (fork will fail with error "unable to create a pipe").

Value

For mclapply, a list of the same length as X and named by X.
For mcmapply, a list, vector or array: see mapply.
For mcMap, a list.

Each forked process runs its job inside try(..., silent = TRUE) so if errors occur they will be stored as class "try-error" objects in the return value and a warning will be given. Note that the job will typically involve more than one value of X and hence a "try-error" object will be returned for all the values involved in the failure, even if not all of them failed.
Warning

It is strongly discouraged to use these functions in GUI or embedded environments, because it leads
to several processes sharing the same GUI which will likely cause chaos (and possibly crashes). Child processes should never use on-screen graphics devices.

Some precautions have been taken to make this usable in R.app on OS X, but users of third-party front-ends should consult their documentation.

Note that tcltk counts as a GUI for these purposes since Tcl runs an event loop. As from R 2.15.3 that event loop is inhibited in a child process but there could still be problems with Tk graphical connections.

mcparallel | Evaluate an R Expression Asynchronously in a Separate Process

**Description**

These functions are based on forking and so are not available on Windows.

mcparallel starts a parallel R process which evaluates the given expression.

mccollect collects results from one or more parallel processes.

**Usage**

```r
mcparallel(expr, name, mc.set.seed = TRUE, silent = FALSE,
            mc.affinity = NULL, mc.interactive = FALSE)
mccollect(jobs, wait = TRUE, timeout = 0, intermediate = FALSE)
```

**Arguments**

- `expr`: expression to evaluate (do not use any on-screen devices or GUI elements in this code).
- `name`: an optional name (character vector of length one) that can be associated with the job.
- `mc.set.seed`: logical: see section ‘Random numbers’.
- `silent`: if set to TRUE then all output on stdout will be suppressed (stderr is not affected).
- `mc.affinity`: either a numeric vector specifying CPUs to restrict the child process to (1-based) or NULL to not modify the CPU affinity
- `mc.interactive`: logical, if TRUE or FALSE then the child process will be set as interactive or non-interactive respectively. If NA then the child process will inherit the interactive flag from the parent.
- `jobs`: list of jobs (or a single job) to collect results for. Alternatively jobs can also be an integer vector of process IDs. If omitted collect will wait for all currently existing children.
- `wait`: if set to FALSE it checks for any results that are available within `timeout` seconds from now, otherwise it waits for all specified jobs to finish.
- `timeout`: timeout (in seconds) to check for job results – applies only if `wait` is FALSE.
- `intermediate`: FALSE or a function which will be called while collect waits for results. The function will be called with one parameter which is the list of results received so far.
mcparallel evaluates the expr expression in parallel to the current R process. Everything is shared read-only (or in fact copy-on-write) between the parallel process and the current process, i.e. no side-effects of the expression affect the main process. The result of the parallel execution can be collected using mccollect function.

mccollect function collects any available results from parallel jobs (or in fact any child process). If wait is TRUE then collect waits for all specified jobs to finish before returning a list containing the last reported result for each job. If wait is FALSE then mccollect merely checks for any results available at the moment and will not wait for jobs to finish. If jobs is specified, jobs not listed there will not be affected or acted upon.

Note: If expr uses low-level multicore functions such as sendMaster a single job can deliver results multiple times and it is the responsibility of the user to interpret them correctly. mccollect will return NULL for a terminating job that has sent its results already after which the job is no longer available.

The mc.affinity parameter can be used to try to restrict the child process to specific CPUs. The availability and the extent of this feature is system-dependent (e.g., some systems will only consider the CPU count, others will ignore it completely).

Value

mcparallel returns an object of the class "parallelJob" which inherits from "childProcess" (see the ‘Value’ section of the help for mcfork). If argument name was supplied this will have an additional component name.

mccollect returns any results that are available in a list. The results will have the same order as the specified jobs. If there are multiple jobs and a job has a name it will be used to name the result, otherwise its process ID will be used. If none of the specified children are still running, it returns NULL.

Random numbers

If mc.set.seed = FALSE, the child process has the same initial random number generator (RNG) state as the current R session. If the RNG has been used (or .Random.seed was restored from a saved workspace), the child will start drawing random numbers at the same point as the current session. If the RNG has not yet been used, the child will set a seed based on the time and process ID when it first uses the RNG: this is pretty much guaranteed to give a different random-number stream from the current session and any other child process.

The behaviour with mc.set.seed = TRUE is different only if RNGkind("L'Ecuyer-CMRG") has been selected. Then each time a child is forked it is given the next stream (see nextRNGStream). So if you select that generator, set a seed and call mc.reset.stream just before the first use of mcparallel the results of simulations will be reproducible provided the same tasks are given to the first, second, ...forked process.

Note

Package multicore also exported functions collect and parallel. These names are easily masked (for example package lattice also has a function parallel) and they are not supplied in this package.
pvec

Parallelize a Vector Map Function using Forking

Description

pvec parallelizes the execution of a function on vector elements by splitting the vector and submitting each part to one core. The function must be a vectorized map, i.e. it takes a vector input and creates a vector output of exactly the same length as the input which doesn’t depend on the partition of the vector.

It relies on forking and hence is not available on Windows unless mc.cores = 1.

Usage

pvec(v, FUN, ..., mc.set.seed = TRUE, mc.silent = FALSE, mc.cores = getOption("mc.cores", 2L), mc.cleanup = TRUE)

Arguments

v vector to operate on
FUN function to call on each part of the vector
... any further arguments passed to FUN after the vector
mc.set.seed See mcparallel.
**pvec**

**mc.silent** if set to TRUE then all output on ‘stdout’ will be suppressed for all parallel processes forked (‘stderr’ is not affected).

**mc.cores** The number of cores to use, i.e. at most how many child processes will be run simultaneously. Must be at least one, and at least two for parallel operation. The option is initialized from environment variable MC_CORES if set.

**mc.cleanup** See the description of this argument in `mclapply`.

**Details**

`pvec` parallelizes `FUN(x, ...)` where `FUN` is a function that returns a vector of the same length as `x`. `FUN` must also be pure (i.e., without side-effects) since side-effects are not collected from the parallel processes. The vector is split into nearly identically sized subvectors on which `FUN` is run. Although it is in principle possible to use functions that are not necessarily maps, the interpretation would be case-specific as the splitting is in theory arbitrary (a warning is given in such cases).

The major difference between `pvec` and `mclapply` is that `mclapply` will run `FUN` on each element separately whereas `pvec` assumes that `c(FUN(x[1]), FUN(x[2]))` is equivalent to `FUN(x[1:2])` and thus will split into as many calls to `FUN` as there are cores (or elements, if fewer), each handling a subset vector. This makes it more efficient than `mclapply` but requires the above assumption on `FUN`.

If `mc.cores == 1` this evaluates `FUN(v, ...)` in the current process.

---

**Value**

The result of the computation – in a successful case it should be of the same length as `v`. If an error occurred or the function was not a map the result may be shorter or longer, and a warning is given.

---

**Note**

Due to the nature of the parallelization, error handling does not follow the usual rules since errors will be returned as strings and results from killed child processes will show up simply as non-existent data. Therefore it is the responsibility of the user to check the length of the result to make sure it is of the correct size. `pvec` raises a warning if that is the case since it does not know whether such an outcome is intentional or not.

See `mcfork` for the inadvisability of using this with GUI front-ends.

x <- pvec(1:1000, sqrt)
stopifnot(all(x == sqrt(1:1000)))
```

# One use is to convert date strings to unix time in large datasets
# as that is a relatively slow operation.
# So let's get some random dates first
# (A small test only with 2 cores: set options("mc.cores")
# and increase N for a larger-scale test.)
N <- 1e4
dates <- sprintf('%/zero.noslash4d-%/zero.noslash2d-%/zero.noslash2d',
                 as.integer(2/zero.noslash/zero.noslash/zero.noslash+rnorm(N)),
                 as.integer(runif(N, 1, 12)), as.integer(runif(N, 1, 28)))

system.time(a <- as.POSIXct(dates))
# This ought to be faster, but system overhead can be high
# - and is on OS X Lion
system.time(b <- pvec(dates, as.POSIXct))
stopifnot(all(a == b))

# using mclapply for this would much slower because each value
# will require a separate call to as.POSIXct()
# as lapply(dates, as.POSIXct) does
system.time(c <- unlist(mclapply(dates, as.POSIXct))
```

---

RNGstreams

**Implementation of Pierre L'Ecuyer's RngStreams**

---

Description

This is an R re-implementation of Pierre L’Ecuyer’s ‘RngStreams’ multiple streams of pseudo-random numbers.

Usage

```r
nextRNGStream(seed)
nextRNGSubStream(seed)

clusterSetRNGStream(cl = NULL, iseed)
mc.reset.stream()
```

Arguments

- **seed** An integer vector of length 7 as given by `.Random.seed` when the ‘"L’Ecuyer-CMRG"’ RNG is in use. See `RNG` for the valid values.
- **cl** A cluster from this package or package `snow`, or (if `NULL`) the registered cluster.
- **iseed** An integer to be supplied to `set.seed`, or `NULL` not to set reproducible seeds.
Details

The `RngStream` interface works with (potentially) multiple streams of pseudo-random numbers: this is particularly suitable for working with parallel computations since each task can be assigned a separate RNG stream.

This uses as its underlying generator `RNGkind("L'Ecuyer-CMRG")`, of L’Ecuyer (1999), which has a seed vector of 6 (signed) integers and a period of around $2^{191}$. Each ‘stream’ is a subsequence of the period of length $2^{127}$ which is in turn divided into ‘substreams’ of length $2^{76}$.

The idea of L’Ecuyer *et al* (2002) is to use a separate stream for each of the parallel computations (which ensures that the random numbers generated never get into sync) and the parallel computations can themselves use substreams if required. The original interface stores the original seed of the first stream, the original seed of the current stream and the current seed: this could be implemented in R, but it is as easy to work by saving the relevant values of `.Random.seed`: see the examples.

`clusterSetRNGStream` selects the "L'Ecuyer-CMRG" RNG and then distributes streams to the members of a cluster, optionally setting the seed of the streams by `set.seed(iseed)` (otherwise they are set from the current seed of the master process: after selecting the L’Ecuyer generator).

Calling `mc.reset.stream()` after setting the L’Ecuyer random number generator and seed makes runs from `mcparallel(mc.set.seed = TRUE)` reproducible. This is done internally in `mclapply` and `pvec`. (Note that it does not set the seed in the master process, so does not affect the fallback-to-serial versions of these functions.)

Value

For `nextRNGStream` and `nextRNGSubStream`, a value which can be assigned to `.Random.seed`.

Note

Interfaces to L’Ecuyer’s C code are available in CRAN packages `rlecuyer` and `rstream`.

splitIndices

Divide Tasks for Distribution in a Cluster

Description

This divides up 1:nx into ncl lists of approximately equal size, as a way to allocate tasks to nodes in a cluster.

It is mainly for internal use, but some package authors have found it useful.

Usage

splitIndices(nx, ncl)

Arguments

- nx: Number of tasks.
- ncl: Number of cluster nodes.

Value

A list of length ncl, each element being an integer vector.

Examples

splitIndices(20, 3)
Chapter 9

The splines package

---

**splines-package**  
*Regression Spline Functions and Classes*

**Description**  
Regression spline functions and classes.

**Details**  
This package provides functions for working with regression splines using the B-spline basis, `bs`, and the natural cubic spline basis, `ns`.

For a complete list of functions, use `library(help = "splines")`.

**Author(s)**

Maintainer: R Core Team <R-core@r-project.org>

---

**asVector**  
*Coerce an Object to a Vector*

**Description**  
This is a generic function. Methods for this function coerce objects of given classes to vectors.

**Usage**  
`asVector(object)`
backSpline

Arguments

object An object.

Details

Methods for vector coercion in new classes must be created for the asVector generic instead of as.vector. The as.vector function is internal and not easily extended. Currently the only class with an asVector method is the xyVector class.

Value

a vector

Author(s)

Douglas Bates and Bill Venables

See Also

xyVector

Examples

require(stats)
isp1 <- interpSpline( weight ~ height, women )
pred <- predict(ispl)
class(pred)
utils::str(pred)
asVector(pred)

Description

Create a monotone inverse of a monotone natural spline.

Usage

backSpline(object)

Arguments

object an object that inherits from class nbSpline or npolySpline. That is, the object must represent a natural interpolation spline but it can be either in the B-spline representation or the piecewise polynomial one. The spline is checked to see if it represents a monotone function.
Value

An object of class polySpline that contains the piecewise polynomial representation of a function that has the appropriate values and derivatives at the knot positions to be an inverse of the spline represented by object. Technically this object is not a spline because the second derivative is not constrained to be continuous at the knot positions. However, it is often a much better approximation to the inverse than fitting an interpolation spline to the y/x pairs.

Author(s)

Douglas Bates and Bill Venables

interpSpline

Examples

```r
require(graphics)
ispl <- interpSpline( women$height, women$weight )
bspl <- backSpline( ispl )
plot( bspl ) # plots over the range of the knots
points( women$weight, women$height )
```

---

**bs**  

*B-Spline Basis for Polynomial Splines*

Description

Generate the B-spline basis matrix for a polynomial spline.

Usage

```r
bs(x, df = NULL, knots = NULL, degree = 3, intercept = FALSE, Boundary.knots = range(x))
```

Arguments

- **x** the predictor variable. Missing values are allowed.
- **df** degrees of freedom; one can specify df rather than knots; bs() then chooses df-degree (minus one if there is an intercept) knots at suitable quantiles of x (which will ignore missing values). The default, NULL, corresponds to no inner knots, i.e., degree = intercept.
- **knots** the *internal* breakpoints that define the spline. The default is NULL, which results in a basis for ordinary polynomial regression. Typical values are the mean or median for one knot, quantiles for more knots. See also Boundary.knots.
- **degree** degree of the piecewise polynomial—default is 3 for cubic splines.
interpSpline

Description

Create an interpolation spline, either from x and y vectors, or from a formula/data.frame combination.

Examples

```
require(stats); require(graphics)
bs(women$height, df = 5)
summary(fm1 <- lm(weight ~ bs(height, df = 5), data = women))

## example of safe prediction
plot(women, xlab = "Height (in)", ylab = "Weight (lb)"
ht <- seq(57, 73, length.out = 200)
lines(ht, predict(fm1, data.frame(height = ht)))
```
Usage

interpSpline(obj1, obj2, bSpline = FALSE, period = NULL,
             na.action = na.fail)

Arguments

obj1
Either a numeric vector of x values or a formula.

obj2
If obj1 is numeric this should be a numeric vector of the same length. If obj1 is
a formula this can be an optional data frame in which to evaluate the names in
the formula.

bSpline
If TRUE the b-spline representation is returned, otherwise the piecewise polyno-
mial representation is returned. Defaults to FALSE.

period
An optional positive numeric value giving a period for a periodic interpolation
spline.

na.action
a optional function which indicates what should happen when the data contain
NA. The default action (na.omit) is to omit any incomplete observations. The
alternative action na.fail causes interpSpline to print an error message and
terminate if there are any incomplete observations.

Value

An object that inherits from class spline. The object can be in the B-spline representation, in which
case it will be of class nbSpline for natural B-spline, or in the piecewise polynomial representation,
in which case it will be of class npolySpline.

Examples

require(graphics); require(stats)
ispl <- interpSpline( women$height, women$weight )
ispl2 <- interpSpline( weight ~ height, women )
# ispl and ispl2 should be the same
plot( predict( ispl, seq( 55, 75, length.out = 51 ) ), type = "l" )
points( women$height, women$weight )
plot( ispl )  # plots over the range of the knots
points( women$height, women$weight )
splineKnots( ispl )
ns

*Generate a Basis Matrix for Natural Cubic Splines*

Description

Generate the B-spline basis matrix for a natural cubic spline.

Usage

```r
ns(x, df = NULL, knots = NULL, intercept = FALSE,
    Boundary.knots = range(x))
```

Arguments

- `x`: the predictor variable. Missing values are allowed.
- `df`: degrees of freedom. One can supply `df` rather than `knots`; `ns()` then chooses `df - 1 - intercept` knots at suitably chosen quantiles of `x` (which will ignore missing values). The default, `df = 1`, corresponds to no knots.
- `knots`: breakpoints that define the spline. The default is no knots; together with the natural boundary conditions this results in a basis for linear regression on `x`. Typical values are the mean or median for one knot, quantiles for more knots. See also `Boundary.knots`.
- `intercept`: if `TRUE`, an intercept is included in the basis; default is `FALSE`.
- `Boundary.knots`: boundary points at which to impose the natural boundary conditions and anchor the B-spline basis (default the range of the data). If both `knots` and `Boundary.knots` are supplied, the basis parameters do not depend on `x`. Data can extend beyond `Boundary.knots`.

Details

`ns` is based on the function `spline.des`. It generates a basis matrix for representing the family of piecewise-cubic splines with the specified sequence of interior knots, and the natural boundary conditions. These enforce the constraint that the function is linear beyond the boundary knots, which can either be supplied or default to the extremes of the data.

A primary use is in modeling formula to directly specify a natural spline term in a model: see the examples.

Value

A matrix of dimension `length(x) * df` where either `df` was supplied or if `knots` were supplied, `df = length(knots) + 1 + intercept`. Attributes are returned that correspond to the arguments to `ns`, and explicitly give the knots, `Boundary.knots` etc for use by `predict.ns()`.

References

**periodicSpline**

**Create a Periodic Interpolation Spline**

**Description**

Create a periodic interpolation spline, either from x and y vectors, or from a formula/data.frame combination.

**Usage**

`periodicSpline(obj1, obj2, knots, period = 2*pi, ord = 4)`

**Arguments**

- `obj1`: either a numeric vector of x values or a formula.
- `obj2`: if `obj1` is numeric this should be a numeric vector of the same length. If `obj1` is a formula this can be an optional data frame in which to evaluate the names in the formula.
- `knots`: optional numeric vector of knot positions.
- `period`: positive numeric value giving the period for the periodic spline. Defaults to `2 * pi`.
- `ord`: integer giving the order of the spline, at least 2. Defaults to 4. See `splineOrder` for a definition of the order of a spline.

**Value**

An object that inherits from class spline. The object can be in the B-spline representation, in which case it will be a `pbSpline` object, or in the piecewise polynomial representation (a `ppolySpline` object).

**See Also**

`bs`, `predict.ns`, `SafePrediction`

**Examples**

```r
require(stats); require(graphics)
ns(women$height, df = 5)
summary(fm1 <- lm(weight ~ ns(height, df = 5), data = women))
## To see what knots were selected
attr(terms(fm1), "predvars")
## example of safe prediction
plot(women, xlab = "Height (in)", ylab = "Weight (lb)"
ht <- seq(57, 73, length.out = 200)
lines(ht, predict(fm1, data.frame(height = ht)))
```
polySpline

DESCRIPTION

Create the piecewise polynomial representation of a spline object.

Usage

polySpline(object, ...)
as.polySpline(object, ...)

Arguments

object An object that inherits from class spline.
... Optional additional arguments. At present no additional arguments are used.

Value

An object that inherits from class polySpline. This is the piecewise polynomial representation of a univariate spline function. It is defined by a set of distinct numeric values called knots. The spline function is a polynomial function between each successive pair of knots. At each interior knot the polynomial segments on each side are constrained to have the same value of the function and some of its derivatives.
predict.bs

Author(s)
Douglas Bates and Bill Venables

See Also
interpSpline, periodicSpline, splineKnots, splineOrder

Examples

```r
require(graphics)
ispl <- polySpline(interpSpline( weight ~ height, women, bSpline = TRUE))
print( ispl )  # print the piecewise polynomial representation
plot( ispl )  # plots over the range of the knots
points( women$height, women$weight )
```

Description
Evaluate a predefined spline basis at given values.

Usage
```
## S3 method for class 'bs'
predict(object, newx, ...)
## S3 method for class 'ns'
predict(object, newx, ...)
```

Arguments
- `object`: the result of a call to `bs` or `ns` having attributes describing knots, degree, etc.
- `newx`: the x values at which evaluations are required.
- `...`: Optional additional arguments. At present no additional arguments are used.

Value
An object just like `object`, except evaluated at the new values of `x`.

These are methods for the generic function `predict` for objects inheriting from classes "bs" or "ns". See `predict` for the general behavior of this function.

See Also
- `bs`, `ns`, `poly`.
Examples

```r
require(stats)
basis <- ns(women$height, df = 5)
newX <- seq(58, 72, length.out = 51)
# evaluate the basis at the new data
predict(basis, newX)
```

**predict.bSpline**  
*Evaluate a Spline at New Values of x*

Description

The `predict` methods for the classes that inherit from the virtual classes `bSpline` and `polySpline` are used to evaluate the spline or its derivatives. The `plot` method for a spline object first evaluates `predict` with the `x` argument missing, then plots the resulting `xyVector` with `type = "l"`.

Usage

```r
## S3 method for class 'bSpline'
predict(object, x, nseg = 50, deriv = 0, ...)
## S3 method for class 'nbSpline'
predict(object, x, nseg = 50, deriv = 0, ...)
## S3 method for class 'pbSpline'
predict(object, x, nseg = 50, deriv = 0, ...)
## S3 method for class 'npolySpline'
predict(object, x, nseg = 50, deriv = 0, ...)
## S3 method for class 'ppolySpline'
predict(object, x, nseg = 50, deriv = 0, ...)
```

Arguments

- `object`  
  An object that inherits from the `bSpline` or the `polySpline` class.
- `x`  
  A numeric vector of x values at which to evaluate the spline. If this argument is missing a suitable set of x values is generated as a sequence of `nseg` segments spanning the range of the knots.
- `nseg`  
  A positive integer giving the number of segments in a set of equally-spaced x values spanning the range of the knots in `object`. This value is only used if `x` is missing.
- `deriv`  
  An integer between 0 and `splineOrder(object) - 1` specifying the derivative to evaluate.
- `...`  
  Further arguments passed to or from other methods.

Value

An `xyVector` with components

- `x`  
  The supplied or inferred numeric vector of x values
- `y`  
  The value of the spline (or its `deriv`’th derivative) at the x vector
splineDesign

Design Matrix for B-splines

Description

Evaluate the design matrix for the B-splines defined by knots at the values in x.

Usage

splineDesign(knots, x, ord = 4, derivs, outer.ok = FALSE, sparse = FALSE)
spline.des (knots, x, ord = 4, derivs, outer.ok = FALSE, sparse = FALSE)

Arguments

- **knots**: a numeric vector of knot positions with non-decreasing values.
- **x**: a numeric vector of values at which to evaluate the B-spline functions or derivatives. Unless outer.ok is true, the values in x must be between knots[ord] and knots[length(knots) + 1 - ord].

Examples

```r
require(graphics); require(stats)
ispl <- interpSpline( weight ~ height, women )
opar <- par(mfrow = c(2, 2), las = 1)
plot(predict(ispl, nseg = 201), # plots over the range of the knots
     main = "Original data with interpolating spline", type = "l",
     xlab = "height", ylab = "weight")
points(women$height, women$weight, col = 4)
plot(predict(ispl, nseg = 201, deriv = 1),
     main = "First derivative of interpolating spline", type = "l",
     xlab = "height", ylab = "weight")
plot(predict(ispl, nseg = 201, deriv = 2),
     main = "Second derivative of interpolating spline", type = "l",
     xlab = "height", ylab = "weight")
plot(predict(ispl, nseg = 401, deriv = 3),
     main = "Third derivative of interpolating spline", type = "l",
     xlab = "height", ylab = "weight")
par(opar)
```
ord a positive integer giving the order of the spline function. This is the number of coefficients in each piecewise polynomial segment, thus a cubic spline has order 4. Defaults to 4.

 derivs an integer vector of the same length as x and with values between 0 and ord - 1. The derivative of the given order is evaluated at the x positions. Defaults to a vector of zeroes of the same length as x.

 outer.ok logical indicating if x should be allowed outside the inner knots, see the x argument.

 sparse logical indicating if the result should inherit from class sparseMatrix (package Matrix).

**Value**

A matrix with `length(x)` rows and `length(knots) - ord` columns. The i'th row of the matrix contains the coefficients of the B-splines (or the indicated derivative of the B-splines) defined by the knot vector and evaluated at the i'th value of x. Each B-spline is defined by a set of ord successive knots so the total number of B-splines is `length(knots)-ord`.

**Note**

The older `spline.des` function takes the same arguments but returns a list with several components including knots, ord, derivs, and design. The design component is the same as the value of the `splineDesign` function.

**Author(s)**

Douglas Bates and Bill Venables

**Examples**

```r
require(graphics)
splineDesign(knots = 1:10, x = 4:7)
# "visualize" band structure
Matrix::drop(zapsmall(6*splineDesign(knots = 1:4/zero.noslash, x = 4:37, sparse = TRUE)))

knots <- c(1,1.8,3:5,6.5,7,8.1,9.2,1/zero.noslash) # 1/zero.noslash => 1/zero.noslash-4 = 6 Basis splines
x <- seq(min(knots)-1, max(knots)+1, length.out = 5/zero.noslash1)
bb <- splineDesign(knots, x = x, outer.ok = TRUE)

plot(range(x), c(0,1), type = "n", xlab = "x", ylab = "",
      main = "B-splines - sum to 1 inside inner knots")
mtext(expression(B[j](x) *" and "* sum(B[j](x), j == 1, 6)), adj = 0)
abline(v = knots, lty = 3, col = "light gray")
abline(v = knots[c(4,length(knots)-3)], lty = 3, col = "gray!10")
lines(x, rowSums(bb), col = "gray", lwd = 2)
matlines(x, bb, ylim = c(0,1), lty = 1)
```

splineKnots

Knot Vector from a Spline

Description
Return the knot vector corresponding to a spline object.

Usage
splineKnots(object)

Arguments
object an object that inherits from class “spline”.

Value
A non-decreasing numeric vector of knot positions.

Author(s)
Douglas Bates and Bill Venables

Examples
ispl <- interpSpline( weight ~ height, women )
splineKnots( ispl )

splineOrder
Determine the Order of a Spline

Description
Return the order of a spline object.

Usage
splineOrder(object)

Arguments
object An object that inherits from class "spline".

Details
The order of a spline is the number of coefficients in each piece of the piecewise polynomial representation. Thus a cubic spline has order 4.
Construct an xyVector Object

Description

Create an object to represent a set of x-y pairs. The resulting object can be treated as a matrix or as a data frame or as a vector. When treated as a vector it reduces to the y component only.

The result of functions such as predict.spline is returned as an xyVector object so the x-values used to generate the y-positions are retained, say for purposes of generating plots.

Usage

xyVector(x, y)

Arguments

x a numeric vector
y a numeric vector of the same length as x

Value

An object of class xyVector with components

x a numeric vector
y a numeric vector of the same length as x

Author(s)

Douglas Bates and Bill Venables
Examples

```r
require(stats); require(graphics)
ispl <- interpSpline( weight ~ height, women )
weights <- predict( ispl, seq( 55, 75, length.out = 51 ))
class( weights )
plot( weights, type = "l", xlab = "height", ylab = "weight" )
points( women$height, women$weight )
weights
```

The stats4 package

---

**stats4-package**  
Statistical Functions using S4 Classes

**Description**

Statistical Functions using S4 classes.

**Details**

This package contains functions and classes for statistics using the S version 4 class system. The methods currently support maximum likelihood (function `mle()` returning class "mle"), including methods for `logLik` for use with AIC.

**Author(s)**

R Core Team and contributors worldwide

Maintainer: R Core Team <R-core@r-project.org>

---

**coef-methods**  
Methods for Function coef in Package stats4

**Description**

Extract the coefficient vector from "mle" objects.

**Methods**

`signature(object = "ANY")` Generic function: see `coef`.

`signature(object = "mle")` Extract the full coefficient vector (including any fixed coefficients) from the fit.

`signature(object = "summary.mle")` Extract the coefficient vector and standard errors from the summary of the fit.
Methods for Function `confint` in Package `stats4`

**Description**

Generate confidence intervals

**Methods**

- `signature(object = "ANY")` Generic function: see `confint`.
- `signature(object = "mle")` First generate profile and then confidence intervals from the profile.
- `signature(object = "profile.mle")` Generate confidence intervals based on likelihood profile.

Methods for Function `logLik` in Package `stats4`

**Description**

Extract the maximized log-likelihood from "mle" objects.

**Methods**

- `signature(object = "ANY")` Generic function: see `logLik`.
- `signature(object = "mle")` Extract log-likelihood from the fit.

**Note**

The `mle` method does not know about the number of observations unless `nobs` was specified on the call and so may not be suitable for use with `BIC`. 
mle

Maximum Likelihood Estimation

Description

Estimate parameters by the method of maximum likelihood.

Usage

mle(minuslogl, start = formals(minuslogl), method = "BFGS",
    fixed = list(), nobs, ...)

Arguments

- minuslogl: Function to calculate negative log-likelihood.
- start: Named list. Initial values for optimizer.
- method: Optimization method to use. See \code{optim}.
- fixed: Named list. Parameter values to keep fixed during optimization.
- nobs: optional integer: the number of observations, to be used for e.g. computing \code{BIC}.
- ...: Further arguments to pass to \code{optim}.

Details

The \code{optim} optimizer is used to find the minimum of the negative log-likelihood. An approximate covariance matrix for the parameters is obtained by inverting the Hessian matrix at the optimum.

Value

An object of class \code{mle-class}.

Note

Be careful to note that the argument is \(-\log L\) (not \(-2 \log L\)). It is for the user to ensure that the likelihood is correct, and that asymptotic likelihood inference is valid.

See Also

\code{mle-class}

Examples

```r
## Avoid printing to unwarranted accuracy
od <- options(digits = 5)
x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)

## Easy one-dimensional MLE:
```
nLL <- function(lambda) -sum(stats::dpois(y, lambda, log = TRUE))
fit0 <- mle(nLL, start = list(lambda = 5), nobs = NROW(y))
# For 1D, this is preferable:
fit1 <- mle(nLL, start = list(lambda = 5), nobs = NROW(y),
  method = "Brent", lower = 1, upper = 2/zero.noslash)
stopifnot(nobs(fit/zero.noslash) == length(y))

## This needs a constrained parameter space: most methods will accept NA
ll <- function(ymax = 15, xhalf = 6) {
  if(ymax > /zero.noslash && xhalf > 0)
    -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
  else NA
}
(fit <- mle(ll, nobs = length(y)))
mle(ll, fixed = list(xhalf = 6))

## alternative using bounds on optimization
ll2 <- function(ymax = 15, xhalf = 6)
  -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
mle(ll2, method = "L-BFGS-B", lower = rep(/zero.noslash, 2))

AIC(fit)
BIC(fit)

summary(fit)
logLik(fit)
vcov(fit)
plot(profile(fit), absVal = FALSE)
confint(fit)

## Use bounded optimization
## The lower bounds are really > 0,
## but we use >=/zero.noslash to stress-test profiling
(fit2 <- mle(ll, method = "L-BFGS-B", lower = c(/zero.noslash, /zero.noslash)))
plot(profile(fit2), absVal = FALSE)

## a better parametrization:
ll3 <- function(lymax = log(15), lxhalf = log(6))
  -sum(stats::dpois(y, lambda = exp(lymax)/(1+x/exp(lxhalf)), log = TRUE))
(fit3 <- mle(ll3))
plot(profile(fit3), absVal = FALSE)
exp(confint(fit3))

options(od)

mle-class

Class "mle" for Results of Maximum Likelihood Estimation

Description

This class encapsulates results of a generic maximum likelihood procedure.
Objects from the Class

Objects can be created by calls of the form new("mle", ...), but most often as the result of a call to mle.

Slots

call: Object of class "language". The call to mle.
coef: Object of class "numeric". Estimated parameters.
fullcoef: Object of class "numeric". Fixed and estimated parameters.
vcov: Object of class "matrix". Approximate variance-covariance matrix.
min: Object of class "numeric". Minimum value of objective function.
details: a "list", as returned from optim.
minuslogl: Object of class "function". The negative loglikelihood function.
nobs: "integer" of length one. The number of observations (often NA, when not set in call explicitly).
method: Object of class "character". The optimization method used.

Methods

confint signature(object = "mle"): Confidence intervals from likelihood profiles.
logLik signature(object = "mle"): Extract maximized log-likelihood.
profile signature(fitted = "mle"): Likelihood profile generation.
nobs signature(object = "mle"): Number of observations, here simply accessing the nobs slot mentioned above.
show signature(object = "mle"): Display object briefly.
summary signature(object = "mle"): Generate object summary.
update signature(object = "mle"): Update fit.
vcov signature(object = "mle"): Extract variance-covariance matrix.

Description

Plot profile likelihoods for "mle" objects.

Usage

## S4 method for signature 'profile.mle,missing'
plot(x, levels, conf = c(99, 95, 90, 80, 50)/100, nseg = 50, absVal = TRUE, ...)
Profile likelihood for "mle" objects.

Usage

```r
## S4 method for signature 'mle'
profile(fitted, which = 1:p, maxsteps = 100, alpha = 0.01,
        zmax = sqrt(qchisq(1 - alpha, 1L)), del = zmax/5,
        trace = FALSE, ...)
```

Arguments

- `fitted`: Object to be profiled.
- `which`: Optionally select subset of parameters to profile.
- `maxsteps`: Maximum number of steps to bracket `zmax`.
- `alpha`: Significance level corresponding to `zmax`, based on a Scheffe-style multiple testing interval. Ignored if `zmax` is specified.
- `zmax`: Cutoff for the profiled value of the signed root-likelihood.
- `del`: Initial stepsize on root-likelihood scale.
- `trace`: Logical. Print intermediate results.
- `...`: Currently unused.
Details

The profiling algorithm tries to find an approximately evenly spaced set of at least five parameter values (in each direction from the optimum) to cover the root-likelihood function. Some care is taken to try and get sensible results in cases of high parameter curvature. Notice that it may not always be possible to obtain the cutoff value, since the likelihood might level off.

Value

An object of class "profile.mle", see "profile.mle-class".

Methods

signature(fitted = "ANY") Generic function: see profile.
signature(fitted = "mle") Profile the likelihood in the vicinity of the optimum of an "mle" object.

profile.mle-class  Class "profile.mle": Profiling information for "mle" object

Description

Likelihood profiles along each parameter of likelihood function

Objects from the Class

Objects can be created by calls of the form new("profile.mle", ...), but most often by invoking profile on an "mle" object.

Slots

profile: Object of class "list". List of profiles, one for each requested parameter. Each profile is a data frame with the first column called z being the signed square root of the -2 log likelihood ratio, and the others being the parameters with names prefixed by par.vals.

summary: Object of class "summary.mle". Summary of object being profiled.

Methods

confint signature(object = "profile.mle"): Use profile to generate approximate confidence intervals for parameters.
plot signature(x = "profile.mle", y = "missing"): Plot profiles for each parameter.

See Also

mle,mle-class,summary.mle-class
**Summary.mle-class**

Methods for Function `show` in Package `stats4`

**Description**

Show objects of classes `mle` and `summary.mle`

**Methods**

- `signature(object = "mle")` Print simple summary of `mle` object. Just the coefficients and the call.
- `signature(object = "summary.mle")` Shows call, table of coefficients and standard errors, and $-2\log L$.

**summary-methods**

Methods for Function `summary` in Package `stats4`

**Description**

Summarize objects

**Methods**

- `signature(object = "ANY")` Generic function
- `signature(object = "mle")` Generate a summary as an object of class "summary.mle", containing estimates, asymptotic SE, and value of $-2\log L$.

**summary.mle-class**

Class "summary.mle", Summary of "mle" Objects

**Description**

Extract of "mle" object

**Objects from the Class**

Objects can be created by calls of the form `new("summary.mle", ...)`, but most often by invoking `summary` on an "mle" object. They contain values meant for printing by `show`.

**Slots**

- `call`: Object of class "language" The call that generated the "mle" object.
- `coef`: Object of class "matrix". Estimated coefficients and standard errors
- `m2logL`: Object of class "numeric". Minus twice the log likelihood.
Methods

show signature(object = "summary.mle"): Pretty-prints object

coef signature(object = "summary.mle"): Extracts the contents of the coef slot

See Also

summary, mle, mle-class

Description

Update "mle" objects.

Usage

## S4 method for signature 'mle'
update(object, ..., evaluate = TRUE)

Arguments

object An existing fit.

... Additional arguments to the call, or arguments with changed values. Use name = NULL to remove the argument name.

evaluate If true evaluate the new call else return the call.

Methods

signature(object = "ANY") Generic function: see update.

signature(object = "mle") Update a fit.

Examples

x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)
ll <- function(ymax = 15, xhalf = 6)
  -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
fit <- mle(ll)
## note the recorded call contains ..1, a problem with S4 dispatch
update(fit, fixed = list(xhalf = 3))
Methods for Function `vcov` in Package `stats4`

**Description**

Extract the approximate variance-covariance matrix from "mle" objects.

**Methods**

- `signature(object = "ANY")` Generic function: see `vcov`.
- `signature(object = "mle")` Extract the estimated variance-covariance matrix for the estimated parameters (if any).

The stats package

The R Stats Package

Description
R statistical functions

Details
This package contains functions for statistical calculations and random number generation. For a complete list of functions, use library(help = "stats").

Author(s)
R Core Team and contributors worldwide
Maintainer: R Core Team <R-core@r-project.org>

Functions to Check the Type of Variables passed to Model Frames

Description
.checkMFClasses checks if the variables used in a predict method agree in type with those used for fitting.
.MFclass categorizes variables for this purpose.

Usage
.checkMFClasses(cl, m, ordNotOK = FALSE)
.MFclass(x)
.getXlevels(Terms, m)
Arguments

cl a character vector of class descriptions to match.
m a model frame.
x any R object.
ordNotOK logical: are ordered factors different?
Terms a terms object.

Details

For applications involving `model.matrix` such as linear models we do not need to differentiate between ordered factors and factors as although these affect the coding, the coding used in the fit is already recorded and imposed during prediction. However, other applications may treat ordered factors differently: `rpart` does, for example.

Value

`.MFclass` returns a character string, one of "logical", "ordered", "factor", "numeric", "nmatrix.*" (a numeric matrix with a number of columns appended) or "other".

`.getXlevels` returns a named character vector, or `NULL`.

---

acf Auto- and Cross- Covariance and -Correlation Function Estimation

Description

The function `acf` computes (and by default plots) estimates of the autocovariance or autocorrelation function. Function `pacf` is the function used for the partial autocorrelations. Function `ccf` computes the cross-correlation or cross-covariance of two univariate series.

Usage

```r
acf(x, lag.max = NULL,
    type = c("correlation", "covariance", "partial"),
    plot = TRUE, na.action = na.fail, demean = TRUE, ...)

pacf(x, lag.max, plot, na.action, ...)
```

```r
## Default S3 method:
pacf(x, lag.max = NULL, plot = TRUE, na.action = na.fail, demean = TRUE, ...)
```

```r
ccf(x, y, lag.max = NULL, type = c("correlation", "covariance"),
    plot = TRUE, na.action = na.fail, ...)
```

```r
## S3 method for class 'acf'
x[i, j]
```
acf

Arguments

x, y  a univariate or multivariate (not ccf) numeric time series object or a numeric vector or matrix, or an "acf" object.

lag.max  maximum lag at which to calculate the acf. Default is \(10 \log_{10}(N/m)\) where \(N\) is the number of observations and \(m\) the number of series. Will be automatically limited to one less than the number of observations in the series.

type  character string giving the type of acf to be computed. Allowed values are "correlation" (the default), "covariance" or "partial".

plot  logical. If TRUE (the default) the acf is plotted.

na.action  function to be called to handle missing values. na.pass can be used.
demean  logical. Should the covariances be about the sample means?

...  further arguments to be passed to plot.acf.
i  a set of lags (time differences) to retain.
j  a set of series (names or numbers) to retain.

Details

For type = "correlation" and "covariance", the estimates are based on the sample covariance. (The lag 0 autocorrelation is fixed at 1 by convention.)

By default, no missing values are allowed. If the na.action function passes through missing values (as na.pass does), the covariances are computed from the complete cases. This means that the estimate computed may well not be a valid autocorrelation sequence, and may contain missing values. Missing values are not allowed when computing the PACF of a multivariate time series.

The partial correlation coefficient is estimated by fitting autoregressive models of successively higher orders up to lag.max.

The generic function plot has a method for objects of class "acf".

The lag is returned and plotted in units of time, and not numbers of observations.

There are print and subsetting methods for objects of class "acf".

Value

An object of class "acf", which is a list with the following elements:

lag  A three dimensional array containing the lags at which the acf is estimated.
acf  An array with the same dimensions as lag containing the estimated acf.
type  The type of correlation (same as the type argument).
n.used  The number of observations in the time series.
series  The name of the series x.
snames  The series names for a multivariate time series.

The lag k value returned by ccf(x, y) estimates the correlation between x[t+k] and y[t]. The result is returned invisibly if plot is TRUE.

acf2AR
Compute an AR Process Exactly Fitting an ACF

Description
Compute an AR process exactly fitting an autocorrelation function.

Usage
acf2AR(acf)

Arguments
acf
An autocorrelation or autocovariance sequence.
add1

Value

A matrix, with one row for the computed AR(p) coefficients for 1 \leq p \leq \text{length}(acf).

See Also

ARMAacf, ar.yw which does this from an empirical ACF.

Examples

(Acf <- ARMAacf(c(0.6, 0.3, -0.2)))
acf2AR(Acf)

add1

Add or Drop All Possible Single Terms to a Model

Description

Compute all the single terms in the scope argument that can be added to or dropped from the model, fit those models and compute a table of the changes in fit.

Usage

add1(object, scope, ...)

## Default S3 method:
add1(object, scope, scale = 0, test = c("none", "Chisq"),
    k = 2, trace = FALSE, ...)

## S3 method for class 'lm'
add1(object, scope, scale = 0, test = c("none", "Chisq", "F"),
    x = NULL, k = 2, ...)

## S3 method for class 'glm'
add1(object, scope, scale = 0,
    test = c("none", "Rao", "LRT", "Chisq", "F"),
    x = NULL, k = 2, ...)

drop1(object, scope, ...)

## Default S3 method:
drop1(object, scope, scale = 0, test = c("none", "Chisq"),
    k = 2, trace = FALSE, ...)

## S3 method for class 'lm'
drop1(object, scope, scale = 0, all.cols = TRUE,
    test = c("none", "Chisq", "F"), k = 2, ...)
## S3 method for class 'glm'
drop1(object, scope, scale = 0,
    test = c("none", "Rao", "LRT", "Chisq", "F"),
    k = 2, ...)

Arguments

- **object**: a fitted model object.
- **scope**: a formula giving the terms to be considered for adding or dropping.
- **scale**: an estimate of the residual mean square to be used in computing $C_p$. Ignored if 0 or NULL.
- **test**: should the results include a test statistic relative to the original model? The F test is only appropriate for `lm` and `aov` models or perhaps for `glm` fits with estimated dispersion. The $\chi^2$ test can be an exact test (lm models with known scale) or a likelihood-ratio test or a test of the reduction in scaled deviance depending on the method. For `glm` fits, you can also choose "LRT" and "Rao" for likelihood ratio tests and Rao's efficient score test. The former is synonymous with "Chisq" (although both have an asymptotic chi-square distribution).
- **k**: the penalty constant in AIC / $C_p$.
- **trace**: if TRUE, print out progress reports.
- **x**: a model matrix containing columns for the fitted model and all terms in the upper scope. Useful if `add1` is to be called repeatedly. **Warning**: no checks are done on its validity.
- **all.cols**: (Provided for compatibility with S.) Logical to specify whether all columns of the design matrix should be used. If FALSE then non-estimable columns are dropped, but the result is not usually statistically meaningful.
- **...**: further arguments passed to or from other methods.

Details

For drop1 methods, a missing scope is taken to be all terms in the model. The hierarchy is respected when considering terms to be added or dropped: all main effects contained in a second-order interaction must remain, and so on.

In a scope formula . means ‘what is already there’.

The methods for `lm` and `glm` are more efficient in that they do not recompute the model matrix and call the fit methods directly.

The default output table gives AIC, defined as minus twice log likelihood plus $2p$ where $p$ is the rank of the model (the number of effective parameters). This is only defined up to an additive constant (like log-likelihoods). For linear Gaussian models with fixed scale, the constant is chosen to give Mallows’ $C_p$, $RSS/scale + 2p - n$. Where $C_p$ is used, the column is labelled as $Cp$ rather than AIC.

The F tests for the "glm" methods are based on analysis of deviance tests, so if the dispersion is estimated it is based on the residual deviance, unlike the F tests of `anova.glm`. 
Value

An object of class "anova" summarizing the differences in fit between the models.

Warning

The model fitting must apply the models to the same dataset. Most methods will attempt to use a subset of the data with no missing values for any of the variables if `na.action = na.omit`, but this may give biased results. Only use these functions with data containing missing values with great care.

The default methods make calls to the function `nobs` to check that the number of observations involved in the fitting process remained unchanged.

Note

These are not fully equivalent to the functions in R. There is no `keep` argument, and the methods used are not quite so computationally efficient.

Their authors’ definitions of Mallows’ $C_p$ and Akaike’s AIC are used, not those of the authors of the models chapter of S.

Author(s)

The design was inspired by the R functions of the same names described in Chambers (1992).

drop1(glm.D93, test = "F")
add1(glm.D93, scope = ~outcome*treatment, test = "Rao") # Pearson Chi-square
```
addmargins \hspace{1em} Puts Arbitrary Margins on Multidimensional Tables or Arrays

Description

For a given table one can specify which of the classifying factors to expand by one or more levels to hold margins to be calculated. One may for example form sums and means over the first dimension and medians over the second. The resulting table will then have two extra levels for the first dimension and one extra level for the second. The default is to sum over all margins in the table. Other possibilities may give results that depend on the order in which the margins are computed. This is flagged in the printed output from the function.

Usage

```
addmargins(A, margin = seq_along(dim(A)), FUN = sum, quiet = FALSE)
```

Arguments

- **A**: table or array. The function uses the presence of the "dim" and "dimnames" attributes of \( A \).
- **margin**: vector of dimensions over which to form margins. Margins are formed in the order in which dimensions are specified in `margin`.
- **FUN**: list of the same length as `margin`, each element of the list being either a function or a list of functions. Names of the list elements will appear as levels in dimnames of the result. Unnamed list elements will have names constructed: the name of a function or a constructed name based on the position in the table.
- **quiet**: logical which suppresses the message telling the order in which the margins were computed.

Details

If the functions used to form margins are not commutative the result depends on the order in which margins are computed. Annotation of margins is done via naming the `FUN` list.

Value

A table or array with the same number of dimensions as \( A \), but with extra levels of the dimensions mentioned in `margin`. The number of levels added to each dimension is the length of the entries in `FUN`. A message with the order of computation of margins is printed.

tx <- addmargins( table(x, y) )
print(tx, zero.print = ".")
Usage

aggregate(x, ...)

## Default S3 method:
aggregate(x, ...)

## S3 method for class 'data.frame'
aggregate(x, by, FUN, ..., simplify = TRUE)

## S3 method for class 'formula'
aggregate(formula, data, FUN, ..., subset, na.action = na.omit)

## S3 method for class 'ts'
aggregate(x, nfrequency = 1, FUN = sum, ndeltat = 1,
          ts.eps = getOption("ts.eps"), ...)

Arguments

x    an R object.
by   a list of grouping elements, each as long as the variables in the data frame x. The elements are coerced to factors before use.
FUN  a function to compute the summary statistics which can be applied to all data subsets.
simplify a logical indicating whether results should be simplified to a vector or matrix if possible.
formula a formula, such as y ~ x or cbind(y1, y2) ~ x1 + x2, where the y variables are numeric data to be split into groups according to the grouping x variables (usually factors).
data  a data frame (or list) from which the variables in formula should be taken.
subset an optional vector specifying a subset of observations to be used.
na.action a function which indicates what should happen when the data contain NA values. The default is to ignore missing values in the given variables.
nfrequency new number of observations per unit of time; must be a divisor of the frequency of x.
ndeltat new fraction of the sampling period between successive observations; must be a divisor of the sampling interval of x.
ts.eps  tolerance used to decide if nfrequency is a sub-multiple of the original frequency.
...    further arguments passed to or used by methods.

Details

aggregate is a generic function with methods for data frames and time series.
The default method, `aggregate.default`, uses the time series method if `x` is a time series, and otherwise coerces `x` to a data frame and calls the data frame method.

`aggregate.data.frame` is the data frame method. If `x` is not a data frame, it is coerced to one, which must have a non-zero number of rows. Then, each of the variables (columns) in `x` is split into subsets of cases (rows) of identical combinations of the components of `by`, and `FUN` is applied to each such subset with further arguments in ... passed to it. The result is reformatted into a data frame containing the variables in `by` and `x`. The ones arising from `by` contain the unique combinations of grouping values used for determining the subsets, and the ones arising from `x` the corresponding summaries for the subset of the respective variables in `x`. If `simplify` is true, summaries are simplified to vectors or matrices if they have a common length of one or greater than one, respectively; otherwise, lists of summary results according to subsets are obtained. Rows with missing values in any of the `by` variables will be omitted from the result. (Note that versions of R prior to 2.11.0 required `FUN` to be a scalar function.)

`aggregate.formula` is a standard formula interface to `aggregate.data.frame`.

`aggregate.ts` is the time series method, and requires `FUN` to be a scalar function. If `x` is not a time series, it is coerced to one. Then, the variables in `x` are split into appropriate blocks of length `frequency(x) / nfrequency`, and `FUN` is applied to each such block, with further (named) arguments in ... passed to it. The result returned is a time series with frequency `nfrequency` holding the aggregated values. Note that this make most sense for a quarterly or yearly result when the original series covers a whole number of quarters or years: in particular aggregating a monthly series to quarters starting in February does not give a conventional quarterly series.

`FUN` is passed to `match.fun`, and hence it can be a function or a symbol or character string naming a function.

**Value**

For the time series method, a time series of class "ts" or class `c("mts", "ts")`.

For the data frame method, a data frame with columns corresponding to the grouping variables in `by` followed by aggregated columns from `x`. If the `by` has names, the non-empty times are used to label the columns in the results, with unnamed grouping variables being named `Group.i` for `by[[i]]`.

aggregate(cbind(ncases, ncontrols) ~ alcgp + tobgp, data = esoph, sum)

## Dot notation:
aggregate(. ~ Species, data = iris, mean)
aggregate(len ~ ., data = ToothGrowth, mean)

## Often followed by xtabs():
ag <- aggregate(len ~ ., data = ToothGrowth, mean)
xtabs(len ~ ., data = ag)

## Compute the average annual approval ratings for American presidents.
aggregate(presidents, nfrequency = 1, FUN = mean)
## Give the summer less weight.
aggregate(presidents, nfrequency = 1,
       FUN = weighted.mean, w = c(1, 1, 0.5, 1))

AIC  
Akaike’s An Information Criterion
**Description**

Generic function calculating Akaike’s ‘An Information Criterion’ for one or several fitted model objects for which a log-likelihood value can be obtained, according to the formula $-2\log\text{likelihood} + kn_{par}$, where $n_{par}$ represents the number of parameters in the fitted model, and $k = 2$ for the usual AIC, or $k = \log(n)$ ($n$ being the number of observations) for the so-called BIC or SBC (Schwarz’s Bayesian criterion).

**Usage**

AIC(object, ..., k = 2)

BIC(object, ...)

**Arguments**

- **object**: a fitted model object for which there exists a `logLik` method to extract the corresponding log-likelihood, or an object inheriting from class `logLik`.
- **...**: optionally more fitted model objects.
- **k**: numeric, the penalty per parameter to be used; the default $k = 2$ is the classical AIC.

**Details**

These are generic functions (with S4 generics defined in package `stats4`): however methods should be defined for the log-likelihood function `logLik` rather than these functions: the action of their default methods is to call `logLik` on all the supplied objects and assemble the results.

When comparing fitted objects, the smaller the AIC or BIC, the better the fit.

The log-likelihood and hence the AIC/BIC is only defined up to an additive constant. Different constants have conventionally be used for different purposes and so `extractAIC` and AIC may give different values (and do for models of class "lm": see the help for `extractAIC`). Particular care is needed when comparing fits of different classes (with, for example, a comparison of a Poisson and gamma GLM being meaningless since one has a discrete response, the other continuous).

BIC is defined as $\text{AIC(object, ..., k = log(nobs(object)))}$. This needs the number of observations to be known: the default method looks first for a "nobs" attribute on the return value from the `logLik` method, then tries the `nobs` generic, and if neither succeed returns BIC as NA.

**Value**

If just one object is provided, a numeric value with the corresponding AIC (or BIC, or ... , depending on k).

If multiple objects are provided, a data.frame with rows corresponding to the objects and columns representing the number of parameters in the model (df) and the AIC or BIC.

**Author(s)**

Originally by José Pinheiro and Douglas Bates, more recent revisions by R-core.

AIC(lm1, lm2)
BIC(lm1, lm2)
```

---

**alias**

*Find Aliases (Dependencies) in a Model*

Description

Find aliases (linearly dependent terms) in a linear model specified by a formula.

Usage

```r
alias(object, ...)
```

## S3 method for class 'formula'

```r
alias(object, data, ...)
```

## S3 method for class 'lm'

```r
alias(object, complete = TRUE, partial = FALSE, partial.pattern = FALSE, ...)
```

Arguments

- `object`: A fitted model object, for example from `lm` or `aov`, or a formula for `alias.formula`.
- `data`: Optionally, a data frame to search for the objects in the formula.
- `complete`: Should information on complete aliasing be included?
- `partial`: Should information on partial aliasing be included?
Should partial aliasing be presented in a schematic way? If this is done, the results are presented in a more compact way, usually giving the deciles of the coefficients.

... further arguments passed to or from other methods.

Details

Although the main method is for class "lm", alias is most useful for experimental designs and so is used with fits from aov. Complete aliasing refers to effects in linear models that cannot be estimated independently of the terms which occur earlier in the model and so have their coefficients omitted from the fit. Partial aliasing refers to effects that can be estimated less precisely because of correlations induced by the design.

Value

A list (of class "listof") containing components

Model Description of the model; usually the formula.
Complete A matrix with columns corresponding to effects that are linearly dependent on the rows.
Partial The correlations of the estimable effects, with a zero diagonal. An object of class "mtable" which has its own print method.

Note

The aliasing pattern may depend on the contrasts in use: Helmert contrasts are probably most useful. The defaults are different from those in S.

Author(s)

The design was inspired by the S function of the same name described in Chambers et al. (1992).

References

Examples

utils::data(npk, package = "MASS")

op <- options(contrasts = c("contr.helmert", "contr.poly"))
npk.aov <- aov(yield ~ block + N*P*K, npk)
alias(npk.aov)
options(op) # reset
Description
Compute analysis of variance (or deviance) tables for one or more fitted model objects.

Usage
anova(object, ...)

Arguments
object an object containing the results returned by a model fitting function (e.g., lm or glm).
... additional objects of the same type.

Value
This (generic) function returns an object of class anova. These objects represent analysis-of-variance and analysis-of-deviance tables. When given a single argument it produces a table which tests whether the model terms are significant. When given a sequence of objects, anova tests the models against one another in the order specified. The print method for anova objects prints tables in a ‘pretty’ form.

Warning
The comparison between two or more models will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and R’s default of na.action = na.omit is used.

References

See Also
coefficients, effects, fitted.values, residuals, summary, drop1, add1.
Description

Compute an analysis of deviance table for one or more generalized linear model fits.

Usage

## S3 method for class 'glm'
anova(object, ..., dispersion = NULL, test = NULL)

Arguments

object, ...  objects of class glm, typically the result of a call to glm, or a list of objects for the "glmlist" method.
dispersion  the dispersion parameter for the fitting family. By default it is obtained from the object(s).
test  a character string, (partially) matching one of "Chisq", "LRT", "Rao", "F" or "Cp". See stat.anova.

Details

Specifying a single object gives a sequential analysis of deviance table for that fit. That is, the reductions in the residual deviance as each term of the formula is added in turn are given in as the rows of a table, plus the residual deviances themselves.

If more than one object is specified, the table has a row for the residual degrees of freedom and deviance for each model. For all but the first model, the change in degrees of freedom and deviance is also given. (This only makes statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

The table will optionally contain test statistics (and P values) comparing the reduction in deviance for the row to the residuals. For models with known dispersion (e.g., binomial and Poisson fits) the chi-squared test is most appropriate, and for those with dispersion estimated by moments (e.g., gaussian, quasibinomial and quasipoisson fits) the F test is most appropriate. Mallows’ $C_p$ statistic is the residual deviance plus twice the estimate of $\sigma^2$ times the residual degrees of freedom, which is closely related to AIC (and a multiple of it if the dispersion is known). You can also choose "LRT" and "Rao" for likelihood ratio tests and Rao’s efficient score test. The former is synonymous with "Chisq" (although both have an asymptotic chi-square distribution).

The dispersion estimate will be taken from the largest model, using the value returned by summary.glm. As this will in most cases use a Chisquared-based estimate, the F tests are not based on the residual deviance in the analysis of deviance table shown.

Value

An object of class "anova" inheriting from class "data.frame".
Warning

The comparison between two or more models by anova or anova.glmlist will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and R’s default of na.action = na.omit is used, and anova.glmlist will detect this with an error.

References

See Also

glm, anova.
drop1 for so-called ‘type II’ anova where each term is dropped one at a time respecting their hierarchy.

Examples

```r
## --- Continuing the Example from '?glm':

anova(glm.D93)
anova(glm.D93, test = "Cp")
anova(glm.D93, test = "Chisq")
glm.D93a <- update(glm.D93, ~treatment*outcome) ## equivalent to Pearson Chi-square
anova(glm.D93, glm.D93a, test = "Rao")
```

### anova.lm

**ANOVA for Linear Model Fits**

Description

Compute an analysis of variance table for one or more linear model fits.

Usage

```r
## S3 method for class 'lm'
anova(object, ...)
anova.lmlist(object, ..., scale = 0, test = "F")
```

Arguments

- `object, ...`: objects of class `lm`, usually, a result of a call to `lm`.
- `test`: a character string specifying the test statistic to be used. Can be one of "F", "Chisq" or "Cp", with partial matching allowed, or NULL for no test.
- `scale`: numeric. An estimate of the noise variance $\sigma^2$. If zero this will be estimated from the largest model considered.
Details

Specifying a single object gives a sequential analysis of variance table for that fit. That is, the reductions in the residual sum of squares as each term of the formula is added in turn are given in as the rows of a table, plus the residual sum of squares.

The table will contain F statistics (and P values) comparing the mean square for the row to the residual mean square.

If more than one object is specified, the table has a row for the residual degrees of freedom and sum of squares for each model. For all but the first model, the change in degrees of freedom and sum of squares is also given. (This only make statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

Optionally the table can include test statistics. Normally the F statistic is most appropriate, which compares the mean square for a row to the residual sum of squares for the largest model considered. If scale is specified chi-squared tests can be used. Mallows’ \( C_p \) statistic is the residual sum of squares plus twice the estimate of \( \sigma^2 \) times the residual degrees of freedom.

Value

An object of class "anova" inheriting from class "data.frame".

Warning

The comparison between two or more models will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and \( \text{R}'s \) default of \texttt{na.action = na.omit} is used, and \texttt{anova.lmlist} will detect this with an error.

Note

Versions of \( \text{R} \) prior to 1.2.0 based F tests on pairwise comparisons, and this behaviour can still be obtained by a direct call to \texttt{anovalist.lm}.

References

## sequential table
fit <- lm(sr ~ ., data = LifeCycleSavings)
anova(fit)

## same effect via separate models
```
```r
fit0 <- lm(sr ~ 1, data = LifeCycleSavings)
fit1 <- update(fit0, . ~ . + pop15)
fit2 <- update(fit1, . ~ . + pop75)
fit3 <- update(fit2, . ~ . + dpi)
fit4 <- update(fit3, . ~ . + ddpi)
anova(fit0, fit1, fit2, fit3, fit4, test = "F")

anova(fit4, fit2, fit0, test = "F") # unconventional order
```

---

**anova.mlm**

*Comparisons between Multivariate Linear Models*

**Description**

Compute a (generalized) analysis of variance table for one or more multivariate linear models.

**Usage**

```r
## S3 method for class 'mlm'
anova(object, ..., 
     test = c("Pillai", "Wilks", "Hotelling-Lawley", "Roy", 
              "Spherical"), 
     Sigma = diag(nrow = p), T = Thin.row(proj(M) - proj(X)), 
     M = diag(nrow = p), X = ~0, 
     idata = data.frame(index = seq_len(p)), tol = 1e-7)
```

**Arguments**

- `object`: an object of class "mlm".
- `...`: further objects of class "mlm".
- `test`: choice of test statistic (see below).
- `Sigma`: (only relevant if `test` == "Spherical"). Covariance matrix assumed proportional to `Sigma`.
- `T`: transformation matrix. By default computed from `M` and `X`.
- `M`: formula or matrix describing the outer projection (see below).
- `X`: formula or matrix describing the inner projection (see below).
- `idata`: data frame describing intra-block design.
- `tol`: tolerance to be used in deciding if the residuals are rank-deficient: see `qr`.

**Details**

The `anova.mlm` method uses either a multivariate test statistic for the summary table, or a test based on sphericity assumptions (i.e. that the covariance is proportional to a given matrix).

For the multivariate test, Wilks’ statistic is most popular in the literature, but the default Pillai–Bartlett statistic is recommended by Hand and Taylor (1987). See `summary.manova` for further details.
For the "Spherical" test, proportionality is usually with the identity matrix but a different matrix can be specified using Sigma. Corrections for asphericity known as the Greenhouse–Geisser, respectively Huynh–Feldt, epsilons are given and adjusted $F$ tests are performed.

It is common to transform the observations prior to testing. This typically involves transformation to intra-block differences, but more complicated within-block designs can be encountered, making more elaborate transformations necessary. A transformation matrix $T$ can be given directly or specified as the difference between two projections onto the spaces spanned by $M$ and $X$, which in turn can be given as matrices or as model formulas with respect to idata (the tests will be invariant to parametrization of the quotient space $M/X$).

As with anova.lm, all test statistics use the SSD matrix from the largest model considered as the (generalized) denominator.

Contrary to other anova methods, the intercept is not excluded from the display in the single-model case. When contrast transformations are involved, it often makes good sense to test for a zero intercept.

Value

An object of class "anova" inheriting from class "data.frame"

Note

The Huynh–Feldt epsilon differs from that calculated by SAS (as of v. 8.2) except when the DF is equal to the number of observations minus one. This is believed to be a bug in SAS, not in R.

```r
require(graphics)
utils::example(SSD) # Brings in the mlmfit and reacttime objects

mlmfit0 <- update(mlmfit, -0)

### Traditional tests of intrasubj. contrasts
## Using MANOVA techniques on contrasts:
anova(mlmfit, mlmfit0, X = ~1)

## Assuming sphericity
anova(mlmfit, mlmfit0, X = ~1, test = "Spherical")

### tests using intra-subject 3x2 design
idata <- data.frame(deg = gl(3, 1, 6, labels = c(0, 4, 8)),
```
noise = gl(2, 3, 6, labels = c("A", "P"))

anova(mlmfit, mlmfit0, X = ~ deg + noise,
    idata = idata, test = "Spherical")
anova(mlmfit, mlmfit0, M = ~ deg + noise, X = ~ noise,
    idata = idata, test = "Spherical" )
anova(mlmfit, mlmfit0, M = ~ deg + noise, X = ~ deg,
    idata = idata, test = "Spherical" )

f <- factor(rep(1:2, 5)) # bogus, just for illustration
mlmfit2 <- update(mlmfit, -f)
anova(mlmfit2, mlmfit, mlmfit0, X = ~1, test = "Spherical")
anova(mlmfit2, X = ~1, test = "Spherical")
# one-model form, eqiv. to previous

### There seems to be a strong interaction in these data
plot(colMeans(reacttime))

---

**ansari.test**

**Ansari-Bradley Test**

**Description**

Performs the Ansari-Bradley two-sample test for a difference in scale parameters.

**Usage**

```r
ansari.test(x, ...)
```

## Default S3 method:

```r
ansari.test(x, y,
    alternative = c("two.sided", "less", "greater"),
    exact = NULL, conf.int = FALSE, conf.level = 0.95,
    ...)
```

## S3 method for class 'formula'

```r
ansari.test(formula, data, subset, na.action, ...)
```

**Arguments**

- **x** numeric vector of data values.
- **y** numeric vector of data values.
- **alternative** indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter.
- **exact** a logical indicating whether an exact p-value should be computed.
- **conf.int** a logical, indicating whether a confidence interval should be computed.
- **conf.level** confidence level of the interval.
ansari.test

formula a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups.
data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset an optional vector specifying a subset of observations to be used.
na.action a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").
... further arguments to be passed to or from methods.

Details

Suppose that x and y are independent samples from distributions with densities \( f((t - m)/s)/s \) and \( f(t - m) \), respectively, where \( m \) is an unknown nuisance parameter and \( s \), the ratio of scales, is the parameter of interest. The Ansari-Bradley test is used for testing the null that \( s = 1 \), the two-sided alternative being that \( s \neq 1 \) (the distributions differ only in variance), and the one-sided alternatives being \( s > 1 \) (the distribution underlying x has a larger variance, "greater") or \( s < 1 \) ("less").

By default (if exact is not specified), an exact p-value is computed if both samples contain less than 50 finite values and there are no ties. Otherwise, a normal approximation is used.

Optionally, a nonparametric confidence interval and an estimator for \( s \) are computed. If exact p-values are available, an exact confidence interval is obtained by the algorithm described in Bauer (1972), and the Hodges-Lehmann estimator is employed. Otherwise, the returned confidence interval and point estimate are based on normal approximations.

Note that mid-ranks are used in the case of ties rather than average scores as employed in Hollander & Wolfe (1973). See, e.g., Hajek, Sidak and Sen (1999), pages 131ff, for more information.

Value

A list with class "htest" containing the following components:

statistic the value of the Ansari-Bradley test statistic.
p.value the p-value of the test.
null.value the ratio of scales \( s \) under the null, 1.
alternative a character string describing the alternative hypothesis.
method the string "Ansari-Bradley test".
data.name a character string giving the names of the data.
conf.int a confidence interval for the scale parameter. (Only present if argument conf.int = TRUE.)
estimate an estimate of the ratio of scales. (Only present if argument conf.int = TRUE.)
Note

To compare results of the Ansari-Bradley test to those of the F test to compare two variances (under the assumption of normality), observe that \( s \) is the ratio of scales and hence \( s^2 \) is the ratio of variances (provided they exist), whereas for the F test the ratio of variances itself is the parameter of interest. In particular, confidence intervals are for \( s \) in the Ansari-Bradley test but for \( s^2 \) in the F test.

ansari_test in package coin for exact and approximate conditional p-values for the Ansari-Bradley test, as well as different methods for handling ties.

Examples

```r
## Hollander & Wolfe (1973, p. 86f):
## Serum iron determination using Hyland control sera
ramsay <- c(111, 107, 100, 99, 102, 106, 109, 108, 104, 99,
            101, 96, 97, 102, 107, 113, 116, 113, 110, 98)
jung.parekh <- c(107, 108, 106, 98, 105, 110, 105, 104,
ansari.test(ramsay, jung.parekh)
ansari.test(rnorm(10), rnorm(10, 0, 2), conf.int = TRUE)

## try more points - failed in 2.4.1
ansari.test(rnorm(100), rnorm(100, 0, 2), conf.int = TRUE)
```

---

**aov**

*Fit an Analysis of Variance Model*

**Description**

Fit an analysis of variance model by a call to `lm` for each stratum.
Usage

aov(formula, data = NULL, projections = FALSE, qr = TRUE,
contrasts = NULL, ...)

Arguments

  formula
      A formula specifying the model.
    data
      A data frame in which the variables specified in the formula will be found. If
      missing, the variables are searched for in the standard way.
  projections
      Logical flag: should the projections be returned?
    qr
      Logical flag: should the QR decomposition be returned?
  contrasts
      A list of contrasts to be used for some of the factors in the formula. These are not
      used for any Error term, and supplying contrasts for factors only in the Error
      term will give a warning.
...  Arguments to be passed to lm, such as subset or na.action. See ‘Details’

about weights.

Details

This provides a wrapper to lm for fitting linear models to balanced or unbalanced experimental
designs.

The main difference from lm is in the way print, summary and so on handle the fit: this is expressed
in the traditional language of the analysis of variance rather than that of linear models.

If the formula contains a single Error term, this is used to specify error strata, and appropriate
models are fitted within each error stratum.

The formula can specify multiple responses.

Weights can be specified by a weights argument, but should not be used with an Error term, and
are incompletely supported (e.g., not by model.tables).

Value

An object of class c("aov", "lm") or for multiple responses of class
c("maov", "aov", "mlm", "lm") or for multiple error strata of class "aovlist". There
are print and summary methods available for these.

Note

aov is designed for balanced designs, and the results can be hard to interpret without balance:
beware that missing values in the response(s) will likely lose the balance. If there are two or more
error strata, the methods used are statistically inefficient without balance, and it may be better to
use lme in package nlme.

Balance can be checked with the replications function.

The default ‘contrasts’ in R are not orthogonal contrasts, and aov and its helper functions will work
better with such contrasts: see the examples for how to select these.
The design was inspired by the S function of the same name described in Chambers et al. (1992).

coefficients(npk.aov)

## to show the effects of re-ordering terms contrast the two fits
aov(yield ~ block + N * P + K, npk)
aov(terms(yield ~ block + N * P + K, keep.order = TRUE), npk)

## as a test, not particularly sensible statistically
npk.aovE <- aov(yield ~ N*P*K + Error(block), npk)
npk.aovE
summary(npk.aovE)
options(op)  # reset to previous

Interpolation Functions

approxfun

Description

Return a list of points which linearly interpolate given data points, or a function performing the linear (or constant) interpolation.

Usage

approx (x, y = NULL, xout, method = "linear", n = 50, yleft, yright, rule = 1, f = 0, ties = mean)

approxfun(x, y = NULL, method = "linear", yleft, yright, rule = 1, f = 0, ties = mean)
approxfun

Arguments

- **x, y**: numeric vectors giving the coordinates of the points to be interpolated. Alternatively a single plotting structure can be specified: see `xy.coords`.
- **xout**: an optional set of numeric values specifying where interpolation is to take place.
- **method**: specifies the interpolation method to be used. Choices are "linear" or "constant".
- **n**: If `xout` is not specified, interpolation takes place at `n` equally spaced points spanning the interval `[min(x), max(x)]`.
- **yleft**: the value to be returned when input `x` values are less than `min(x)`. The default is defined by the value of `rule` given below.
- **yright**: the value to be returned when input `x` values are greater than `max(x)`. The default is defined by the value of `rule` given below.
- **rule**: an integer (of length 1 or 2) describing how interpolation is to take place outside the interval `[min(x), max(x)]`. If `rule` is 1 then NAs are returned for such points and if it is 2, the value at the closest data extreme is used. Use, e.g., `rule = 2:1`, if the left and right side extrapolation should differ.
- **f**: for `method = "constant"` a number between 0 and 1 inclusive, indicating a compromise between left- and right-continuous step functions. If `y0` and `y1` are the values to the left and right of the point then the value is `y0*(1-f)+y1*f` so that `f = 0` is right-continuous and `f = 1` is left-continuous.
- **ties**: Handling of tied `x` values. Either a function with a single vector argument returning a single number result or the string "ordered".

Details

The inputs can contain missing values which are deleted, so at least two complete `(x, y)` pairs are required (for `method = "linear"`, one otherwise). If there are duplicated (tied) `x` values and `ties` is a function it is applied to the `y` values for each distinct `x` value. Useful functions in this context include `mean`, `min`, and `max`. If `ties = "ordered"` the `x` values are assumed to be already ordered. The first `y` value will be used for interpolation to the left and the last one for interpolation to the right.

Value

`approx` returns a list with components `x` and `y`, containing `n` coordinates which interpolate the given data points according to the `method` (and `rule`) desired.

The function `approxfun` returns a function performing (linear or constant) interpolation of the given data points. For a given set of `x` values, this function will return the corresponding interpolated values. It uses data stored in its environment when it was created, the details of which are subject to change.

Warning

The value returned by `approxfun` contains references to the code in the current version of R: it is not intended to be saved and loaded into a different R session. This is safer for R >= 3.0.0.
References

See Also

`spline` and `splinefun` for spline interpolation.

Examples

```r
require(graphics)
x <- 1:10
y <- rnorm(10)
par(mfrow = c(2,1))
plot(x, y, main = "approx(.) and approxfun(.)")
points(approx(x, y), col = 2, pch = "*")
points(approx(x, y, method = "constant"), col = 4, pch = "*")

f <- approxfun(x, y)
curve(f(x), 0, 11, col = "green2")
points(x, y)
is.function(fc <- approxfun(x, y, method = "const")) # TRUE
curve(fc(x), 0, 10, col = "darkblue", add = TRUE)
## different extrapolation on left and right side :
plot(approxfun(x, y, rule = 2:1), 0, 11,
     col = "tomato", add = TRUE, lty = 3, lwd = 2)

## Show treatment of 'ties' :
x <- c(2,2:4,4,5,5,7,7,7)
y <- c(1:6, 5:4, 3:1)
approx(x, y, xout = x)$y # warning
(ay <- approx(x, y, xout = x, ties = "ordered")$y)
stopifnot(ay == c(2,2,3,6,6,6,4,4,1,1,1))
approx(x, y, xout = x, ties = min)$y
approx(x, y, xout = x, ties = max)$y
```

---

**ar**

*Fit Autoregressive Models to Time Series*

Description

Fit an autoregressive time series model to the data, by default selecting the complexity by AIC.
Usage

```r
ar(x, aic = TRUE, order.max = NULL,
   method = c("yule-walker", "burg", "ols", "mle", "yw"),
   na.action, series, ...)

ar.burg(x, ...)
## Default S3 method:
ar.burg(x, aic = TRUE, order.max = NULL,
   na.action = na.fail, demean = TRUE, series,
   var.method = 1, ...)
## S3 method for class 'mts'
ar.burg(x, aic = TRUE, order.max = NULL,
   na.action = na.fail, demean = TRUE, series,
   var.method = 1, ...)

ar.yw(x, ...)
## Default S3 method:
ar.yw(x, aic = TRUE, order.max = NULL,
   na.action = na.fail, demean = TRUE, series, ...)
## S3 method for class 'mts'
ar.yw(x, aic = TRUE, order.max = NULL,
   na.action = na.fail, demean = TRUE, series,
   var.method = 1, ...)

ar.mle(x, aic = TRUE, order.max = NULL, na.action = na.fail,
   demean = TRUE, series, ...)
## S3 method for class 'ar'
predict(object, newdata, n.ahead = 1, se.fit = TRUE, ...)
```

Arguments

- **x**: A univariate or multivariate time series.
- **aic**: Logical flag. If TRUE then the Akaike Information Criterion is used to choose the order of the autoregressive model. If FALSE, the model of order order.max is fitted.
- **order.max**: Maximum order (or order) of model to fit. Defaults to the smaller of $N - 1$ and $10 \log_{10}(N)$ where $N$ is the number of observations except for method = "mle" where it is the minimum of this quantity and 12.
- **method**: Character string giving the method used to fit the model. Must be one of the strings in the default argument (the first few characters are sufficient). Defaults to "yule-walker".
- **na.action**: function to be called to handle missing values.
- **demean**: should a mean be estimated during fitting?
- **series**: names for the series. Defaults to `deparse(substitute(x))`.
- **var.method**: the method to estimate the innovations variance (see ‘Details’).
... additional arguments for specific methods.

object a fit from `ar`.

newdata data to which to apply the prediction.

n.ahead number of steps ahead at which to predict.

se.fit logical: return estimated standard errors of the prediction error?

details

For definiteness, note that the AR coefficients have the sign in

\[ x_t - \mu = a_1(x_{t-1} - \mu) + \cdots + a_p(x_{t-p} - \mu) + e_t \]

`ar` is just a wrapper for the functions `ar.yw`, `ar.burg`, `ar.ols` and `ar.mle`.

Order selection is done by AIC if `aic` is true. This is problematic, as of the methods here only `ar.mle` performs true maximum likelihood estimation. The AIC is computed as if the variance estimate were the MLE, omitting the determinant term from the likelihood. Note that this is not the same as the Gaussian likelihood evaluated at the estimated parameter values. In `ar.yw` the variance matrix of the innovations is computed from the fitted coefficients and the autocovariance of \( x \).

`ar.burg` allows two methods to estimate the innovations variance and hence AIC. Method 1 is to use the update given by the Levinson-Durbin recursion (Brockwell and Davis, 1991, (8.2.6) on page 242), and follows S-PLUS. Method 2 is the mean of the sum of squares of the forward and backward prediction errors (as in Brockwell and Davis, 1996, page 145). Percival and Walden (1998) discuss both. In the multivariate case the estimated coefficients will depend (slightly) on the variance estimation method.

Remember that `ar` includes by default a constant in the model, by removing the overall mean of \( x \) before fitting the AR model, or (`ar.mle`) estimating a constant to subtract.

value

For `ar` and its methods a list of class "ar" with the following elements:

`order` The order of the fitted model. This is chosen by minimizing the AIC if `aic = TRUE`, otherwise it is `order.max`.

`ar` Estimated autoregression coefficients for the fitted model.

`var.pred` The prediction variance: an estimate of the portion of the variance of the time series that is not explained by the autoregressive model.

`x.mean` The estimated mean of the series used in fitting and for use in prediction.

`x.intercept` (``ar.ols`` only.) The intercept in the model for \( x - x.mean \).

`aic` The differences in AIC between each model and the best-fitting model. Note that the latter can have an AIC of `-Inf`.

`n.used` The number of observations in the time series.

`order.max` The value of the `order.max` argument.

`partialacf` The estimate of the partial autocorrelation function up to lag `order.max`.
resid:

residuals from the fitted model, conditioning on the first order observations. The first order residuals are set to NA. If x is a time series, so is resid.

method:
The value of the method argument.

series:
The name(s) of the time series.

frequency:
The frequency of the time series.

call:
The matched call.

asy.var.coef:

(univariate case, order > 0.) The asymptotic-theory variance matrix of the coefficient estimates.

For predict.ar, a time series of predictions, or if se.fit = TRUE, a list with components pred, the predictions, and se, the estimated standard errors. Both components are time series.

Note:

Only the univariate case of ar.mle is implemented.

Fitting by method="mle" to long series can be very slow.

Examples:

```r
ar(lh)
ar(lh, method = "burg")
ar(lh, method = "ols")
ar(lh, FALSE, 4) # fit ar(4)

(sunspot.ar <- ar(sunspot.year))
predict(sunspot.ar, n.ahead = 25)
```
## try the other methods too

ar(ts.union(BJsales, BJsales.lead))

## Burg is quite different here, as is OLS (see ar.ols)
ar(ts.union(BJsales, BJsales.lead), method = "burg")

---

### ar.ols

**Fit Autoregressive Models to Time Series by OLS**

#### Description

Fit an autoregressive time series model to the data by ordinary least squares, by default selecting the complexity by AIC.

#### Usage

```r
ar.ols(x, aic = TRUE, order.max = NULL, na.action = na.fail,
  demean = TRUE, intercept = demean, series, ...)
```

#### Arguments

- `x`: A univariate or multivariate time series.
- `aic`: Logical flag. If TRUE then the Akaike Information Criterion is used to choose the order of the autoregressive model. If FALSE, the model of order `order.max` is fitted.
- `order.max`: Maximum order (or order) of model to fit. Defaults to `10 \log_{10}(N)` where $N$ is the number of observations.
- `na.action`: function to be called to handle missing values.
- `demean`: should the AR model be for $x$ minus its mean?
- `intercept`: should a separate intercept term be fitted?
- `series`: names for the series. Defaults to `deparse(substitute(x))`.
- `...`: further arguments to be passed to or from methods.

#### Details

`ar.ols` fits the general AR model to a possibly non-stationary and/or multivariate system of series $x$. The resulting unconstrained least squares estimates are consistent, even if some of the series are non-stationary and/or co-integrated. For definiteness, note that the AR coefficients have the sign in

$$x_t - \mu = a_0 + a_1(x_{t-1} - \mu) + \cdots + a_p(x_{t-p} - \mu) + e_t$$

where $a_0$ is zero unless `intercept` is true, and $\mu$ is the sample mean if `demean` is true, zero otherwise.

Order selection is done by AIC if `aic` is true. This is problematic, as `ar.ols` does not perform true maximum likelihood estimation. The AIC is computed as if the variance estimate (computed
from the variance matrix of the residuals) were the MLE, omitting the determinant term from the likelihood. Note that this is not the same as the Gaussian likelihood evaluated at the estimated parameter values.

Some care is needed if intercept is true and demean is false. Only use this is the series are roughly centred on zero. Otherwise the computations may be inaccurate or fail entirely.

Value

A list of class "ar" with the following elements:

- **order**: The order of the fitted model. This is chosen by minimizing the AIC if aic = TRUE, otherwise it is order.max.
- **ar**: Estimated autoregression coefficients for the fitted model.
- **var.pred**: The prediction variance: an estimate of the portion of the variance of the time series that is not explained by the autoregressive model.
- **x.mean**: The estimated mean (or zero if demean is false) of the series used in fitting and for use in prediction.
- **x.intercept**: The intercept in the model for x - x.mean, or zero if intercept is false.
- **aic**: The differences in AIC between each model and the best-fitting model. Note that the latter can have an AIC of -Inf.
- **n.used**: The number of observations in the time series.
- **order.max**: The value of the order.max argument.
- **partialacf**: NULL. For compatibility with ar.
- **resid**: residuals from the fitted model, conditioning on the first order observations. The first order residuals are set to NA. If x is a time series, so is resid.
- **method**: The character string "Unconstrained LS".
- **series**: The name(s) of the time series.
- **frequency**: The frequency of the time series.
- **call**: The matched call.
- **asy.se.coef**: The asymptotic-theory standard errors of the coefficient estimates.

arima

ARIMA Modelling of Time Series

Description

Fit an ARIMA model to a univariate time series.

Usage

arima(x, order = c(0, 0, 0),
      seasonal = list(order = c(0, 0, 0), period = NA),
      xreg = NULL, include.mean = TRUE,
      transform.pars = TRUE,
      fixed = NULL, init = NULL,
      method = c("CSS-ML", "ML", "CSS"),
      n.cond, optim.method = "BFGS",
      optim.control = list(), kappa = 1e6)

Arguments

x a univariate time series

order A specification of the non-seasonal part of the ARIMA model: the three components \((p, d, q)\) are the AR order, the degree of differencing, and the MA order.

seasonal A specification of the seasonal part of the ARIMA model, plus the period (which defaults to \text{frequency}(x)). This should be a list with components order and period, but a specification of just a numeric vector of length 3 will be turned into a suitable list with the specification as the order.

xreg Optionally, a vector or matrix of external regressors, which must have the same number of rows as \(x\).

include.mean Should the ARMA model include a mean/intercept term? The default is \text{TRUE} for undifferenced series, and it is ignored for ARIMA models with differencing.

transform.pars Logical. If true, the AR parameters are transformed to ensure that they remain in the region of stationarity. Not used for method = "CSS".
fixed optional numeric vector of the same length as the total number of parameters. If supplied, only NA entries in fixed will be varied. transform.pars = TRUE will be overridden (with a warning) if any AR parameters are fixed. It may be wise to set transform.pars = FALSE when fixing MA parameters, especially near non-invertibility.

init optional numeric vector of initial parameter values. Missing values will be filled in, by zeroes except for regression coefficients. Values already specified in fixed will be ignored.

method Fitting method: maximum likelihood or minimize conditional sum-of-squares. The default (unless there are missing values) is to use conditional-sum-of-squares to find starting values, then maximum likelihood.

n.cond Only used if fitting by conditional-sum-of-squares: the number of initial observations to ignore. It will be ignored if less than the maximum lag of an AR term.

optim.method The value passed as the method argument to optim.

optim.control List of control parameters for optim.

kappa the prior variance (as a multiple of the innovations variance) for the past observations in a differenced model. Do not reduce this.

Details

Different definitions of ARMA models have different signs for the AR and/or MA coefficients. The definition used here has

\[ X_t = a_1 X_{t-1} + \cdots + a_p X_{t-p} + e_t + b_1 e_{t-1} + \cdots + b_q e_{t-q} \]

and so the MA coefficients differ in sign from those of S-PLUS. Further, if include.mean is true (the default for an ARMA model), this formula applies to \( X - m \) rather than \( X \). For ARIMA models with differencing, the differenced series follows a zero-mean ARMA model. If an xreg term is included, a linear regression (with a constant term if include.mean is true and there is no differencing) is fitted with an ARMA model for the error term.

The variance matrix of the estimates is found from the Hessian of the log-likelihood, and so may only be a rough guide.

Optimization is done by optim. It will work best if the columns in xreg are roughly scaled to zero mean and unit variance, but does attempt to estimate suitable scalings.

Value

A list of class "Arima" with components:

- coef a vector of AR, MA and regression coefficients, which can be extracted by the coef method.
- sigma2 the MLE of the innovations variance.
- var.coef the estimated variance matrix of the coefficients coef, which can be extracted by the vcov method.
loglik the maximized log-likelihood (of the differenced data), or the approximation to it used.

arma A compact form of the specification, as a vector giving the number of AR, MA, seasonal AR and seasonal MA coefficients, plus the period and the number of non-seasonal and seasonal differences.

aic the AIC value corresponding to the log-likelihood. Only valid for method = "ML" fits.

residuals the fitted innovations.

call the matched call.

series the name of the series \( x \).

code the convergence value returned by \texttt{optim}.

n.cond the number of initial observations not used in the fitting.

model A list representing the Kalman Filter used in the fitting. See \texttt{KalmanLike}.

**Fitting methods**

The exact likelihood is computed via a state-space representation of the ARIMA process, and the innovations and their variance found by a Kalman filter. The initialization of the differenced ARMA process uses stationarity and is based on Gardner \textit{et al.} (1980). For a differenced process the non-stationary components are given a diffuse prior (controlled by \( \kappa \)). Observations which are still controlled by the diffuse prior (determined by having a Kalman gain of at least 1e4) are excluded from the likelihood calculations. (This gives comparable results to \texttt{arima0} in the absence of missing values, when the observations excluded are precisely those dropped by the differencing.)

Missing values are allowed, and are handled exactly in method "ML".

If \texttt{transform.pars} is true, the optimization is done using an alternative parametrization which is a variation on that suggested by Jones (1980) and ensures that the model is stationary. For an AR(p) model the parametrization is via the inverse tanh of the partial autocorrelations: the same procedure is applied (separately) to the AR and seasonal AR terms. The MA terms are not constrained to be invertible during optimization, but they will be converted to invertible form after optimization if \texttt{transform.pars} is true.

Conditional sum-of-squares is provided mainly for expositional purposes. This computes the sum of squares of the fitted innovations from observation \( n.\text{cond} \) on, (where \( n.\text{cond} \) is at least the maximum lag of an AR term), treating all earlier innovations to be zero. Argument \( n.\text{cond} \) can be used to allow comparability between different fits. The ‘part log-likelihood’ is the first term, half the log of the estimated mean square. Missing values are allowed, but will cause many of the innovations to be missing.

When regressors are specified, they are orthogonalized prior to fitting unless any of the coefficients is fixed. It can be helpful to roughly scale the regressors to zero mean and unit variance.

**Note**

The results are likely to be different from S-PLUS’s \texttt{arima.mle}, which computes a conditional likelihood and does not include a mean in the model. Further, the convention used by \texttt{arima.mle} reverses the signs of the MA coefficients.
arima is very similar to arima0 for ARMA models or for differenced models without missing values, but handles differenced models with missing values exactly. It is somewhat slower than arima0, particularly for seasonally differenced models.

require(graphics)
(fit1 <- arima(presidents, c(1, 0, 0)))
tsdiag(fit1)
(fit3 <- arima(presidents, c(3, 0, 0))) # smaller AIC
tsdiag(fit3)
```
Simulate from an ARIMA Model

Description

Simulate from an ARIMA model.

Usage

arima.sim(model, n, rand.gen = rnorm, innov = rand.gen(n, ...),
          n.start = NA, start.innov = rand.gen(n.start, ...),
          ...)  

Arguments

  model A list with component ar and/or ma giving the AR and MA coefficients respectively. Optionally a component order can be used. An empty list gives an ARIMA(0, 0, 0) model, that is white noise.
  n length of output series, before un-differencing. A strictly positive integer.
  rand.gen optional: a function to generate the innovations.
  innov an optional times series of innovations. If not provided, rand.gen is used.
  n.start length of ‘burn-in’ period. If NA, the default, a reasonable value is computed.
  start.innov an optional times series of innovations to be used for the burn-in period. If supplied there must be at least n.start values (and n.start is by default computed inside the function).
  ... additional arguments for rand.gen. Most usefully, the standard deviation of the innovations generated by rnorm can be specified by sd.

Details

See arima for the precise definition of an ARIMA model.

The ARMA model is checked for stationarity.

ARIMA models are specified via the order component of model, in the same way as for arima. Other aspects of the order component are ignored, but inconsistent specifications of the MA and AR orders are detected. The un-differencing assumes previous values of zero, and to remind the user of this, those values are returned.

Random inputs for the ‘burn-in’ period are generated by calling rand.gen.

Value

A time-series object of class "ts".

See Also

arima
Examples

require(graphics)

arima.sim(n = 63, list(ar = c(0.8897, -0.4858), ma = c(-0.2279, 0.2488)),
sd = sqrt(0.1796))
# mildly long-tailed
arima.sim(n = 63, list(ar = c(0.8897, -0.4858), ma = c(-0.2279, 0.2488)),
  rand.gen = function(n, ...) sqrt(0.1796) * rt(n, df = 5))

# An ARIMA simulation
ts.sim <- arima.sim(list(order = c(1,1,0), ar = 0.7), n = 200)
ts.plot(ts.sim)

Description

Fit an ARIMA model to a univariate time series, and forecast from the fitted model.

Usage

arima0(x, order = c(0, 0, 0),
seasonal = list(order = c(0, 0, 0), period = NA),
xreg = NULL, include.mean = TRUE, delta = 0.1,
transform.pars = TRUE, fixed = NULL, init = NULL,
method = c("ML", "CSS"), n.cond, optim.control = list())

## S3 method for class 'arima0'
predict(object, n.ahead = 1, newxreg, se.fit = TRUE, ...)

Arguments

x a univariate time series

order A specification of the non-seasonal part of the ARIMA model: the three components \((p, d, q)\) are the AR order, the degree of differencing, and the MA order.

seasonal A specification of the seasonal part of the ARIMA model, plus the period (which defaults to frequency(x)). This should be a list with components order and period, but a specification of just a numeric vector of length 3 will be turned into a suitable list with the specification as the order.

xreg Optionally, a vector or matrix of external regressors, which must have the same number of rows as x.

include.mean Should the ARIMA model include a mean term? The default is TRUE for undifferenced series, FALSE for differenced ones (where a mean would not affect the fit nor predictions).
delta  A value to indicate at which point ‘fast recursions’ should be used. See the
‘Details’ section.
transform.pars Logical. If true, the AR parameters are transformed to ensure that they remain
in the region of stationarity. Not used for method = "CSS".
fixed  optional numeric vector of the same length as the total number of parameters.
If supplied, only NA entries in fixed will be varied. transform.pars = TRUE
will be overridden (with a warning) if any ARMA parameters are fixed.
init  optional numeric vector of initial parameter values. Missing values will be filled
in, by zeroes except for regression coefficients. Values already specified in
fixed will be ignored.
method  Fitting method: maximum likelihood or minimize conditional sum-of-squares.
n.cond  Only used if fitting by conditional-sum-of-squares: the number of initial obser-
vations to ignore. It will be ignored if less than the maximum lag of an AR
term.
optim.control List of control parameters for optim.
object  The result of an arima fit.
newxreg  New values of xreg to be used for prediction. Must have at least n.ahead rows.
n.ahead  The number of steps ahead for which prediction is required.
se.fit  Logical: should standard errors of prediction be returned?
...  arguments passed to or from other methods.

Details

Different definitions of ARMA models have different signs for the AR and/or MA coefficients. The
definition here has

\[ X_t = a_1 X_{t-1} + \cdots + a_p X_{t-p} + e_t + b_1 e_{t-1} + \cdots + b_q e_{t-q} \]

and so the MA coefficients differ in sign from those of S-PLUS. Further, if include.mean is true,
this formula applies to \( X - m \) rather than \( X \). For ARIMA models with differencing, the differenced
series follows a zero-mean ARMA model.

The variance matrix of the estimates is found from the Hessian of the log-likelihood, and so may
only be a rough guide, especially for fits close to the boundary of invertibility.

Optimization is done by optim. It will work best if the columns in xreg are roughly scaled to zero
mean and unit variance, but does attempt to estimate suitable scalings.

Finite-history prediction is used. This is only statistically efficient if the MA part of the fit is
invertible, so predict.arima will give a warning for non-invertible MA models.

Value

For arima, a list of class "arima" with components:

coef  a vector of AR, MA and regression coefficients,
sigma2  the MLE of the innovations variance.
var.coef  the estimated variance matrix of the coefficients coef.
loglik   the maximized log-likelihood (of the differenced data), or the approximation to
         it used.
arma     A compact form of the specification, as a vector giving the number of AR, MA,
         seasonal AR and seasonal MA coefficients, plus the period and the number of
         non-seasonal and seasonal differences.
aic      the AIC value corresponding to the log-likelihood. Only valid for
         method = "ML" fits.
residuals the fitted innovations.
call     the matched call.
series   the name of the series x.
convergence the value returned by optim.
n.cond   the number of initial observations not used in the fitting.

For predict.arima0, a time series of predictions, or if se.fit = TRUE, a list with components
         pred, the predictions, and se, the estimated standard errors. Both components are time series.

Fitting methods

The exact likelihood is computed via a state-space representation of the ARMA process, and the
innovations and their variance found by a Kalman filter based on Gardner et al. (1980). This has the
option to switch to ‘fast recursions’ (assume an effectively infinite past) if the innovations variance
is close enough to its asymptotic bound. The argument delta sets the tolerance: at its default value
the approximation is normally negligible and the speed-up considerable. Exact computations can
be ensured by setting delta to a negative value.

If transform.pars is true, the optimization is done using an alternative parametrization which is a
variation on that suggested by Jones (1980) and ensures that the model is stationary. For an AR(p)
model the parametrization is via the inverse tanh of the partial autocorrelations: the same procedure
is applied (separately) to the AR and seasonal AR terms. The MA terms are also constrained to
be invertible during optimization by the same transformation if transform.pars is true. Note that
the MLE for MA terms does sometimes occur for MA polynomials with unit roots: such models
can be fitted by using transform.pars = FALSE and specifying a good set of initial values (often
obtainable from a fit with transform.pars = TRUE).

Missing values are allowed, but any missing values will force delta to be ignored and full recur-
sions used. Note that missing values will be propagated by differencing, so the procedure used in
this function is not fully efficient in that case.

Conditional sum-of-squares is provided mainly for expositional purposes. This computes the sum
of squares of the fitted innovations from observation n.cond on, (where n.cond is at least the
maximum lag of an AR term), treating all earlier innovations to be zero. Argument n.cond can
be used to allow comparability between different fits. The ‘part log-likelihood’ is the first term,
half the log of the estimated mean square. Missing values are allowed, but will cause many of the
innovations to be missing.

When regressors are specified, they are orthogonalized prior to fitting unless any of the coefficients
is fixed. It can be helpful to roughly scale the regressors to zero mean and unit variance.
Note

This is a preliminary version, and will be replaced by \texttt{arima}.

The standard errors of prediction exclude the uncertainty in the estimation of the ARMA model and the regression coefficients.

The results are likely to be different from S-PLUS’s \texttt{arima.mle}, which computes a conditional likelihood and does not include a mean in the model. Further, the convention used by \texttt{arima.mle} reverses the signs of the MA coefficients.

Compute Theoretical ACF for an ARMA Process

Description

Compute the theoretical autocorrelation function or partial autocorrelation function for an ARMA process.

Usage

ARMAacf(ar = numeric(), ma = numeric(), lag.max = r, pacf = FALSE)

Arguments

- ar: numeric vector of AR coefficients
- ma: numeric vector of MA coefficients
- lag.max: integer. Maximum lag required. Defaults to \( \max(p, q+1) \), where \( p \), \( q \) are the numbers of AR and MA terms respectively.
- pacf: logical. Should the partial autocorrelations be returned?

Details

The methods used follow Brockwell & Davis (1991, section 3.3). Their equations (3.3.8) are solved for the autocovariances at lags \( 0, \ldots, \max(p, q+1) \), and the remaining autocorrelations are given by a recursive filter.

Value

A vector of (partial) autocorrelations, named by the lags.

## answer 2^(-n) * (32/3 + 8 * n) /(32/3)
n <- 1:10; 2^(-n) * (32/3 + 8 * n) /(32/3)
ARMAacf(c(1.0, -0.25), 1.0, lag.max = 10, pacf = TRUE)
zapsmall(ARMAacf(c(1.0, -0.25), lag.max = 10, pacf = TRUE))
## Cov-Matrix of length-7 sub-sample of AR(1) example:
toeplitz(ARMAacf(0.8, lag.max = 7))

### Description
Convert ARMA process to infinite MA process.

### Usage

```r
ARMAtoMA(ar = numeric(), ma = numeric(), lag.max)
```

### Arguments

- `ar`
  - numeric vector of AR coefficients
- `ma`
  - numeric vector of MA coefficients
- `lag.max`
  - Largest MA(Inf) coefficient required.

### Value
A vector of coefficients.

### References

### See Also
`arima`, `ARMAacf`.

### Examples

```r
ARMAtoMA(c(1.0, -0.25), 1.0, 10)
## Example from Brockwell & Davis (1991, p.92)
## answer (1 + 3*n)*2^(-n)
```

```r
n <- 1:10; (1 + 3*n)*2^(-n)
```
**as.hclust**

Convert Objects to Class hclust

---

**Description**

Converts objects from other hierarchical clustering functions to class "hclust".

**Usage**

```r
as.hclust(x, ...)  
```

**Arguments**

- `x`: Hierarchical clustering object
- `...`: further arguments passed to or from other methods.

**Details**

Currently there is only support for converting objects of class "twins" as produced by the functions diana and agnes from the package **cluster**. The default method throws an error unless passed an "hclust" object.

**Value**

An object of class "hclust".

**See Also**

`hclust`, and from package **cluster**, **diana** and **agnes**

**Examples**

```r
x <- matrix(rnorm(30), ncol = 3)
hc <- hclust(dist(x), method = "complete")
if(require("cluster", quietly = TRUE)) {# is a recommended package
  ag <- agnes(x, method = "complete")
hcag <- as.hclust(ag)
  ## The dendrograms order slightly differently:
op <- par(mfrow = c(1,2))
  plot(hc); mtext("hclust", side = 1)
  plot(hcag); mtext("agnes", side = 1)
}
```
asOneSidedFormula  *Convert to One-Sided Formula*

**Description**

Names, expressions, numeric values, and character strings are converted to one-sided formulae. If object is a formula, it must be one-sided, in which case it is returned unaltered.

**Usage**

asOneSidedFormula(object)

**Arguments**

object  
a one-sided formula, an expression, a numeric value, or a character string.

**Value**

a one-sided formula representing object

**Author(s)**

José Pinheiro and Douglas Bates

**See Also**

formula

**Examples**

asOneSidedFormula("age")
asOneSidedFormula(~ age)

ave  *Group Averages Over Level Combinations of Factors*

**Description**

Subsets of x[.] are averaged, where each subset consist of those observations with the same factor levels.

**Usage**

ave(x, ..., FUN = mean)
**Arguments**

- **x**  A numeric.
- **...**  Grouping variables, typically factors, all of the same length as `x`.
- **FUN**  Function to apply for each factor level combination.

**Value**

A numeric vector, say `y` of length `length(x)`. If `...` is `g1`, `g2`, e.g., `y[i]` is equal to `FUN(x[j], for all j with `g1[j] == g1[i]` and `g2[j] == g2[i]`).

**See Also**

- `mean`, `median`.

**Examples**

```r
require(graphics)

ave(1:3) # no grouping -> grand mean

attach(warpbreaks)
ave(breaks, wool)
ave(breaks, tension)
ave(breaks, tension, FUN = function(x) mean(x, trim = 0.1))
plot(breaks, main =
   "ave( Warpbreaks ) for wool x tension combinations")
lines(ave(breaks, wool, tension ), type = "s", col = "blue")
lines(ave(breaks, wool, tension, FUN = median), type = "s", col = "green")
legend(40, 70, c("mean", "median"), lty = 1,
   col = c("blue","green"), bg = "gray90")
detach()
```

**Description**

Bandwidth selectors for Gaussian kernels in `density`.

**Usage**

```r
bw.nrd0(x)

bw.nrd(x)

bw.ucv(x, nb = 1000, lower = 0.1 * hmax, upper = hmax,
   tol = 0.1 * lower)
```
bw.bcv(x, nb = 1000, lower = 0.1 * hmax, upper = hmax, tol = 0.1 * lower)

bw.SJ(x, nb = 1000, lower = 0.1 * hmax, upper = hmax, method = c("ste", "dpi"), tol = 0.1 * lower)

Arguments

x numeric vector.

nb number of bins to use.

lower, upper range over which to minimize. The default is almost always satisfactory. hmax is calculated internally from a normal reference bandwidth.

method either "ste" ("solve-the-equation") or "dpi" ("direct plug-in").

tol for method "ste", the convergence tolerance for uniroot. The default leads to bandwidth estimates with only slightly more than one digit accuracy, which is sufficient for practical density estimation, but possibly not for theoretical simulation studies.

Details

bw.nrd0 implements a rule-of-thumb for choosing the bandwidth of a Gaussian kernel density estimator. It defaults to 0.9 times the minimum of the standard deviation and the interquartile range divided by 1.34 times the sample size to the negative one-fifth power (= Silverman’s ‘rule of thumb’, Silverman (1986, page 48, eqn (3.31)) unless the quartiles coincide when a positive result will be guaranteed.

bw.nrd is the more common variation given by Scott (1992), using factor 1.06.

bw.ucv and bw.bcv implement unbiased and biased cross-validation respectively.

bw.SJ implements the methods of Sheather & Jones (1991) to select the bandwidth using pilot estimation of derivatives.

The algorithm for method "ste" solves an equation (via uniroot) and because of that, enlarges the interval c(lower, upper) when the boundaries were not user-specified and do not bracket the root.

Value

A bandwidth on a scale suitable for the bw argument of density.

References

See Also

density.

bandwidth.nrd, ucv, bcv and width.SJ in package MASS, which are all scaled to the width argument of density and so give answers four times as large.

Examples

require(graphics)

plot(density(precip, n = 1000))
rug(precip)
lines(density(precip, bw = "nrd"), col = 2)
lines(density(precip, bw = "ucv"), col = 3)
lines(density(precip, bw = "bcv"), col = 4)
lines(density(precip, bw = "SJ-ste"), col = 5)
lines(density(precip, bw = "SJ-dpi"), col = 6)
legend(55, 0.035,
legend = c("nrd", "nrd", "ucv", "bcv", "SJ-ste", "SJ-dpi"),
col = 1:6, lty = 1)
data an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.

subset an optional vector specifying a subset of observations to be used.

na.action a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.

... further arguments to be passed to or from methods.

Details

If `x` is a list, its elements are taken as the samples or fitted linear models to be compared for homogeneity of variances. In this case, the elements must either all be numeric data vectors or fitted linear model objects, `g` is ignored, and one can simply use `bartlett.test(x)` to perform the test. If the samples are not yet contained in a list, use `bartlett.test(list(x, ...))`.

Otherwise, `x` must be a numeric data vector, and `g` must be a vector or factor object of the same length as `x` giving the group for the corresponding elements of `x`.

Value

A list of class "htest" containing the following components:

- statistic Bartlett’s K-squared test statistic.
- parameter the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- p.value the p-value of the test.
- method the character string "Bartlett test of homogeneity of variances".
- data.name a character string giving the names of the data.

References

See Also

- `var.test` for the special case of comparing variances in two samples from normal distributions;
- `fligner.test` for a rank-based (nonparametric) k-sample test for homogeneity of variances;
- `ansari.test` and `mood.test` for two rank based two-sample tests for difference in scale.

Examples

```r
require(graphics)
plot(count ~ spray, data = InsectSprays)
bartlett.test(InsectSprays$count, InsectSprays$spray)
bartlett.test(count ~ spray, data = InsectSprays)
```
The Beta Distribution

Description

Density, distribution function, quantile function and random generation for the Beta distribution with parameters shape1 and shape2 (and optional non-centrality parameter ncp).

Usage

dbeta(x, shape1, shape2, ncp = 0, log = FALSE)
pbeta(q, shape1, shape2, ncp = 0, lower.tail = TRUE, log.p = FALSE)
qbeta(p, shape1, shape2, ncp = 0, lower.tail = TRUE, log.p = FALSE)
rbeta(n, shape1, shape2, ncp = 0)

Arguments

x, q
vector of quantiles.
p
vector of probabilities.
n
number of observations. If length(n) > 1, the length is taken to be the number required.
shape1, shape2
positive parameters of the Beta distribution.
cp
non-centrality parameter.
log, log.p
logical; if TRUE, probabilities p are given as log(p).
lower.tail
logical; if TRUE (default), probabilities are P[X ≤ x], otherwise, P[X > x].

Details

The Beta distribution with parameters shape1 = a and shape2 = b has density

\[ f(x) = \frac{\Gamma(a + b)}{\Gamma(a)\Gamma(b)} x^{a-1}(1 - x)^{b-1} \]

for \( a > 0, b > 0 \) and \( 0 ≤ x ≤ 1 \) where the boundary values at \( x = 0 \) or \( x = 1 \) are defined as by continuity (as limits).

The mean is \( a/(a + b) \) and the variance is \( ab/((a + b)^2(a + b + 1)) \).

\( \text{pbeta} \) is closely related to the incomplete beta function. As defined by Abramowitz and Stegun 6.6.1

\[ B_x(a, b) = \int_0^x t^{a-1}(1 - t)^{b-1}dt, \]

and 6.6.2 \( I_x(a, b) = B_x(a, b)/B(a, b) \) where \( B(a, b) = B_1(a, b) \) is the Beta function (\text{beta}).

\( I_x(a, b) \) is \( \text{pbeta}(x, a, b) \).

The noncentral Beta distribution (with \( ncp = \lambda \)) is defined (Johnson et al, 1995, pp. 502) as the distribution of \( X/(X + Y) \) where \( X \sim \chi^2_{2a}(\lambda) \) and \( Y \sim \chi^2_{2b} \).
Value

dbeta gives the density, pbeta the distribution function, qbeta the quantile function, and rbeta generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by n for rbeta, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than n are recycled to the length of the result. Only the first elements of the logical parameters are used.

Note

Supplying ncp = 0 uses the algorithm for the non-central distribution, which is not the same algorithm used if ncp is omitted. This is to give consistent behaviour in extreme cases with values of ncp very near zero.

Source

The central dbeta is based on a binomial probability, using code contributed by Catherine Loader (see dbinom) if either shape parameter is larger than one, otherwise directly from the definition. The non-central case is based on the derivation as a Poisson mixture of betas (Johnson et al, 1995, pp. 502–3).

The central pbeta uses a C translation (and enhancement for log_p = TRUE) of

The non-central pbeta uses a C translation of

Frick, H. (1990)’s AS R84, Appl. Statist, 39, 311–2, and

This computes the lower tail only, so the upper tail suffers from cancellation and a warning will be given when this is likely to be significant.

The central case of qbeta is based on a C translation of

The central case of rbeta is based on a C translation of

binom.test

See Also

*Distributions* for other standard distributions.

*beta* for the Beta function.

Examples

```r
x <- seq(0, 1, length = 21)
dbeta(x, 1, 1)
pbeta(x, 1, 1)
```

---

**binom.test**

*Exact Binomial Test*

Description

Performs an exact test of a simple null hypothesis about the probability of success in a Bernoulli experiment.

Usage

```r
binom.test(x, n, p = 0.5,
   alternative = c("two.sided", "less", "greater"),
   conf.level = 0.95)
```

Arguments

- **x**: number of successes, or a vector of length 2 giving the numbers of successes and failures, respectively.
- **n**: number of trials; ignored if `x` has length 2.
- **p**: hypothesized probability of success.
- **alternative**: indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter.
- **conf.level**: confidence level for the returned confidence interval.

Details

Confidence intervals are obtained by a procedure first given in Clopper and Pearson (1934). This guarantees that the confidence level is at least `conf.level`, but in general does not give the shortest-length confidence intervals.
Value

A list with class "htest" containing the following components:

- **statistic** the number of successes.
- **parameter** the number of trials.
- **p.value** the p-value of the test.
- **conf.int** a confidence interval for the probability of success.
- **estimate** the estimated probability of success.
- **null.value** the probability of success under the null, p.
- **alternative** a character string describing the alternative hypothesis.
- **method** the character string "Exact binomial test".
- **data.name** a character string giving the names of the data.

References

See Also

- `prop.test` for a general (approximate) test for equal or given proportions.

Examples

```r
## Under (the assumption of) simple Mendelian inheritance, a cross
## between plants of two particular genotypes produces progeny 1/4 of
## which are "dwarf" and 3/4 of which are "giant", respectively.
## In an experiment to determine if this assumption is reasonable, a
## cross results in progeny having 243 dwarf and 682 giant plants.
## If "giant" is taken as success, the null hypothesis is that p =
## binom.test(c(682, 243), p = 3/4)
## binom.test(682, 682 + 243, p = 3/4)  # The same.
## => Data are in agreement with the null hypothesis.
```
Description

Density, distribution function, quantile function and random generation for the binomial distribution with parameters size and prob.

Usage

dbinom(x, size, prob, log = FALSE)
pbinom(q, size, prob, lower.tail = TRUE, log.p = FALSE)
qbinom(p, size, prob, lower.tail = TRUE, log.p = FALSE)
rbinom(n, size, prob)

Arguments

x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
size number of trials (zero or more).
prob probability of success on each trial.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

The binomial distribution with size = n and prob = p has density

$$p(x) = \binom{n}{x} p^x (1 - p)^{n-x}$$

for $x = 0, \ldots, n$. Note that binomial coefficients can be computed by choose in R.

If an element of x is not integer, the result of dbinom is zero, with a warning. $p(x)$ is computed using Loader’s algorithm, see the reference below.

The quantile is defined as the smallest value $x$ such that $F(x) \geq p$, where $F$ is the distribution function.

Value

dbinom gives the density, pbinom gives the distribution function, qbinom gives the quantile function and rbinom generates random deviates.

If size is not an integer, NaN is returned.
The length of the result is determined by \( n \) for \( \text{rbinom} \), and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than \( n \) are recycled to the length of the result. Only the first elements of the logical parameters are used.

**Source**

For \( \text{dbinom} \) a saddle-point expansion is used: see Catherine Loader (2000). *Fast and Accurate Computation of Binomial Probabilities*; available from http://www.herine.net/stat/software/dbinom.html.

\( \text{pbinom} \) uses \( \text{pbeta} \).

\( \text{qbinom} \) uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.

For larger values it uses inversion.

**See Also**

\( \text{Distributions} \) for other standard distributions, including \( \text{dnbinom} \) for the negative binomial, and \( \text{dpois} \) for the Poisson distribution.

**Examples**

```r
require(graphics)
# Compute P(45 < X < 55) for X Binomial(100,0.5)
sum(dbinom(46:54, 1/10, 0.5))
## Using "log = TRUE" for an extended range :
# n <- 2000
# k <- seq(0, n, by = 20)
plot(k, dbinom(k, n, pi/10, log = TRUE), type = "l", ylab = "log density",
     main = "dbinom(*, log=TRUE) is better than  log(dbinom(*))")
lines(k, log(dbinom(k, n, pi/10)), col = "red", lwd = 2)
# extreme points are omitted since dbinom gives 0.
mtext("dbinom(k, log=TRUE)", adj = 0)
mtext("extended range", adj = 0, line = -1, font = 4)
mtext("log(dbinom(k))", col = "red", adj = 1)
```

---

**biplot**

*Biplot of Multivariate Data*

**Description**

Plot a biplot on the current graphics device.
Usage

biplot(x, ...)

## Default S3 method:
biplot(x, y, var.axes = TRUE, col, cex = rep(par("cex"), 2),
xlabs = NULL, ylabs = NULL, expand = 1,
xlim = NULL, ylim = NULL, arrow.len = 0.1,
main = NULL, sub = NULL, xlab = NULL, ylab = NULL, ...)

Arguments

x
The biplot, a fitted object. For biplot.default, the first set of points (a two-column matrix), usually associated with observations.
y
The second set of points (a two-column matrix), usually associated with variables.
var.axes
If TRUE the second set of points have arrows representing them as (unscaled) axes.
col
A vector of length 2 giving the colours for the first and second set of points respectively (and the corresponding axes). If a single colour is specified it will be used for both sets. If missing the default colour is looked for in the palette: if there it and the next colour as used, otherwise the first two colours of the palette are used.
cex
The character expansion factor used for labelling the points. The labels can be of different sizes for the two sets by supplying a vector of length two.
xlabs
A vector of character strings to label the first set of points: the default is to use the row dimname of x, or 1:n if the dimname is NULL.
ylabs
A vector of character strings to label the second set of points: the default is to use the row dimname of y, or 1:n if the dimname is NULL.
expand
An expansion factor to apply when plotting the second set of points relative to the first. This can be used to tweak the scaling of the two sets to a physically comparable scale.
arrow.len
The length of the arrow heads on the axes plotted in var.axes is true. The arrow head can be suppressed by arrow.len = 0.
xlim, ylim
Limits for the x and y axes in the units of the first set of variables.
main, sub, xlab, ylab, ...
graphical parameters.

Details

A biplot is plot which aims to represent both the observations and variables of a matrix of multivariate data on the same plot. There are many variations on biplots (see the references) and perhaps the most widely used one is implemented by biplot.princomp. The function biplot.default merely provides the underlying code to plot two sets of variables on the same figure.

Graphical parameters can also be given to biplot: the size of xlabs and ylabs is controlled by cex.
Side Effects

a plot is produced on the current graphics device.

References

See Also

`biplot.princomp`, also for examples.

---

**biplot.princomp** | **Biplot for Principal Components**

Description

Produces a biplot (in the strict sense) from the output of `princomp` or `prcomp`.

Usage

```r
## S3 method for class 'prcomp'
biplot(x, choices = 1:2, scale = 1, pc.biplot = FALSE, ...)

## S3 method for class 'princomp'
biplot(x, choices = 1:2, scale = 1, pc.biplot = FALSE, ...)
```

Arguments

- `x` an object of class "princomp".
- `choices` length 2 vector specifying the components to plot. Only the default is a biplot in the strict sense.
- `scale` The variables are scaled by `lambda ^ scale` and the observations are scaled by `lambda ^ (1-scale)` where `lambda` are the singular values as computed by `princomp`. Normally `0 <= scale <= 1`, and a warning will be issued if the specified scale is outside this range.
- `pc.biplot` If true, use what Gabriel (1971) refers to as a "principal component biplot", with `lambda = 1` and observations scaled up by `sqrt(n)` and variables scaled down by `sqrt(n)`. Then inner products between variables approximate covariances and distances between observations approximate Mahalanobis distance.
- `...` optional arguments to be passed to `biplot.default`. 
Details

This is a method for the generic function biplot. There is considerable confusion over the precise definitions: those of the original paper, Gabriel (1971), are followed here. Gabriel and Odoroff (1990) use the same definitions, but their plots actually correspond to pc.biplot = TRUE.

Side Effects

a plot is produced on the current graphics device.

`biplot`, `princomp`.

Examples

```r
require(graphics)
biplot(princomp(USArrests))
```

---

### birthday

**Probability of coincidences**

<table>
<thead>
<tr>
<th>birthday</th>
<th>Probability of coincidences</th>
</tr>
</thead>
</table>

#### Description

Computes answers to a generalised *birthday paradox* problem. pbirthday computes the probability of a coincidence and qbirthday computes the smallest number of observations needed to have at least a specified probability of coincidence.

#### Usage

```r
qbirthday(prob = 0.5, classes = 365, coincident = 2)
pbirthday(n, classes = 365, coincident = 2)
```

#### Arguments

- `classes`: How many distinct categories the people could fall into
- `prob`: The desired probability of coincidence
- `n`: The number of people
- `coincident`: The number of people to fall in the same category
Details

The birthday paradox is that a very small number of people, 23, suffices to have a 50-50 chance that two or more of them have the same birthday. This function generalises the calculation to probabilities other than 0.5, numbers of coincident events other than 2, and numbers of classes other than 365.

The formula used is approximate for coincident > 2. The approximation is very good for moderate values of prob but less good for very small probabilities.

Value

qbirthday Minimum number of people needed for a probability of at least prob that k or more of them have the same one out of classes equiprobable labels.
pbirthday Probability of the specified coincidence.

Note

Prior to R 2.14.0 the approximate formula was used even for coincident = 2.

References

Examples

```
require(graphics)

## the standard version
qbirthday() # 23
## probability of > 2 people with the same birthday
pbirthday(23, coincident = 3)

## examples from Diaconis & Mosteller p. 858.
## 'coincidence' is that husband, wife, daughter all born on the 16th
qbirthday(classes = 3/zero.noslash, coincident = 3) # approximately 18
qbirthday(coincident = 4) # exact value 187
qbirthday(coincident = 10) # exact value 1181

## same 4-digit PIN number
qbirthday(classes = 10^4)

## 0.9 probability of three or more coincident birthdays
qbirthday(coincident = 3, prob = 0.9)

## Chance of 4 or more coincident birthdays in 150 people
pbirthday(150, coincident = 4)

## 100 or more coincident birthdays in 1000 people: very rare
pbirthday(1000, coincident = 100)
```
Box.test

Box-Pierce and Ljung-Box Tests

Description

Compute the Box–Pierce or Ljung–Box test statistic for examining the null hypothesis of independence in a given time series. These are sometimes known as ‘portmanteau’ tests.

Usage

Box.test(x, lag = 1, type = c("Box-Pierce", "Ljung-Box"), fitdf = 0)

Arguments

  x a numeric vector or univariate time series.
  lag the statistic will be based on lag autocorrelation coefficients.
  type test to be performed: partial matching is used.
  fitdf number of degrees of freedom to be subtracted if x is a series of residuals.

Details

These tests are sometimes applied to the residuals from an ARMA(p, q) fit, in which case the references suggest a better approximation to the null-hypothesis distribution is obtained by setting fitdf = p+q, provided of course that lag > fitdf.

Value

A list with class "htest" containing the following components:

  statistic the value of the test statistic.
  parameter the degrees of freedom of the approximate chi-squared distribution of the test statistic (taking fitdf into account).
  p.value the p-value of the test.
  method a character string indicating which type of test was performed.
  data.name a character string giving the name of the data.

Note

Missing values are not handled.

Author(s)

A. Trapletti
References

Examples

```r
x <- rnorm(100)
Box.test(x, lag = 1)
Box.test(x, lag = 1, type = "Ljung")
```

---

C

Sets Contrasts for a Factor

Description

Sets the "contrasts" attribute for the factor.

Usage

```r
C(object, contr, how.many, ...)
```

Arguments

- `object`: a factor or ordered factor
- `contr`: which contrasts to use. Can be a matrix with one row for each level of the factor or a suitable function like `contr.poly` or a character string giving the name of the function
- `how.many`: the number of contrasts to set, by default one less than `nlevels(object)`.
- `...`: additional arguments for the function `contr`.

Details

For compatibility with S, `contr` can be `treatment`, `helmert`, `sum` or `poly` (without quotes) as shorthand for `contr.treatment` and so on.

Value

The factor object with the "contrasts" attribute set.

References

cancor

See Also
contrasts, contr.sum, etc.

Examples

## reset contrasts to defaults
options(contrasts = c("contr.treatment", "contr.poly"))
tens <- with(warpbreaks, C(tension, poly, 1))
attributes(tens)
## tension SHOULD be an ordered factor, but as it is not we can use
aov(breaks ~ wool + tens + tension, data = warpbreaks)

## show the use of ... The default contrast is contr.treatment here
summary(lm(breaks ~ wool + C(tension, base = 2), data = warpbreaks))

# following on from help(esoph)
model3 <- glm(cbind(ncases, ncontrols) ~ agegp + C(tobgp, , 1) +
               C(alcgp, , 1), data = esoph, family = binomial())
summary(model3)

cancor

Canonical Correlations

Description
Compute the canonical correlations between two data matrices.

Usage
cancor(x, y, xcenter = TRUE, ycenter = TRUE)

Arguments

- **x**: numeric matrix \(n \times p_1\), containing the x coordinates.
- **y**: numeric matrix \(n \times p_2\), containing the y coordinates.
- **xcenter**: logical or numeric vector of length \(p_1\), describing any centering to be done on the x values before the analysis. If TRUE (default), subtract the column means. If FALSE, do not adjust the columns. Otherwise, a vector of values to be subtracted from the columns.
- **ycenter**: analogous to xcenter, but for the y values.

Details
The canonical correlation analysis seeks linear combinations of the y variables which are well explained by linear combinations of the x variables. The relationship is symmetric as ‘well explained’ is measured by correlations.
Value

A list containing the following components:

- **cor**: correlations.
- **xcoef**: estimated coefficients for the \( x \) variables.
- **ycoef**: estimated coefficients for the \( y \) variables.
- **xcenter**: the values used to adjust the \( x \) variables.
- **ycenter**: the values used to adjust the \( x \) variables.

References

See Also

- `qr`, `svd`.

Examples

```r
## signs of results are random
pop <- LifeCycleSavings[, 2:3]
oec <- LifeCycleSavings[, -(2:3)]
cancor(pop, oec)

x <- matrix(rnorm(150), 50, 3)
y <- matrix(rnorm(250), 50, 5)
(cxy <- cancor(x, y))
all(abs(cor(x %*% cxy$xcoef, y %*% cxy$ycoef)[,1:3] - diag(cxy$cor)) < 1e-15)
all(abs(cor(x %*% cxy$xcoef) - diag(3)) < 1e-15)
all(abs(cor(y %*% cxy$ycoef) - diag(5)) < 1e-15)
```

Description

Simple utilities returning (non-missing) case names, and (non-eliminated) variable names.
Cauchy

Usage

```r
case.names(object, ...)
## S3 method for class 'lm'
case.names(object, full = FALSE, ...)
```

```r
variable.names(object, ...)
## S3 method for class 'lm'
variable.names(object, full = FALSE, ...)
```

Arguments

- `object` an R object, typically a fitted model.
- `full` logical; if TRUE, all names (including zero weights, ...) are returned.
- `...` further arguments passed to or from other methods.

Value

A character vector.

See Also

- `lm`: further, `all.names`, `all.vars` for functions with a similar name but only slightly related purpose.

Examples

```r
x <- 1:20
y <- setNames(x + (x/4 - 2)^3 + rnorm(20, sd = 3),
paste("O", x, sep = "."))
ww <- rep(1, 20); ww[13] <- 0
summary(lmxy <- lm(y ~ x + I(x^2)+I(x^3) + I((x-1)^2), weights = ww),
cor = TRUE)
variable.names(lmxy)
variable.names(lmxy, full = TRUE) # includes the last
case.names(lmxy)
```

The Cauchy Distribution

Description

Density, distribution function, quantile function and random generation for the Cauchy distribution with location parameter `location` and scale parameter `scale`.
Cauchy

Usage

dcauchy(x, location = 0, scale = 1, log = FALSE)
pcauchy(q, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
qcauchy(p, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
rcauchy(n, location = 0, scale = 1)

Arguments

x, q
vector of quantiles.
p
vector of probabilities.
n
number of observations. If length(n) > 1, the length is taken to be the number required.
location, scale
location and scale parameters.
log, log.p
logical; if TRUE, probabilities p are given as log(p).
lower.tail
logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

If location or scale are not specified, they assume the default values of 0 and 1 respectively.
The Cauchy distribution with location \( l \) and scale \( s \) has density

\[
f(x) = \frac{1}{\pi s} \left( 1 + \left( \frac{x - l}{s} \right)^2 \right)^{-1}
\]

for all \( x \).

Value

dcauchy, pcauchy, and qcauchy are respectively the density, distribution function and quantile function of the Cauchy distribution. rcauchy generates random deviates from the Cauchy.
The length of the result is determined by \( n \) for rcauchy, and is the maximum of the lengths of the numerical parameters for the other functions.
The numerical parameters other than \( n \) are recycled to the length of the result. Only the first elements of the logical parameters are used.

Source

dcauchy, pcauchy and qcauchy are all calculated from numerically stable versions of the definitions.
rcauchy uses inversion.

References

**See Also**

Distributions for other standard distributions, including `dt` for the t distribution which generalizes `dcauchy(*, l = /zero.noslash, s = 1)`.

**Examples**

dcauchy(-1:4)

---

**chisq.test**  

*Pearson’s Chi-squared Test for Count Data*

**Description**

chisq.test performs chi-squared contingency table tests and goodness-of-fit tests.

**Usage**

```r
chisq.test(x, y = NULL, correct = TRUE,  
            p = rep(1/length(x), length(x)), rescale.p = FALSE,  
            simulate.p.value = FALSE, B = 2/zero.noslash/zero.noslash/zero.noslash)
```

**Arguments**

- **x**: a numeric vector or matrix. x and y can also both be factors.
- **y**: a numeric vector; ignored if x is a matrix. If x is a factor, y should be a factor of the same length.
- **correct**: a logical indicating whether to apply continuity correction when computing the test statistic for 2 by 2 tables: one half is subtracted from all \(|O−E|\) differences; however, the correction will not be bigger than the differences themselves. No correction is done if `simulate.p.value = TRUE`.
- **p**: a vector of probabilities of the same length of x. An error is given if any entry of p is negative.
- **rescale.p**: a logical scalar; if TRUE then p is rescaled (if necessary) to sum to 1. If `rescale.p` is FALSE, and p does not sum to 1, an error is given.
- **simulate.p.value**: a logical indicating whether to compute p-values by Monte Carlo simulation.
- **B**: an integer specifying the number of replicates used in the Monte Carlo test.

**Details**

If x is a matrix with one row or column, or if x is a vector and y is not given, then a goodness-of-fit test is performed (x is treated as a one-dimensional contingency table). The entries of x must be non-negative integers. In this case, the hypothesis tested is whether the population probabilities equal those in p, or are all equal if p is not given.
If \( x \) is a matrix with at least two rows and columns, it is taken as a two-dimensional contingency table: the entries of \( x \) must be non-negative integers. Otherwise, \( x \) and \( y \) must be vectors or factors of the same length; cases with missing values are removed, the objects are coerced to factors, and the contingency table is computed from these. Then Pearson’s chi-squared test is performed of the null hypothesis that the joint distribution of the cell counts in a 2-dimensional contingency table is the product of the row and column marginals.

If \( \text{simulate.p.value} \) is \( \text{FALSE} \), the p-value is computed from the asymptotic chi-squared distribution of the test statistic; continuity correction is only used in the 2-by-2 case (if \( \text{correct} \) is \( \text{TRUE} \), the default). Otherwise the p-value is computed for a Monte Carlo test (Hope, 1968) with \( B \) replicates.

In the contingency table case simulation is done by random sampling from the set of all contingency tables with given marginals, and works only if the marginals are strictly positive. Continuity correction is never used, and the statistic is quoted without it. Note that this is not the usual sampling situation assumed for the chi-squared test but rather that for Fisher’s exact test.

In the goodness-of-fit case simulation is done by random sampling from the discrete distribution specified by \( p \), each sample being of size \( n = \text{sum}(x) \). This simulation is done in \( R \) and may be slow.

Value

A list with class "htest" containing the following components:

- \text{statistic} \quad \text{the value the chi-squared test statistic.}
- \text{parameter} \quad \text{the degrees of freedom of the approximate chi-squared distribution of the test statistic, \( NA \) if the p-value is computed by Monte Carlo simulation.}
- \text{p.value} \quad \text{the p-value for the test.}
- \text{method} \quad \text{a character string indicating the type of test performed, and whether Monte Carlo simulation or continuity correction was used.}
- \text{data.name} \quad \text{a character string giving the name(s) of the data.}
- \text{observed} \quad \text{the observed counts.}
- \text{expected} \quad \text{the expected counts under the null hypothesis.}
- \text{residuals} \quad \text{the Pearson residuals, \( (\text{observed} - \text{expected}) / \sqrt{\text{expected}} \).}
- \text{stdres} \quad \text{standardized residuals, \( (\text{observed} - \text{expected}) / \sqrt{\text{V}} \), where \( V \) is the residual cell variance (Agresti, 2007, section 2.4.5 for the case where \( x \) is a matrix, \( n \star p \star (1 - p) \) otherwise).}

Source

The code for Monte Carlo simulation is a C translation of the Fortran algorithm of Patefield (1981).

References

Chisquare

The (non-central) Chi-Squared Distribution

Description

Density, distribution function, quantile function and random generation for the chi-squared (\(\chi^2\)) distribution with \(df\) degrees of freedom and optional non-centrality parameter \(ncp\).
Usage

dchisq(x, df, ncp = 0, log = FALSE)
pchisq(q, df, ncp = 0, lower.tail = TRUE, log.p = FALSE)
qchisq(p, df, ncp = 0, lower.tail = TRUE, log.p = FALSE)
rchisq(n, df, ncp = 0)

Arguments

x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
df degrees of freedom (non-negative, but can be non-integer).
ncp non-centrality parameter (non-negative).
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

The chi-squared distribution with \( df = n \geq 0 \) degrees of freedom has density

\[
f_n(x) = \frac{1}{2^{n/2}\Gamma(n/2)} x^{n/2-1} e^{-x/2}
\]

for \( x > 0 \). The mean and variance are \( n \) and \( 2n \).

The non-central chi-squared distribution with \( df = n \) degrees of freedom and non-centrality parameter \( ncp = \lambda \) has density

\[
f(x) = e^{-\lambda/2} \sum_{r=0}^{\infty} \frac{\lambda^r}{r!} f_{n+2r}(x)
\]

for \( x \geq 0 \). For integer \( n \), this is the distribution of the sum of squares of \( n \) normals each with variance one, \( \lambda \) being the sum of squares of the normal means; further, \( E(X) = n + \lambda, \ Var(X) = 2(n + 2 \ast \lambda), \) and \( E((X - E(X))^3) = 8(n + 3 \ast \lambda) \).

Note that the degrees of freedom \( df = n \), can be non-integer, and also \( n = 0 \) which is relevant for non-centrality \( \lambda > 0 \), see Johnson et al. (1995, chapter 29).

Note that \( ncp \) values larger than about \( 1e5 \) may give inaccurate results with many warnings for \( pchisq \) and \( qchisq \).

Value

dchisq gives the density, pchisq gives the distribution function, qchisq gives the quantile function, and rchisq generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by \( n \) for rchisq, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than \( n \) are recycled to the length of the result. Only the first elements of the logical parameters are used.
Note
Supplying ncp = 0 uses the algorithm for the non-central distribution, which is not the same algorithm used if ncp is omitted. This is to give consistent behaviour in extreme cases with values of ncp very near zero.

The code for non-zero ncp is principally intended to be used for moderate values of ncp: it will not be highly accurate, especially in the tails, for large values.

Source
The central cases are computed via the gamma distribution.
The non-central dchisq and rchisq are computed as a Poisson mixture central of chi-squares (Johnson et al, 1995, p.436).
The non-central pchisq is for ncp < 80 computed from the Poisson mixture of central chi-squares and for larger ncp via a C translation of
which computes the lower tail only (so the upper tail suffers from cancellation and a warning will be given when this is likely to be significant).
The non-central qchisq is based on inversion of pchisq.

References

See Also
Distributions for other standard distributions.
A central chi-squared distribution with \( n \) degrees of freedom is the same as a Gamma distribution with shape \( \alpha = n/2 \) and scale \( \sigma = 2 \). Hence, see dgamma for the Gamma distribution.

Examples
```r
require(graphics)
dchisq(1, df = 1:3)
pchisq(1, df = 3)
pchisq(1, df = 3, ncp = 0:4) # includes the above
x <- 1:10
## Chi-squared(df = 2) is a special exponential distribution
all.equal(dchisq(x, df = 2), dexp(x, 1/2))
all.equal(pchisq(x, df = 2), pexp(x, 1/2))

## non-central RNG -- df = 0 with ncp > 0: Z0 has point mass at 0!
```
Z0 <- rchisq(100, df = 0, ncp = 2.)
graphics::stem(Z0)

## Not run: ## visual testing
## do P-P plots for 1000 points at various degrees of freedom
L <- 1.2; n <- 1000; pp <- ppoints(n)
op <- par(mfrow = c(3,3), mar = c(3,3,1,1)+.1, mgp = c(1.5,.6,0), oma = c(0,0,3,0))
for(df in 2^(4*rnorm(9))) {
  plot(pp, sort(pchisq(rr <- rchisq(n, df = df, ncp = L), df = df, ncp = L)), ylab = "pchisq(rchisq(.),.)", pch = ".")

stopifnot(all.equal(p00, exp(-lam/2)), all.equal(p.0, exp(-lam/2)))

---

**cmdscale**

*Classical (Metric) Multidimensional Scaling*

**Description**

Classical multidimensional scaling of a data matrix. Also known as *principal coordinates analysis* (Gower, 1966).

**Usage**

```r
cmdscale(d, k = 2, eig = FALSE, add = FALSE, x.ret = FALSE)
```

**Arguments**

- **d**: a distance structure such as that returned by `dist` or a full symmetric matrix containing the dissimilarities.
- **k**: the maximum dimension of the space which the data are to be represented in; must be in \(\{1, 2, \ldots, n-1\}\).
- **eig**: indicates whether eigenvalues should be returned.
- **add**: logical indicating if an additive constant \(c^*\) should be computed, and added to the non-diagonal dissimilarities such that the modified dissimilarities are Euclidean.
cmdscale

x.ret indicates whether the doubly centred symmetric distance matrix should be returned.

Details

Multidimensional scaling takes a set of dissimilarities and returns a set of points such that the distances between the points are approximately equal to the dissimilarities. (It is a major part of what ecologists call ‘ordination’.)

A set of Euclidean distances on \( n \) points can be represented exactly in at most \( n - 1 \) dimensions. cmdscale follows the analysis of Mardia (1978), and returns the best-fitting \( k \)-dimensional representation, where \( k \) may be less than the argument \( k \).

The representation is only determined up to location (cmdscale takes the column means of the configuration to be at the origin), rotations and reflections. The configuration returned is given in principal-component axes, so the reflection chosen may differ between R platforms (see prcomp).

When \( \text{add} = \text{TRUE} \), a minimal additive constant \( c^* \) is computed such that the dissimilarities \( d_{ij} + c^* \) are Euclidean and hence can be represented in \( n - 1 \) dimensions. Whereas S (Becker et al., 1988) computes this constant using an approximation suggested by Torgerson, R uses the analytical solution of Cailliez (1983), see also Cox and Cox (2001). Note that because of numerical errors the computed eigenvalues need not all be non-negative, and even theoretically the representation could be in fewer than \( n - 1 \) dimensions.

Value

If \( \text{eig} = \text{FALSE} \), \( \text{add} = \text{FALSE} \) and \( \text{x.ret} = \text{FALSE} \) (default), a matrix with \( k \) columns whose rows give the coordinates of the points chosen to represent the dissimilarities.

Otherwise, a list containing the following components.

points a matrix with up to \( k \) columns whose rows give the coordinates of the points chosen to represent the dissimilarities.

eig the \( n \) eigenvalues computed during the scaling process if \( \text{eig} \) is true. \textbf{NB}: versions of R before 2.12.1 returned only \( k \) but were documented to return \( n - 1 \).

x the doubly centered distance matrix if \( \text{x.ret} \) is true.

ac the additive constant \( c^* \), 0 if \( \text{add} = \text{FALSE} \).

GOF a numeric vector of length 2, equal to say \( (g_1, g_2) \), where \( g_i = (\sum_{j=1}^{k} \lambda_j)/ (\sum_{j=1}^{n} T_i(\lambda_j)) \), where \( \lambda_j \) are the eigenvalues (sorted in decreasing order), \( T_1(v) = |v| \), and \( T_2(v) = \max(v, 0) \).

dist.
isoMDS and sammon in package MASS provide alternative methods of multidimensional scaling.

Examples

require(graphics)

loc <- cmdscale(eurodist)
x <- loc[, 1]
y <- -loc[, 2] # reflect so North is at the top
## note asp = 1, to ensure Euclidean distances are represented correctly
plot(x, y, type = "n", xlab = "", ylab = "", asp = 1, axes = FALSE,
     main = "cmdscale(eurodist)"
)  
text(x, y, rownames(loc), cex = 0.6)

---

coefficients

Extract Model Coefficients

description

coeff is a generic function which extracts model coefficients from objects returned by modeling functions. coefficients is an alias for it.

Usage

coeff(object, ...)
coefficients(object, ...)

Arguments

object an object for which the extraction of model coefficients is meaningful.

... other arguments.
**complete.cases**

**Details**

All object classes which are returned by model fitting functions should provide a `coef` method or use the default one. (Note that the method is for `coef` and not `coefficients`.)

Class "aov" has a `coef` method that does not report aliased coefficients (see `alias`).

**Value**

Coefficients extracted from the model object object.

For standard model fitting classes this will be a named numeric vector.

**References**

**See Also**

`fitted.values` and `residuals` for related methods; `glm`, `lm` for model fitting.

**Examples**

```r
x <- 1:5; coef(lm(c(1:3, 7, 6) ~ x))
```

---

**complete.cases**

**Find Complete Cases**

**Description**

Return a logical vector indicating which cases are complete, i.e., have no missing values.

**Usage**

```r
complete.cases(...)  
```

**Arguments**

`...` a sequence of vectors, matrices and data frames.

**Value**

A logical vector specifying which observations/rows have no missing values across the entire sequence.

**See Also**

`is.na`, `na.omit`, `na.fail`.
Examples

```r
x <- airquality[, -1] # x is a regression design matrix
y <- airquality[, 1] # y is the corresponding response

stopifnot(complete.cases(y) != is.na(y))
ok <- complete.cases(x, y)
sum(!ok) # how many are not "ok" ?
x <- x[ok,]
y <- y[ok]
```

---

confint

**Confidence Intervals for Model Parameters**

Description

Computes confidence intervals for one or more parameters in a fitted model. There is a default and a method for objects inheriting from class "lm".

Usage

```r
confint(object, parm, level = 0.95, ...)
```

Arguments

- `object`: a fitted model object.
- `parm`: a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered.
- `level`: the confidence level required.
- `...`: additional argument(s) for methods.

Details

confint is a generic function. The default method assumes asymptotic normality, and needs suitable `coef` and `vcov` methods to be available. The default method can be called directly for comparison with other methods.

For objects of class "lm" the direct formulae based on t values are used.

There are stub methods for classes "glm" and "nls" which invoke those in package MASS which are based on profile likelihoods.

Value

A matrix (or vector) with columns giving lower and upper confidence limits for each parameter. These will be labelled as (1-level)/2 and 1 - (1-level)/2 in % (by default 2.5% and 97.5%).
constrOptim

See Also

confint.glm and confint.nls in package MASS.

Examples

```r
fit <- lm(100/mpg ~ disp + hp + wt + am, data = mtcars)
confint(fit)
confint(fit, "wt")
```

```r
## from example(glm) (needs MASS to be present on the system)
counts <- c(18,17,15,20,10,25,13,12)
outcome <- gl(3, 1, 9); treatment <- gl(3, 3)
glm.D93 <- glm(counts ~ outcome + treatment, family = poisson())
confint(glm.D93)
confint.default(glm.D93) # based on asymptotic normality
```

---

**constrOptim**  
*Linearly Constrained Optimization*

**Description**

Minimise a function subject to linear inequality constraints using an adaptive barrier algorithm.

**Usage**

```r
constrOptim(theta, f, grad, ui, ci, mu = 1e-4, control = list(),
  method = if(is.null(grad)) "Nelder-Mead" else "BFGS",
  outer.iterations = 100, outer.eps = 1e-05, ..., 
  hessian = FALSE)
```

**Arguments**

- `theta`  
  numeric (vector) starting value (of length `p`): must be in the feasible region.
- `f`  
  function to minimise (see below).
- `grad`  
  gradient of `f` (a function as well), or NULL (see below).
- `ui`  
  constraint matrix (k x p), see below.
- `ci`  
  constraint vector of length k (see below).
- `mu`  
  (Small) tuning parameter.
- `control, method, hessian`  
  passed to `optim`.
- `outer.iterations`  
  iterations of the barrier algorithm.
- `outer.eps`  
  non-negative number; the relative convergence tolerance of the barrier algorithm.
- `...`  
  Other named arguments to be passed to `f` and `grad`: needs to be passed through `optim` so should not match its argument names.
Details

The feasible region is defined by \( u_i \%*% \theta - c_i \geq 0 \). The starting value must be in the interior of the feasible region, but the minimum may be on the boundary.

A logarithmic barrier is added to enforce the constraints and then \texttt{optim} is called. The barrier function is chosen so that the objective function should decrease at each outer iteration. Minima in the interior of the feasible region are typically found quite quickly, but a substantial number of outer iterations may be needed for a minimum on the boundary.

The tuning parameter \( \mu \) multiplies the barrier term. Its precise value is often relatively unimportant. As \( \mu \) increases the augmented objective function becomes closer to the original objective function but also less smooth near the boundary of the feasible region.

Any \texttt{optim} method that permits infinite values for the objective function may be used (currently all but "L-BFGS-B").

The objective function \( f \) takes as first argument the vector of parameters over which minimisation is to take place. It should return a scalar result. Optional arguments \ldots\ will be passed to \texttt{optim} and then (if not used by \texttt{optim}) to \( f \). As with \texttt{optim}, the default is to minimise, but maximisation can be performed by setting \texttt{control$fnscale} to a negative value.

The gradient function \( \text{grad} \) must be supplied except with \texttt{method = "Nelder-Mead"}. It should take arguments matching those of \( f \) and return a vector containing the gradient.

Value

As for \texttt{optim}, but with two extra components: \texttt{barrier.value} giving the value of the barrier function at the optimum and \texttt{outer.iterations} gives the number of outer iterations (calls to \texttt{optim}). The \texttt{counts} component contains the sum of all \texttt{optim()}$counts.

\texttt{optim}, especially \texttt{method = "L-BFGS-B"} which does box-constrained optimisation.

Examples

```r
## from optim
fr <- function(x) {  ## Rosenbrock Banana function
  x1 <- x[1]
  x2 <- x[2]
  100 * (x2 - x1 * x1)^2 + (1 - x1)^2
}
grr <- function(x) {  ## Gradient of 'fr'
  x1 <- x[1]
  x2 <- x[2]
  c(-400 * x1 * (x2 - x1 * x1) - 2 * (1 - x1),
    200 * (x2 - x1 * x1))
}
```
optim(c(-1.2, 1), fr, grr)
# Box-constraint, optimum on the boundary
constrOptim(c(-1.2, 0.9), fr, grr, ui = rbind(c(-1, 0), c(0, -1)), ci = c(-1, -1))
# x <= 0.9, y - x > 0.1
constrOptim(c(0.5, 0), fr, grr, ui = rbind(c(-1, 0), c(1, -1)), ci = c(-0.9, 0.1))

## Solves linear and quadratic programming problems
## but needs a feasible starting value
#
# from example(solve.QP) in 'quadprog'
# no derivative
fQP <- function(b) {-sum(c(0, 5, 0)*b) + 0.5*sum(b*b)}
Amat <- matrix(c(-4, -3, 0, 2, 1, 0, 0, -2, 1), 3, 3)
bvec <- c(-8, 2, 0)
constrOptim(c(2, -1, -1), fQP, NULL, ui = t(Amat), ci = bvec)
# derivative
gQP <- function(b) {-c(0, 5, 0) + b}
constrOptim(c(2, -1, -1), fQP, gQP, ui = t(Amat), ci = bvec)

## Now with maximisation instead of minimisation
hQP <- function(b) {sum(c(0, 5, 0)*b) - 0.5*sum(b*b)}
constrOptim(c(2, -1, -1), hQP, NULL, ui = t(Amat), ci = bvec, control = list(fnscale = -1))

contrast (Possibly Sparse) Contrast Matrices

Description

Return a matrix of contrasts.

Usage

contr.helmert(n, contrasts = TRUE, sparse = FALSE)
contr.poly(n, scores = 1:n, contrasts = TRUE, sparse = FALSE)
contr.sum(n, contrasts = TRUE, sparse = FALSE)
contr.treatment(n, base = 1, contrasts = TRUE, sparse = FALSE)
contr.SAS(n, contrasts = TRUE, sparse = FALSE)

Arguments

n a vector of levels for a factor, or the number of levels.
contrasts a logical indicating whether contrasts should be computed.
sparse logical indicating if the result should be sparse (of class dgCMatrix), using package Matrix.
scores the set of values over which orthogonal polynomials are to be computed.
base an integer specifying which group is considered the baseline group. Ignored if contrasts is FALSE.
Details

These functions are used for creating contrast matrices for use in fitting analysis of variance and regression models. The columns of the resulting matrices contain contrasts which can be used for coding a factor with \( n \) levels. The returned value contains the computed contrasts. If the argument `contrasts` is `FALSE` a square indicator matrix (the dummy coding) is returned except for `contr.poly` (which includes the 0-degree, i.e. constant, polynomial when `contrasts = FALSE`).

`contr.helmert` returns Helmert contrasts, which contrast the second level with the first, the third with the average of the first two, and so on. `contr.poly` returns contrasts based on orthogonal polynomials. `contr.sum` uses ‘sum to zero contrasts’.

`contr.treatment` contrasts each level with the baseline level (specified by `base`): the baseline level is omitted. Note that this does not produce ‘contrasts’ as defined in the standard theory for linear models as they are not orthogonal to the intercept.

`contr.SAS` is a wrapper for `contr.treatment` that sets the base level to be the last level of the factor. The coefficients produced when using these contrasts should be equivalent to those produced by many (but not all) SAS procedures.

For consistency, `sparse` is an argument to all these contrast functions, however `sparse = TRUE` for `contr.poly` is typically pointless and is rarely useful for `contr.helmert`.

Value

A matrix with \( n \) rows and \( k \) columns, with \( k = n-1 \) if `contrasts` is `TRUE` and \( k = n \) if `contrasts` is `FALSE`.

References

See Also

`contrasts`, `C`, and `aov`, `glm`, `lm`.

Examples

```r
(cH <- contr.helmert(4))
apply(cH, 2, sum) # column sums are 0
crossprod(cH) # diagonal -- columns are orthogonal
contr.helmert(4, contrasts = FALSE) # just the 4 x 4 identity matrix

(cT <- contr.treatment(5))
all(crossprod(cT) == diag(4)) # TRUE: even orthonormal

(cT. <- contr.SAS(5))
all(crossprod(cT.) == diag(4)) # TRUE

zapsmall(cP <- contr.poly(3)) # Linear and Quadratic
zapsmall(crossprod(cP), digits = 15) # orthonormal up to fuzz
```
contrasts

Get and Set Contrast Matrices

Description
Set and view the contrasts associated with a factor.

Usage
contrasts(x, contrasts = TRUE, sparse = FALSE)
contrasts(x, how.many) <- value

Arguments
x
a factor or a logical variable.
contrasts
logical. See ‘Details’.
sparse
logical indicating if the result should be sparse (of class dgCMatrix), using package Matrix.
how.many
How many contrasts should be made. Defaults to one less than the number of levels of x. This need not be the same as the number of columns of value.
value
either a numeric matrix (or a sparse or dense matrix of a class extending dMatrix from package Matrix) whose columns give coefficients for contrasts in the levels of x, or the (quoted) name of a function which computes such matrices.

Details
If contrasts are not set for a factor the default functions from options("contrasts") are used.
A logical vector x is converted into a two-level factor with levels c(FALSE, TRUE) (regardless of which levels occur in the variable).
The argument contrasts is ignored if x has a matrix contrasts attribute set. Otherwise if contrasts = TRUE it is passed to a contrasts function such as contr.treatment and if contrasts = FALSE an identity matrix is returned. Suitable functions have a first argument which is the character vector of levels, a named argument contrasts (always called with contrasts = TRUE) and optionally from R 2.10.0 a logical argument sparse.
If value supplies more than how.many contrasts, the first how.many are used. If too few are supplied, a suitable contrast matrix is created by extending value after ensuring its columns are contrasts (orthogonal to the constant term) and not collinear.

stopifnot(all.equal(ffs, fff))
contrasts(ffs) <- contr.sum(5, sparse = TRUE); contrasts(ffs)

convolve

Convolution of Sequences via FFT

Description

Use the Fast Fourier Transform to compute the several kinds of convolutions of two sequences.

Usage

convolve(x, y, conj = TRUE, type = c("circular", "open", "filter"))

Arguments

x, y numeric sequences of the same length to be convolved.
conj logical; if TRUE, take the complex conjugate before back-transforming (default, and used for usual convolution).
type character; one of "circular", "open", "filter" (beginning of word is ok). For circular, the two sequences are treated as circular, i.e., periodic. For open and filter, the sequences are padded with 0s (from left and right) first; "filter" returns the middle sub-vector of "open", namely, the result of running a weighted mean of x with weights y.

Details

The Fast Fourier Transform, fft, is used for efficiency.
The input sequences x and y must have the same length if circular is true.
Note that the usual definition of convolution of two sequences x and y is given by convolve(x, rev(y), type = "o").
Value

If \( r \leftarrow \text{convolve}(x, y, \text{type} = \text{"open"}) \) and \( n \leftarrow \text{length}(x), m \leftarrow \text{length}(y) \), then

\[
r_k = \sum_i x_{k-m+i} y_i
\]

where the sum is over all valid indices \( i \), for \( k = 1, \ldots, n + m - 1 \).

If \( \text{type} = \text{"circular"} \), \( n = m \) is required, and the above is true for \( i, k = 1, \ldots, n \) when \( x_j := x_{n+j} \) for \( j < 1 \).

References

See Also

\texttt{fft, nextn}, and particularly \texttt{filter} (from the \texttt{stats} package) which may be more appropriate.

Examples

\begin{verbatim}
require(graphics)

x <- c(0,0,0,0,0,0)
y <- c(0,0,1,2,1,0)/4
zapsmall(convolve(x, y))  # *NOT* what you first thought.
zapsmall(convolve(x, y[3:5], type = "f")) # rather
x <- rnorm(5)
y <- rnorm(5)
# Circular convolution *has* this symmetry:
all.equal(convolve(x, y, conj = FALSE), rev(convolve(rev(y), x)))

n <- length(x <- -2:24)
y <- (x-1)^2/1 + rnorm(x)/8
Han <- function(y) # Hanning
  convolve(y, c(1,2,1)/4, type = "filter")

plot(x, y, main = "Using convolve(.) for Hanning filters")
lines(x[-c(1 , n)], Han(y), col = "red")
lines(x[-c(1:2, (n-1):n)], Han(Han(y)), lwd = 2, col = "dark blue")
\end{verbatim}
Usage

cophenetic(x)
## Default S3 method:
cophenetic(x)
## S3 method for class 'dendrogram'
cophenetic(x)

Arguments

x an R object representing a hierarchical clustering. For the default method, an object of class "hclust" or with a method for as.hclust() such as "agnes" in package cluster.

Details

The cophenetic distance between two observations that have been clustered is defined to be the intergroup dissimilarity at which the two observations are first combined into a single cluster. Note that this distance has many ties and restrictions.

It can be argued that a dendrogram is an appropriate summary of some data if the correlation between the original distances and the cophenetic distances is high. Otherwise, it should simply be viewed as the description of the output of the clustering algorithm.

cophenetic is a generic function. Support for classes which represent hierarchical clusterings (total indexed hierarchies) can be added by providing an as.hclust() or, more directly, a cophenetic() method for such a class.

The method for objects of class "dendrogram" requires that all leaves of the dendrogram object have non-null labels.

Value

An object of class "dist".

**cor**

**Correlation, Variance and Covariance (Matrices)**

**Description**

var, cov and cor compute the variance of x and the covariance or correlation of x and y if these are vectors. If x and y are matrices then the covariances (or correlations) between the columns of x and the columns of y are computed.

cov2cor scales a covariance matrix into the corresponding correlation matrix efficiently.

**Usage**

var(x, y = NULL, na.rm = FALSE, use)

cov(x, y = NULL, use = "everything",
    method = c("pearson", "kendall", "spearman"))

cor(x, y = NULL, use = "everything",
    method = c("pearson", "kendall", "spearman"))

cov2cor(V)

**Arguments**

x a numeric vector, matrix or data frame.
y NULL (default) or a vector, matrix or data frame with compatible dimensions to x. The default is equivalent to y = x (but more efficient).
na.rm logical. Should missing values be removed?

use an optional character string giving a method for computing covariances in the presence of missing values. This must be (an abbreviation of) one of the strings "everything", "all.obs", "complete.obs", "na.or.complete", or "pairwise.complete.obs".

method a character string indicating which correlation coefficient (or covariance) is to be computed. One of "pearson" (default), "kendall", or "spearman", can be abbreviated.

V symmetric numeric matrix, usually positive definite such as a covariance matrix.

Details

For cov and cor one must either give a matrix or data frame for x or give both x and y.

The inputs must be numeric (as determined by is.numeric: logical values are also allowed for historical compatibility): the "kendall" and "spearman" methods make sense for ordered inputs but xtfrm can be used to find a suitable prior transformation to numbers.

var is just another interface to cov, where na.rm is used to determine the default for use when that is unspecified. If na.rm is TRUE then the complete observations (rows) are used (use = "na.or.complete") to compute the variance. Otherwise, by default use = "everything". If use is "everything", NAs will propagate conceptually, i.e., a resulting value will be NA whenever one of its contributing observations is NA.

If use is "all.obs", then the presence of missing observations will produce an error. If use is "complete.obs" then missing values are handled by casewise deletion (and if there are no complete cases, that gives an error).

"na.or.complete" is the same unless there are no complete cases, that gives NA. Finally, if use has the value "pairwise.complete.obs" then the correlation or covariance between each pair of variables is computed using all complete pairs of observations on those variables. This can result in covariance or correlation matrices which are not positive semi-definite, as well as NA entries if there are no complete pairs for that pair of variables. For cov and var, "pairwise.complete.obs" only works with the "pearson" method. Note that (the equivalent of) var(double(0), use = *) gives NA for use = "everything" and "na.or.complete", and gives an error in the other cases.

The denominator \( n - 1 \) is used which gives an unbiased estimator of the (co)variance for i.i.d. observations. These functions return NA when there is only one observation (whereas S-PLUS has been returning NaN), and fail if x has length zero.

For cor(), if method is "kendall" or "spearman", Kendall’s \( \tau \) or Spearman’s \( \rho \) statistic is used to estimate a rank-based measure of association. These are more robust and have been recommended if the data do not necessarily come from a bivariate normal distribution.

For cov(), a non-Pearson method is unusual but available for the sake of completeness. Note that "spearman" basically computes \( \text{cor}(R(x), R(y)) \) (or \( \text{cov}(., .) \)) where \( R(u) := \text{rank}(u, \text{na.last} = "\text{keep}"). \) In the case of missing values, the ranks are calculated depending on the value of use, either based on complete observations, or based on pairwise completeness with reranking for each pair.

Scaling a covariance matrix into a correlation one can be achieved in many ways, mathematically most appealing by multiplication with a diagonal matrix from left and right, or more efficiently by using \texttt{sweep(., FUN = "/") twice. The \texttt{cov2cor} function is even a bit more efficient, and provided mostly for didactical reasons.
cor

Value

For \( r \leftarrow \text{cor}(\ast, \text{use} = \"all.obs\") \), it is now guaranteed that \( \text{all}(r \leq 1) \).

Note

Some people have noted that the code for Kendall’s tau is slow for very large datasets (many more than 1000 cases). It rarely makes sense to do such a computation, but see function cor.fk in package pcaPP.

range(eigen(C2, only.values = TRUE)$values) # 6.46 1930
C3 <- cov(swM, use = "pairwise")
range(eigen(C3, only.values = TRUE)$values) # 6.19 1938

## Kendall's tau doesn't change much:
symnum(Rc <- cor(swM, method = "kendall", use = "complete"))
symnum(Rp <- cor(swM, method = "kendall", use = "pairwise"))
symnum(R. <- cor(swiss, method = "kendall"))

## "pairwise" is closer componentwise,
summary(abs(c(1 - Rp/R.)))
summary(abs(c(1 - Rc/R.)))

## but "complete" is closer in Eigen space:
EV <- function(m) eigen(m, only.values=TRUE)$values
summary(abs(1 - EV(Rp)/EV(R.)) / abs(1 - EV(Rc)/EV(R.)))

---

### cor.test

Test for Association/Correlation Between Paired Samples

**Description**

Test for association between paired samples, using one of Pearson’s product moment correlation coefficient, Kendall’s τ or Spearman’s ρ.

**Usage**

```r
 cor.test(x, ...)  
```

## Default S3 method:
```r
cor.test(x, y,  
 alternative = c("two.sided", "less", "greater"),  
 method = c("pearson", "kendall", "spearman"),  
 exact = NULL, conf.level = 0.95, continuity = FALSE, ...)  
```

## S3 method for class 'formula'
```r
cor.test(formula, data, subset, na.action, ...)  
```
Arguments

\texttt{x, y} \hspace{1cm} \text{numeric vectors of data values. \texttt{x} and \texttt{y} must have the same length.}

\texttt{alternative} \hspace{1cm} \text{indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. "greater" corresponds to positive association, "less" to negative association.}

\texttt{method} \hspace{1cm} \text{a character string indicating which correlation coefficient is to be used for the test. One of "pearson", "kendall", or "spearman", can be abbreviated.}

\texttt{exact} \hspace{1cm} \text{a logical indicating whether an exact p-value should be computed. Used for Kendall’s \( \tau \) and Spearman’s \( \rho \). See ‘Details’ for the meaning of NULL (the default).}

\texttt{conf.level} \hspace{1cm} \text{confidence level for the returned confidence interval. Currently only used for the Pearson product moment correlation coefficient if there are at least 4 complete pairs of observations.}

\texttt{continuity} \hspace{1cm} \text{logical: if true, a continuity correction is used for Kendall’s \( \tau \) and Spearman’s \( \rho \) when not computed exactly.}

\texttt{formula} \hspace{1cm} \text{a formula of the form \(~ \sim \) u + v, where each of \texttt{u} and \texttt{v} are numeric variables giving the data values for one sample. The samples must be of the same length.}

\texttt{data} \hspace{1cm} \text{an optional matrix or data frame (or similar: see \texttt{model.frame}) containing the variables in the formula \texttt{formula}. By default the variables are taken from \texttt{environment(formula)}.}

\texttt{subset} \hspace{1cm} \text{an optional vector specifying a subset of observations to be used.}

\texttt{na.action} \hspace{1cm} \text{a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").}

\texttt{...} \hspace{1cm} \text{further arguments to be passed to or from methods.}

Details

The three methods each estimate the association between paired samples and compute a test of the value being zero. They use different measures of association, all in the range \([-1, 1]\) with 0 indicating no association. These are sometimes referred to as tests of no \textit{correlation}, but that term is often confused to the default method.

If \texttt{method} is "pearson", the test statistic is based on Pearson’s product moment correlation coefficient \( \texttt{cor(x, y)} \) and follows a \( \texttt{t} \) distribution with \( \texttt{length(x)}-2 \) degrees of freedom if the samples follow independent normal distributions. If there are at least 4 complete pairs of observation, an asymptotic confidence interval is given based on Fisher’s \( \texttt{Z} \) transform.

If \texttt{method} is "kendall" or "spearman", Kendall’s \( \tau \) or Spearman’s \( \rho \) statistic is used to estimate a rank-based measure of association. These tests may be used if the data do not necessarily come from a bivariate normal distribution.

For Kendall’s test, by default (if \texttt{exact} is NULL), an exact p-value is computed if there are less than 50 paired samples containing finite values and there are no ties. Otherwise, the test statistic is the estimate scaled to zero mean and unit variance, and is approximately normally distributed.

For Spearman’s test, p-values are computed using algorithm AS 89 for \( n < 1290 \) and \texttt{exact = TRUE}, otherwise via the asymptotic \( \texttt{t} \) approximation. Note that these are ‘exact’ for \( n < 10 \), and use an Edgeworth series approximation for larger sample sizes (the cutoff has been changed from the original paper).
Value
A list with class "htest" containing the following components:

- statistic: the value of the test statistic.
- parameter: the degrees of freedom of the test statistic in the case that it follows a t distribution.
- p.value: the p-value of the test.
- estimate: the estimated measure of association, with name "cor", "tau", or "rho" corresponding to the method employed.
- null.value: the value of the association measure under the null hypothesis, always 0.
- alternative: a character string describing the alternative hypothesis.
- method: a character string indicating how the association was measured.
- data.name: a character string giving the names of the data.
- conf.int: a confidence interval for the measure of association. Currently only given for Pearson's product moment correlation coefficient in case of at least 4 complete pairs of observations.

pKendall and pSpearman in package SuppDists, spearman.test in package pspearman, which supply different (and often more accurate) approximations.

Examples
```r
## Assessment of tuna quality. We compare the Hunter L measure of
## lightness to the averages of consumer panel scores (recoded as
## integer values from 1 to 6 and averaged over 8 such values) in
## 9 lots of canned tuna.

x <- c(44.4, 45.9, 41.9, 53.3, 44.7, 44.1, 50.7, 45.2, 60.1)
y <- c( 2.6,  3.1,  2.5,  3.6,  4.0,  5.2,  2.8,  3.8)

cor.test(x, y, method = "kendall", alternative = "greater")
## => p=0.05972
```
cov.wt

Weighted Covariance Matrices

description

Returns a list containing estimates of the weighted covariance matrix and the mean of the data, and optionally of the (weighted) correlation matrix.

Usage

cov.wt(x, wt = rep(1/nrow(x), nrow(x)), cor = FALSE, center = TRUE,
method = c("unbiased", "ML"))

Arguments

x a matrix or data frame. As usual, rows are observations and columns are variables.
wt a non-negative and non-zero vector of weights for each observation. Its length must equal the number of rows of x.
cor a logical indicating whether the estimated correlation weighted matrix will be returned as well.
center either a logical or a numeric vector specifying the centers to be used when computing covariances. If TRUE, the (weighted) mean of each variable is used, if FALSE, zero is used. If center is numeric, its length must equal the number of columns of x.
method string specifying how the result is scaled, see ‘Details’ below.

details

By default, method = "unbiased". The covariance matrix is divided by one minus the sum of squares of the weights, so if the weights are the default (1/n) the conventional unbiased estimate of the covariance matrix with divisor (n − 1) is obtained. This differs from the behaviour in S-PLUS which corresponds to method = "ML" and does not divide.
Value

A list containing the following named components:

- **cov**: the estimated (weighted) covariance matrix
- **center**: an estimate for the center (mean) of the data.
- **n.obs**: the number of observations (rows) in \( x \).
- **wt**: the weights used in the estimation. Only returned if given as an argument.
- **cor**: the estimated correlation matrix. Only returned if cor is TRUE.

See Also

cov and var.

Examples

```r
(xy <- cbind(x = 1:10, y = c(1:3, 8:5, 8:1)))
w1 <- c(0,0,0,1,1,1,1,1,0,0)
cov.wt(xy, wt = w1) # i.e. method = "unbiased"
cov.wt(xy, wt = w1, method = "ML", cor = TRUE)
```

---

**cpgram**

Plot Cumulative Periodogram

Description

Plots a cumulative periodogram.

Usage

```r
cpgram(ts, taper = 0.1,
      main = paste("Series: ", deparse(substitute(ts))),
      ci.col = "blue")
```

Arguments

- **ts**: a univariate time series
- **taper**: proportion tapered in forming the periodogram
- **main**: main title
- **ci.col**: colour for confidence band.

Value

None.

Side Effects

Plots the cumulative periodogram in a square plot.
Note

From package MASS.

Author(s)

B.D. Ripley

Examples

```r
require(graphics)

par(pty = "s", mfrow = c(1,2))
cpgram(lh)
lh.ar <- ar(lh, order.max = 9)
cpgram(lh.ar$resid, main = "AR(3) fit to lh")
cpgram(ldeaths)
```

---

**cutree**

*Cut a Tree into Groups of Data*

**Description**

Cuts a tree, e.g., as resulting from `hclust`, into several groups either by specifying the desired number(s) of groups or the cut height(s).

**Usage**

```r
cutree(tree, k = NULL, h = NULL)
```

**Arguments**

- `tree`: a tree as produced by `hclust`. `cutree()` only expects a list with components `merge`, `height`, and `labels`, of appropriate content each.
- `k`: an integer scalar or vector with the desired number of groups
- `h`: numeric scalar or vector with heights where the tree should be cut. At least one of `k` or `h` must be specified, `k` overrides `h` if both are given.

**Details**

Cutting trees at a given height is only possible for ultrametric trees (with monotone clustering heights).

**Value**

`cutree` returns a vector with group memberships if `k` or `h` are scalar, otherwise a matrix with group memberships is returned where each column corresponds to the elements of `k` or `h`, respectively (which are also used as column names).
decompose

References

See Also

`hclust`, `dendrogram` for cutting trees themselves.

Examples

```r
c <- hclust(dist(USArrests))
cutree(c, k = 1:5)  # k = 1 is trivial
cutree(c, h = 250)

## Compare the 2 and 4 grouping:
g24 <- cutree(c, k = c(2,4))
table(grp2 = g24[, "2"], grp4 = g24[, "4"])
```

---

decompose

Classical Seasonal Decomposition by Moving Averages

Description
Decompose a time series into seasonal, trend and irregular components using moving averages. Deals with additive or multiplicative seasonal component.

Usage

```r
decompose(x, type = c("additive", "multiplicative"), filter = NULL)
```

Arguments

- `x`: A time series.
- `type`: The type of seasonal component. Can be abbreviated.
- `filter`: A vector of filter coefficients in reverse time order (as for AR or MA coefficients), used for filtering out the seasonal component. If NULL, a moving average with symmetric window is performed.

Details
The additive model used is:

\[ Y_t = T_t + S_t + e_t \]

The multiplicative model used is:

\[ Y_t = T_t S_t e_t \]
The function first determines the trend component using a moving average (if filter is NULL, a symmetric window with equal weights is used), and removes it from the time series. Then, the seasonal figure is computed by averaging, for each time unit, over all periods. The seasonal figure is then centered. Finally, the error component is determined by removing trend and seasonal figure (recycled as needed) from the original time series.

This only works well if x covers an integer number of complete periods.

Value

An object of class "decomposed.ts" with following components:

- x: The original series. (Only since R 2.14.0.)
- seasonal: The seasonal component (i.e., the repeated seasonal figure).
- figure: The estimated seasonal figure only.
- trend: The trend component.
- random: The remainder part.
- type: The value of type.

Note

The function stl provides a much more sophisticated decomposition.

stl

Examples

```r
require(graphics)

m <- decompose(co2)
m$figure
plot(m)

## example taken from Kendall/Stuart
x <- ts(x, start = c(1951, 1), end = c(1958, 4), frequency = 4)
m <- decompose(x)

## seasonal figure: 6.25, 8.62, -8.84, -6.3
round(decompose(x)$figure / 10, 2)
```
delete.response  Modify Terms Objects

Description

delete.response returns a terms object for the same model but with no response variable.
drop.terms removes variables from the right-hand side of the model. There is also a "[.terms" method to perform the same function (with keep.response = TRUE).
reformulate creates a formula from a character vector.

Usage

delete.response(termobj)

reformulate(termlabels, response = NULL, intercept = TRUE)

drop.terms(termobj, dropx = NULL, keep.response = FALSE)

Arguments

termobj  A terms object

termlabels character vector giving the right-hand side of a model formula. Cannot be zero-length.
response character string, symbol or call giving the left-hand side of a model formula, or NULL.
intercept logical: should the formula have an intercept? New in R 2.13.0.
dropx vector of positions of variables to drop from the right-hand side of the model.
keep.response Keep the response in the resulting object?

Value

delete.response and drop.terms return a terms object.
reformulate returns a formula.

See Also

terms

Examples

ff <- y ~ z + x + w
tt <- terms(ff)
tt
delete.response(tt)
drop.terms(tt, 2:3, keep.response = TRUE)
dendrapply

Apply a Function to All Nodes of a Dendrogram

Description

Apply function FUN to each node of a dendrogram recursively. When y <- dendrapply(x, fn), then y is a dendrogram of the same graph structure as x and for each node, y.node[j] <- FUN( x.node[j], ... ) (where y.node[j] is an (invalid!) notation for the j-th node of y.

Usage

dendrapply(X, FUN, ...)

Arguments

X an object of class "dendrogram".
FUN an R function to be applied to each dendrogram node, typically working on its attributes alone, returning an altered version of the same node.
...

Value

Usually a dendrogram of the same (graph) structure as X. For that, the function must be conceptually of the form FUN <- function(X) { attributes(X) <- .....; X }, i.e. returning the node with some attributes added or changed.

Note

this is still somewhat experimental, and suggestions for enhancements (or nice examples of usage) are very welcome.
Author(s)
Martin Maechler

dendrogram General Tree Structures

Description

Class "dendrogram" provides general functions for handling tree-like structures. It is intended as a replacement for similar functions in hierarchical clustering and classification/regression trees, such that all of these can use the same engine for plotting or cutting trees.
Usage

as.dendrogram(object, ...)  # S3 method for class 'hclust'
as.dendrogram(object, hang = -1, ...)

# S3 method for class 'dendrogram'
as.hclust(x, ...)

# S3 method for class 'dendrogram'
plot(x, type = c("rectangle", "triangle"),
     center = FALSE,
     edge.root = is.leaf(x) || !is.null(attr(x,"edgetext")),
     nodePar = NULL, edgePar = list(),
     leaflab = c("perpendicular", "textlike", "none"),
     dLeaf = NULL, xlab = "", ylab = "", xaxt = "n", yaxt = "s",
     horiz = FALSE, frame.plot = FALSE, xlim, ylim, ...)

# S3 method for class 'dendrogram'
cut(x, h, ...)

# S3 method for class 'dendrogram'
merge(x, y, ..., height)

# S3 method for class 'dendrogram'
print(x, digits, ...)

# S3 method for class 'dendrogram'
rev(x)

# S3 method for class 'dendrogram'
str(object, max.level = NA, digits.d = 3,
     give.attr = FALSE, wid = getOption("width"),
     nest.lev = 0, indent.str = "",
     last.str = getOption("str.dendrogram.last"), stem = "--",
     ...)

is.leaf(object)

Arguments

object any R object that can be made into one of class "dendrogram".

x, y object(s) of class "dendrogram".

hang numeric scalar indicating how the height of leaves should be computed from the heights of their parents; see plot.hclust.

type type of plot.

center logical; if TRUE, nodes are plotted centered with respect to the leaves in the branch. Otherwise (default), plot them in the middle of all direct child nodes.
edge.root logical; if true, draw an edge to the root node.

nodePar a list of plotting parameters to use for the nodes (see points) or NULL by default which does not draw symbols at the nodes. The list may contain components named pch, cex, col, xpd, and/or bg each of which can have length two for specifying separate attributes for inner nodes and leaves. Note that the default of pch is 1:2, so you may want to use pch = NA if you specify nodePar.

dLeaf a number specifying the distance in user coordinates between the tip of a leaf and its label. If NULL as per default, 3/4 of a letter width or height is used.

horiz logical indicating if the dendrogram should be drawn horizontally or not.

frame.plot logical indicating if a box around the plot should be drawn, see plot.default.

h height at which the tree is cut.

height height at which the two dendrogram should be merged. If not specified (or NULL), the default is ten percent larger than the (larger of the) two component heights.

xlim, ylim optional x- and y-limits of the plot, passed to plot.default. The defaults for these show the full dendrogram.

..., xlab, ylab, xaxt, yaxt graphical parameters, or arguments for other methods.

digits integer specifying the precision for printing, see print.default.

max.level, digits.d, give.attr, wid, nest.lev, indent.str arguments to str, see str.default(). Note that give.attr = FALSE still shows height and members attributes for each node.

last.str, stem strings used for str() specifying how the last branch (at each level) should start and the stem to use for each dendrogram branch. In some environments, using last.str = "", will provide much nicer looking output, than the historical default last.str = "·".

Details

The dendrogram is directly represented as a nested list where each component corresponds to a branch of the tree. Hence, the first branch of tree z is z[[1]], the second branch of the corresponding subtree is z[[1]][[2]], or shorter z[[c(1,2)]], etc.. Each node of the tree carries some information needed for efficient plotting or cutting as attributes, of which only members, height and leaf for leaves are compulsory:

members total number of leaves in the branch
height numeric non-negative height at which the node is plotted.

midpoint numeric horizontal distance of the node from the left border (the leftmost leaf) of the branch (unit 1 between all leaves). This is used for plot(*, center = FALSE).

label character; the label of the node

x.member for cut()$upper, the number of former members; more generally a substitute for the members component used for ‘horizontal’ (when horiz = FALSE, else ‘vertical’) alignment.

edgetext character; the label for the edge leading to the node

nodePar a named list (of length-1 components) specifying node-specific attributes for points plotting, see the nodePar argument above.

edgePar a named list (of length-1 components) specifying attributes for segments plotting of the edge leading to the node, and drawing of the edgetext if available, see the edgePar argument above.

leaf logical, if TRUE, the node is a leaf of the tree.

cut.dendrogram() returns a list with components $upper and $lower, the first is a truncated version of the original tree, also of class dendrogram, the latter a list with the branches obtained from cutting the tree, each a dendrogram.

There are [[, print, and str methods for "dendrogram" objects where the first one (extraction) ensures that selecting sub-branches keeps the class.

Objects of class "hclust" can be converted to class "dendrogram" using method as.dendrogram(), and since R 2.13.0, there is also a as.hclust() method as an inverse.

rev.dendrogram simply returns the dendrogram x with reversed nodes, see also reorder.dendrogram.

The merge(x, y, ...) method which merges two or more dendrograms into a new one which has x and y (and optional further arguments) as branches.

is.leaf(object) returns logical indicating if object is a leaf (the most simple dendrogram).

plotNode() and plotNodeLimit() are helper functions.

Warning

Some operations on dendrograms (including plotting) make use of recursion. For very deep trees it may be necessary to increase options("expressions"): if you do you are likely to need to set the C stack size larger than the default where possible.

Note

plot(): When using type = "triangle", center = TRUE often looks better.

str(d): If you really want to see the internal structure, use str(unclass(d)) instead.

See Also
dendrapply for applying a function to each node. order.dendrogram and reorder.dendrogram; further, the labels method.
Examples

require(graphics); require(utils)

hc <- hclust(dist(USArrests), "ave")
(dend1 <- as.dendrogram(hc)) # "print()" method
str(dend1) # "str()" method
str(dend1, max = 2, last.str = "\") # only the first two sub-levels
oo <- options(str.dendrogram.last = "\") # yet another possibility
str(dend1, max = 2) # only the first two sub-levels
options(oo) # .. resetting them

op <- par(mfrow = c(2,2), mar = c(5,2,1,4))
plot(dend1)
## "triangle" type and show inner nodes:
plot(dend1, nodePar = list(pch = c(1,NA), cex = 0.8, lab.cex = 0.8),
     type = "t", center = TRUE)
plot(dend1, edgePar = list(col = 1:2, lty = 2:3),
     dLeaf = 1, edge.root = TRUE)
plot(dend1, nodePar = list(pch = 2:1, cex = .4*2:1, col = 2:3),
     horiz = TRUE)

## simple test for as.hclust() as the inverse of as.dendrogram():
stopifnot(identical(as.hclust(dend1)[1:4], hc[1:4]))

dend2 <- cut(dend1, h = 70)
plot(dend2$upper)
## leaves are wrong horizontally:
plot(dend2$upper, nodePar = list(pch = c(1,7), col = 2:1))
## dend2$lower is *NOT* a dendrogram, but a list of .. :
plot(dend2$lower[[3]], nodePar = list(col = 4), horiz = TRUE, type = "tr")
## "inner" and "leaf" edges in different type & color :
plot(dend2$lower[[2]], nodePar = list(col = 1), # non empty list
     edgePar = list(lty = 1:2, col = 2:1), edge.root = TRUE)
par(op)
d3 <- dend2$lower[[2]][[2]][[1]]
stopifnot(identical(d3, dend2$lower[[2]][[c(2,1)]]))
str(d3, last.str = "")

## merge() to join dendrograms:
(d13 <- merge(dend2$lower[[1]], dend2$lower[[3]]))
## merge() all parts back (using default 'height' instead of original one):
den.1 <- Reduce(merge, dend2$lower)
## or merge() all four parts at same height --> 4 branches (!)
d. <- merge(dend2$lower[[1]], dend2$lower[[2]], dend2$lower[[3]],
            dend2$lower[[4]])
## (with a warning) or the same using do.call :
stopifnot(identical(d., do.call(merge, dend2$lower)))
plot(d., main = "merge(d1, d2, d3, d4) |-> dendrogram with a 4-split")

## "Zoom" in to the first dendrogram :
plot(dend1, xlim = c(1,20), ylim = c(1,50))
density

Kernel Density Estimation

density

Description

The (S3) generic function density computes kernel density estimates. Its default method does so with the given kernel and bandwidth for univariate observations.

Usage

density(x, ...)  
## Default S3 method:  
density(x, bw = "nrd0", adjust = 1,  
   kernel = c("gaussian", "epanechnikov", "rectangular",  
   "triangular", "biweight",  
   "cosine", "optcosine"),  
   weights = NULL, window = kernel, width,  
   give.Rkern = FALSE,  
   n = 512, from, to, cut = 3, na.rm = FALSE, ...)

Arguments

x  
the data from which the estimate is to be computed.

bw  
the smoothing bandwidth to be used. The kernels are scaled such that this is the standard deviation of the smoothing kernel. (Note this differs from the reference books cited below, and from S-PLUS.)
bw can also be a character string giving a rule to choose the bandwidth. See bw.nrd.
The default, "nrd0", has remained the default for historical and compatibility
density

The specified (or computed) value of bw is multiplied by adjust.

adjust  the bandwidth used is actually adjust*bw. This makes it easy to specify values like ‘half the default’ bandwidth.

kernel, window a character string giving the smoothing kernel to be used. This must be one of "gaussian", "rectangular", "triangular", "epanechnikov", "biweight", "cosine" or "optcosine", with default "gaussian", and may be abbreviated to a unique prefix (single letter).

"cosine" is smoother than "optcosine", which is the usual ‘cosine’ kernel in the literature and almost MSE-efficient. However, "cosine" is the version used by S.

weights numeric vector of non-negative observation weights, hence of same length as x. The default NULL is equivalent to weights = rep(1/nx, nx) where nx is the length of (the finite entries of) x[].

width this exists for compatibility with S; if given, and bw is not, will set bw to width if this is a character string, or to a kernel-dependent multiple of width if this is numeric.

give.Rkern logical; if true, no density is estimated, and the ‘canonical bandwidth’ of the chosen kernel is returned instead.

n the number of equally spaced points at which the density is to be estimated. When n > 512, it is rounded up to a power of 2 during the calculations (as fft is used) and the final result is interpolated by approx. So it almost always makes sense to specify n as a power of two.

from,to the left and right-most points of the grid at which the density is to be estimated; the defaults are cut * bw outside of range(x).

cut by default, the values of from and to are cut bandwidths beyond the extremes of the data. This allows the estimated density to drop to approximately zero at the extremes.

na.rm logical; if TRUE, missing values are removed from x. If FALSE any missing values cause an error.

... further arguments for (non-default) methods.

Details

The algorithm used in density.default disperses the mass of the empirical distribution function over a regular grid of at least 512 points and then uses the fast Fourier transform to convolve this approximation with a discretized version of the kernel and then uses linear approximation to evaluate the density at the specified points.

The statistical properties of a kernel are determined by $\sigma^2_K = \int t^2 K(t) dt$ which is always $= 1$ for our kernels (and hence the bandwidth bw is the standard deviation of the kernel) and $R(K) = \int K^2(t) dt$.

MSE-equivalent bandwidths (for different kernels) are proportional to $\sigma_K R(K)$ which is scale invariant and for our kernels equal to $R(K)$. This value is returned when give.Rkern = TRUE. See the examples for using exact equivalent bandwidths.
Infinite values in \( x \) are assumed to correspond to a point mass at +/-\( \text{Inf} \) and the density estimate is of the sub-density on \((-\text{Inf}, +\text{Inf})\).

**Value**

If `give.Rkern` is true, the number \( R(K) \), otherwise an object with class "density" whose underlying structure is a list containing the following components.

- **\( x \)**: the \( n \) coordinates of the points where the density is estimated.
- **\( y \)**: the estimated density values. These will be non-negative, but can be zero.
- **\( bw \)**: the bandwidth used.
- **\( n \)**: the sample size after elimination of missing values.
- **call**: the call which produced the result.
- **data.name**: the deparsed name of the \( x \) argument.
- **has.na**: logical, for compatibility (always FALSE).

The print method reports summary values on the \( x \) and \( y \) components.

  lines(density(precip, bw = bw, kernel = kernels[i]), col = i)
## Bandwidth Adjustment for "Exactly Equivalent Kernels"

```r
h.f <- sapply(kernels, function(k)density(kernel = k, give.Rkern = TRUE))
h.f <- (h.f["gaussian"] / h.f)^.2
## -> 1, 1.01, .995, 1.007,... close to 1 => adjustment barely visible..
```

```r
plot(density(precip, bw = bw),
     main = "equivalent bandwidths, 7 different kernels")
for(i in 2:length(kernels))
  lines(density(precip, bw = bw, adjust = h.f[i], kernel = kernels[i]),
        col = i)
legend(55, 35, legend = kernels, col = seq(kernels), lty = 1)
```

---

### deriv

**Symbolic and Algorithmic Derivatives of Simple Expressions**

**Description**

Compute derivatives of simple expressions, symbolically.

**Usage**

```r
D (expr, name)
deriv(expr, ...)
deriv3(expr, ...)
```

```r
## Default S3 method:
deriv(expr, namevec, function.arg = NULL, tag = ".expr",
    hessian = FALSE, ...)
## S3 method for class 'formula'
deriv(expr, namevec, function.arg = NULL, tag = ".expr",
    hessian = FALSE, ...)
```

```r
## Default S3 method:
deriv3(expr, namevec, function.arg = NULL, tag = ".expr",
    hessian = TRUE, ...)
## S3 method for class 'formula'
deriv3(expr, namevec, function.arg = NULL, tag = ".expr",
    hessian = TRUE, ...)
```

**Arguments**

- `expr` A expression or call or (except D) a formula with no lhs.
- `name, namevec` character vector, giving the variable names (only one for D()) with respect to which derivatives will be computed.
- `function.arg` If specified and non-NULL, a character vector of arguments for a function return, or a function (with empty body) or TRUE, the latter indicating that a function with argument names namevec should be used.
tag
character; the prefix to be used for the locally created variables in result.
hessian
a logical value indicating whether the second derivatives should be calculated
and incorporated in the return value.

Details
D is modelled after its S namesake for taking simple symbolic derivatives.

deriv is a generic function with a default and a formula method. It returns a call for computing
the expr and its (partial) derivatives, simultaneously. It uses so-called algorithmic derivatives. If
function.arg is a function, its arguments can have default values, see the fx example below.
Currently, deriv.formula just calls deriv.default after extracting the expression to the right of ~.
deriv3 and its methods are equivalent to deriv and its methods except that hessian defaults to
TRUE for deriv3.
The internal code knows about the arithmetic operators +, -, *, / and ^, and the single-variable
functions exp, log, sin, cos, tan, sinh, cosh, sqrt, pnorm, dnorm, asin, acos, atan, gamma,
lgamma, digamma and trigamma, as well as psigamma for one or two arguments (but derivative only
with respect to the first). (Note that only the standard normal distribution is considered.)

Value
D returns a call and therefore can easily be iterated for higher derivatives.
deriv and deriv3 normally return an expression object whose evaluation returns the function values
with a "gradient" attribute containing the gradient matrix. If hessian is TRUE the evaluation
also returns a "hessian" attribute containing the Hessian array.
If function.arg is not NULL, deriv and deriv3 return a function with those arguments rather than
an expression.

See Also
nlm and optim for numeric minimization which could make use of derivatives,

Examples
## formula argument :
dx2x <- deriv(~ x^2, "x") ; dx2x
## Not run: expression({
  .value <- x^2
  .grad <- array(0, c(length(.value), 1), list(NULL, c("x")))
})
## deviance

### Model Deviance

Returns the deviance of a fitted model object.
Usage

deviance(object, ...)

Arguments

object an object for which the deviance is desired.
... additional optional argument.

Details

This is a generic function which can be used to extract deviances for fitted models. Consult the individual modeling functions for details on how to use this function.

Value

The value of the deviance extracted from the object object.

References

See Also
df.residual, extractAIC, glm, lm.

---

df.residual Residual Degrees-of-Freedom

Description

Returns the residual degrees-of-freedom extracted from a fitted model object.

Usage

df.residual(object, ...)

Arguments

object an object for which the degrees-of-freedom are desired.
... additional optional arguments.

Details

This is a generic function which can be used to extract residual degrees-of-freedom for fitted models. Consult the individual modeling functions for details on how to use this function.

The default method just extracts the df.residual component.
Value
The value of the residual degrees-of-freedom extracted from the object x.

See Also
deviance, glm, lm.

diffinv
Discrete Integration: Inverse of Differencing

Description
Computes the inverse function of the lagged differences function diff.

Usage
diffinv(x, ...)

## Default S3 method:
diffinv(x, lag = 1, differences = 1, xi, ...)
## S3 method for class 'ts'
diffinv(x, lag = 1, differences = 1, xi, ...)

Arguments
x a numeric vector, matrix, or time series.
lag a scalar lag parameter.
differences an integer representing the order of the difference.
xi a numeric vector, matrix, or time series containing the initial values for the integrals. If missing, zeros are used.
... arguments passed to or from other methods.

Details
diffinv is a generic function with methods for class "ts" and default for vectors and matrices. Missing values are not handled.

Value
A numeric vector, matrix, or time series (the latter for the "ts" method) representing the discrete integral of x.

Author(s)
A. Trapletti
dist

Distance Matrix Computation

Description

This function computes and returns the distance matrix computed by using the specified distance measure to compute the distances between the rows of a data matrix.

Usage

dist(x, method = "euclidean", diag = FALSE, upper = FALSE, p = 2)
as.dist(m, diag = FALSE, upper = FALSE)
## Default S3 method:
as.dist(m, diag = FALSE, upper = FALSE)
## S3 method for class 'dist'
print(x, diag = NULL, upper = NULL,
digits =getOption("digits"), justify = "none",
right = TRUE, ...)
## S3 method for class 'dist'
as.matrix(x, ...)

Arguments

x a numeric matrix, data frame or "dist" object.
method the distance measure to be used. This must be one of "euclidean", "maximum", "manhattan", "canberra", "binary" or "minkowski". Any unambiguous substring can be given.
diag logical value indicating whether the diagonal of the distance matrix should be printed by print.dist.
upper logical value indicating whether the upper triangle of the distance matrix should be printed by print.dist.
p The power of the Minkowski distance.

See Also
diff

Examples

s <- 1:10
d <- diff(s)
diffinv(d, xi = 1)
An object with distance information to be converted to a "dist" object. For the
default method, a "dist" object, or a matrix (of distances) or an object which
can be coerced to such a matrix using `as.matrix()`. (Only the lower triangle of
the matrix is used, the rest is ignored).

digits, justify
passed to `format` inside of `print()`.

right, ...
further arguments, passed to other methods.

Details

Available distance measures are (written for two vectors \( x \) and \( y \)):

- **euclidean**: Usual square distance between the two vectors (2 norm).
- **maximum**: Maximum distance between two components of \( x \) and \( y \) (supremum norm)
- **manhattan**: Absolute distance between the two vectors (1 norm).
- **canberra**: \( \sum_i |x_i - y_i|/|x_i + y_i| \). Terms with zero numerator and denominator are omitted from
the sum and treated as if the values were missing.
This is intended for non-negative values (e.g. counts): taking the absolute value of the denom-
inator is a 1998 R modification to avoid negative distances.

- **binary**: (aka asymmetric binary): The vectors are regarded as binary bits, so non-zero elements
are ‘on’ and zero elements are ‘off’. The distance is the proportion of bits in which only one
is on amongst those in which at least one is on.

- **minkowski**: The \( p \) norm, the \( p \)th root of the sum of the \( p \)th powers of the differences of the com-
ponents.

Missing values are allowed, and are excluded from all computations involving the rows within
which they occur. Further, when Inf values are involved, all pairs of values are excluded when
their contribution to the distance gave NaN or NA. If some columns are excluded in calculating a
Euclidean, Manhattan, Canberra or Minkowski distance, the sum is scaled up proportionally to the
number of columns used. If all pairs are excluded when calculating a particular distance, the value
is NA.

The "dist" method of `as.matrix()` and `as.dist()` can be used for conversion between objects
of class "dist" and conventional distance matrices.

`as.dist()` is a generic function. Its default method handles objects inheriting from class "dist",
or coercible to matrices using `as.matrix()`. Support for classes representing distances (also known
as dissimilarities) can be added by providing an `as.matrix()` or, more directly, an as.dist method
for such a class.

Value

`dist` returns an object of class "dist".

The lower triangle of the distance matrix stored by columns in a vector, say `do`. If \( n \) is the number
of observations, i.e., \( n \leftarrow \text{attr}(do, "Size") \), then for \( i < j \leq n \), the dissimilarity between (row)
i and \( j \) is `do[n*(i-1) - i*(i-1)/2 + j-1]`. The length of the vector is \( n \times (n - 1)/2 \), i.e., of
order \( n^2 \).

The object has the following attributes (besides "class" equal to "dist"):
Size integer, the number of observations in the dataset.
Labels optionally, contains the labels, if any, of the observations of the dataset.
Diag, Upper logicals corresponding to the arguments diag and upper above, specifying how the object should be printed.
call optionally, the call used to create the object.
method optionally, the distance method used; resulting from dist(), the (match.arg()ed) method argument.

References

See Also
daisy in the cluster package with more possibilities in the case of mixed (continuous / categorical) variables. hclust.

Examples

```r
require(graphics)
x <- matrix(rnorm(100), nrow = 5)
dist(x)
dist(x, diag = TRUE)
dist(x, upper = TRUE)
m <- as.matrix(dist(x))
d <- as.dist(m)
stopifnot(d == dist(x))

## Use correlations between variables "as distance"
dd <- as.dist((1 - cor(USJudgeRatings))/2)
round(1000 * dd) # (prints more nicely)
plot(hclust(dd)) # to see a dendrogram of clustered variables

## example of binary and canberra distances.
x <- c(0, 0, 1, 1, 1)
y <- c(1, 0, 1, 1, 0, 1)
dist(rbind(x, y), method = "binary")
## answer 0.4 = 2/5

## answer 2 * (6/5)

## To find the names
labels(eurodist)

## Examples involving "Inf":
```
### 1)
x[6] <- Inf
(m2 <- rbind(x, y))
dist(m2, method = "binary")  # warning, answer 0.5 = 2/4
## These all give "Inf":
stopifnot(Inf == dist(m2, method = "euclidean"),
          Inf == dist(m2, method = "maximum"),
          Inf == dist(m2, method = "manhattan"))
## "Inf" is same as very large number:
x1 <- x; x1[6] <- 1e1/zero.noslash/zero.noslash
stopifnot(dist(cbind(x, y), method = "canberra") ==
          print(dist(cbind(x1, y), method = "canberra")))

### 2)
y[6] <- Inf  #-> 6-th pair is excluded
dist(rbind(x, y), method = "binary")  # warning; 0.5
dist(rbind(x, y), method = "canberra")  # 3
dist(rbind(x, y), method = "maximum")  # 1
dist(rbind(x, y), method = "manhattan")  # 2.4

**Distributions in the stats package**

**Description**

Density, cumulative distribution function, quantile function and random variate generation for many standard probability distributions are available in thestatspackage.

**Details**

The functions for the density/mass function, cumulative distribution function, quantile function and random variate generation are named in the form $dxxx$, $pxxx$, $qxxx$ and $rxxx$ respectively.

For the beta distribution see $dbeta$.

For the binomial (including Bernoulli) distribution see $dbinom$.

For the Cauchy distribution see $dcauchy$.

For the chi-squared distribution see $dchisq$.

For the exponential distribution see $dexp$.

For the F distribution see $df$.

For the gamma distribution see $dgamma$.

For the geometric distribution see $dgeom$. (This is also a special case of the negative binomial.)

For the hypergeometric distribution see $dhyper$.

For the log-normal distribution see $dlnorm$.

For the multinomial distribution see $dmultinom$.

For the negative binomial distribution see $dnbinom$. 

---
For the normal distribution see `dnorm`.
For the Poisson distribution see `dpois`.
For the Student’s t distribution see `dt`.
For the uniform distribution see `dunif`.
For the Weibull distribution see `dweibull`.
For less common distributions of test statistics see `pbirthday`, `dsignrank`, `ptukey` and `dwilcox` (and see the ‘See Also’ section of `cor.test`).

See Also

- `RNG` about random number generation in R.
- The CRAN task view on distributions, [http://cran.r-project.org/web/views/Distributions.html](http://cran.r-project.org/web/views/Distributions.html), mentioning several CRAN packages for additional distributions.

---

dummy.coef  
*Extract Coefficients in Original Coding*

### Description

This extracts coefficients in terms of the original levels of the coefficients rather than the coded variables.

### Usage

```r
dummy.coef(object, ...)
```

```r
## S3 method for class 'lm'
dummy.coef(object, use.na = FALSE, ...)
```

```r
## S3 method for class 'aovlist'
dummy.coef(object, use.na = FALSE, ...)
```

### Arguments

- **object**  
a linear model fit.

- **use.na**  
logical flag for coefficients in a singular model. If `use.na` is true, undetermined coefficients will be missing; if false they will get one possible value.

- **...**  
arguments passed to or from other methods.
Details

A fitted linear model has coefficients for the contrasts of the factor terms, usually one less in number than the number of levels. This function re-expresses the coefficients in the original coding; as the coefficients will have been fitted in the reduced basis, any implied constraints (e.g., zero sum for \texttt{contr.helmert} or \texttt{contr.sum}) will be respected. There will be little point in using \texttt{dummy.coef} for \texttt{contr.treatment} contrasts, as the missing coefficients are by definition zero.

The method used has some limitations, and will give incomplete results for terms such as \texttt{poly(x, 2)}. However, it is adequate for its main purpose, \texttt{aov} models.

Value

A list giving for each term the values of the coefficients. For a multistratum \texttt{aov} model, such a list for each stratum.

Warning

This function is intended for human inspection of the output: it should not be used for calculations. Use coded variables for all calculations.

The results differ from S for singular values, where S can be incorrect.

See Also

\texttt{aov}, \texttt{model.tables}

Examples

```r
options(contrasts = c("contr.helmert", "contr.poly"))
## From Venables and Ripley (2/zero.noslash/zero.noslash2) p.165.
utils::data(npk, package = "MASS")
npk.aov <- aov(yield ~ block + N*P*K, npk)
dummy.coef(npk.aov)

npk.aovE <- aov(yield ~ N*P*K + Error(block), npk)
dummy.coef(npk.aovE)
```

\texttt{ecdf}

\textit{Empirical Cumulative Distribution Function}

Description

Compute an empirical cumulative distribution function, with several methods for plotting, printing and computing with such an "\texttt{ecdf}" object.
Usage

ecdf(x)

## S3 method for class 'ecdf'
plot(x, ..., ylab="F_n(x)", verticals = FALSE,
col.0line = "gray70", pch = 19)

## S3 method for class 'ecdf'
print(x, digits= getOption("digits") - 2, ...)

## S3 method for class 'ecdf'
summary(object, ...)

## S3 method for class 'ecdf'
quantile(x, ...)

Arguments

x, object numeric vector of the observations for ecdf; for the methods, an object inheriting from class "ecdf".
...
arguments to be passed to subsequent methods, e.g., plot.stepfun for the plot method.
ylab label for the y-axis.
verticals see plot.stepfun.
col.0line numeric or character specifying the color of the horizontal lines at y = 0 and 1, see colors.
pch plotting character.
digits number of significant digits to use, see print.

Details

The e.c.d.f. (empirical cumulative distribution function) \( F_n \) is a step function with jumps \( i/n \) at observation values, where \( i \) is the number of tied observations at that value. Missing values are ignored.

For observations \( x = (x_1, x_2, \ldots, x_n) \), \( F_n \) is the fraction of observations less or equal to \( t \), i.e.,

\[
F_n(t) = \frac{\#\{x_i \leq t\}}{n} = \frac{1}{n} \sum_{i=1}^{n} 1_{[x_i \leq t]}.
\]

The function plot.ecdf which implements the plot method for ecdf objects, is implemented via a call to plot.stepfun; see its documentation.

Value

For ecdf, a function of class "ecdf", inheriting from the "stepfun" class, and hence inheriting a knots() method.

For the summary method, a summary of the knots of object with a "header" attribute.
The `quantile(obj, ...)` method computes the same quantiles as `quantile(x, ...)` would where `x` is the original sample.

**Author(s)**

Martin Maechler, <maechler@stat.math.ethz.ch>. Corrections by R-core.

**See Also**

`stepfun`, the more general class of step functions, `approxfun` and `splinefun`.

**Examples**

```r
#-- Simple didactical ecdf example :
x <- rnorm(12)
Fn <- ecdf(x)
Fn    # a *function*
Fn(x)  # returns the percentiles for x
tt <- seq(-2, 2, by = 0.1)
12 * Fn(tt) # Fn is a 'simple' function (with values k/12)
summary(Fn)
#---> see below for graphics
knots(Fn) # the unique data values (12 of them if there were no ties)

y <- round(rnorm(12), 1); y[3] <- y[1]
Fn12 <- ecdf(y)
Fn12
knots(Fn12) # unique values (always less than 12!)
summary(Fn12)
summary.stepfun(Fn12)

## Advanced: What's inside the function closure?
print(ls.Fn12 <- ls(environment(Fn12)))

eff.aovlist

Compute Efficiencies of Multistratum Analysis of Variance

Description

Computes the efficiencies of fixed-effect terms in an analysis of variance model with multiple strata.

Usage

eff.aovlist(aovlist)

Arguments

aovlist The result of a call to aov with an Error term.

Details

Fixed-effect terms in an analysis of variance model with multiple strata may be estimable in more than one stratum, in which case there is less than complete information in each. The efficiency for a term is the fraction of the maximum possible precision (inverse variance) obtainable by estimating in just that stratum. Under the assumption of balance, this is the same for all contrasts involving that term.

This function is used to pick strata in which to estimate terms in model.tables.aovlist and se.contrast.aovlist.

In many cases terms will only occur in one stratum, when all the efficiencies will be one: this is detected and no further calculations are done.

The calculation used requires orthogonal contrasts for each term, and will throw an error if non-orthogonal contrasts (e.g. treatment contrasts or an unbalanced design) are detected.

Value

A matrix giving for each non-pure-error stratum (row) the efficiencies for each fixed-effect term in the model.

---

effects

Description

Returns (orthogonal) effects from a fitted model, usually a linear model. This is a generic function, but currently only has a methods for objects inheriting from classes "lm" and "glm".

Usage

effects(object, ...)

## S3 method for class 'lm'
effects(object, set.sign = FALSE, ...)

---

Effects from Fitted Model

Description

Returns (orthogonal) effects from a fitted model, usually a linear model. This is a generic function, but currently only has a methods for objects inheriting from classes "lm" and "glm".

Usage

effects(object, ...)

## S3 method for class 'lm'
effects(object, set.sign = FALSE, ...)
Arguments

object an R object; typically, the result of a model fitting function such as `lm`.

set.sign logical. If TRUE, the sign of the effects corresponding to coefficients in the model will be set to agree with the signs of the corresponding coefficients, otherwise the sign is arbitrary.

... arguments passed to or from other methods.

Details

For a linear model fitted by `lm` or `aov`, the effects are the uncorrelated single-degree-of-freedom values obtained by projecting the data onto the successive orthogonal subspaces generated by the QR decomposition during the fitting process. The first \( r \) (the rank of the model) are associated with coefficients and the remainder span the space of residuals (but are not associated with particular residuals).

Empty models do not have effects.

Value

A (named) numeric vector of the same length as `residuals`, or a matrix if there were multiple responses in the fitted model, in either case of class "coef".

The first \( r \) rows are labelled by the corresponding coefficients, and the remaining rows are unlabelled. Note that in rank-deficient models the corresponding coefficients will be in a different order if pivoting occurred.

References

See Also

`coef`

Examples

```r
y <- c(1:3, 7, 5)
x <- c(1:3, 6:7)
( ee <- effects(lm(y ~ x)) )
c( round(ee - effects(lm(y+1/zero.noslash ~ I(x-3.8))), 3) )
# just the first is different
```
Description

Embeds the time series \( x \) into a low-dimensional Euclidean space.

Usage

\[
\text{embed} \ (x, \ \text{dimension} = 1)
\]

Arguments

- \( x \) a numeric vector, matrix, or time series.
- \( \text{dimension} \) a scalar representing the embedding dimension.

Details

Each row of the resulting matrix consists of sequences \( x[t], x[t-1], \ldots, x[t-\text{dimension}+1] \), where \( t \) is the original index of \( x \). If \( x \) is a matrix, i.e., \( x \) contains more than one variable, then \( x[t] \) consists of the \( t \)th observation on each variable.

Value

A matrix containing the embedded time series \( x \).

Author(s)

A. Trapletti, B.D. Ripley

Examples

\[
x \leftarrow 1:10
\]

\[
\text{embed} \ (x, \ 3)
\]

Description

Evaluates new variables as if they had been part of the formula of the specified model. This ensures that the same \texttt{na.action} and \texttt{subset} arguments are applied and allows, for example, \( x \) to be recovered for a model using \( \sin(x) \) as a predictor.
Usage

```r
expand.model.frame(model, extras,
  envir = environment(formula(model)),
  na.expand = FALSE)
```

Arguments

- `model`: a fitted model
- `extras`: one-sided formula or vector of character strings describing new variables to be added
- `envir`: an environment to evaluate things in
- `na.expand`: logical; see below

Details

If `na.expand = FALSE` then NA values in the extra variables will be passed to the `na.action` function used in `model`. This may result in a shorter data frame (with `na.omit`) or an error (with `na.fail`). If `na.expand = TRUE` the returned data frame will have precisely the same rows as `model.frame(model)`, but the columns corresponding to the extra variables may contain NA.

Value

A data frame.

See Also

- `model.frame`, `predict`

Examples

```r
model <- lm(log(Volume) ~ log(Girth) + log(Height), data = trees)
expand.model.frame(model, ~ Girth) # prints data.frame like

dd <- data.frame(x = 1:5, y = rnorm(5), z = c(1,2,NA,4,5))
model <- glm(y ~ x, data = dd, subset = 1:4, na.action = na.omit)
expand.model.frame(model, "z", na.expand = FALSE) # = default
expand.model.frame(model, "z", na.expand = TRUE)
```

---

**Exponential**

Description

Density, distribution function, quantile function and random generation for the exponential distribution with rate `rate` (i.e., mean `1/rate`).
Exponential

Usage

dexp(x, rate = 1, log = FALSE)
pexp(q, rate = 1, lower.tail = TRUE, log.p = FALSE)
qexp(p, rate = 1, lower.tail = TRUE, log.p = FALSE)
rexp(n, rate = 1)

Arguments

x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
rate vector of rates.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

If rate is not specified, it assumes the default value of 1.
The exponential distribution with rate \( \lambda \) has density

\[
f(x) = \lambda e^{-\lambda x}
\]

for \( x \geq 0 \).

Value
dexp gives the density, pexp gives the distribution function, qexp gives the quantile function, and rexp generates random deviates.
The length of the result is determined by n for rexp, and is the maximum of the lengths of the numerical parameters for the other functions.
The numerical parameters other than n are recycled to the length of the result. Only the first elements of the logical parameters are used.

Note

The cumulative hazard \( H(t) = -\log(1 - F(t)) \) is \(-\text{pexp}(t, \ rate, \ lower = FALSE, \ log = TRUE)\).

Source
dexp, pexp and qexp are all calculated from numerically stable versions of the definitions.
rexp uses
References

See Also

`exp` for the exponential function.

`Distributions` for other standard distributions, including `dgamma` for the gamma distribution and `dweibull` for the Weibull distribution, both of which generalize the exponential.

Examples

---

**extractAIC**

Extract AIC from a Fitted Model

**Description**

Computes the (generalized) Akaike An Information Criterion for a fitted parametric model.

**Usage**

```r
extractAIC(fit, scale, k = 2, ...)  
```

**Arguments**

- **fit**
  fitted model, usually the result of a fitter like `lm`.
- **scale**
  optional numeric specifying the scale parameter of the model, see scale in `step`. Currently only used in the "lm" method, where scale specifies the estimate of the error variance, and scale = 0 indicates that it is to be estimated by maximum likelihood.
- **k**
  numeric specifying the ‘weight’ of the equivalent degrees of freedom (≡ edf) part in the AIC formula.
- **...**
  further arguments (currently unused in base R).
extractAIC

Details

This is a generic function, with methods in base \( \mathcal{R} \) for classes "aov", "glm" and "lm" as well as for "negbin" (package MASS) and "coxph" and "survreg" (package survival).

The criterion used is

\[
AIC = -2 \log L + k \times \text{edf},
\]

where \( L \) is the likelihood and edf the equivalent degrees of freedom (i.e., the number of free parameters for usual parametric models) of fit.

For linear models with unknown scale (i.e., for \texttt{lm} and \texttt{aov}), \(-2 \log L\) is computed from the deviance and uses a different additive constant to \texttt{logLik} and hence \texttt{AIC}. If RSS denotes the (weighted) residual sum of squares then \texttt{extractAIC} uses for \(-2 \log L\) the formulae \(RSS/s-n\) (corresponding to Mallows’ \( C_p \)) in the case of known scale \( s \) and \( n \log(RSS/n) \) for unknown scale. \texttt{AIC} only handles unknown scale and uses the formula \( n \log(RSS/n) + n + n \log 2\pi - \sum \log w \) where \( w \) are the weights. Further \texttt{AIC} counts the scale estimation as a parameter in the edf and \texttt{extractAIC} does not.

For \texttt{glm} fits the family’s \texttt{aic()} function is used to compute the AIC: see the note under \texttt{logLik} about the assumptions this makes.

\( k = 2 \) corresponds to the traditional AIC, using \( k = \log(n) \) provides the BIC (Bayesian IC) instead.

Note that the methods for this function may differ in their assumptions from those of methods for \texttt{AIC} (usually via a method for \texttt{logLik}). We have already mentioned the case of "lm" models with estimated scale, and there are similar issues in the "glm" and "negbin" methods where the dispersion parameter may or may not be taken as ‘free’. This is immaterial as \texttt{extractAIC} is only used to compare models of the same class (where only differences in AIC values are considered).

Value

A numeric vector of length 2, with first and second elements giving

- \texttt{edf} the ‘equivalent degrees of freedom’ for the fitted model \texttt{fit}.
- \texttt{AIC} the (generalized) Akaike Information Criterion for \texttt{fit}.

Note

This function is used in \texttt{add1}, \texttt{drop1} and \texttt{step} and the similar functions in package MASS from which it was adopted.

Author(s)

B. D. Ripley

References

See Also

AIC, deviance, add1, step

Examples

utils::example(glm)
extractAIC(glm.D93)  #>> 5 15.129
nstart The number of starting values to be tried if start = NULL. Default 1.
trace logical. Output tracing information? Default FALSE.
lower The lower bound for uniquenesses during optimization. Should be > 0. Default 0.005.
opt A list of control values to be passed to optim’s control argument.
rotate a list of additional arguments for the rotation function.

Details

The factor analysis model is

\[ x = \Lambda f + e \]

for a \( p \)-element row-vector \( x \), a \( p \times k \) matrix \( \Lambda \) of loadings, a \( k \)-element vector \( f \) of scores and a \( p \)-element vector \( e \) of errors. None of the components other than \( x \) is observed, but the major restriction is that the scores be uncorrelated and of unit variance, and that the errors be independent with variances \( \Psi \), the uniquenesses. It is also common to scale the observed variables to unit variance, and done in this function.

Thus factor analysis is in essence a model for the correlation matrix of \( x \),

\[ \Sigma = \Lambda' \Lambda + \Psi \]

There is still some indeterminacy in the model for it is unchanged if \( \Lambda \) is replaced by \( G\Lambda \) for any orthogonal matrix \( G \). Such matrices \( G \) are known as rotations (although the term is applied also to non-orthogonal invertible matrices).

If covmat is supplied it is used. Otherwise \( x \) is used if it is a matrix, or a formula \( x \) is used with data to construct a model matrix, and that is used to construct a covariance matrix. (It makes no sense for the formula to have a response, and all the variables must be numeric.) Once a covariance matrix is found or calculated from \( x \), it is converted to a correlation matrix for analysis. The correlation matrix is returned as component correlation of the result.

The fit is done by optimizing the log likelihood assuming multivariate normality over the uniquenesses. (The maximizing loadings for given uniquenesses can be found analytically: Lawley & Maxwell (1971, p. 27).) All the starting values supplied in start are tried in turn and the best fit obtained is used. If start = NULL then the first fit is started at the value suggested by Jöreskog (1963) and given by Lawley & Maxwell (1971, p. 31), and then control$nstart - 1 other values are tried, randomly selected as equal values of the uniquenesses.

The uniquenesses are technically constrained to lie in \([0, 1]\), but near-zero values are problematical, and the optimization is done with a lower bound of control$lower, default 0.005 (Lawley & Maxwell, 1971, p. 32).

Scores can only be produced if a data matrix is supplied and used. The first method is the regression method of Thomson (1951), the second the weighted least squares method of Bartlett (1937, 8). Both are estimates of the unobserved scores \( f \). Thomson’s method regresses (in the population) the unknown \( f \) on \( x \) to yield

\[ \hat{f} = \Lambda' \Sigma^{-1} x \]

and then substitutes the sample estimates of the quantities on the right-hand side. Bartlett’s method minimizes the sum of squares of standardized errors over the choice of \( f \), given (the fitted) \( \Lambda \).
If \( x \) is a formula then the standard NA-handling is applied to the scores (if requested): see `napredict`. The print method (documented under `loadings`) follows the factor analysis convention of drawing attention to the patterns of the results, so the default precision is three decimal places, and small loadings are suppressed.

**Value**

An object of class "factanal" with components

- **loadings**: A matrix of loadings, one column for each factor. The factors are ordered in decreasing order of sums of squares of loadings, and given the sign that will make the sum of the loadings positive. This is of class "loadings": see `loadings` for its print method.
- **uniquenesses**: The uniquenesses computed.
- **correlation**: The correlation matrix used.
- **criteria**: The results of the optimization: the value of the negative log-likelihood and information on the iterations used.
- **factors**: The argument `factors`.
- **dof**: The number of degrees of freedom of the factor analysis model.
- **method**: The method: always "mle".
- **rotmat**: The rotation matrix if relevant.
- **scores**: If requested, a matrix of scores. `napredict` is applied to handle the treatment of values omitted by the `na.action`.
- **n.obs**: The number of observations if available, or `NA`.
- **call**: The matched call.
- **na.action**: If relevant.
- **STATISTIC, PVAL**: The significance-test statistic and P value, if it can be computed.

**Note**

There are so many variations on factor analysis that it is hard to compare output from different programs. Further, the optimization in maximum likelihood factor analysis is hard, and many other examples we compared had less good fits than produced by this function. In particular, solutions which are ‘Heywood cases’ (with one or more uniquenesses essentially zero) are much more common than most texts and some other programs would lead one to believe.

factor.scope

Compute Allowed Changes in Adding to or Dropping from a Formula

Description

add.scope and drop.scope compute those terms that can be individually added to or dropped from a model while respecting the hierarchy of terms.

Usage

add.scope(terms1, terms2)

drop.scope(terms1, terms2)

factor.scope(factor, scope)
Arguments

- `terms1`: the terms or formula for the base model.
- `terms2`: the terms or formula for the upper (add.scope) or lower (drop.scope) scope. If missing for drop.scope it is taken to be the null formula, so all terms (except any intercept) are candidates to be dropped.
- `factor`: the "factor" attribute of the terms of the base object.
- `scope`: a list with one or both components drop and add giving the "factor" attribute of the lower and upper scopes respectively.

Details

`factor.scope` is not intended to be called directly by users.

Value

For add.scope and drop.scope a character vector of terms labels. For factor.scope, a list with components drop and add, character vectors of terms labels.

See Also

- `add1`, `drop1`, `aov`, `lm`

Examples

```r
add.scope(~ a + b + c + a:b, ~ (a + b + c)^3)
# [1] "a:c"  "b:c"
drop.scope(~ a + b + c + a:b)
# [1] "c"  "a:b"
```

Description

Family objects provide a convenient way to specify the details of the models used by functions such as `glm`. See the documentation for `glm` for the details on how such model fitting takes place.

Usage

```r
family(object, ...)
binomial(link = "logit")
gaussian(link = "identity")
Gamma(link = "inverse")
inverse.gaussian(link = "1/mu^2")
poisson(link = "log")
quasi(link = "identity", variance = "constant")
```
family

quasibinomial(link = "logit")
quasipoisson(link = "log")

Arguments

link a specification for the model link function. This can be a name/expression, a literal character string, a length-one character vector or an object of class "link-glm" (such as generated by make.link) provided it is not specified via one of the standard names given next.

The gaussian family accepts the links (as names) identity, log and inverse; the binomial family the links logit, probit, cauchit, (corresponding to logistic, normal and Cauchy CDFs respectively) log and cloglog (complementary log-log); the Gamma family the links inverse, identity and log; the poisson family the links log, identity, and sqrt and the inverse.gaussian family the links 1/mu^2, inverse, identity and log.

The quasi family accepts the links logit, probit, cloglog, identity, inverse, log, 1/mu^2 and sqrt, and the function power can be used to create a power link function.

variance for all families other than quasi, the variance function is determined by the family. The quasi family will accept the literal character string (or unquoted as a name/expression) specifications "constant", "mu(1-mu)", "mu", "mu^2" and "mu^3", a length-one character vector taking one of those values, or a list containing components varfun, validmu, dev.resids, initialize and name.

object the function family accesses the family objects which are stored within objects created by modelling functions (e.g., glm).

... further arguments passed to methods.

Details

family is a generic function with methods for classes "glm" and "lm" (the latter returning gaussian()).

The quasibinomial and quasipoisson families differ from the binomial and poisson families only in that the dispersion parameter is not fixed at one, so they can model over-dispersion. For the binomial case see McCullagh and Nelder (1989, pp. 124–8). Although they show that there is (under some restrictions) a model with variance proportional to mean as in the quasi-binomial model, note that glm does not compute maximum-likelihood estimates in that model. The behaviour of S is closer to the quasi- variants.

Value

An object of class "family" (which has a concise print method). This is a list with elements

family character: the family name.
link character: the link name.
linkfun function: the link.
linkinv function: the inverse of the link function.
variance function: the variance as a function of the mean.
dev.resids  function giving the deviance residuals as a function of (y, mu, wt).
aic        function giving the AIC value if appropriate (but NA for the quasi- families). See
            logLik for the assumptions made about the dispersion parameter.
mu.eta      function: derivative function(eta) dµ/dη.
initialize  expression. This needs to set up whatever data objects are needed for the family
            as well as n (needed for AIC in the binomial family) and mustart (see glm.
valid.mu    logical function. Returns TRUE if a mean vector mu is within the domain of
            variance.
valid.eta   logical function. Returns TRUE if a linear predictor eta is within the domain of
            linkinv.
simulate   (optional) function simulate(object, nsim) to be called by the “lm” method
            of simulate. It will normally return a matrix with nsim columns and one row
            for each fitted value, but it can also return a list of length nsim. Clearly this will
            be missing for ‘quasi-’ families.

Note
The link and variance arguments have rather awkward semantics for back-compatibility. The
recommended way is to supply them as is as quoted character strings, but they can also be supplied
unquoted (as names or expressions). In addition, they can also be supplied as a length-one character
vector giving the name of one of the options, or as a list (for link, of class ”link-glm”). The
restrictions apply only to links given as names: when given as a character string all the links known
to make.link are accepted.
This is potentially ambiguous: supplying link = logit could mean the unquoted name of a link
or the value of object logit. It is interpreted if possible as the name of an allowed link, then as an
object. (You can force the interpretation to always be the value of an object via logit[1].)

Author(s)
The design was inspired by S functions of the same names described in Hastie & Pregibon (1992)
(except quasibinomial and quasipoisson).

y <- rpois(100, exp(1+x))
glm(y ~ x, family = quasi(variance = "mu", link = "log"))
# which is the same as
glm(y ~ x, family = poisson)
glm(y ~ x, family = quasi(variance = "mu^2", link = "log"))
## Not run: glm(y ~ x, family = quasi(variance = "mu^3", link = "log")) # fails
y <- rbinom(100, 1, plogis(x))
# needs to set a starting value for the next fit
glm(y ~ x, family = quasi(variance = "mu(1-mu)", link = "logit"), start = c(0,1))

FDist

The F Distribution

Description

Density, distribution function, quantile function and random generation for the F distribution with df1 and df2 degrees of freedom (and optional non-centrality parameter ncp).

Usage

df(x, df1, df2, ncp, log = FALSE)

pf(q, df1, df2, ncp, lower.tail = TRUE, log.p = FALSE)

qf(p, df1, df2, ncp, lower.tail = TRUE, log.p = FALSE)

rf(n, df1, df2, ncp)

Arguments

x, q  vector of quantiles.

p     vector of probabilities.

n     number of observations. If length(n) > 1, the length is taken to be the number required.

df1, df2 degrees of freedom. Inf is allowed.

ncp   non-centrality parameter. If omitted the central F is assumed.

log, log.p logical; if TRUE, probabilities p are given as log(p).

lower.tail logical; if TRUE (default), probabilities are P[X ≤ x], otherwise, P[X > x].

Details

The F distribution with df1 = n1 and df2 = n2 degrees of freedom has density

\[ f(x) = \frac{\Gamma(n_1/2 + n_2/2)}{\Gamma(n_1/2)\Gamma(n_2/2)} \left( \frac{n_1}{n_2} \right)^{n_1/2} x^{n_1/2-1} \left( 1 + \frac{n_1 x}{n_2} \right)^{-(n_1+n_2)/2} \]

for x > 0.

It is the distribution of the ratio of the mean squares of n1 and n2 independent standard normals, and hence of the ratio of two independent chi-squared variates each divided by its degrees of freedom.
Since the ratio of a normal and the root mean-square of \(m\) independent normals has a Student’s \(t_m\) distribution, the square of a \(t_m\) variate has a F distribution on 1 and \(m\) degrees of freedom.

The non-central F distribution is again the ratio of mean squares of independent normals of unit variance, but those in the numerator are allowed to have non-zero means and \(ncp\) is the sum of squares of the means. See Chisquare for further details on non-central distributions.

Value

\(df\) gives the density, \(pf\) gives the distribution function \(qf\) gives the quantile function, and \(rf\) generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by \(n\) for \(rf\), and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than \(n\) are recycled to the length of the result. Only the first elements of the logical parameters are used.

Note

Supplying \(ncp = 0\) uses the algorithm for the non-central distribution, which is not the same algorithm used if \(ncp\) is omitted. This is to give consistent behaviour in extreme cases with values of \(ncp\) very near zero.

The code for non-zero \(ncp\) is principally intended to be used for moderate values of \(ncp\): it will not be highly accurate, especially in the tails, for large values.

Source

For the central case of \(df\), computed via a binomial probability, code contributed by Catherine Loader (see \texttt{dbinom}); for the non-central case computed via \texttt{dbeta}, code contributed by Peter Ruckdeschel.

For \(pf\), via \texttt{pbeta} (or for large \(df2\), via \texttt{pchisq}).

For \(qf\), via \texttt{qchisq} for large \(df2\), else via \texttt{qbeta}.

Examples

```r
## Equivalence of pt(.\cdot,nu) with pf(.^2, 1,nu):
x <- seq(0.001, 5, len = 100)
nu <- 4
stopifnot(all.equal(2*pt(x,nu) - 1, pf(x^2, 1,nu)),
  ## upper tails:
  all.equal(2*pt(x, nu, lower=FALSE),
    pf(x^2, 1,nu, lower=FALSE)))

## the density of the square of a t_m is 2*dt(x, m)/(2*x)
# check this is the same as the density of F_{1,m}
all.equal(df(x^2, 1, 5), dt(x, 5)/x)

## Identity: qf(2*p - 1, 1, df)) == qt(p, df)*2) for p >= 1/2
p <- seq(1/2, .99, length = 50); df <- 10
rel.err <- function(x, y) ifelse(x == y, 0, abs(x-y)/mean(abs(c(x,y))))
quantile(rel.err(qf(2*p - 1, df1 = 1, df2 = df), qt(p, df)*2), .9)  # ~= 7e-9
```

fft

**Fast Discrete Fourier Transform**

Description

Performs the Fast Fourier Transform of an array.

Usage

```r
fft(z, inverse = FALSE)
mvfft(z, inverse = FALSE)
```

Arguments

- **z**: a real or complex array containing the values to be transformed.
- **inverse**: if TRUE, the unnormalized inverse transform is computed (the inverse has a + in the exponent of e, but here, we do not divide by 1/length(x)).

Value

When z is a vector, the value computed and returned by `fft` is the unnormalized univariate Fourier transform of the sequence of values in z.

When z contains an array, `fft` computes and returns the multivariate (spatial) transform. If `inverse` is TRUE, the (unnormalized) inverse Fourier transform is returned, i.e., if y <- `fft`(z), then z is `fft`(y, inverse = TRUE) / length(y).

By contrast, `mvfft` takes a real or complex matrix as argument, and returns a similar shaped matrix, but with each column replaced by its discrete Fourier transform. This is useful for analyzing vector-valued series.
The FFT is fastest when the length of the series being transformed is highly composite (i.e., has many factors). If this is not the case, the transform may take a long time to compute and will use a large amount of memory.

`convolve`, `nextn`.

Examples

```r
x <- 1:4
fft(x)
fft(fft(x), inverse = TRUE)/length(x)
```

---

**filter**

*Linear Filtering on a Time Series*

Description

Applies linear filtering to a univariate time series or to each series separately of a multivariate time series.

Usage

```r
filter(x, filter, method = c("convolution", "recursive"),
       sides = 2, circular = FALSE, init)
```

Arguments

- `x`: a univariate or multivariate time series.
- `filter`: a vector of filter coefficients in reverse time order (as for AR or MA coefficients).
- `method`: Either "convolution" or "recursive" (and can be abbreviated). If "convolution" a moving average is used; if "recursive" an autoregression is used.
sides for convolution filters only. If sides = 1 the filter coefficients are for past values only; if sides = 2 they are centred around lag 0. In this case the length of the filter should be odd, but if it is even, more of the filter is forward in time than backward.

circular for convolution filters only. If TRUE, wrap the filter around the ends of the series, otherwise assume external values are missing (NA).

init for recursive filters only. Specifies the initial values of the time series just prior to the start value, in reverse time order. The default is a set of zeros.

Details

Missing values are allowed in x but not in filter (where they would lead to missing values everywhere in the output).

Note that there is an implied coefficient 1 at lag 0 in the recursive filter, which gives

\[ y_i = x_i + f_1 y_{i-1} + \cdots + f_p y_{i-p} \]

No check is made to see if recursive filter is invertible: the output may diverge if it is not.

The convolution filter is

\[ y_i = f_1 x_{i+o} + \cdots + f_p x_{i+o-(p-1)} \]

where o is the offset: see sides for how it is determined.

Value

A time series object.

Note

convolve(, type = "filter") uses the FFT for computations and so may be faster for long filters on univariate series, but it does not return a time series (and so the time alignment is unclear), nor does it handle missing values. filter is faster for a filter of length 100 on a series of length 1000, for example.

cfilter(x, rep(1, 3))
cfilter(x, rep(1, 3), sides = 1)
cfilter(x, rep(1, 3), sides = 1, circular = TRUE)
cfilter(presidents, rep(1, 3))
```
**fisher.test**  
*Fisher’s Exact Test for Count Data*

**Description**

Performs Fisher’s exact test for testing the null of independence of rows and columns in a contingency table with fixed marginals.

**Usage**

```r
fisher.test(x, y = NULL, workspace = 200000, hybrid = FALSE,
control = list(), or = 1, alternative = "two.sided",
conf.int = TRUE, conf.level = 0.95,
simulate.p.value = FALSE, B = 2000)
```

**Arguments**

- `x` either a two-dimensional contingency table in matrix form, or a factor object.
- `y` a factor object; ignored if `x` is a matrix.
- `workspace` an integer specifying the size of the workspace used in the network algorithm. In units of 4 bytes. Only used for non-simulated p-values larger than $2 \times 2$ tables.
- `hybrid` a logical. Only used for larger than $2 \times 2$ tables, in which cases it indicates whether the exact probabilities (default) or a hybrid approximation thereof should be computed. See ‘Details’.
- `control` a list with named components for low level algorithm control. At present the only one used is "mult", a positive integer $\geq 2$ with default 30 used only for larger than $2 \times 2$ tables. This says how many times as much space should be allocated to paths as to keys: see file ‘fexact.c’ in the sources of this package.
- `or` the hypothesized odds ratio. Only used in the $2 \times 2$ case.
- `alternative` indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. Only used in the $2 \times 2$ case.
- `conf.int` logical indicating if a confidence interval for the odds ratio in a $2 \times 2$ table should be computed (and returned).
- `conf.level` confidence level for the returned confidence interval. Only used in the $2 \times 2$ case and if `conf.int = TRUE`.
- `simulate.p.value` a logical indicating whether to compute p-values by Monte Carlo simulation, in larger than $2 \times 2$ tables.
- `B` an integer specifying the number of replicates used in the Monte Carlo test.
Details

If \( x \) is a matrix, it is taken as a two-dimensional contingency table, and hence its entries should be nonnegative integers. Otherwise, both \( x \) and \( y \) must be vectors of the same length. Incomplete cases are removed, the vectors are coerced into factor objects, and the contingency table is computed from these.

For \( 2 \times 2 \) cases, p-values are obtained directly using the (central or non-central) hypergeometric distribution. Otherwise, computations are based on a C version of the FORTRAN subroutine FEXACT which implements the network developed by Mehta and Patel (1986) and improved by Clarkson, Fan and Joe (1993). The FORTRAN code can be obtained from http://www.netlib.org/toms/643. Note this fails (with an error message) when the entries of the table are too large. (It transposes the table if necessary so it has no more rows than columns. One constraint is that the product of the row marginals be less than \( 2^{31} - 1 \).

For \( 2 \times 2 \) tables, the null of conditional independence is equivalent to the hypothesis that the odds ratio equals one. ‘Exact’ inference can be based on observing that in general, given all marginal totals fixed, the first element of the contingency table has a non-central hypergeometric distribution with non-centrality parameter given by the odds ratio (Fisher, 1935). The alternative for a one-sided test is based on the odds ratio, so \( \text{alternative} = \text{"greater"} \) is a test of the odds ratio being bigger than or.

Two-sided tests are based on the probabilities of the tables, and take as ‘more extreme’ all tables with probabilities less than or equal to that of the observed table, the p-value being the sum of such probabilities.

For larger than \( 2 \times 2 \) tables and \( \text{hybrid = TRUE} \), asymptotic chi-squared probabilities are only used if the ‘Cochran conditions’ are satisfied, that is if no cell has count zero, and more than 80% of the cells have counts at least 5: otherwise the exact calculation is used.

Simulation is done conditional on the row and column marginals, and works only if the marginals are strictly positive. (A C translation of the algorithm of Patefield (1981) is used.)

Value

A list with class "htest" containing the following components:

- \( \text{p.value} \) the p-value of the test.
- \( \text{conf.int} \) a confidence interval for the odds ratio. Only present in the \( 2 \times 2 \) case and if argument \( \text{conf.int = TRUE} \).
- \( \text{estimate} \) an estimate of the odds ratio. Note that the conditional Maximum Likelihood Estimate (MLE) rather than the unconditional MLE (the sample odds ratio) is used. Only present in the \( 2 \times 2 \) case.
- \( \text{null.value} \) the odds ratio under the null, or. Only present in the \( 2 \times 2 \) case.
- \( \text{alternative} \) a character string describing the alternative hypothesis.
- \( \text{method} \) the character string "Fisher’s Exact Test for Count Data".
- \( \text{data.name} \) a character string giving the names of the data.

fitted.test(Job, simulate.p.value = TRUE, B = 1e5)

---

### fitted

**Extract Model Fitted Values**

#### Description

fitted is a generic function which extracts fitted values from objects returned by modeling functions. fitted.values is an alias for it.

All object classes which are returned by model fitting functions should provide a fitted method. (Note that the generic is fitted and not fitted.values.) Methods can make use of napredict methods to compensate for the omission of missing values. The default and nls methods do.

#### Usage

```r
fitted(object, ...)
fitted.values(object, ...)
```

#### Arguments

- `object`: an object for which the extraction of model fitted values is meaningful.
- `...`: other arguments.

#### Value

Fitted values extracted from the object object.

#### References

#### See Also

coefficients, glm, lm, residuals.
### fivenum

Tukey Five-Number Summaries

**Description**

Returns Tukey’s five number summary (minimum, lower-hinge, median, upper-hinge, maximum) for the input data.

**Usage**

```r
fivenum(x, na.rm = TRUE)
```

**Arguments**

- `x`: numeric, maybe including NAs and ±Inf's.
- `na.rm`: logical; if TRUE, all NA and NaNs are dropped, before the statistics are computed.

**Value**

A numeric vector of length 5 containing the summary information. See `boxplot.stats` for more details.

**See Also**

`IQR`, `boxplot.stats`, `median`, `quantile`, `range`.

**Examples**

```r
fivenum(c(rnorm(100, -1:1))
```

### fligner.test

Fligner-Killeen Test of Homogeneity of Variances

**Description**

Performs a Fligner-Killeen (median) test of the null that the variances in each of the groups (samples) are the same.

**Usage**

```r
fligner.test(x, ...)
```

```r
## Default S3 method:
fligner.test(x, g, ...)
```

```r
## S3 method for class 'formula'
fligner.test(formula, data, subset, na.action, ...)
```

---

**Examples**

```r
fligner.test(c(rnorm(100, -1:1))
```
Arguments

- **x**: a numeric vector of data values, or a list of numeric data vectors.
- **g**: a vector or factor object giving the group for the corresponding elements of x. Ignored if x is a list.
- **formula**: a formula of the form `lhs ~ rhs` where `lhs` gives the data values and `rhs` the corresponding groups.
- **data**: an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- **subset**: an optional vector specifying a subset of observations to be used.
- **na.action**: a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.
- **...**: further arguments to be passed to or from methods.

Details

If x is a list, its elements are taken as the samples to be compared for homogeneity of variances, and hence have to be numeric data vectors. In this case, g is ignored, and one can simply use `fligner.test(x)` to perform the test. If the samples are not yet contained in a list, use `fligner.test(list(x, ...))`.

Otherwise, x must be a numeric data vector, and g must be a vector or factor object of the same length as x giving the group for the corresponding elements of x.

The Fligner-Killeen (median) test has been determined in a simulation study as one of the many tests for homogeneity of variances which is most robust against departures from normality, see Conover, Johnson & Johnson (1981). It is a k-sample simple linear rank which uses the ranks of the absolute values of the centered samples and weights $a(i) = \text{qnorm}((1+i/(n+1))/2)$. The version implemented here uses median centering in each of the samples (F-K:med $X^2$ in the reference).

Value

A list of class "htest" containing the following components:

- **statistic**: the Fligner-Killeen:med $X^2$ test statistic.
- **parameter**: the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- **p.value**: the p-value of the test.
- **method**: the character string "Fligner-Killeen test of homogeneity of variances".
- **data.name**: a character string giving the names of the data.

fligner.test(count ~ spray, data = InsectSprays)
    ## Compare this to bartlett.test()

---

Description

The generic function formula and its specific methods provide a way of extracting formulae which have been included in other objects.

as.formula is almost identical, additionally preserving attributes when object already inherits from "formula".

Usage

formula(x, ...)
as.formula(object, env = parent.frame())

    ## S3 method for class 'formula'
print(x, showEnv = !identical(e, .GlobalEnv), ...)

Arguments

x, object R object.
...
      further arguments passed to or from other methods.
env
      the environment to associate with the result, if not already a formula.
showEnv
      logical indicating if the environment should be printed as well.

Details

The models fit by, e.g., the lm and glm functions are specified in a compact symbolic form. The ~ operator is basic in the formation of such models. An expression of the form y ~ model is interpreted as a specification that the response y is modelled by a linear predictor specified symbolically by model. Such a model consists of a series of terms separated by + operators. The terms themselves consist of variable and factor names separated by : operators. Such a term is interpreted as the interaction of all the variables and factors appearing in the term.
In addition to + and :, a number of other operators are useful in model formulae. The \* operator denotes factor crossing: \( a+b \) interpreted as \( a+b+a:b \). The \^ operator indicates crossing to the specified degree. For example, \((a+b+c)^2\) is identical to \((a+b+c)\times(a+b+c)\) which in turn expands to a formula containing the main effects for \(a\), \(b\) and \(c\) together with their second-order interactions. The \%in\% operator indicates that the terms on its left are nested within those on the right. For example \(a + b \%in\% a\) expands to the formula \(a + a:b\). The \- operator removes the specified terms, so that \((a+b+c)^2 - a:b\) is identical to \(a + b + c + b:c + a:c\). It can also be used to remove the intercept term: when fitting a linear model \(y \sim x - 1\) specifies a line through the origin. A model with no intercept can be also specified as \(y \sim x + 0\) or \(y \sim /zero.noslash + x\).

While formulae usually involve just variable and factor names, they can also involve arithmetic expressions. The formula \(\log(y) \sim a + \log(x)\) is quite legal. When such arithmetic expressions involve operators which are also used symbolically in model formulae, there can be confusion between arithmetic and symbolic operator use.

To avoid this confusion, the function `I()` can be used to bracket those portions of a model formula where the operators are used in their arithmetic sense. For example, in the formula \(y \sim a + I(b+c)\), the term \(b+c\) is to be interpreted as the sum of \(b\) and \(c\).

Variable names can be quoted by backticks 'like this' in formulae, although there is no guarantee that all code using formulae will accept such non-syntactic names.

Most model-fitting functions accept formulae with right-hand-side including the function `offset` to indicate terms with a fixed coefficient of one. Some functions accept other ‘specials’ such as `strata` or `cluster` (see the `specials` argument of `terms.formula`).

There are two special interpretations of . in a formula. The usual one is in the context of a data argument of model fitting functions and means ‘all columns not otherwise in the formula’: see `terms.formula`. In the context of `update.formula`, `only`, it means ‘what was previously in this part of the formula’.

When `formula` is called on a fitted model object, either a specific method is used (such as that for class "nls") or the default method. The default first looks for a "formula" component of the object (and evaluates it), then a "terms" component, then a `formula` parameter of the call (and evaluates its value) and finally a "formula" attribute.

There is a `formula` method for data frames. If there is only one column this forms the RHS with an empty LHS. For more columns, the first column is the LHS of the formula and the remaining columns separated by + form the RHS.

**Value**

All the functions above produce an object of class "formula" which contains a symbolic model formula.

**Environments**

A formula object has an associated environment, and this environment (rather than the parent environment) is used by `model.frame` to evaluate variables that are not found in the supplied data argument.

Formulas created with the ~ operator use the environment in which they were created. Formulas created with `as.formula` will use the `env` argument for their environment.

Examples
fm1 <- nls(circumference ~ A/(1+exp((B-age)/C)), Orange,
           start = list(A = 160, B = 700, C = 350))
formula(fm1)

friedman.test
Friedman Rank Sum Test

Description
Performs a Friedman rank sum test with unreplicated blocked data.

Usage
friedman.test(y, ...)

## Default S3 method:
friedman.test(y, groups, blocks, ...)

## S3 method for class 'formula'
friedman.test(formula, data, subset, na.action, ...)

Arguments
y either a numeric vector of data values, or a data matrix.
groups a vector giving the group for the corresponding elements of y if this is a vector; ignored if y is a matrix. If not a factor object, it is coerced to one.
blocks a vector giving the block for the corresponding elements of y if this is a vector; ignored if y is a matrix. If not a factor object, it is coerced to one.
formula a formula of the form a ~ b | c, where a, b and c give the data values and corresponding groups and blocks, respectively.
data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset an optional vector specifying a subset of observations to be used.
na.action a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").
... further arguments to be passed to or from methods.
Details

friedman.test can be used for analyzing unreplicated complete block designs (i.e., there is exactly one observation in y for each combination of levels of groups and blocks) where the normality assumption may be violated.

The null hypothesis is that apart from an effect of blocks, the location parameter of y is the same in each of the groups.

If y is a matrix, groups and blocks are obtained from the column and row indices, respectively. NA’s are not allowed in groups or blocks; if y contains NA’s, corresponding blocks are removed.

Value

A list with class "htest" containing the following components:

- statistic: the value of Friedman's chi-squared statistic.
- parameter: the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- p.value: the p-value of the test.
- method: the character string "Friedman rank sum test".
- data.name: a character string giving the names of the data.

ftable

Flat Contingency Tables

Description
Create ‘flat’ contingency tables.

Usage
ftable(x, ...)

## Default S3 method:
ftable(..., exclude = c(NA, NaN), row.vars = NULL,
col.vars = NULL)

Arguments

x, ... R objects which can be interpreted as factors (including character strings), or a
list (or data frame) whose components can be so interpreted, or a contingency
table object of class "table" or "ftable".

exclude values to use in the exclude argument of factor when interpreting non-factor
objects.
row.vars  a vector of integers giving the numbers of the variables, or a character vector
giving the names of the variables to be used for the rows of the flat contingency
table.

col.vars  a vector of integers giving the numbers of the variables, or a character vector giv-
ing the names of the variables to be used for the columns of the flat contingency
table.

Details

ftable creates ‘flat’ contingency tables. Similar to the usual contingency tables, these contain the
counts of each combination of the levels of the variables (factors) involved. This information is
then re-arranged as a matrix whose rows and columns correspond to unique combinations of the
levels of the row and column variables (as specified by row.vars and col.vars, respectively). The
combinations are created by looping over the variables in reverse order (so that the levels of the
left-most variable vary the slowest). Displaying a contingency table in this flat matrix form (via
print.ftable, the print method for objects of class "ftable") is often preferable to showing it as
a higher-dimensional array.

ftable is a generic function. Its default method, ftable.default, first creates a contingency table
in array form from all arguments except row.vars and col.vars. If the first argument is of class
"table", it represents a contingency table and is used as is; if it is a flat table of class "ftable", the
information it contains is converted to the usual array representation using as.ftable. Otherwise,
the arguments should be R objects which can be interpreted as factors (including character strings),
or a list (or data frame) whose components can be so interpreted, which are cross-tabulated using
table. Then, the arguments row.vars and col.vars are used to collapse the contingency table
into flat form. If neither of these two is given, the last variable is used for the columns. If both are
given and their union is a proper subset of all variables involved, the other variables are summed
out.

When the arguments are R expressions interpreted as factors, additional arguments will be passed
to table to control how the variable names are displayed; see the last example below.

Function ftable.formula provides a formula method for creating flat contingency tables.

There are methods for as.table and as.data.frame.

Value

ftable returns an object of class "ftable", which is a matrix with counts of each combination of
the levels of variables with information on the names and levels of the (row and columns) variables
stored as attributes "row.vars" and "col.vars".

See Also

ftable.formula for the formula interface (which allows a data = . argument); read.ftable
for information on reading, writing and coercing flat contingency tables; table for ordinary cross-
tabulation; xtabs for formula-based cross-tabulation.

Examples

## Start with a contingency table.
ftable(Titanic, row.vars = 1:3)
ftable(Titanic, row.vars = 1:2, col.vars = "Survived")
ftable(Titanic, row.vars = 2:1, col.vars = "Survived")

## Start with a data frame.
x <- ftable(mtcars[c("cyl", "vs", "am", "gear")])
x
ftable(x, row.vars = c(2, 4))

## Start with expressions, use table()'s "dnn" to change labels
ftable(mtcars$cyl, mtcars$vs, mtcars$am, mtcars$gear, row.vars = c(2, 4),
       dnn = c("Cylinders", "V/S", "Transmission", "Gears"))

---

## S3 method for class 'formula'
ftable(formula, data = NULL, subset, na.action, ...)

### Arguments

- **formula**: a formula object with both left and right hand sides specifying the column and row variables of the flat table.
- **data**: a data frame, list or environment (or similar: see `model.frame`) containing the variables to be cross-tabulated, or a contingency table (see below).
- **subset**: an optional vector specifying a subset of observations to be used. Ignored if data is a contingency table.
- **na.action**: a function which indicates what should happen when the data contain NAs. Ignored if data is a contingency table.
- **...**: further arguments to the default `ftable` method may also be passed as arguments, see `ftable.default`.

### Details

This is a method of the generic function `ftable`. The left and right hand side of `formula` specify the column and row variables, respectively, of the flat contingency table to be created. Only the `+` operator is allowed for combining the variables. A `.` may be used once in the formula to indicate inclusion of all the remaining variables.

If `data` is an object of class "table" or an array with more than 2 dimensions, it is taken as a contingency table, and hence all entries should be nonnegative. Otherwise, if it is not a flat contingency table (i.e., an object of class "ftable"), it should be a data frame or matrix, list or
environment containing the variables to be cross-tabulated. In this case, na.action is applied to
the data to handle missing values, and, after possibly selecting a subset of the data as specified by
the subset argument, a contingency table is computed from the variables.

The contingency table is then collapsed to a flat table, according to the row and column variables
specified by formula.

Value

A flat contingency table which contains the counts of each combination of the levels of the variables,
collapsed into a matrix for suitably displaying the counts.

See Also

ftable, ftable.default; table.

Examples

Titanic
x <- ftable(Survived ~ ., data = Titanic)
x
ftable(Sex ~ Class + Age, data = x)
log, log.p logical; if TRUE, probabilities/densities \( p \) are returned as \( \log(p) \).
lower.tail logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

**Details**

If `scale` is omitted, it assumes the default value of 1.

The Gamma distribution with parameters \( \text{shape} = \alpha \) and \( \text{scale} = \sigma \) has density

\[
f(x) = \frac{1}{\sigma^\alpha \Gamma(\alpha)} x^{\alpha-1} e^{-x/\sigma}
\]

for \( x \geq 0, \alpha > 0 \) and \( \sigma > 0 \). (Here \( \Gamma(\alpha) \) is the function implemented by R's `gamma()` and defined in its help. Note that \( \alpha = 0 \) corresponds to the trivial distribution with all mass at point 0.)

The mean and variance are \( E(X) = \alpha \sigma \) and \( Var(X) = \alpha \sigma^2 \).

The cumulative hazard \( H(t) = -\log(1 - F(t)) \) is

\[-\text{pgamma}(t, \ldots, \text{lower} = \text{FALSE}, \text{log} = \text{TRUE})\]

Note that for smallish values of shape (and moderate `scale`) a large parts of the mass of the Gamma distribution is on values of \( x \) so near zero that they will be represented as zero in computer arithmetic. So `rgamma` may well return values which will be represented as zero. (This will also happen for very large values of `scale` since the actual generation is done for `scale = 1`.)

**Value**

dgamma gives the density, pgamma gives the distribution function, qgamma gives the quantile function, and rgamma generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by `n` for `rgamma`, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than `n` are recycled to the length of the result. Only the first elements of the logical parameters are used.

**Note**

The S (Becker et al (1988) parametrization was via shape and rate: S had no scale parameter. In R 2.x.y scale took precedence over rate, but now it is an error to supply both.

pgamma is closely related to the incomplete gamma function. As defined by Abramowitz and Stegun 6.5.1 (and by ‘Numerical Recipes’) this is

\[
P(a, x) = \frac{1}{\Gamma(a)} \int_0^x t^{a-1} e^{-t} dt
\]

\( P(a, x) \) is `pgamma(\( x \), \( a \))`. Other authors (for example Karl Pearson in his 1922 tables) omit the normalizing factor, defining the incomplete gamma function \( \gamma(a, x) \) as \( \gamma(a, x) = \int_0^x t^{a-1} e^{-t} dt \), i.e., `pgamma(\( x \), \( a \)) * gamma(\( a \))`. Yet other use the ‘upper’ incomplete gamma function,

\[
\Gamma(a, x) = \int_x^\infty t^{a-1} e^{-t} dt,
\]
which can be computed by pgamma(x, a, lower = FALSE) * gamma(a).

Note however that pgamma(x, a, ...) currently requires $a > 0$, whereas the incomplete gamma function is also defined for negative $a$. In that case, you can use gamma_inc(a, x) (for $\Gamma(a, x)$) from package gsl.

See also http://en.wikipedia.org/wiki/Incomplete_gamma_function, or http://dlmf.nist.gov/8.2#i.

Source

dgamma is computed via the Poisson density, using code contributed by Catherine Loader (see dbinom).

pgamma uses an unpublished (and not otherwise documented) algorithm ‘mainly by Morten Welinder’.

qgamma is based on a C translation of

plus a final Newton step to improve the approximation.

rgamma for shape $\geq 1$ uses

and for $0 < \text{shape} < 1$ uses

References

See Also

gamma for the gamma function.

Distributions for other standard distributions, including dbeta for the Beta distribution and dchisq for the chi-squared distribution which is a special case of the Gamma distribution.
Examples

- \log(dgamma(1:4, \text{shape} = 1))
  
p <- (1:9)/10
  pgamma(qgamma(p, \text{shape} = 2), \text{shape} = 2)
  1 - 1/exp(qgamma(p, \text{shape} = 1))

# even for \text{shape} = 0.001 about half the mass is on numbers
# that cannot be represented accurately (and most of those as zero)
  pgamma(.Machine$double.xmin, 0.001)
  pgamma(5e-324, 0.001)  # on most machines 5e-324 is the smallest
  # representable non-zero number
  table(rgamma(1e4, 0.001) == 0)/1e4

The Geometric Distribution

Description

Density, distribution function, quantile function and random generation for the geometric distribution with parameter prob.

Usage

dgeom(x, prob, log = FALSE)
pgeom(q, prob, lower.tail = TRUE, log.p = FALSE)
qgeom(p, prob, lower.tail = TRUE, log.p = FALSE)
rggeom(n, prob)

Arguments

x, q vector of quantiles representing the number of failures in a sequence of Bernoulli trials before success occurs.
p vector of probabilities.
 n number of observations. If length(n) > 1, the length is taken to be the number required.
prob probability of success in each trial. 0 < prob <= 1.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

The geometric distribution with \( \text{prob} = p \) has density

\[
p(x) = p(1 - p)^x
\]

for \( x = 0, 1, 2, \ldots, 0 < p \leq 1 \).

If an element of x is not integer, the result of dgeom is zero, with a warning.

The quantile is defined as the smallest value \( x \) such that \( F(x) \geq p \), where \( F \) is the distribution function.
**Value**

dgeom gives the density, pgeom gives the distribution function, qgeom gives the quantile function, and rgeom generates random deviates.

Invalid prob will result in return value NaN, with a warning.

The length of the result is determined by n for rgeom, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than n are recycled to the length of the result. Only the first elements of the logical parameters are used.

**Source**

dgeom computes via dbinom, using code contributed by Catherine Loader (see dbinom).
pgeom and qgeom are based on the closed-form formulae.
rgeom uses the derivation as an exponential mixture of Poissons, see

**See Also**

Distributions for other standard distributions, including dnbinom for the negative binomial which generalizes the geometric distribution.

**Examples**

```r
qgeom((1:9)/10, prob = .2)
Ni <- rgeom(20, prob = 1/4); table(factor(Ni, 0:max(Ni)))
```

---

**getInitial**

*Get Initial Parameter Estimates*

**Description**

This function evaluates initial parameter estimates for a nonlinear regression model. If data is a parameterized data frame or pframe object, its parameters attribute is returned. Otherwise the object is examined to see if it contains a call to a selfStart object whose initial attribute can be evaluated.

**Usage**

```r
getInitial(object, data, ...)
```

**Arguments**

- **object**: a formula or a selfStart model that defines a nonlinear regression model
- **data**: a data frame in which the expressions in the formula or arguments to the selfStart model can be evaluated
- **...**: optional additional arguments
A named numeric vector or list of starting estimates for the parameters. The construction of many selfStart models is such that these "starting" estimates are, in fact, the converged parameter estimates.

Author(s)
José Pinheiro and Douglas Bates

Examples
PurTrt <- Puromycin[ Puromycin$state == "treated", ]
print(getInitial( rate ~ SSmicmen( conc, Vm, K ), PurTrt ), digits = 3)

Description
glm is used to fit generalized linear models, specified by giving a symbolic description of the linear predictor and a description of the error distribution.

Usage
glm(formula, family = gaussian, data, weights, subset,
na.action, start = NULL, etastart, mustart, offset,
control = list(...), model = TRUE, method = "glm.fit",
x = FALSE, y = TRUE, contrasts = NULL, ...)

glm.fit(x, y, weights = rep(1, nobs),
start = NULL, etastart = NULL, mustart = NULL,
offset = rep(0, nobs), family = gaussian(),
control = list(), intercept = TRUE)

# S3 method for class 'glm'
weights(object, type = c("prior", "working"), ...)

Arguments

formula an object of class "formula" (or one that can be coerced to that class): a symbolic description of the model to be fitted. The details of model specification are given under 'Details'.

family

a description of the error distribution and link function to be used in the model. This can be a character string naming a family function, a family function or the result of a call to a family function. (See family for details of family functions.)

data

an optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model. If not found in data, the variables are taken from environment(formula), typically the environment from which glm is called.

weights

an optional vector of ‘prior weights’ to be used in the fitting process. Should be NULL or a numeric vector.

subset

an optional vector specifying a subset of observations to be used in the fitting process.

na.action

a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The ‘factory-fresh’ default is na.omit. Another possible value is NULL, no action. Value na.exclude can be useful.

start

starting values for the parameters in the linear predictor.

etastart

starting values for the linear predictor.

mustart

starting values for the vector of means.

offset

this can be used to specify an a priori known component to be included in the linear predictor during fitting. This should be NULL or a numeric vector of length equal to the number of cases. One or more offset terms can be included in the formula instead or as well, and if more than one is specified their sum is used. See model.offset.

control

a list of parameters for controlling the fitting process. For glm.fit this is passed to glm.control.

model

a logical value indicating whether model frame should be included as a component of the returned value.

method

the method to be used in fitting the model. The default method "glm.fit" uses iteratively reweighted least squares (IWLS); the alternative "model.frame" returns the model frame and does no fitting.

User-supplied fitting functions can be supplied either as a function or a character string naming a function, with a function which takes the same arguments as glm.fit. If specified as a character string it is looked up from within the stats namespace.

x, y

For glm: logical values indicating whether the response vector and model matrix used in the fitting process should be returned as components of the returned value.

For glm.fit: x is a design matrix of dimension n * p, and y is a vector of observations of length n.

contrasts

an optional list. See the contrasts.arg of model.matrix.default.

intercept

logical. Should an intercept be included in the null model?

object

an object inheriting from class "glm".

type

character, partial matching allowed. Type of weights to extract from the fitted model object.
For \texttt{glm}: arguments to be used to form the default control argument if it is not supplied directly.
For \texttt{weights}: further arguments passed to or from other methods.

\section*{Details}

A typical predictor has the form \texttt{response \sim terms} where \texttt{response} is the (numeric) response vector and \texttt{terms} is a series of terms which specifies a linear predictor for \texttt{response}. For binomial and quasibinomial families the response can also be specified as a \texttt{factor} (when the first level denotes failure and all others success) or as a two-column matrix with the columns giving the numbers of successes and failures. A terms specification of the form \texttt{first + second} indicates all the terms in \texttt{first} together with all the terms in \texttt{second} with any duplicates removed.

A specification of the form \texttt{first:second} indicates the the set of terms obtained by taking the interactions of all terms in \texttt{first} with all terms in \texttt{second}. The specification \texttt{first*second} indicates the cross of \texttt{first} and \texttt{second}. This is the same as \texttt{first + second + first:second}.

The terms in the formula will be re-ordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on: to avoid this pass a \texttt{terms} object as the formula.

Non-NULL \texttt{weights} can be used to indicate that different observations have different dispersions (with the values in \texttt{weights} being inversely proportional to the dispersions); or equivalently, when the elements of \texttt{weights} are positive integers \(w_i\), that each response \(y_i\) is the mean of \(w_i\) unit-weight observations. For a binomial GLM prior weights are used to give the number of trials when the response is the proportion of successes: they would rarely be used for a Poisson GLM.

\texttt{glm.fit} is the workhorse function: it is not normally called directly but can be more efficient where the response vector and design matrix have already been calculated.

If more than one of \texttt{etastart}, \texttt{start} and \texttt{mustart} is specified, the first in the list will be used. It is often advisable to supply starting values for a \texttt{quasi} family, and also for families with unusual links such as \texttt{gaussian("log")}.

All of \texttt{weights}, \texttt{subset}, \texttt{offset}, \texttt{etastart} and \texttt{mustart} are evaluated in the same way as variables in \texttt{formula}, that is first in \texttt{data} and then in the environment of \texttt{formula}.

For the background to warning messages about ‘fitted probabilities numerically 0 or 1 occurred’ for binomial GLMs, see Venables \& Ripley (2002, pp. 197–8).

\section*{Value}

\texttt{glm} returns an object of class inheriting from "\texttt{glm}" which inherits from the class "\texttt{lmm}". See later in this section. If a non-standard method is used, the object will also inherit from the class (if any) returned by that function.

The function \texttt{summary} (i.e., \texttt{summary.glm}) can be used to obtain or print a summary of the results and the function \texttt{anova} (i.e., \texttt{anova.glm}) to produce an analysis of variance table.

The generic accessor functions \texttt{coefficients}, \texttt{effects}, \texttt{fitted.values} and \texttt{residuals} can be used to extract various useful features of the value returned by \texttt{glm}.

\texttt{weights} extracts a vector of weights, one for each case in the fit (after subsetting and \texttt{na.action}).

An object of class "\texttt{glm}" is a list containing at least the following components:

\begin{itemize}
  \item \texttt{coefficients} \quad a named vector of coefficients
\end{itemize}
residuals  the working residuals, that is the residuals in the final iteration of the IWLS fit. Since cases with zero weights are omitted, their working residuals are NA.

fitted.values  the fitted mean values, obtained by transforming the linear predictors by the inverse of the link function.

rank  the numeric rank of the fitted linear model.

family  the family object used.

linear.predictors  the linear fit on link scale.

deviance  up to a constant, minus twice the maximized log-likelihood. Where sensible, the constant is chosen so that a saturated model has deviance zero.

aic  A version of Akaike’s An Information Criterion, minus twice the maximized log-likelihood plus twice the number of parameters, computed by the aic component of the family. For binomial and Poisson families the dispersion is fixed at one and the number of parameters is the number of coefficients. For gaussian, Gamma and inverse gaussian families the dispersion is estimated from the residual deviance, and the number of parameters is the number of coefficients plus one. For a gaussian family the MLE of the dispersion is used so this is a valid value of AIC, but for Gamma and inverse gaussian families it is not. For families fitted by quasi-likelihood the value is NA.

null.deviance  The deviance for the null model, comparable with deviance. The null model will include the offset, and an intercept if there is one in the model. Note that this will be incorrect if the link function depends on the data other than through the fitted mean: specify a zero offset to force a correct calculation.

iter  the number of iterations of IWLS used.

weights  the working weights, that is the weights in the final iteration of the IWLS fit.

prior.weights  the weights initially supplied, a vector of 1s if none were.

df.residual  the residual degrees of freedom.

df.null  the residual degrees of freedom for the null model.

y  if requested (the default) the y vector used. (It is a vector even for a binomial model.)

x  if requested, the model matrix.

model  if requested (the default), the model frame.

converged  logical. Was the IWLS algorithm judged to have converged?

boundary  logical. Is the fitted value on the boundary of the attainable values?

call  the matched call.

formula  the formula supplied.

terms  the terms object used.

data  the data argument.

offset  the offset vector used.

control  the value of the control argument used.

method  the name of the fitter function used, currently always "glm.fit".
contrasts  (where relevant) the contrasts used.
xlevels    (where relevant) a record of the levels of the factors used in fitting.
na.action  (where relevant) information returned by \texttt{model.frame} on the special handling of NAs.

In addition, non-empty fits will have components \texttt{qr}, \texttt{R} and \texttt{effects} relating to the final weighted linear fit.

Objects of class "glm" are normally of class \texttt{c("glm", "lm")}, that is inherit from class "lm", and well-designed methods for class "lm" will be applied to the weighted linear model at the final iteration of IWLS. However, care is needed, as extractor functions for class "glm" such as \texttt{residuals} and \texttt{weights} do \textbf{not} just pick out the component of the fit with the same name.

If a binomial \texttt{glm} model was specified by giving a two-column response, the weights returned by \texttt{prior.weights} are the total numbers of cases (factored by the supplied case weights) and the component \texttt{y} of the result is the proportion of successes.

### Fitting functions

The argument \texttt{method} serves two purposes. One is to allow the model frame to be recreated with no fitting. The other is to allow the default fitting function \texttt{glm.fit} to be replaced by a function which takes the same arguments and uses a different fitting algorithm. If \texttt{glm.fit} is supplied as a character string it is used to search for a function of that name, starting in the \texttt{stats} namespace.

The class of the object return by the fitter (if any) will be prepended to the class returned by \texttt{glm}.

### Author(s)

The original \texttt{R} implementation of \texttt{glm} was written by Simon Davies working for Ross Ihaka at the University of Auckland, but has since been extensively re-written by members of the \texttt{R} Core team.

The design was inspired by the \texttt{S} function of the same name described in Hastie & Pregibon (1992).

glm.control

---

**glm.control**

**Auxiliary for Controlling GLM Fitting**

**Description**

Auxiliary function for glm fitting. Typically only used internally by glm.fit, but may be used to construct a control argument to either function.

**Usage**

```r
glm.control(epsilon = 1e-8, maxit = 25, trace = FALSE)
```

**Arguments**

- **epsilon**
  - positive convergence tolerance $\epsilon$: the iterations converge when $|dev - dev_{old}|/(|dev| + 0.1) < \epsilon$.
- **maxit**
  - integer giving the maximal number of IWLS iterations.
- **trace**
  - logical indicating if output should be produced for each iteration.
Details

The control argument of `glm` is by default passed to the control argument of `glm.fit`, which uses its elements as arguments to `glm.control`: the latter provides defaults and sanity checking.

If epsilon is small (less than $10^{-10}$) it is also used as the tolerance for the detection of collinearity in the least squares solution.

When trace is true, calls to `cat` produce the output for each IWLS iteration. Hence, `options(digits = *)` can be used to increase the precision, see the example.

Value

A list with components named as the arguments.

References

See Also

`glm.fit`, the fitting procedure used by `glm`.

Examples

```r
### A variation on example(glm) :

## Annette Dobson's example ...
counts <- c(18,17,15,20,10,20,25,13,12)
outcome <- gl(3,1,9)
treatment <- gl(3,3)
oo <- options(digits = 12) # to see more when tracing :
glm.D93X <- glm(counts ~ outcome + treatment, family = poisson(),
                 trace = TRUE, epsilon = 1e-14)
options(o)
coef(glm.D93X) # the last two are closer to 0 than in ?glm's glm.D93
```
glm.summaries

Usage

```r
## S3 method for class 'glm'
family(object, ...)

## S3 method for class 'glm'
residuals(object, type = c("deviance", "pearson", "working",
                          "response", "partial"), ...)
```

Arguments

- **object**: an object of class `glm`, typically the result of a call to `glm`
- **type**: the type of residuals which should be returned. The alternatives are: "deviance" (default), "pearson", "working", "response", and "partial".
- **...**: further arguments passed to or from other methods.

Details

The references define the types of residuals: Davison & Snell is a good reference for the usages of each.

The partial residuals are a matrix of working residuals, with each column formed by omitting a term from the model.

How `residuals` treats cases with missing values in the original fit is determined by the `na.action` argument of that fit. If `na.action = na.omit` omitted cases will not appear in the residuals, whereas if `na.action = na.exclude` they will appear, with residual value NA. See also `naresid`.

For fits done with `y = FALSE` the response values are computed from other components.

References

Hierarchical Clustering

Description

Hierarchical cluster analysis on a set of dissimilarities and methods for analyzing it.

Usage

hclust(d, method = "complete", members = NULL)

# S3 method for class 'hclust'
plot(x, labels = NULL, hang = 0.1,
     axes = TRUE, frame.plot = FALSE, ann = TRUE,
     main = "Cluster Dendrogram",
     sub = NULL, xlab = NULL, ylab = "Height", ...)

plclust(tree, hang = 0.1, unit = FALSE, level = FALSE, hmin = 0,
        square = TRUE, labels = NULL, plot. = TRUE,
        axes = TRUE, frame.plot = FALSE, ann = TRUE,
        main = "", sub = NULL, xlab = NULL, ylab = "Height")

Arguments

d             a dissimilarity structure as produced by dist.
method         the agglomeration method to be used. This should be (an unambiguous abbreviation of) one of "ward", "single", "complete", "average", "mcquitty", "median" or "centroid".
members        NULL or a vector with length size of d. See the ‘Details’ section.
x,tree          an object of the type produced by hclust.
hang          The fraction of the plot height by which labels should hang below the rest of the plot. A negative value will cause the labels to hang down from 0.
labels        A character vector of labels for the leaves of the tree. By default the row names or row numbers of the original data are used. If labels = FALSE no labels at all are plotted.
axes, frame.plot, ann
               logical flags as in plot.default.
main, sub, xlab, ylab
               character strings for title. sub and xlab have a non-NULL default when there's a tree$call.
...          Further graphical arguments.
unit          logical. If true, the splits are plotted at equally-spaced heights rather than at the height in the object.
hclust

hmin numeric. All heights less than hmin are regarded as being hmin: this can be used to suppress detail at the bottom of the tree.

level, square, plot. as yet unimplemented arguments of plclust for S-PLUS compatibility.

Details

This function performs a hierarchical cluster analysis using a set of dissimilarities for the $n$ objects being clustered. Initially, each object is assigned to its own cluster and then the algorithm proceeds iteratively, at each stage joining the two most similar clusters, continuing until there is just a single cluster. At each stage distances between clusters are recomputed by the Lance–Williams dissimilarity update formula according to the particular clustering method being used.

A number of different clustering methods are provided. Ward’s minimum variance method aims at finding compact, spherical clusters. The complete linkage method finds similar clusters. The single linkage method (which is closely related to the minimal spanning tree) adopts a ‘friends of friends’ clustering strategy. The other methods can be regarded as aiming for clusters with characteristics somewhere between the single and complete link methods. Note however, that methods "median" and "centroid" are not leading to a monotone distance measure, or equivalently the resulting dendrograms can have so called inversions (which are hard to interpret).

If members != NULL, then d is taken to be a dissimilarity matrix between clusters instead of dissimilarities between singletons and members gives the number of observations per cluster. This way the hierarchical cluster algorithm can be ‘started in the middle of the dendrogram’, e.g., in order to reconstruct the part of the tree above a cut (see examples). Dissimilarities between clusters can be efficiently computed (i.e., without hclust itself) only for a limited number of distance/linkage combinations, the simplest one being squared Euclidean distance and centroid linkage. In this case the dissimilarities between the clusters are the squared Euclidean distances between cluster means.

In hierarchical cluster displays, a decision is needed at each merge to specify which subtree should go on the left and which on the right. Since, for $n$ observations there are $n - 1$ merges, there are $2^{(n-1)}$ possible orderings for the leaves in a cluster tree, or dendrogram. The algorithm used in hclust is to order the subtree so that the tighter cluster is on the left (the last, i.e., most recent, merge of the left subtree is at a lower value than the last merge of the right subtree). Single observations are the tightest clusters possible, and merges involving two observations place them in order by their observation sequence number.

Value

An object of class hclust which describes the tree produced by the clustering process. The object is a list with components:

merge an $n - 1$ by 2 matrix. Row $i$ of merge describes the merging of clusters at step $i$ of the clustering. If an element $j$ in the row is negative, then observation $-j$ was merged at this stage. If $j$ is positive then the merge was with the cluster formed at the (earlier) stage $j$ of the algorithm. Thus negative entries in merge indicate agglomerations of singletons, and positive entries indicate agglomerations of non-singletons.

height a set of $n - 1$ real values (non-decreasing for ultrametric trees). The clustering height: that is, the value of the criterion associated with the clustering method for the particular agglomeration.
order a vector giving the permutation of the original observations suitable for plotting, in the sense that a cluster plot using this ordering and matrix merge will not have crossings of the branches.

labels labels for each of the objects being clustered.

call the call which produced the result.

method the cluster method that has been used.

dist.method the distance that has been used to create d (only returned if the distance object has a "method" attribute).

There are print, plot and identify (see identify.hclust) methods and the rect.hclust() function for hclust objects. The plclust() function is basically the same as the plot method, plot.hclust, primarily for back compatibility with S-PLUS. Its extra arguments are not yet implemented.

Author(s)

The hclust function is based on Fortran code contributed to STATLIB by F. Murtagh.

For the Lance–Williams formula and methods that apply it generally, see agnes from package cluster.

Examples

require(graphics)

hc <- hclust(dist(USArrests), "ave")
plot(hc)
plot(hc, hang = -1)
Do the same with centroid clustering and squared Euclidean distance, cut the tree into ten clusters and reconstruct the upper part of the tree from the cluster centers.

```r
hc <- hclust(dist(USArrests)^2, "cen")
memb <- cutree(hc, k = 10)
cent <- NULL
for(k in 1:10){
  cent <- rbind(cent, colMeans(USArrests[memb == k, , drop = FALSE]))
}
hc1 <- hclust(dist(cent)^2, method = "cen", members = table(memb))
opar <- par(mfrow = c(1, 2))
plot(hc, labels = FALSE, hang = -1, main = "Original Tree")
plot(hc1, labels = FALSE, hang = -1, main = "Re-start from 1/zero.noslash clusters")
par(opar)
```

---

**heatmap**

**Draw a Heat Map**

### Description

A heat map is a false color image (basically `image(t(x))`) with a dendrogram added to the left side and to the top. Typically, reordering of the rows and columns according to some set of values (row or column means) within the restrictions imposed by the dendrogram is carried out.

### Usage

```r
heatmap(x, Rowv = NULL, Colv = if(symm)"Rowv" else NULL,
distfun = dist, hclustfun = hclust,
reorderfun = function(d, w) reorder(d, w),
add.expr, symm = FALSE, revC = identical(Colv, "Rowv"),
scale = c("row", "column", "none"), na.rm = TRUE,
margins = c(5, 5), ColSideColors, RowSideColors,
cexRow = 0.2 + 1/log10(nr), cexCol = 0.2 + 1/log10(nc),
labRow = NULL, labCol = NULL, main = NULL,
xlab = NULL, ylab = NULL,
keep.dendro = FALSE, verbose = getOption("verbose"), ...)
```

### Arguments

- **x**
  - numeric matrix of the values to be plotted.

- **Rowv**
  - determines if and how the row dendrogram should be computed and reordered. Either a dendrogram or a vector of values used to reorder the row dendrogram or NA to suppress any row dendrogram (and reordering) or by default, NULL, see 'Details' below.

- **Colv**
  - determines if and how the column dendrogram should be reordered. Has the same options as the Rowv argument above and additionally when x is a square matrix, Colv = "Rowv" means that columns should be treated identically to the rows (and so if there is to be no row dendrogram there will not be a column one either).
distfun function used to compute the distance (dissimilarity) between both rows and columns. Defaults to dist.

hclustfun function used to compute the hierarchical clustering when Rowv or Colv are not dendrograms. Defaults to hclust. Should take as argument a result of distfun and return an object to which as.dendrogram can be applied.

reorderfun function(d, w) of dendrogram and weights for reordering the row and column dendrograms. The default uses reorder.dendrogram.

add.expr expression that will be evaluated after the call to image. Can be used to add components to the plot.

symm logical indicating if x should be treated symmetrically; can only be true when x is a square matrix.

revC logical indicating if the column order should be reversed for plotting, such that e.g., for the symmetric case, the symmetry axis is as usual.

scale character indicating if the values should be centered and scaled in either the row direction or the column direction, or none. The default is "row" if symm false, and "none" otherwise.

na.rm logical indicating whether NA’s should be removed.

margins numeric vector of length 2 containing the margins (see par(mar = *)) for column and row names, respectively.

ColSideColors (optional) character vector of length ncol(x) containing the color names for a horizontal side bar that may be used to annotate the columns of x.

RowSideColors (optional) character vector of length nrow(x) containing the color names for a vertical side bar that may be used to annotate the rows of x.

cexRow, cexCol positive numbers, used as cex.axis in for the row or column axis labeling. The defaults currently only use number of rows or columns, respectively.

labRow, labCol character vectors with row and column labels to use; these default to rrownames(x) or colnames(x), respectively.

main, xlab, ylab main, x- and y-axis titles; defaults to none.

keep.dendro logical indicating if the dendrogram(s) should be kept as part of the result (when Rowv and/or Colv are not NA).

verbose logical indicating if information should be printed.

... additional arguments passed on to image, e.g., col specifying the colors.

Details

If either Rowv or Colv are dendrograms they are honored (and not reordered). Otherwise, dendrograms are computed as dd <- as.dendrogram(hclustfun(distfun(X))) where X is either x or t(x).

If either is a vector (of 'weights') then the appropriate dendrogram is reordered according to the supplied values subject to the constraints imposed by the dendrogram, by reorder(dd, Rowv), in the row case. If either is missing, as by default, then the ordering of the corresponding dendrogram is by the mean value of the rows/columns, i.e., in the case of rows,
Rowv <- rowMeans(x, na.rm = na.rm). If either is NA, no reordering will be done for the corresponding side.

By default (scale = "row") the rows are scaled to have mean zero and standard deviation one. There is some empirical evidence from genomic plotting that this is useful.

The default colors are not pretty. Consider using enhancements such as the RColorBrewer package.

Value

Invisibly, a list with components

rowInd row index permutation vector as returned by order.dendrogram.

colInd column index permutation vector.

Rowv the row dendrogram; only if input Rowv was not NA and keep.dendro is true.

Colv the column dendrogram; only if input Colv was not NA and keep.dendro is true.

Note

Unless Rowv = NA (or Colw = NA), the original rows and columns are reordered in any case to match the dendrogram, e.g., the rows by order.dendrogram(Rowv) where Rowv is the (possibly reorder()ed) row dendrogram.

heatmap() uses layout and draws the image in the lower right corner of a 2x2 layout. Consequentially, it can not be used in a multi column/row layout, i.e., when par(mfrow = *) or (mfcol = *) has been called.

HoltWinters

**Holt-Winters Filtering**

**Description**

Computes Holt-Winters Filtering of a given time series. Unknown parameters are determined by minimizing the squared prediction error.

**Usage**

`HoltWinters(x, alpha = NULL, beta = NULL, gamma = NULL, seasonal = c("additive", "multiplicative"), start.periods = 2, l.start = NULL, b.start = NULL, s.start = NULL, optim.start = c(alpha = 0.3, beta = 0.1, gamma = 0.1), optim.control = list())`

**Arguments**

- `x` An object of class `ts`
alpha

-alpha parameter of Holt-Winters Filter.

beta

-beta parameter of Holt-Winters Filter. If set to FALSE, the function will do exponential smoothing.

gamma

gamma parameter used for the seasonal component. If set to FALSE, an non-seasonal model is fitted.

seasonal

Character string to select an "additive" (the default) or "multiplicative" seasonal model. The first few characters are sufficient. (Only takes effect if gamma is non-zero).

start.periods

Start periods used in the autodetection of start values. Must be at least 2.

l.start

Start value for level (a[0]).

b.start

Start value for trend (b[0]).

s.start

Vector of start values for the seasonal component (s[1][0]...s[p][0])

optim.start

Vector with named components alpha, beta, and gamma containing the starting values for the optimizer. Only the values needed must be specified. Ignored in the one-parameter case.

optim.control

Optional list with additional control parameters passed to optim if this is used. Ignored in the one-parameter case.

Details

The additive Holt-Winters prediction function (for time series with period length p) is

\[ \hat{Y}[t+h] = a[t] + hb[t] + s[t-p+1 + (h-1) \mod p], \]

where \( a[t], b[t] \) and \( s[t] \) are given by

\[ a[t] = \alpha(Y[t] - s[t-p]) + (1-\alpha)(a[t-1] + b[t-1]) \]
\[ b[t] = \beta(a[t] - a[t-1]) + (1-\beta)b[t-1] \]
\[ s[t] = \gamma(Y[t] - a[t]) + (1-\gamma)s[t-p] \]

The multiplicative Holt-Winters prediction function (for time series with period length p) is

\[ \hat{Y}[t+h] = (a[t] + hb[t]) \times s[t-p+1 + (h-1) \mod p]. \]

where \( a[t], b[t] \) and \( s[t] \) are given by

\[ a[t] = \alpha(Y[t]/s[t-p]) + (1-\alpha)(a[t-1] + b[t-1]) \]
\[ b[t] = \beta(a[t] - a[t-1]) + (1-\beta)b[t-1] \]
\[ s[t] = \gamma(Y[t]/a[t]) + (1-\gamma)s[t-p] \]

The data in \( x \) are required to be non-zero for a multiplicative model, but it makes most sense if they are all positive.

The function tries to find the optimal values of \( \alpha \) and/or \( \beta \) and/or \( \gamma \) by minimizing the squared one-step prediction error if they are NULL (the default). optimize will be used for the single-parameter case, and optim otherwise.
For seasonal models, start values for $a$, $b$ and $s$ are inferred by performing a simple decomposition in trend and seasonal component using moving averages (see function `decompose`) on the `start.periods` first periods (a simple linear regression on the trend component is used for starting level and trend). For level/trend-models (no seasonal component), start values for $a$ and $b$ are $x[2]$ and $x[2] - x[1]$, respectively. For level-only models (ordinary exponential smoothing), the start value for $a$ is $x[1]$.

**Value**

An object of class "HoltWinters", a list with components:

- `fitted`: A multiple time series with one column for the filtered series as well as for the level, trend and seasonal components, estimated contemporaneously (that is at time $t$ and not at the end of the series).
- `x`: The original series
- `alpha`: alpha used for filtering
- `beta`: beta used for filtering
- `gamma`: gamma used for filtering
- `coefficients`: A vector with named components $a$, $b$, $s1$, ..., $sp$ containing the estimated values for the level, trend and seasonal components
- `seasonal`: The specified seasonal parameter
- `SSE`: The final sum of squared errors achieved in optimizing
- `call`: The call used

**Examples**

```R
require(graphics)

## Seasonal Holt-Winters
(m <- HoltWinters(co2))
plot(m)
plot(fitted(m))
```
Hypergeometric

The Hypergeometric Distribution

Description

Density, distribution function, quantile function and random generation for the hypergeometric distribution.

Usage

dhyper(x, m, n, k, log = FALSE)
phyper(q, m, n, k, lower.tail = TRUE, log.p = FALSE)
qhyper(p, m, n, k, lower.tail = TRUE, log.p = FALSE)
rhyper(nn, m, n, k)

Arguments

x, q vector of quantiles representing the number of white balls drawn without replacement from an urn which contains both black and white balls.
m the number of white balls in the urn.
n the number of black balls in the urn.
k the number of balls drawn from the urn.
p probability, it must be between 0 and 1.
nn number of observations. If length(nn) > 1, the length is taken to be the number required.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).
The hypergeometric distribution is used for sampling without replacement. The density of this distribution with parameters \( m, n \) and \( k \) (named \( Np, N - Np \), and \( n \), respectively in the reference below) is given by

\[
p(x) = \frac{\binom{m}{x} \binom{n}{k-x}}{\binom{m+n}{k}}
\]

for \( x = 0, \ldots, k \).

The quantile is defined as the smallest value \( x \) such that \( F(x) \geq p \), where \( F \) is the distribution function.

**Value**

dhyper gives the density, phyper gives the distribution function, qhyper gives the quantile function, and rhyper generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by \( n \) for rhyper, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than \( n \) are recycled to the length of the result. Only the first elements of the logical parameters are used.

**Source**

dhyper computes via binomial probabilities, using code contributed by Catherine Loader (see dbinom).

phyper is based on calculating dhyper and phyper(...)/dhyper(...) (as a summation), based on ideas of Ian Smith and Morten Welinder.

qhyper is based on inversion.

**References**

**See Also**

Distributions for other standard distributions.

**Examples**

```r
m <- 10; n <- 7; k <- 8
x <- 0:(k+1)
rbind(phyper(x, m, n, k), dhyper(x, m, n, k))
all(phyper(x, m, n, k) == cumsum(dhyper(x, m, n, k)))  # FALSE
```
## but error is very small:
signif(phyper(x, m, n, k) - cumsum(dhyper(x, m, n, k)), digits = 3)

---

**identify.hclust**  
*Identify Clusters in a Dendrogram*

### Description

`identify.hclust` reads the position of the graphics pointer when the (first) mouse button is pressed. It then cuts the tree at the vertical position of the pointer and highlights the cluster containing the horizontal position of the pointer. Optionally a function is applied to the index of data points contained in the cluster.

### Usage

```r
## S3 method for class 'hclust'
identify(x, FUN = NULL, N = 2/zero.noslash, MAXCLUSTER = 2/zero.noslash, DEV.FUN = NULL, ...
```

### Arguments

- `x`: an object of the type produced by `hclust`.
- `FUN`: (optional) function to be applied to the index numbers of the data points in a cluster (see ‘Details’ below).
- `N`: the maximum number of clusters to be identified.
- `MAXCLUSTER`: the maximum number of clusters that can be produced by a cut (limits the effective vertical range of the pointer).
- `DEV.FUN`: (optional) integer scalar. If specified, the corresponding graphics device is made active before `FUN` is applied.
- `...`: further arguments to `FUN`.

### Details

By default clusters can be identified using the mouse and an *invisible* list of indices of the respective data points is returned.

If `FUN` is not NULL, then the index vector of data points is passed to this function as first argument, see the examples below. The active graphics device for `FUN` can be specified using `DEV.FUN`.

The identification process is terminated by pressing any mouse button other than the first, see also `identify`.

### Value

Either a list of data point index vectors or a list of return values of `FUN`. 
influence.measures

Regression Deletion Diagnostics

Description

This suite of functions can be used to compute some of the regression (leave-one-out deletion) diagnostics for linear and generalized linear models discussed in Belsley, Kuh and Welsch (1980), Cook and Weisberg (1982), etc.

Usage

influence.measures(model)

rstandard(model, ...)

## S3 method for class 'lm'
rstandard(model, infl = lm.influence(model, do.coef = FALSE),
    sd = sqrt(deviance(model)/df.residual(model)), ...)

## S3 method for class 'glm'
rstandard(model, infl = influence(model, do.coef = FALSE),
    type = c("deviance", "pearson"), ...)
rstudent(model, ...)  
## S3 method for class 'lm'  
rstudent(model, infl = lm.influence(model, do.coef = FALSE),  
        res = infl$wt.res, ...)  
## S3 method for class 'glm'  
rstudent(model, infl = influence(model, do.coef = FALSE), ...)  

dffits(model, infl = , res = )  

dfbeta(model, ...)  
## S3 method for class 'lm'  
dfbeta(model, infl = lm.influence(model, do.coef = TRUE), ...)  

dfbetas(model, ...)  
## S3 method for class 'lm'  
dfbetas(model, infl = lm.influence(model, do.coef = TRUE), ...)  

covratio(model, infl = lm.influence(model, do.coef = FALSE),  
        res = weighted.residuals(model))  

cooks.distance(model, ...)  
## S3 method for class 'lm'  
cooks.distance(model, infl = lm.influence(model, do.coef = FALSE),  
                  res = weighted.residuals(model),  
                  sd = sqrt(deviance(model)/df.residual(model)),  
                  hat = infl$hat, ...)  
## S3 method for class 'glm'  
cooks.distance(model, infl = influence(model, do.coef = FALSE),  
                  res = infl$pear.res,  
                  dispersion = summary(model)$dispersion,  
                  hat = infl$hat, ...)  

hatvalues(model, ...)  
## S3 method for class 'lm'  
hatvalues(model, infl = lm.influence(model, do.coef = FALSE), ...)  

hat(x, intercept = TRUE)

Arguments

model       an R object, typically returned by lm or glm.
inf1        influence structure as returned by lm.influence or influence (the latter only for the glm method of rstudent and cooks.distance).
res         (possibly weighted) residuals, with proper default.
sd          standard deviation to use, see default.
dispersion  dispersion (for glm objects) to use, see default.
hat         hat values $H_{ii}$, see default.
type: type of residuals for glm method for rstandard.

x: the X or design matrix.

intercept: should an intercept column be prepended to x?

...: further arguments passed to or from other methods.

Details

The primary high-level function is influence.measures which produces a class "infl" object tabular display showing the DFBETAS for each model variable, DFFITS, covariance ratios, Cook's distances and the diagonal elements of the hat matrix. Cases which are influential with respect to any of these measures are marked with an asterisk.

The functions dfbetas, dfits, covratio and cooks.distance provide direct access to the corresponding diagnostic quantities. Functions rstandard and rstudent give the standardized and Studentized residuals respectively. (These re-normalize the residuals to have unit variance, using an overall and leave-one-out measure of the error variance respectively.)

Values for generalized linear models are approximations, as described in Williams (1987) (except that Cook's distances are scaled as $F$ rather than as chi-square values). The approximations can be poor when some cases have large influence.

The optional infl, res and sd arguments are there to encourage the use of these direct access functions, in situations where, e.g., the underlying basic influence measures (from lm.influence or the generic influence) are already available.

Note that cases with weights == 0 are dropped from all these functions, but that if a linear model has been fitted with na.action = na.exclude, suitable values are filled in for the cases excluded during fitting.

The function hat() exists mainly for S (version 2) compatibility; we recommend using hatvalues() instead.

Note

For hatvalues, dfbeta, and dfbetas, the method for linear models also works for generalized linear models.

Author(s)

Several R core team members and John Fox, originally in his ‘car’ package.

cooks.distance(lmI)))

---

integrate

*Integration of One-Dimensional Functions*

**Description**

Adaptive quadrature of functions of one variable over a finite or infinite interval.
Usage

integrate(f, lower, upper, ..., subdivisions = 100L,
       rel.tol = .Machine$double.eps^0.25, abs.tol = rel.tol,
       stop.on.error = TRUE, keep.xy = FALSE, aux = NULL)

Arguments

f       an R function taking a numeric first argument and returning a numeric vector of
         the same length. Returning a non-finite element will generate an error.
lower, upper     the limits of integration. Can be infinite.
...          additional arguments to be passed to f.
subdivisions    the maximum number of subintervals.
rel.tol         relative accuracy requested.
abs.tol         absolute accuracy requested.
stop.on.error   logical. If true (the default) an error stops the function. If false some errors will
                give a result with a warning in the message component.
keep.xy         unused. For compatibility with S.
aux             unused. For compatibility with S.

Details

Note that arguments after ... must be matched exactly.

If one or both limits are infinite, the infinite range is mapped onto a finite interval.

For a finite interval, globally adaptive interval subdivision is used in connection with extrapolation
by Wynn’s Epsilon algorithm, with the basic step being Gauss–Kronrod quadrature.

rel.tol cannot be less than max(50*.Machine$double.eps, 0.5e-28) if abs.tol <= 0.

Value

A list of class "integrate" with components

value       the final estimate of the integral.
abs.error   estimate of the modulus of the absolute error.
subdivisions the number of subintervals produced in the subdivision process.
message     "OK" or a character string giving the error message.
call        the matched call.

Note

Like all numerical integration routines, these evaluate the function on a finite set of points. If the
function is approximately constant (in particular, zero) over nearly all its range it is possible that the
result and error estimate may be seriously wrong.

When integrating over infinite intervals do so explicitly, rather than just using a large number as
the endpoint. This increases the chance of a correct answer – any function whose integral over an
infinite interval is finite must be near zero for most of that interval.
For values at a finite set of points to be a fair reflection of the behaviour of the function elsewhere, the function needs to be well-behaved, for example differentiable except perhaps for a small number of jumps or integrable singularities.

f must accept a vector of inputs and produce a vector of function evaluations at those points. The Vectorize function may be helpful to convert f to this form.

Source

Based on QUADPACK routines dqags and dqagi by R. Piessens and E. deDoncker–Kapenga, available from Netlib.

Examples

```r
integrate(dnorm, -1.96, 1.96)
integrate(dnorm, -Inf, Inf)

## a slowly-convergent integral
integrand <- function(x) {1/((x+1)*sqrt(x))}
integrate(integrand, lower = 0, upper = Inf)

## don't do this if you really want the integral from 0 to Inf
integrate(integrand, lower = 0, upper = 10)
integrate(integrand, lower = 0, upper = 100000)
integrate(integrand, lower = 0, upper = 1000000, stop.on.error = FALSE)

## some functions do not handle vector input properly
f <- function(x) 2.0
try(integrate(f, 0, 1))
integrate(Vectorize(f), 0, 1)  ## correct
integrate(function(x) rep(2.0, length(x)), 0, 1)  ## correct

## integrate can fail if misused
integrate(dnorm, 0, 2)
integrate(dnorm, 0, 20)
integrate(dnorm, 0, 200)
integrate(dnorm, 0, 2000)
integrate(dnorm, 0, 20000)  ## fails on many systems
integrate(dnorm, 0, Inf)  ## works
```
**interaction.plot**

**Description**

Plots the mean (or other summary) of the response for two-way combinations of factors, thereby illustrating possible interactions.

**Usage**

```r
interaction.plot(x.factor, trace.factor, response, fun = mean,
                 type = c("l", "p", "b", "o", "c"), legend = TRUE,
                 trace.label = deparse(substitute(trace.factor)),
                 fixed = FALSE,
                 xlab = deparse(substitute(x.factor)),
                 ylab = ylabel,
                 ylim = range(cells, na.rm = TRUE),
                 lty = nc:1, col = 1, pch = c(1:9, 0, letters),
                 xpd = NULL, leg.bg = par("bg"), leg.bty = "n",
                 xtick = FALSE, xaxt = par("xaxt"), axes = TRUE,
                 ...)  
```

**Arguments**

- **x.factor**: a factor whose levels will form the x axis.
- **trace.factor**: another factor whose levels will form the traces.
- **response**: a numeric variable giving the response
- **fun**: the function to compute the summary. Should return a single real value.
- **type**: the type of plot (see `plot.default`): lines or points or both.
- **legend**: logical. Should a legend be included?
- **trace.label**: overall label for the legend.
- **fixed**: logical. Should the legend be in the order of the levels of `trace.factor` or in the order of the traces at their right-hand ends?
- **xlab, ylab**: the x and y label of the plot each with a sensible default.
- **ylim**: numeric of length 2 giving the y limits for the plot.
- **lty**: line type for the lines drawn, with sensible default.
- **col**: the color to be used for plotting.
- **pch**: a vector of plotting symbols or characters, with sensible default.
- **xpd**: determines clipping behaviour for the `legend` used, see `par(xpd)`. Per default, the legend is not clipped at the figure border.
- **leg.bg, leg.bty**: arguments passed to `legend()`.
- **xtick**: logical. Should tick marks be used on the x axis?
- **xaxt, axes, ...**: graphics parameters to be passed to the plotting routines.
Details

By default the levels of x.factor are plotted on the x axis in their given order, with extra space left at the right for the legend (if specified). If x.factor is an ordered factor and the levels are numeric, these numeric values are used for the x axis.

The response and hence its summary can contain missing values. If so, the missing values and the line segments joining them are omitted from the plot (and this can be somewhat disconcerting).

The graphics parameters xlab, ylab, ylim, lty, col and pch are given suitable defaults (and xlim and xaxs are set and cannot be overridden). The defaults are to cycle through the line types, use the foreground colour, and to use the symbols 1:9, 0, and the capital letters to plot the traces.

Note

Some of the argument names and the precise behaviour are chosen for S-compatibility.

  with(esophNA, {
    interaction.plot(agegp, alcgp, ncases/ncontrols, col = 2:5)
IQR

The Interquartile Range

Description

computes interquartile range of the \( x \) values.

Usage

\[
\text{IQR}(x, \ na.rm = \text{FALSE}, \ type = 7)
\]

Arguments

- \( x \) a numeric vector.
- \( na.rm \) logical. Should missing values be removed?
- \( type \) an integer selecting one of the many quantile algorithms, see \texttt{quantile}.

Details

Note that this function computes the quartiles using the \texttt{quantile} function rather than following Tukey’s recommendations, i.e., \( \text{IQR}(x) = \text{quantile}(x, 3/4) - \text{quantile}(x, 1/4) \).

For normally \( N(m,1) \) distributed \( X \), the expected value of \( \text{IQR}(X) \) is \( 2*\text{qnorm}(3/4) = 1.3490 \), i.e., for a normal-consistent estimate of the standard deviation, use \( \text{IQR}(x) / 1.349 \).

Examples

\[
\text{IQR(rivers)}
\]
Test if a Model's Formula is Empty

Description

R's formula notation allows models with no intercept and no predictors. These require special handling internally. `is.empty.model()` checks whether an object describes an empty model.

Usage

```r
is.empty.model(x)
```

Arguments

- `x`: A `terms` object or an object with a `terms` method.

Value

`TRUE` if the model is empty.

See Also

- `lm`, `glm`

Examples

```r
y <- rnorm(20)
is.empty.model(y ~ 0)
is.empty.model(y ~ -1)
is.empty.model(lm(y ~ 0))
```

Isotonic / Monotone Regression

Description

Compute the isotonic (monotonely increasing nonparametric) least squares regression which is piecewise constant.

Usage

```r
isoreg(x, y = NULL)
```

Arguments

- `x`, `y`: coordinate vectors of the regression points. Alternatively a single plotting structure can be specified: see `xy.coords`.
Details

The algorithm determines the convex minorant \( m(x) \) of the cumulative data (i.e., \( \text{cumsum}(y) \)) which is piecewise linear and the result is \( m'(x) \), a step function with level changes at locations where the convex \( m(x) \) touches the cumulative data polygon and changes slope. \( \text{as.stepfun()} \) returns a stepfun object which can be more parsimonious.

Value

`isoreg()` returns an object of class `isoreg` which is basically a list with components

- `x` original (constructed) abscissa values \( x \).
- `y` corresponding \( y \) values.
- `yf` fitted values corresponding to ordered \( x \) values.
- `yc` cumulative \( y \) values corresponding to ordered \( x \) values.
- `iKnots` integer vector giving indices where the fitted curve jumps, i.e., where the convex minorant has kinks.
- `isOrd` logical indicating if original \( x \) values were ordered increasingly already.
- `ord` if(!isOrd): integer permutation `order(x)` of original \( x \).
- `call` the call to `isoreg()` used.

Note

The code should be improved to accept `weights` additionally and solve the corresponding weighted least squares problem.

‘Patches are welcome!’

References

See Also

the plotting method `plot.isoreg` with more examples; `isoMDS()` from the MASS package internally uses isotonic regression.

Examples

```r
require(graphics)

(ir <- isoreg(c(1,0,4,3,3,5,4,2)))
plot(ir, plot.type = "row")

(ir3 <- isoreg(y3 <- c(1,0,4,3,3,5,4,2, 3))) # last "3", not "0"
(fi3 <- as.stepfun(ir3))
(ir4 <- isoreg(1:10, y4 <- c(5, 9, 1:2, 5:8, 3, 8)))
```
\[
\text{cat(sprintf("R^2 = %.2f\n",}
1 - \text{sum(residuals(ir4)^2) / ((1/zero.noslash-1)*var(y4))})
\]

## If you are interested in the knots alone:
\text{with(ir4, cbind(iKnots, yf[iKnots])})

## Example of unordered \text{x[]} with ties:
\text{x <- sample((/zero.noslash:3/zero.noslash)/8)}
y <- \text{exp(x)}
x. <- \text{round(x)} \# ties!
\text{plot(m <- isoreg(x., y))}
\text{stopifnot(all.equal(with(m, yf[iKnots]),}
\text{as.vector(tapply(y, x., mean))})}

---

**KalmanLike**

**Kalman Filtering**

**Description**

Use Kalman Filtering to find the (Gaussian) log-likelihood, or for forecasting or smoothing.

**Usage**

- `KalmanLike(y, mod, nit = /zero.noslash, fast = TRUE)`
- `KalmanRun(y, mod, nit = /zero.noslash, fast = TRUE)`
- `KalmanSmooth(y, mod, nit = /zero.noslash)`
- `KalmanForecast(n.ahead = /zero.noslash, mod, fast = TRUE)`
- `makeARIMA(phi, theta, Delta, kappa = 1e6)`

**Arguments**

- **y**
  - a univariate time series.
- **mod**
  - A list describing the state-space model: see ‘Details’.
- **nit**
  - The time at which the initialization is computed. \text{nit = 0} implies that the initialization is for a one-step prediction, so \text{Pn} should not be computed at the first step.
- **n.ahead**
  - The number of steps ahead for which prediction is required.
- **phi, theta**
  - numeric vectors of length ≥ 0 giving AR and MA parameters.
- **Delta**
  - vector of differencing coefficients, so an ARMA model is fitted to \text{y[t] - Delta[1]*y[t-1] - ...}
- **kappa**
  - the prior variance (as a multiple of the innovations variance) for the past observations in a differenced model.
- **fast**
  - If TRUE the mod object may be modified.
Details

These functions work with a general univariate state-space model with state vector \( a \), transitions \( a \leftarrow T a + R e \), \( e \sim \mathcal{N}(0, \kappa Q) \) and observation equation \( y = Z'a + \eta \), \( \eta \sim \mathcal{N}(0, \kappa h) \). The likelihood is a profile likelihood after estimation of \( \kappa \).

The model is specified as a list with at least components

- \( T \) the transition matrix
- \( Z \) the observation coefficients
- \( h \) the observation variance
- \( V \) ‘RQR’
- \( a \) the current state estimate
- \( P \) the current estimate of the state uncertainty matrix
- \( P_n \) the estimate at time \( t - 1 \) of the state uncertainty matrix

KalmanSmooth is the workhorse function for \( \text{tsSmooth} \).
makeARIMA constructs the state-space model for an ARIMA model.

Value

For \( \text{KalmanLike} \), a list with components \( \text{Lik} \) (the log-likelihood less some constants) and \( s2 \), the estimate of \( \kappa \).

For \( \text{KalmanRun} \), a list with components \( \text{values} \), a vector of length 2 giving the output of \( \text{KalmanLike} \), \( \text{resid} \) (the residuals) and \( \text{states} \), the contemporaneous state estimates, a matrix with one row for each time.

For \( \text{KalmanSmooth} \), a list with two components. Component \( \text{smooth} \) is a \( n \) by \( p \) matrix of state estimates based on all the observations, with one row for each time. Component \( \text{var} \) is a \( n \) by \( p \) by \( p \) array of variance matrices.

For \( \text{KalmanForecast} \), a list with components \( \text{pred} \), the predictions, and \( \text{var} \), the unscaled variances of the prediction errors (to be multiplied by \( s2 \)).

For \( \text{makeARIMA} \), a model list including components for its arguments.

Warning

These functions are designed to be called from other functions which check the validity of the arguments passed, so very little checking is done.

In particular, \( \text{KalmanLike} \) alters the objects passed as the elements \( a, P \) and \( P_n \) of \( \text{mod} \), so these should not be shared. Use \( \text{fast=FALSE} \) to prevent this.

References

See Also

\( \text{arima, StructTS, tsSmooth} \).
Description

kernapply computes the convolution between an input sequence and a specific kernel.

Usage

kernapply(x, ...)

## Default S3 method:
kernapply(x, k, circular = FALSE, ...)
## S3 method for class 'ts'
kernapply(x, k, circular = FALSE, ...)
## S3 method for class 'vector'
kernapply(x, k, circular = FALSE, ...)
## S3 method for class 'tskernel'
kernapply(x, k, circular = FALSE, ...)

Arguments

x an input vector, matrix, time series or kernel to be smoothed.
k smoothing "tskernel" object.
circular a logical indicating whether the input sequence to be smoothed is treated as circular, i.e., periodic.
... arguments passed to or from other methods.

Value

A smoothed version of the input sequence.

Note

This uses fft to perform the convolution, so is fastest when NROW(x) is a power of 2 or some other highly composite integer.

Examples

## see 'kernel' for examples

### Smoothing Kernel Objects

#### Description

The "tskernel" class is designed to represent discrete symmetric normalized smoothing kernels. These kernels can be used to smooth vectors, matrices, or time series objects.

There are `print`, `plot` and `[ methods for these kernel objects.

#### Usage

```r
kernel(coef, m = 2, r, name)
df.kernel(k)
bandwidth.kernel(k)
is.tskernel(k)
```

#### Arguments

- `coef` the upper half of the smoothing kernel coefficients (including coefficient zero) or the name of a kernel (currently "daniell", "dirichlet", "fejer" or "modified.daniell".
- `m` the kernel dimension(s) if `coef` is a name. When `m` has length larger than one, it means the convolution of kernels of dimension `m[j]`, for `j` in `1:length(m)`. Currently this is supported only for the named "daniell" kernels.
- `name` the name the kernel will be called.
- `r` the kernel order for a Fejer kernel.
- `k, x` a "tskernel" object.
- `type, xlab, ylab, main, ...` arguments passed to `plot.default`.

#### Details

`kernel` is used to construct a general kernel or named specific kernels. The modified Daniell kernel halves the end coefficients (as used by S-PLUS).

The `[ method allows natural indexing of kernel objects with indices in `(−m) : m`. The normalization is such that for `k <- kernel(*)`, `sum(k[-k$m : k$m])` is one.

`df.kernel` returns the ‘equivalent degrees of freedom’ of a smoothing kernel as defined in Brockwell and Davis (1991), page 362, and `bandwidth.kernel` returns the equivalent bandwidth as defined in Bloomfield (1976), p. 201, with a continuity correction.
Value

kernel() returns an object of class "tskernel" which is basically a list with the two components coef and the kernel dimension m. An additional attribute is "name".

Examples

```r
require(graphics)

## Demonstrate a simple trading strategy for the
## financial time series German stock index DAX.

x <- EuStockMarkets[,1]
k1 <- kernel("daniell", 50)  # a long moving average
k2 <- kernel("daniell", 10)  # and a short one
plot(k1)
plot(k2)
x1 <- kernapply(x, k1)
x2 <- kernapply(x, k2)
plot(x)
lines(x1, col = "red")  # go long if the short crosses the long upwards
lines(x2, col = "green")  # and go short otherwise

## More interesting kernels

kd <- kernel("daniell", c(3, 3))
kd # note the unusual indexing
kd[-2:2]
plot(kernel("fejer", 100, r = 6))
plot(kernel("modified.daniell", c(7,5,3)))

# Reproduce example 10.4.3 from Brockwell and Davis (1991)
spectrum(sunspot.year, kernel = kernel("daniell", c(11,7,3)), log = "no")
```
**kmeans**

**K-Means Clustering**

**Description**
Perform k-means clustering on a data matrix.

**Usage**
```r
kmeans(x, centers, iter.max = 10, nstart = 1,
       algorithm = c("Hartigan-Wong", "Lloyd", "Forgy",
                    "MacQueen"))
```

**Arguments**
- **x** numeric matrix of data, or an object that can be coerced to such a matrix (such as a numeric vector or a data frame with all numeric columns).
- **centers** either the number of clusters, say k, or a set of initial (distinct) cluster centres. If a number, a random set of (distinct) rows in x is chosen as the initial centres.
- **iter.max** the maximum number of iterations allowed.
- **nstart** if centers is a number, how many random sets should be chosen?
- **algorithm** character: may be abbreviated.
- **object** an R object of class "kmeans", typically the result of object <- kmeans(..).
- **method** character: may be abbreviated. "centers" causes fitted to return cluster centres (one for each input point) and "classes" causes fitted to return a vector of class assignments.
- **...** not used.

**Details**
The data given by x is clustered by the k-means method, which aims to partition the points into k groups such that the sum of squares from points to the assigned cluster centres is minimized. At the minimum, all cluster centres are at the mean of their Voronoi sets (the set of data points which are nearest to the cluster centre).

The algorithm of Hartigan and Wong (1979) is used by default. Note that some authors use k-means to refer to a specific algorithm rather than the general method: most commonly the algorithm given by MacQueen (1967) but sometimes that given by Lloyd (1957) and Forgy (1965). The Hartigan–Wong algorithm generally does a better job than either of those, but trying several random starts (nstart > 1) is often recommended. For ease of programmatic exploration, k = 1 is allowed, notably returning the center and withins.

Except for the Lloyd–Forgy method, k clusters will always be returned if a number is specified. If an initial matrix of centres is supplied, it is possible that no point will be closest to one or more centres, which is currently an error for the Hartigan–Wong method.
**Value**

`kmeans` returns an object of class "kmeans" which has a `print` and a `fitted` method. It is a list with components:

- **cluster**
  A vector of integers (from 1:k) indicating the cluster to which each point is allocated.

- **centers**
  A matrix of cluster centres.

- **totss**
  The total sum of squares.

- **withinss**
  Vector of within-cluster sum of squares, one component per cluster.

- **tot.withinss**
  Total within-cluster sum of squares, i.e., `sum(withinss)`.

- **betweenss**
  The between-cluster sum of squares, i.e. `totss - tot.withinss`.

- **size**
  The number of points in each cluster.

**References**

**Examples**

```r
require(graphics)

# a 2-dimensional example
x <- rbind(matrix(rnorm(100, sd = 0.3), ncol = 2),
           matrix(rnorm(100, mean = 1, sd = 0.3), ncol = 2))
colnames(x) <- c("x", "y")
(cl <- kmeans(x, 2))
plot(x, col = cl$cluster)
points(cl$centers, col = 1:2, pch = 8, cex = 2)

# sum of squares
ss <- function(x) sum(scale(x, scale = FALSE)^2)
## cluster centers "fitted" to each obs.:
fitted.x <- fitted(cl);  head(fitted.x)
resid.x <- x - fitted(cl)

## Equalities : ----------------------------------
cbind(cl[c("betweens", "tot.withinss", "totss")], # the same two columns
      c(ss(fitted.x), ss(resid.x), ss(x)))
stopifnot(all.equal(cl$totss, ss(x)),
          all.equal(cl$totss - cl$tot.withinss, ss(x)),
          all.equal(SSB, SSW))
```

```
all.equal(cl$ tot.withinss, ss(resid.x)),
## these three are the same:
all.equal(cl$ betweenss, ss(fitted.x)),
all.equal(cl$ betweenss, cl$totss - cl$tot.withinss),
## and hence also
all.equal(ss(x), ss(fitted.x) + ss(resid.x))
)
kmeans(x,1)$withinss # trivial one-cluster, (its W.SS == ss(x))

## random starts do help here with too many clusters
## (and are often recommended anyway!):
(cl <- kmeans(x, 5, nstart = 25))
plot(x, col = cl$cluster)
points(cl$centers, col = 1:5, pch = 8)

kruskal.test  Kruskal-Wallis Rank Sum Test

Description

Performs a Kruskal-Wallis rank sum test.

Usage

kruskal.test(x, ...)

## Default S3 method:
kruskal.test(x, g, ...)

## S3 method for class 'formula'
kruskal.test(formula, data, subset, na.action, ...)

Arguments

x            a numeric vector of data values, or a list of numeric data vectors.
g            a vector or factor object giving the group for the corresponding elements of x.
             Ignored if x is a list.
formula      a formula of the form lhs ~ rhs where lhs gives the data values and rhs the
             corresponding groups.
data          an optional matrix or data frame (or similar: see model.frame) containing
             the variables in the formula formula. By default the variables are taken from
             environment(formula).
subset        an optional vector specifying a subset of observations to be used.
na.action     a function which indicates what should happen when the data contain NAs. De-
             fault togetOption("na.action").
...           further arguments to be passed to or from methods.
kruskal.test

Details

kruskal.test performs a Kruskal-Wallis rank sum test of the null that the location parameters of the distribution of \( x \) are the same in each group (sample). The alternative is that they differ in at least one.

If \( x \) is a list, its elements are taken as the samples to be compared, and hence have to be numeric data vectors. In this case, \( g \) is ignored, and one can simply use \( \text{kruskal.test}(x) \) to perform the test. If the samples are not yet contained in a list, use \( \text{kruskal.test(list}(x, \ldots)) \).

Otherwise, \( x \) must be a numeric data vector, and \( g \) must be a vector or factor object of the same length as \( x \) giving the group for the corresponding elements of \( x \).

Value

A list with class "htest" containing the following components:

- **statistic**: the Kruskal-Wallis rank sum statistic.
- **parameter**: the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- **p.value**: the p-value of the test.
- **method**: the character string "Kruskal-Wallis rank sum test".
- **data.name**: a character string giving the names of the data.

require(graphics)
boxplot(Ozone ~ Month, data = airquality)
kruskal.test(Ozone ~ Month, data = airquality)

---

### ks.test

**Kolmogorov-Smirnov Tests**

**Description**

Perform a one- or two-sample Kolmogorov-Smirnov test.

**Usage**

```r
ks.test(x, y, ..., 
  alternative = c("two.sided", "less", "greater"), 
  exact = NULL)
```

**Arguments**

- **x**: a numeric vector of data values.
- **y**: either a numeric vector of data values, or a character string naming a cumulative distribution function or an actual cumulative distribution function such as `pnorm`. Only continuous CDFs are valid.
- **...**: parameters of the distribution specified (as a character string) by y.
- **alternative**: indicates the alternative hypothesis and must be one of "two.sided" (default), "less", or "greater". You can specify just the initial letter of the value, but the argument name must be give in full. See ‘Details’ for the meanings of the possible values.
- **exact**: NULL or a logical indicating whether an exact p-value should be computed. See ‘Details’ for the meaning of NULL. Not available in the two-sample case for a one-sided test or if ties are present.

**Details**

If `y` is numeric, a two-sample test of the null hypothesis that `x` and `y` were drawn from the same continuous distribution is performed.

Alternatively, `y` can be a character string naming a continuous (cumulative) distribution function, or such a function. In this case, a one-sample test is carried out of the null that the distribution function which generated `x` is distribution `y` with parameters specified by . . .

The presence of ties always generates a warning, since continuous distributions do not generate them. If the ties arose from rounding the tests may be approximately valid, but even modest amounts of rounding can have a significant effect on the calculated statistic.
Missing values are silently omitted from \( x \) and (in the two-sample case) \( y \).

The possible values "two.sided", "less" and "greater" of alternative specify the null hypothesis that the true distribution function of \( x \) is equal to, not less than or not greater than the hypothesized distribution function (one-sample case) or the distribution function of \( y \) (two-sample case), respectively. This is a comparison of cumulative distribution functions, and the test statistic is the maximum difference in value, with the statistic in the "greater" alternative being

\[
D^+ = \max_u [F_x(u) - F_y(u)].
\]

Thus in the two-sample case alternative = "greater" includes distributions for which \( x \) is stochastically smaller than \( y \) (the CDF of \( x \) lies above and hence to the left of that for \( y \)), in contrast to \texttt{t.test} or \texttt{wilcox.test}.

Exact p-values are not available for the two-sample case if one-sided or in the presence of ties. If \texttt{exact} = \texttt{NULL} (the default), an exact p-value is computed if the sample size is less than 100 in the one-sample case and there are no ties, and if the product of the sample sizes is less than 10000 in the two-sample case. Otherwise, asymptotic distributions are used whose approximations may be inaccurate in small samples. In the one-sample two-sided case, exact p-values are obtained as described in Marsaglia, Tsang & Wang (2003) (but not using the optional approximation in the right tail, so this can be slow for small p-values). The formula of Birnbaum & Tingey (1951) is used for the one-sample one-sided case.

If a single-sample test is used, the parameters specified in ... must be pre-specified and not estimated from the data. There is some more refined distribution theory for the KS test with estimated parameters (see Durbin, 1973), but that is not implemented in \texttt{ks.test}.

**Value**

A list with class "htest" containing the following components:

- \texttt{statistic} the value of the test statistic.
- \texttt{p.value} the p-value of the test.
- \texttt{alternative} a character string describing the alternative hypothesis.
- \texttt{method} a character string indicating what type of test was performed.
- \texttt{data.name} a character string giving the name(s) of the data.

**Source**

See Also

`shapiro.test` which performs the Shapiro-Wilk test for normality.

Examples

```r
require(graphics)

x <- rnorm(50)
y <- runif(30)
# Do x and y come from the same distribution?
ks.test(x, y)
# Does x come from a shifted gamma distribution with shape 3 and rate 2?
ks.test(x+2, "pgamma", 3, 2) # two-sided, exact
ks.test(x+2, "pgamma", 3, 2, exact = FALSE)
ks.test(x+2, "pgamma", 3, 2, alternative = "gr")

# test if x is stochastically larger than x2
x2 <- rnorm(50, -1)
plot(ecdf(x), xlim = range(c(x, x2)))
plot(ecdf(x2), add = TRUE, lty = "dashed")
t.test(x, x2, alternative = "g")
wilcox.test(x, x2, alternative = "g")
ks.test(x, x2, alternative = "l")
```

Description

The Nadaraya–Watson kernel regression estimate.

Usage

```r
ksmooth(x, y, kernel = c("box", "normal"), bandwidth = 0.5,
range.x = range(x),
n.points = max(100L, length(x)), x.points)
```

Arguments

- `x` input x values. Long vectors are supported.
- `y` input y values. Long vectors are supported.
- `kernel` the kernel to be used.
- `bandwidth` the bandwidth. The kernels are scaled so that their quartiles (viewed as probability densities) are at ± 0.25*bandwidth.
- `range.x` the range of points to be covered in the output.
- `n.points` the number of points at which to evaluate the fit.
- `x.points` points at which to evaluate the smoothed fit. If missing, `n.points` are chosen uniformly to cover `range.x`. Long vectors are supported.
Value

A list with components

- \( x \) values at which the smoothed fit is evaluated. Guaranteed to be in increasing order.
- \( y \) fitted values corresponding to \( x \).

Note

This function was implemented for compatibility with S, although it is nowhere near as slow as the S function. Better kernel smoothers are available in other packages such as **KernSmooth**.

Examples

```r
require(graphics)

with(cars, {
  plot(speed, dist)
  lines(ksmooth(speed, dist, "normal", bandwidth = 2), col = 2)
  lines(ksmooth(speed, dist, "normal", bandwidth = 5), col = 3)
})
```

### lag

**Lag a Time Series**

Description

Compute a lagged version of a time series, shifting the time base back by a given number of observations.

Usage

```r
lag(x, ...)
```

#### Default S3 method:

```r
lag(x, k = 1, ...)
```

Arguments

- \( x \) A vector or matrix or univariate or multivariate time series
- \( k \) The number of lags (in units of observations).
- \( ... \) further arguments to be passed to or from methods.

Details

Vector or matrix arguments \( x \) are coerced to time series.

`lag` is a generic function; this page documents its default method.
Value
A time series object.

Note
Note the sign of k: a series lagged by a positive k starts earlier.

References

See Also
diff, deltat

Examples
lag(ldeaths, 12) # starts one year earlier

---

**lag.plot**  
*Time Series Lag Plots*

Description
Plot time series against lagged versions of themselves. Helps visualizing ‘auto-dependence’ even when auto-correlations vanish.

Usage

```r
lag.plot(x, lags = 1, layout = NULL, set.lags = 1:lags,
main = NULL, asp = 1,
diag = TRUE, diag.col = "gray", type = "p", oma = NULL,
ask = NULL, do.lines = (n <= 150), labels = do.lines,
...)
```

Arguments
- **x**  
time-series (univariate or multivariate)
- **lags**  
number of lag plots desired, see arg set.lags.
- **layout**  
the layout of multiple plots, basically the mfrow par() argument. The default uses about a square layout (see n2mfrow such that all plots are on one page.
- **set.lags**  
vector of positive integers allowing specification of the set of lags used; defaults to 1:lags.
- **main**  
character with a main header title to be done on the top of each page.
- **asp**  
Aspect ratio to be fixed, see plot.default.
lag.plot

diag logical indicating if the x=y diagonal should be drawn.
diag.col color to be used for the diagonal if(diag).
type plot type to be used, but see plot.ts about its restricted meaning.
oma outer margins, see par.
ask logical or NULL; if true, the user is asked to confirm before a new page is started.
do.lines logical indicating if lines should be drawn.
layers logical indicating if labels should be used.
...

Further arguments to plot.ts. Several graphical parameters are set in this function and so cannot be changed: these include xlab, ylab, mgp, col.lab and font.lab: this also applies to the arguments xy.labels and xy.lines.

Details

If just one plot is produced, this is a conventional plot. If more than one plot is to be produced, par(mfrow) and several other graphics parameters will be set, so it is not (easily) possible to mix such lag plots with other plots on the same page.

If ask = NULL, par(ask = TRUE) will be called if more than one page of plots is to be produced and the device is interactive.

Note

It is more flexible and has different default behaviour than the S version. We use main = instead of head = for internal consistency.

Author(s)

Martin Maechler

See Also

plot.ts which is the basic work horse.

Examples

require(graphics)

lag.plot(nhtemp, 8, diag.col = "forest green")
lag.plot(nhtemp, 5, main = "Average Temperatures in New Haven")
## ask defaults to TRUE when we have more than one page:
lag.plot(nhtemp, 6, layout = c(2,1), asp = NA,
        main = "New Haven Temperatures", col.main = "blue")

## Multivariate (but non-stationary! ...)
lag.plot(freney.x, lags = 3)
## Not run:
no lines for long series :
lag.plot(sqrt(sunspots), set = c(1:4, 9:12), pch = ".", col = "gold")

## End(Not run)
Description

Fit a line robustly as recommended in *Exploratory Data Analysis*.

Usage

```r
line(x, y)
```

Arguments

- `x`, `y` the arguments can be any way of specifying x-y pairs. See `xy.coords`.

Details

Cases with missing values are omitted.
Long vectors are not supported.

Value

An object of class "tukeyline".
Methods are available for the generic functions `coef`, `residuals`, `fitted`, and `print`.

References

See Also

`lm`.

Examples

```r
require(graphics)
plot(cars)
(z <- line(cars))
abline(coef(z))
## Tukey-Anscombe Plot :
plot(residuals(z) ~ fitted(z), main = deparse(z$call))
```
Description

`lm` is used to fit linear models. It can be used to carry out regression, single stratum analysis of variance and analysis of covariance (although `aov` may provide a more convenient interface for these).

Usage

```r
lm(formula, data, subset, weights, na.action, 
   method = "qr", model = TRUE, x = FALSE, y = FALSE, qr = TRUE, 
   singular.ok = TRUE, contrasts = NULL, offset, ...) 
```

Arguments

- **formula**: an object of class "formula" (or one that can be coerced to that class): a symbolic description of the model to be fitted. The details of model specification are given under ‘Details’.
- **data**: an optional data frame, list or environment (or object coercible by `as.data.frame` to a data frame) containing the variables in the model. If not found in `data`, the variables are taken from `environment(formula)`, typically the environment from which `lm` is called.
- **subset**: an optional vector specifying a subset of observations to be used in the fitting process.
- **weights**: an optional vector of weights to be used in the fitting process. Should be `NULL` or a numeric vector. If non-NULL, weighted least squares is used with weights `weights` (that is, minimizing `sum(w*e^2)`); otherwise ordinary least squares is used. See also ‘Details’.
- **na.action**: a function which indicates what should happen when the data contain NAs. The default is set by the `na.action` setting of `options`, and is `na.fail` if that is unset. The ‘factory-fresh’ default is `na.omit`. Another possible value is `NULL`, no action. Value `na.exclude` can be useful.
- **method**: the method to be used; for fitting, currently only method = "qr" is supported; method = "model.frame" returns the model frame (the same as with model = TRUE, see below).
- **model, x, y, qr**: logicals. If TRUE the corresponding components of the fit (the model frame, the model matrix, the response, the QR decomposition) are returned.
- **singular.ok**: logical. If FALSE (the default in S but not in R) a singular fit is an error.
- **contrasts**: an optional list. See the contrasts.arg of `model.matrix.default`. 

offset this can be used to specify an \textit{a priori} known component to be included in the linear predictor during fitting. This should be NULL or a numeric vector of length equal to the number of cases. One or more offset terms can be included in the formula instead or as well, and if more than one are specified their sum is used. See \texttt{model.offset}.

... additional arguments to be passed to the low level regression fitting functions (see below).

Details

Models for \texttt{lm} are specified symbolically. A typical model has the form \texttt{response \sim terms} where \texttt{response} is the (numeric) response vector and \texttt{terms} is a series of terms which specifies a linear predictor for \texttt{response}. A terms specification of the form \texttt{first + second} indicates all the terms in \texttt{first} together with all the terms in \texttt{second} with duplicates removed. A specification of the form \texttt{first:second} indicates the set of terms obtained by taking the interactions of all terms in \texttt{first} with all terms in \texttt{second}. The specification \texttt{first*second} indicates the cross of \texttt{first} and \texttt{second}. This is the same as \texttt{first + second + first:second}.

If the formula includes an offset, this is evaluated and subtracted from the response.

If \texttt{response} is a matrix a linear model is fitted separately by least-squares to each column of the matrix.

See \texttt{model.matrix} for some further details. The terms in the formula will be re-ordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on: to avoid this pass a \texttt{terms} object as the formula (see \texttt{aov} and \texttt{demo(glm.vr)} for an example).

A formula has an implied intercept term. To remove this use either \texttt{y \sim x - 1} or \texttt{y \sim 0 + x}. See \texttt{formula} for more details of allowed formulae.

Non-NULL \texttt{weights} can be used to indicate that different observations have different variances (with the values in \texttt{weights} being inversely proportional to the variances); or equivalently, when the elements of \texttt{weights} are positive integers \texttt{w}_i, that each response \texttt{y}_i is the mean of \texttt{w}_i unit-weight observations (including the case that there are \texttt{w}_i observations equal to \texttt{y}_i and the data have been summarized).

\texttt{lm} calls the lower level functions \texttt{lm.fit} etc, see below, for the actual numerical computations. For programming only, you may consider doing likewise.

All of \texttt{weights}, \texttt{subset} and \texttt{offset} are evaluated in the same way as variables in \texttt{formula}, that is first in \texttt{data} and then in the environment of \texttt{formula}.

Value

\texttt{lm} returns an object of \texttt{class} "\texttt{lm}" or for multiple responses of class \texttt{c("mlm", "\texttt{lm}").}

The functions \texttt{summary} and \texttt{anova} are used to obtain and print a summary and analysis of variance table of the results. The generic accessor functions \texttt{coefficients}, \texttt{effects}, \texttt{fitted.values} and \texttt{residuals} extract various useful features of the value returned by \texttt{lm}.

An object of class "\texttt{lm}" is a list containing at least the following components:

\begin{itemize}
  \item \texttt{coefficients} a named vector of coefficients
  \item \texttt{residuals} the residuals, that is \texttt{response} minus fitted values.
\end{itemize}
fitted.values the fitted mean values.
rank the numeric rank of the fitted linear model.
weights (only for weighted fits) the specified weights.
df.residual the residual degrees of freedom.
call the matched call.
terms the terms object used.
contrasts (only where relevant) the contrasts used.
xlevels (only where relevant) a record of the levels of the factors used in fitting.
offset the offset used (missing if none were used).
y if requested, the response used.
x if requested, the model matrix used.
model if requested (the default), the model frame used.
na.action (where relevant) information returned by model.frame on the special handling of NAs.

In addition, non-null fits will have components assign, effects and (unless not requested) qr relating to the linear fit, for use by extractor functions such as summary and effects.

Using time series
Considerable care is needed when using lm with time series.
Unless na.action = NULL, the time series attributes are stripped from the variables before the regression is done. (This is necessary as omitting NAs would invalidate the time series attributes, and if NAs are omitted in the middle of the series the result would no longer be a regular time series.)

Even if the time series attributes are retained, they are not used to line up series, so that the time shift of a lagged or differenced regressor would be ignored. It is good practice to prepare a data argument by ts.intersect(..., dframe = TRUE), then apply a suitable na.action to that data frame and call lm with na.action = NULL so that residuals and fitted values are time series.

Note
Offsets specified by offset will not be included in predictions by predict.lm, whereas those specified by an offset term in the formula will be.

Author(s)
The design was inspired by the S function of the same name described in Chambers (1992). The implementation of model formula by Ross Ihaka was based on Wilkinson & Rogers (1973).

References
lm.fit

Fitter Functions for Linear Models

Description

These are the basic computing engines called by \texttt{lm} used to fit linear models. These should usually \textit{not} be used directly unless by experienced users.
Usage

\texttt{lm.fit (x, y, offset = NULL, method = "qr", tol = 1e-7,}
\texttt{ singular.ok = TRUE, ...)}

\texttt{lm.wfit(x, y, w, offset = NULL, method = "qr", tol = 1e-7,}
\texttt{ singular.ok = TRUE, ...)}

Arguments

\texttt{x} \hspace{1cm} \text{design matrix of dimension n * p.}

\texttt{y} \hspace{1cm} \text{vector of observations of length n, or a matrix with n rows.}

\texttt{w} \hspace{1cm} \text{vector of weights (length n) to be used in the fitting process for the wfit functions. Weighted least squares is used with weights w, i.e., sum(w * e^2) is minimized.}

\texttt{offset} \hspace{1cm} \text{numeric of length n). This can be used to specify an a priori known component to be included in the linear predictor during fitting.}

\texttt{method} \hspace{1cm} \text{currently, only method = "qr" is supported.}

\texttt{tol} \hspace{1cm} \text{tolerance for the qr decomposition. Default is 1e-7.}

\texttt{singular.ok} \hspace{1cm} \text{logical. If FALSE, a singular model is an error.}

\texttt{...} \hspace{1cm} \text{currently disregarded.}

Value

\text{a list with components}

\texttt{coefficients} \hspace{1cm} p vector

\texttt{residuals} \hspace{1cm} n vector or matrix

\texttt{fitted.values} \hspace{1cm} n vector or matrix

\texttt{effects} \hspace{1cm} (not null fits)n vector of orthogonal single-df effects. The first rank of them correspond to non-aliased coefficients, and are named accordingly.

\texttt{weights} \hspace{1cm} n vector — only for the *wfit* functions.

\texttt{rank} \hspace{1cm} integer, giving the rank

\texttt{df.residual} \hspace{1cm} degrees of freedom of residuals

\texttt{qr} \hspace{1cm} (not null fits) the QR decomposition, see \texttt{qr}.

See Also

\texttt{lm} which you should use for linear least squares regression, unless you know better.
Examples

```r
require(stats)

set.seed(129)
n <- 7 ; p <- 2
X <- matrix(rnorm(n * p), n, p) # no intercept!
y <- rnorm(n)
w <- rnorm(n)^2

str(lmw <- lm.wfit(x = X, y = y, w = w))
str(lm. <- lm.fit (x = X, y = y))
```

---

**lm.influence**

**Regression Diagnostics**

### Description

This function provides the basic quantities which are used in forming a wide variety of diagnostics for checking the quality of regression fits.

### Usage

```r
influence(model, ...)
```  
```r
## S3 method for class 'lm'
influence(model, do.coef = TRUE, ...)
```  
```r
## S3 method for class 'glm'
influence(model, do.coef = TRUE, ...)
```  
```r
lm.influence(model, do.coef = TRUE)
```

### Arguments

- **model**: an object as returned by `lm` or `glm`.
- **do.coef**: logical indicating if the changed coefficients (see below) are desired. These need $O(n^2 p)$ computing time.
- **...**: further arguments passed to or from other methods.

### Details

The `influence.measures()` and other functions listed in See Also provide a more user oriented way of computing a variety of regression diagnostics. These all build on `lm.influence`. Note that for GLMs (other than the Gaussian family with identity link) these are based on one-step approximations which may be inadequate if a case has high influence.
An attempt is made to ensure that computed hat values that are probably one are treated as one, and 
the corresponding rows in sigma and coefficients are NaN. (Dropping such a case would normally 
result in a variable being dropped, so it is not possible to give simple drop-one diagnostics.)

naresid is applied to the results and so will fill in with NAs it the fit had na.action = na.exclude.

Value

A list containing the following components of the same length or number of rows n, which is the 
number of non-zero weights. Cases omitted in the fit are omitted unless a na.action method was 
used (such as na.exclude) which restores them.

hat a vector containing the diagonal of the ‘hat’ matrix.

coefficients (unless do.coef is false) a matrix whose i-th row contains the change in the 
estimated coefficients which results when the i-th case is dropped from the re-
gression. Note that aliased coefficients are not included in the matrix.

sigma a vector whose i-th element contains the estimate of the residual standard devi-
ation obtained when the i-th case is dropped from the regression. (The approxi-
mations needed for GLMs can result in this being NaN.)

wt.res a vector of weighted (or for class glm rather deviance) residuals.

Note

The coefficients returned by the R version of lm.influence differ from those computed by S. 
Rather than returning the coefficients which result from dropping each case, we return the changes 
in the coefficients. This is more directly useful in many diagnostic measures. 
Since these need \(O(n^2p)\) computing time, they can be omitted by do.coef = FALSE.

Note that cases with weights == /zero.noslash are dropped (contrary to the situation in S).

If a model has been fitted with na.action = na.exclude (see na.exclude), cases excluded in the 
fit are considered here.

References

## Analysis of the life-cycle savings data
## given in Belsley, Kuh and Welsch.
summary(lm.SR <- lm(sr ~ pop15 + pop75 + dpi + ddpi,
                   data = LifeCycleSavings),
       corr = TRUE)
utils::str(lmI <- lm.influence(lm.SR))

## For more "user level" examples, use example(influence.measures)
```

---

**lm.summaries**

### Accessing Linear Model Fits

**Description**

All these functions are methods for class "lm" objects.

**Usage**

```r
## S3 method for class 'lm'
family(object, ...)

## S3 method for class 'lm'
formula(x, ...)

## S3 method for class 'lm'
residuals(object,
           type = c("working", "response", "deviance", "pearson",
                    "partial"),
           ...)

## S3 method for class 'lm'
labels(object, ...)
```

**Arguments**

- `object, x`  
an object inheriting from class lm, usually the result of a call to `lm` or `aov`.
- `...`  
further arguments passed to or from other methods.
- `type`  
the type of residuals which should be returned.

**Details**

The generic accessor functions `coef`, `effects`, `fitted` and `residuals` can be used to extract various useful features of the value returned by `lm`.

The working and response residuals are ‘observed - fitted’. The deviance and pearson residuals are weighted residuals, scaled by the square root of the weights used in fitting. The partial
residuals are a matrix with each column formed by omitting a term from the model. In all these, zero weight cases are never omitted (as opposed to the standardized \texttt{rstudent} residuals, and the \texttt{weighted.residuals}).

How residuals treats cases with missing values in the original fit is determined by the \texttt{na.action} argument of that fit. If \texttt{na.action = na.omit} omitted cases will not appear in the residuals, whereas if \texttt{na.action = na.exclude} they will appear, with residual value \texttt{NA}. See also \texttt{naresid}.

The "lm" method for generic \texttt{labels} returns the term labels for estimable terms, that is the names of the terms with an least one estimable coefficient.

**loadings**

\textit{Print Loadings in Factor Analysis}

**Description**

Extract or print loadings in factor analysis (or principal components analysis).
Usage

```r
loadings(x)
```

```r
## S3 method for class 'loadings'
print(x, digits = 3, cutoff = 0.1, sort = FALSE, ...)

## S3 method for class 'factanal'
print(x, digits = 3, ...)
```

Arguments

- `x`: an object of class "factanal" or "princomp" or the loadings component of such an object.
- `digits`: number of decimal places to use in printing uniquenesses and loadings.
- `cutoff`: loadings smaller than this (in absolute value) are suppressed.
- `sort`: logical. If true, the variables are sorted by their importance on each factor. Each variable with any loading larger than 0.5 (in modulus) is assigned to the factor with the largest loading, and the variables are printed in the order of the factor they are assigned to, then those unassigned.
- `...`: further arguments for other methods.

Details

‘Loadings’ is a term from *factor analysis*, but because factor analysis and principal component analysis (PCA) are often conflated in the social science literature, it was used for PCA by SPSS and hence by `princomp` in S-PLUS to help SPSS users.

Small loadings are conventionally not printed (replaced by spaces), to draw the eye to the pattern of the larger loadings.

The `print` method for class "factanal" calls the "loadings" method to print the loadings, and so passes down arguments such as `cutoff` and `sort`.

See Also

`factanal`, `princomp`
Usage

loess(formula, data, weights, subset, na.action, model = FALSE,
span = 0.75, enp.target, degree = 2,
parametric = FALSE, drop.square = FALSE, normalize = TRUE,
family = c("gaussian", "symmetric"),
method = c("loess", "model.frame"),
control = loess.control(...), ...)

Arguments

formula a formula specifying the numeric response and one to four numeric predictors
(best specified via an interaction, but can also be specified additively). Will be
coerced to a formula if necessary.
data an optional data frame, list or environment (or object coercible by
as.data.frame to a data frame) containing the variables in the model. If not
found in data, the variables are taken from environment(formula), typically
the environment from which loess is called.
weights optional weights for each case.
subset an optional specification of a subset of the data to be used.
na.action the action to be taken with missing values in the response or predictors. The
default is given by getOption("na.action").
model should the model frame be returned?
span the parameter $\alpha$ which controls the degree of smoothing.
enp.target an alternative way to specify span, as the approximate equivalent number of
parameters to be used.
degree the degree of the polynomials to be used, normally 1 or 2. (Degree 0 is also
allowed, but see the ‘Note’.)
parametric should any terms be fitted globally rather than locally? Terms can be specified
by name, number or as a logical vector of the same length as the number of
predictors.
drop.square for fits with more than one predictor and degree = 2, should the quadratic term
be dropped for particular predictors? Terms are specified in the same way as for
parametric.
normalize should the predictors be normalized to a common scale if there is more than one?
The normalization used is to set the 10% trimmed standard deviation to one. Set
to false for spatial coordinate predictors and others know to be a common scale.
family if "gaussian" fitting is by least-squares, and if "symmetric" a re-descending
M estimator is used with Tukey’s biweight function.
method fit the model or just extract the model frame.
control control parameters: see loess.control.
... control parameters can also be supplied directly.
Details
Fitting is done locally. That is, for the fit at point x, the fit is made using points in a neighbourhood of x, weighted by their distance from x (with differences in ‘parametric’ variables being ignored when computing the distance). The size of the neighbourhood is controlled by \( \alpha \) (set by \texttt{span} or \texttt{enp.target}). For \( \alpha < 1 \), the neighbourhood includes proportion \( \alpha \) of the points, and these have tricubic weighting (proportional to \((1 - (\text{dist}/\maxdist)^3)^3\)). For \( \alpha > 1 \), all points are used, with the ‘maximum distance’ assumed to be \( \alpha^{1/p} \) times the actual maximum distance for \( p \) explanatory variables.

For the default family, fitting is by (weighted) least squares. For \texttt{family="symmetric"} a few iterations of an M-estimation procedure with Tukey’s biweight are used. Be aware that as the initial value is the least-squares fit, this need not be a very resistant fit.

It can be important to tune the control list to achieve acceptable speed. See \texttt{loess.control} for details.

Value
An object of class "\texttt{loess}".

Note
As this is based on \texttt{cloess}, it is similar to but not identical to the \texttt{loess} function of S. In particular, conditioning is not implemented.

The memory usage of this implementation of \texttt{loess} is roughly quadratic in the number of points, with 1000 points taking about 10Mb.

\texttt{degree = 0}, local constant fitting, is allowed in this implementation but not documented in the reference. It seems very little tested, so use with caution.

Author(s)
B. D. Ripley, based on the \texttt{cloess} package of Cleveland, Grosse and Shyu.

Source
The 1998 version of \texttt{cloess} package of Cleveland, Grosse and Shyu. A later version is available as \texttt{dloess} at \url{http://www.netlib.org/a}.

\texttt{loess.control}, \texttt{predict.loess}.
\texttt{lowess}, the ancestor of \texttt{loess} (with different defaults!).
Examples

cars.lo <- loess(dist ~ speed, cars)
predict(cars.lo, data.frame(speed = seq(5, 30, 1)), se = TRUE)
# to allow extrapolation
cars.lo2 <- loess(dist ~ speed, cars,
    control = loess.control(surface = "direct"))
predict(cars.lo2, data.frame(speed = seq(5, 30, 1)), se = TRUE)

---

loess.control | Set Parameters for Loess

Description

Set control parameters for loess fits.

Usage

loess.control(surface = c("interpolate", "direct"),
    statistics = c("approximate", "exact"),
    trace.hat = c("exact", "approximate"),
    cell = 0.2, iterations = 4, ...)

Arguments

- **surface**: should the fitted surface be computed exactly or via interpolation from a kd tree?
- **statistics**: should the statistics be computed exactly or approximately? Exact computation can be very slow.
- **trace.hat**: should the trace of the smoother matrix be computed exactly or approximately? It is recommended to use the approximation for more than about 1000 data points.
- **cell**: if interpolation is used this controls the accuracy of the approximation via the maximum number of points in a cell in the kd tree. Cells with more than \( \text{floor}(n \times \text{span} \times \text{cell}) \) points are subdivided.
- **iterations**: the number of iterations used in robust fitting.
- **...**: further arguments which are ignored.

Value

A list with components

- **surface**
- **statistics**
- **trace.hat**
- **cell**
- **iterations**

with meanings as explained under ‘Arguments’.
The Logistic Distribution

Description

Density, distribution function, quantile function and random generation for the logistic distribution with parameters location and scale.

Usage

dlogis(x, location = 0, scale = 1, log = FALSE)
plogis(q, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
qlogis(p, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
rlogis(n, location = 0, scale = 1)

Arguments

x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
location, scale location and scale parameters.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

If location or scale are omitted, they assume the default values of 0 and 1 respectively.

The Logistic distribution with location = \( \mu \) and scale = \( \sigma \) has distribution function

\[
F(x) = \frac{1}{1 + e^{-(x-\mu)/\sigma}}
\]

and density

\[
f(x) = \frac{e^{(x-\mu)/\sigma}}{\sigma (1 + e^{(x-\mu)/\sigma})^2}
\]

It is a long-tailed distribution with mean \( \mu \) and variance \( \pi^2/3\sigma^2 \).
Value
dlogis gives the density, plogis gives the distribution function, qlogis gives the quantile function, and rlogis generates random deviates.
The length of the result is determined by n for rlogis, and is the maximum of the lengths of the
numerical parameters for the other functions.
The numerical parameters other than n are recycled to the length of the result. Only the first elements
of the logical parameters are used.

Note
qlogis(p) is the same as the well known 'logit' function, \(\logit(p) = \log p/(1-p)\), and plogis(x)
has consequently been called the 'inverse logit'.
The distribution function is a rescaled hyperbolic tangent, plogis(x) == (1+ tanh(x/2))/2, and
it is called a sigmoid function in contexts such as neural networks.

Source
[dpq]logis are calculated directly from the definitions.
rlogis uses inversion.

References
Brooks/Cole.

Distributions for other standard distributions.

Examples
var(rlogis(4000, 0, scale = 5)) # approximately (+/- 3)
pi^2/3 * 5^2

logLik

Extract Log-Likelihood

Description
This function is generic; method functions can be written to handle specific classes of objects.
Classes which have methods for this function include: "glm", "lm", "nls" and "Arima". Packages
contain methods for other classes, such as "fitdistr", "negbin" and "polr" in package MASS,
"multinom" in package nnet and "gls", "gnls" "lme" and others in package nlme.
Usage

logLik(object, ...)

## S3 method for class 'lm'
logLik(object, REML = FALSE, ...)

Arguments

object any object from which a log-likelihood value, or a contribution to a log-
likelihood value, can be extracted.

... some methods for this generic function require additional arguments.

REML an optional logical value. If TRUE the restricted log-likelihood is returned, else,
if FALSE, the log-likelihood is returned. Defaults to FALSE.

Details

For a "glm" fit the family does not have to specify how to calculate the log-likelihood, so this
is based on using the family's aic() function to compute the AIC. For the gaussian, Gamma and
inverse.gaussian families it assumed that the dispersion of the GLM is estimated and has been
counted as a parameter in the AIC value, and for all other families it is assumed that the dispersion
is known. Note that this procedure does not give the maximized likelihood for "glm" fits from the
Gamma and inverse gaussian families, as the estimate of dispersion used is not the MLE.

For "lm" fits it is assumed that the scale has been estimated (by maximum likelihood or REML),
and all the constants in the log-likelihood are included. That method is only applicable to single-
response fits.

Value

Returns an object of class logLik. This is a number with at least one attribute, "df" (degrees of
freedom), giving the number of (estimated) parameters in the model.

There is a simple print method for "logLik" objects.

There may be other attributes depending on the method used: see the appropriate documentation.
One that is used by several methods is "nobs", the number of observations used in estimation (after
the restrictions if REML = TRUE).

Author(s)

José Pinheiro and Douglas Bates

```r
x <- 1:5
lmx <- lm(x ~ 1)
logLik(lmx) # using print.logLik() method
utils::str(logLik(lmx))

## lm method
(fm1 <- lm(rating ~ ., data = attitude))
logLik(fm1)
logLik(fm1, REML = TRUE)

utils::data(Orthodont, package = "nlme")
fm1 <- lm(distance ~ Sex * age, Orthodont)
logLik(fm1)
logLik(fm1, REML = TRUE)
```

---

loglin

### Fitting Log-Linear Models

**Description**

`loglin` is used to fit log-linear models to multidimensional contingency tables by Iterative Proportional Fitting.

**Usage**

```r
loglin(table, margin, start = rep(1, length(table)), fit = FALSE, 
eps = 0.1, iter = 20, param = FALSE, print = TRUE)
```

**Arguments**

- `table`: a contingency table to be fit, typically the output from `table`.
- `margin`: a list of vectors with the marginal totals to be fit.
  (Hierarchical) log-linear models can be specified in terms of these marginal totals which give the 'maximal' factor subsets contained in the model. For example, in a three-factor model, `list(c(1, 2), c(1, 3))` specifies a model which contains parameters for the grand mean, each factor, and the 1-2 and 1-3 interactions, respectively (but no 2-3 or 1-2-3 interaction), i.e., a model where factors 2 and 3 are independent conditional on factor 1 (sometimes represented as '[12][13]').
  The names of factors (i.e., `names(dimnames(table))`) may be used rather than numeric indices.
- `start`: a starting estimate for the fitted table. This optional argument is important for incomplete tables with structural zeros in table which should be preserved in the fit. In this case, the corresponding entries in start should be zero and the others can be taken as one.
- `fit`: a logical indicating whether the fitted values should be returned.
eps maximum deviation allowed between observed and fitted margins.
iter maximum number of iterations.
param a logical indicating whether the parameter values should be returned.
print a logical. If TRUE, the number of iterations and the final deviation are printed.

Details

The Iterative Proportional Fitting algorithm as presented in Haberman (1972) is used for fitting the model. At most iter iterations are performed, convergence is taken to occur when the maximum deviation between observed and fitted margins is less than eps. All internal computations are done in double precision; there is no limit on the number of factors (the dimension of the table) in the model.

Assuming that there are no structural zeros, both the Likelihood Ratio Test and Pearson test statistics have an asymptotic chi-squared distribution with df degrees of freedom.

Note that the IPF steps are applied to the factors in the order given in margin. Hence if the model is decomposable and the order given in margin is a running intersection property ordering then IPF will converge in one iteration.

Package MASS contains loglm, a front-end to loglin which allows the log-linear model to be specified and fitted in a formula-based manner similar to that of other fitting functions such as lm or glm.

Value

A list with the following components.

lrt the Likelihood Ratio Test statistic.
pearson the Pearson test statistic (X-squared).
df the degrees of freedom for the fitted model. There is no adjustment for structural zeros.
margin list of the margins that were fit. Basically the same as the input margin, but with numbers replaced by names where possible.
fit An array like table containing the fitted values. Only returned if fit is TRUE.
param A list containing the estimated parameters of the model. The ‘standard’ constraints of zero marginal sums (e.g., zero row and column sums for a two factor parameter) are employed. Only returned if param is TRUE.

Lognormal

The Log Normal Distribution

Description

Density, distribution function, quantile function and random generation for the log normal distribution whose logarithm has mean equal to meanlog and standard deviation equal to sdlog.

Usage

dlnorm(x, meanlog = 0, sdlog = 1, log = FALSE)
plnorm(q, meanlog = 0, sdlog = 1, lower.tail = TRUE, log.p = FALSE)
qlnorm(p, meanlog = 0, sdlog = 1, lower.tail = TRUE, log.p = FALSE)
rlnorm(n, meanlog = 0, sdlog = 1)

Arguments

x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
meanlog, sdlog mean and standard deviation of the distribution on the log scale with default values of 0 and 1 respectively.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$. 
Details

The log normal distribution has density

\[ f(x) = \frac{1}{\sqrt{2\pi}\sigma x} e^{-(\log(x) - \mu)^2/(2\sigma^2)} \]

where \( \mu \) and \( \sigma \) are the mean and standard deviation of the logarithm. The mean is \( E(X) = \exp(\mu + 1/2\sigma^2) \), the median is \( \text{med}(X) = \exp(\mu) \), and the variance \( \text{Var}(X) = \exp(2\mu + \sigma^2)(\exp(\sigma^2) - 1) \) and hence the coefficient of variation is \( \sqrt{\exp(\sigma^2) - 1} \) which is approximately \( \sigma \) when that is small (e.g., \( \sigma < 1/2 \)).

Value

dlnorm gives the density, plnorm gives the distribution function, qlnorm gives the quantile function, and rlnorm generates random deviates.

The length of the result is determined by \( n \) for rlnorm, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than \( n \) are recycled to the length of the result. Only the first elements of the logical parameters are used.

Note

The cumulative hazard \( H(t) = -\log(1-F(t)) \) is -plnorm(t, r, lower = FALSE, log = TRUE).

Source

dlnorm is calculated from the definition (in ‘Details’). [pqr]lnorm are based on the relationship to the normal.

Distributions for other standard distributions, including dnorm for the normal distribution.

Examples

dlnorm(1) == dnorm(0)
lowess

Scatter Plot Smoothing

Description

This function performs the computations for the LOWESS smoother which uses locally-weighted polynomial regression (see the references).

Usage

lowess(x, y = NULL, f = 2/3, iter = 3, delta = 0.01 * diff(range(x)))

Arguments

x, y vectors giving the coordinates of the points in the scatter plot. Alternatively a single plotting structure can be specified – see xy.coords.

f the smoother span. This gives the proportion of points in the plot which influence the smooth at each value. Larger values give more smoothness.

iter the number of ‘robustifying’ iterations which should be performed. Using smaller values of iter will make lowess run faster.

delta See ‘Details’. Defaults to 1/100th of the range of x.

Details

lowess is defined by a complex algorithm, the Ratfor original of which (by W. S. Cleveland) can be found in the R sources as file ‘src/appl/lowess.doc’. Normally a local linear polynomial fit is used, but under some circumstances (see the file) a local constant fit can be used. ‘Local’ is defined by the distance to the floor(f*n)th nearest neighbour, and tricubic weighting is used for x which fall within the neighbourhood.

The initial fit is done using weighted least squares. If iter > 0, further weighted fits are done using the product of the weights from the proximity of the x values and case weights derived from the residuals at the previous iteration. Specifically, the case weight is Tukey’s biweight, with cutoff 6 times the MAD of the residuals. (The current R implementation differs from the original in stopping iteration if the MAD is effectively zero since the algorithm is highly unstable in that case.)

delta is used to speed up computation: instead of computing the local polynomial fit at each data point it is not computed for points within delta of the last computed point, and linear interpolation is used to fill in the fitted values for the skipped points.

Value

lowess returns a list containing components x and y which give the coordinates of the smooth. The smooth can be added to a plot of the original points with the function line: see the examples.

```

---

`ls.diag`  
*Compute Diagnostics for `lsfit` Regression Results*

Description

Computes basic statistics, including standard errors, t- and p-values for the regression coefficients.

Usage

```r
ls.diag(ls.out)
```

Arguments

- `ls.out`  
  Typically the result of `lsfit()`

Value

A list with the following numeric components.

- `std.dev`  
  The standard deviation of the errors, an estimate of $\sigma$.

- `hat`  
  diagonal entries $h_{ii}$ of the hat matrix $H$

- `std.res`  
  standardized residuals

- `stud.res`  
  studentized residuals

- `cooks`  
  Cook's distances

- `dfits`  
  DFITS statistics
correlation matrix

standard errors of the regression coefficients

Scaled covariance matrix of the coefficients

Unscaled covariance matrix of the coefficients

References

See Also

hat for the hat matrix diagonals, **ls.print**, **lm.influence**, **summary.lm**, **anova**.

Examples

```r
#-- Using the same data as the lm(.) example:
lsD9 <- lsfit(x = as.numeric(gl(2, 10, 20)), y = weight)
dlsD9 <- ls.diag(lsD9)
utils::str(dlsD9, give.attr = FALSE)
abs(1 - sum(dlsD9$hat) / 2) < 10*.Machine$double.eps # sum(h.ii) = p
plot(dlsD9$hat, dlsD9$stud.res, xlim = c(0, 0.11))
abline(h = 0, lty = 2, col = "lightgray")
```

### Describe

Print lsfit Regression Results

Computes basic statistics, including standard errors, t- and p-values for the regression coefficients and prints them if print.it is TRUE.

Usage

```r
ls.print(ls.out, digits = 4, print.it = TRUE)
```

Arguments

- `ls.out` Typically the result of **lsfit()**
- `digits` The number of significant digits used for printing
- `print.it` a logical indicating whether the result should also be printed

Value

A list with the components

- `summary` The ANOVA table of the regression
- `coef.table` matrix with regression coefficients, standard errors, t- and p-values
Note

Usually you would use `summary(lm(...))` and `anova(lm(...))` to obtain similar output.

See Also

`ls.diag, lsfit`, also for examples; `lm, lm.influence` which usually are preferable.

lsfit  
Find the Least Squares Fit

Description

The least squares estimate of $\beta$ in the model

$$ Y = X\beta + \epsilon $$

is found.

Usage

```r
lsfit(x, y, wt = NULL, intercept = TRUE, tolerance = 1e-07,
      yname = NULL)
```

Arguments

- `x` a matrix whose rows correspond to cases and whose columns correspond to variables.
- `y` the responses, possibly a matrix if you want to fit multiple left hand sides.
- `wt` an optional vector of weights for performing weighted least squares.
- `intercept` whether or not an intercept term should be used.
- `tolerance` the tolerance to be used in the matrix decomposition.
- `yname` names to be used for the response variables.

Details

If weights are specified then a weighted least squares is performed with the weight given to the $j$th case specified by the $j$th entry in `wt`.

If any observation has a missing value in any field, that observation is removed before the analysis is carried out. This can be quite inefficient if there is a lot of missing data.

The implementation is via a modification of the LINPACK subroutines which allow for multiple left-hand sides.
**mad**

**Value**

A list with the following named components:

- `coef`: the least squares estimates of the coefficients in the model ($\beta$ as stated above).
- `residuals`: residuals from the fit.
- `intercept`: indicates whether an intercept was fitted.
- `qr`: the QR decomposition of the design matrix.

**References**

**See Also**

`lm` which usually is preferable: `ls.print, ls.diag`.

**Examples**

```r
#-- Using the same data as the lm(.) example:
lsD9 <- lsfit(x = unclass(gl(2, 1/zero.noslash)), y = weight)
ls.print(lsD9)
```

## mad

**Median Absolute Deviation**

**Description**

Compute the median absolute deviation, i.e., the (lo-/hi-) median of the absolute deviations from the median, and (by default) adjust by a factor for asymptotically normal consistency.

**Usage**

```r
mad(x, center = median(x), constant = 1.4826, na.rm = FALSE, 
    low = FALSE, high = FALSE)
```

**Arguments**

- `x`: a numeric vector.
- `center`: Optionally, the centre: defaults to the median.
- `constant`: scale factor.
- `na.rm`: if TRUE then NA values are stripped from x before computation takes place.
- `low`: if TRUE, compute the ‘lo-median’, i.e., for even sample size, do not average the two middle values, but take the smaller one.
- `high`: if TRUE, compute the ‘hi-median’, i.e., take the larger of the two middle values for even sample size.
Details

The actual value calculated is constant \( \times \) \( \text{cMedian}(\text{abs}(x - \text{center})) \) with the default value of center being \( \text{median}(x) \), and \( \text{cMedian} \) being the usual, the ‘low’ or ‘high’ median, see the arguments description for low and high above.

The default constant = 1.4826 (approximately \( 1/\Phi^{-1}(3/4) = 1/qnorm(3/4) \)) ensures consistency, i.e.,

\[
E[\text{mad}(X_1, \ldots, X_n)] = \sigma
\]

for \( X_i \) distributed as \( N(\mu, \sigma^2) \) and large \( n \).

If \( \text{na.rm} \) is TRUE then NA values are stripped from \( x \) before computation takes place. If this is not done then an NA value in \( x \) will cause \( \text{mad} \) to return NA.

See Also

IQR which is simpler but less robust, median, var.

Examples

\[
\begin{align*}
\text{mad}(c(1:9)) \\
\text{print}(\text{mad}(c(1:9), \text{constant} = 1)) & == \\
\text{mad}(c(1:8, 100), \text{constant} = 1) & # = 2 ; \text{TRUE} \\
\text{x} & <- c(1,2,3,5,7,8) \\
\text{sort}(\text{abs}(x - \text{median}(x))) \\
\text{c}(\text{mad}(x, \text{constant} = 1), \\
\text{mad}(x, \text{constant} = 1, \text{low} = \text{TRUE}), \\
\text{mad}(x, \text{constant} = 1, \text{high} = \text{TRUE}))
\end{align*}
\]

mahalanobis

Mahalanobis Distance

Description

Returns the squared Mahalanobis distance of all rows in \( x \) and the vector \( \mu = \text{center} \) with respect to \( \Sigma = \text{cov} \). This is (for vector \( x \)) defined as

\[
D^2 = (x - \mu)'\Sigma^{-1}(x - \mu)
\]

Usage

\[
\text{mahalanobis}(x, \text{center}, \text{cov}, \text{inverted} = \text{FALSE}, \ldots)
\]

Arguments

- \( x \) vector or matrix of data with, say, \( p \) columns.
- \( \text{center} \) mean vector of the distribution or second data vector of length \( p \).
- \( \text{cov} \) covariance matrix (\( p \times p \)) of the distribution.
- \( \text{inverted} \) logical. If TRUE, \( \text{cov} \) is supposed to contain the inverse of the covariance matrix.
- \( \ldots \) passed to \text{solve} for computing the inverse of the covariance matrix (if \text{inverted} is false).

makepredictcall Utility Function for Safe Prediction

Description

A utility to help model.frame.default create the right matrices when predicting from models with
terms like poly or ns.

Usage

makepredictcall(var, call)

Arguments

var A variable.
call The term in the formula, as a call.

Details

This is a generic function with methods for poly, bs and ns: the default method handles scale.
If model.frame.default encounters such a term when creating a model frame, it modifies the
predvars attribute of the terms supplied by replacing the term with one which will work for pre-
dicting new data. For example makepredictcall.ns adds arguments for the knots and intercept.

To make use of this, have your model-fitting function return the terms attribute of the model frame,
or copy the predvars attribute of the terms attribute of the model frame to your terms object.

To extend this, make sure the term creates variables with a class, and write a suitable method for
that class.

Value

A replacement for call for the predvars attribute of the terms.
manova

See Also

\texttt{model.frame}, \texttt{poly}, \texttt{scale}; \texttt{bs} and \texttt{ns} in package \texttt{splines}.
\texttt{cars} for an example of prediction from a polynomial fit.

Examples

\begin{verbatim}
require(graphics)

## using poly: this did not work in R < 1.5.0
fm <- lm(weight ~ poly(height, 2), data = women)
plot(women, xlab = "Height (in)", ylab = "Weight (lb)"
ht <- seq(57, 73, len = 200)
lines(ht, predict(fm, data.frame(height = ht)))

## see also example(cars)

## see bs and ns for spline examples.
\end{verbatim}

Description

A class for the multivariate analysis of variance.

Usage

\texttt{manova(\ldots)}

Arguments

\ldots \hspace{2cm} \text{Arguments to be passed to \texttt{aov}.}

Details

Class "manova" differs from class "aov" in selecting a different summary method. Function \texttt{manova} calls \texttt{aov} and then add class "manova" to the result object for each stratum.

Value

See \texttt{aov} and the comments in ‘Details’ here.

References

utils::data(npk, package = "MASS")

## Set orthogonal contrasts.
op <- options(contrasts = c("contr.helmert", "contr.poly"))

## Fake a 2nd response variable
npk2 <- within(npk, foo <- rnorm(24))
(npk2.aov <- manova(cbind(yield, foo) ~ block + N*P*K, npk2))
summary(npk2.aov)

(npk2.aovE <- manova(cbind(yield, foo) ~ N*P*K + Error(block), npk2))
summary(npk2.aovE)
```

**mantelhaen.test**  
*Cochran-Mantel-Haenszel Chi-Squared Test for Count Data*

**Description**

Performs a Cochran-Mantel-Haenszel chi-squared test of the null that two nominal variables are conditionally independent in each stratum, assuming that there is no three-way interaction.

**Usage**

```r
mantelhaen.test(x, y = NULL, z = NULL, 
alternative = c("two.sided", "less", "greater"), 
correct = TRUE, exact = FALSE, conf.level = 0.95)
```

**Arguments**

- **x**: either a 3-dimensional contingency table in array form where each dimension is at least 2 and the last dimension corresponds to the strata, or a factor object with at least 2 levels.
- **y**: a factor object with at least 2 levels; ignored if `x` is an array.
- **z**: a factor object with at least 2 levels identifying to which stratum the corresponding elements in `x` and `y` belong; ignored if `x` is an array.
- **alternative**: indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. Only used in the 2 by 2 by `K` case.
correct
- a logical indicating whether to apply continuity correction when computing the test statistic. Only used in the 2 by 2 by \( K \) case.

exact
- a logical indicating whether the Mantel-Haenszel test or the exact conditional test (given the strata margins) should be computed. Only used in the 2 by 2 by \( K \) case.

conf.level
- confidence level for the returned confidence interval. Only used in the 2 by 2 by \( K \) case.

Details
If \( x \) is an array, each dimension must be at least 2, and the entries should be nonnegative integers. NA's are not allowed. Otherwise, \( x \), \( y \) and \( z \) must have the same length. Triples containing NA's are removed. All variables must take at least two different values.

Value
A list with class "htest" containing the following components:

- statistic
  - Only present if no exact test is performed. In the classical case of a 2 by 2 by \( K \) table (i.e., of dichotomous underlying variables), the Mantel-Haenszel chi-squared statistic; otherwise, the generalized Cochran-Mantel-Haenszel statistic.

- parameter
  - the degrees of freedom of the approximate chi-squared distribution of the test statistic (1 in the classical case). Only present if no exact test is performed.

- p.value
  - the p-value of the test.

- conf.int
  - a confidence interval for the common odds ratio. Only present in the 2 by 2 by \( K \) case.

- estimate
  - an estimate of the common odds ratio. If an exact test is performed, the conditional Maximum Likelihood Estimate is given; otherwise, the Mantel-Haenszel estimate. Only present in the 2 by 2 by \( K \) case.

- null.value
  - the common odds ratio under the null of independence, 1. Only present in the 2 by 2 by \( K \) case.

- alternative
  - a character string describing the alternative hypothesis. Only present in the 2 by 2 by \( K \) case.

- method
  - a character string indicating the method employed, and whether or not continuity correction was used.

- data.name
  - a character string giving the names of the data.

Note
The asymptotic distribution is only valid if there is no three-way interaction. In the classical 2 by 2 by \( K \) case, this is equivalent to the conditional odds ratios in each stratum being identical. Currently, no inference on homogeneity of the odds ratios is performed.

See also the example below.

### mauchly.test

Mauchly’s Test of Sphericity

**Description**

Tests whether a Wishart-distributed covariance matrix (or transformation thereof) is proportional to a given matrix.

**Usage**

```r
mauchly.test(object, ...) # S3 method for class 'mlm'
mauchly.test(object, ...) # S3 method for class 'SSD'
```

**Arguments**

- `object` object of class SSD or mlm.
- `Sigma` matrix to be proportional to.
- `T` transformation matrix. By default computed from M and X.
- `M` formula or matrix describing the outer projection (see below).
- `X` formula or matrix describing the inner projection (see below).
- `idata` data frame describing intra-block design.
- `...` arguments to be passed to or from other methods.
Details

Mauchly’s test test for whether a covariance matrix can be assumed to be proportional to a given matrix.

This is a generic function with methods for classes "mlm" and "SSD".

The basic method is for objects of class SSD the method for mlm objects just extracts the SSD matrix and invokes the corresponding method with the same options and arguments.

The T argument is used to transform the observations prior to testing. This typically involves transformation to intra-block differences, but more complicated within-block designs can be encountered, making more elaborate transformations necessary. A matrix T can be given directly or specified as the difference between two projections onto the spaces spanned by M and X, which in turn can be given as matrices or as model formulas with respect to idata (the tests will be invariant to parametrization of the quotient space M/X).

The common use of this test is in repeated measurements designs, with X = ~1. This is almost, but not quite the same as testing for compound symmetry in the untransformed covariance matrix.

Notice that the defaults involve p, which is calculated internally as the dimension of the SSD matrix, and a couple of hidden functions in the stats namespace, namely proj which calculates projection matrices from design matrices or model formulas and Thin.row which removes linearly dependent rows from a matrix until it has full row rank.

Value

An object of class "htest"

Note

The p-value differs slightly from that of SAS because a second order term is included in the asymptotic approximation in R.

References

See Also

SSD, anova.mlm, rWishart

Examples

utils::example(SSD) # Brings in the mlmfit and reacttime objects

### traditional test of intrasubj. contrasts
mauchly.test(mlmfit, X = ~1)

### tests using intra-subject 3x2 design
idata <- data.frame(deg = gl(3, 1, 6, labels = c(0,4,8)),
noise = gl(2, 3, 6, labels = c("A","P")))
mauchly.test(mlmfit, X = ~ deg + noise, idata = idata)
mauchly.test(mlmfit, M = ~ deg + noise, X = ~ noise, idata = idata)
**Description**

Performs McNemar’s chi-squared test for symmetry of rows and columns in a two-dimensional contingency table.

**Usage**

```r
mcnemar.test(x, y = NULL, correct = TRUE)
```

**Arguments**

- `x`: either a two-dimensional contingency table in matrix form, or a factor object.
- `y`: a factor object; ignored if `x` is a matrix.
- `correct`: a logical indicating whether to apply continuity correction when computing the test statistic.

**Details**

The null is that the probabilities of being classified into cells \([i,j]\) and \([j,i]\) are the same.

If `x` is a matrix, it is taken as a two-dimensional contingency table, and hence its entries should be nonnegative integers. Otherwise, both `x` and `y` must be vectors or factors of the same length. Incomplete cases are removed, vectors are coerced into factors, and the contingency table is computed from these.

Continuity correction is only used in the 2-by-2 case if `correct` is `TRUE`.

**Value**

A list with class "htest" containing the following components:

- `statistic`: the value of McNemar’s statistic.
- `parameter`: the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- `p.value`: the p-value of the test.
- `method`: a character string indicating the type of test performed, and whether continuity correction was used.
- `data.name`: a character string giving the name(s) of the data.

**median**

<table>
<thead>
<tr>
<th>Median Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>Compute the sample median.</td>
</tr>
</tbody>
</table>

**Usage**

```r
median(x, na.rm = FALSE)
```

**Arguments**

- `x`, an object for which a method has been defined, or a numeric vector containing the values whose median is to be computed.
- `na.rm`, a logical value indicating whether NA values should be stripped before the computation proceeds.

**Details**

This is a generic function for which methods can be written. However, the default method makes use of `sort` and `mean` from package base both of which are generic, and so the default method will work for most classes (e.g. "Date") for which a median is a reasonable concept.

**Value**

The default method returns a length-one object of the same type as `x`, except when `x` is integer of even length, when the result will be double.

If there are no values or if `na.rm = FALSE` and there are NA values the result is NA of the same type as `x` (or more generally the result of `x[FALSE][NA]`).

**References**

**medpolish**

See Also

quantile for general quantiles.

Examples

```r
median(1:4) # = 2.5 [even number]
median(c(1:3, 100, 1000)) # = 3 [odd, robust]
```

---

**medpolish**

*Median Polish of a Matrix*

Description

Fits an additive model using Tukey’s *median polish* procedure.

Usage

```r
medpolish(x, eps = 0.01, maxiter = 10, trace.iter = TRUE, na.rm = FALSE)
```

Arguments

- `x` a numeric matrix.
- `eps` real number greater than 0. A tolerance for convergence: see ‘Details’.
- `maxiter` the maximum number of iterations
- `trace.iter` logical. Should progress in convergence be reported?
- `na.rm` logical. Should missing values be removed?

Details

The model fitted is additive (constant + rows + columns). The algorithm works by alternately removing the row and column medians, and continues until the proportional reduction in the sum of absolute residuals is less than `eps` or until there have been `maxiter` iterations. The sum of absolute residuals is printed at each iteration of the fitting process, if `trace.iter` is `TRUE`. If `na.rm` is `FALSE` the presence of any NA value in `x` will cause an error, otherwise NA values are ignored.

`medpolish` returns an object of class `medpolish` (see below). There are printing and plotting methods for this class, which are invoked via the generics `print` and `plot`.

Value

An object of class `medpolish` with the following named components:

- `overall` the fitted constant term.
- `row` the fitted row effects.
- `col` the fitted column effects.
- `residuals` the residuals.
- `name` the name of the dataset.
References

`median`; `aov` for a mean instead of median decomposition.

Examples

```r
require(graphics)

## Deaths from sport parachuting; from ABC of EDA, p.224:
deaths <-
  rbind(c(14,15,14),
         c( 7, 4, 7),
         c( 8, 2,10),
         c(15, 9,10),
         c( 0, 2, 0))
dimnames(deaths) <- list(c("1-24", "25-74", "75-199", "200++", "NA"),
                           paste(1973:1975))
deaths
(med.d <- medpolish(deaths))
plot(med.d)
## Check decomposition:
all(deaths ==
    med.d$overall + outer(med.d$row,med.d$col, "+") + med.d$residuals)
```

---

**model.extract**

*Extract Components from a Model Frame*

**Description**

Returns the response, offset, subset, weights or other special components of a model frame passed as optional arguments to `model.frame`.

**Usage**

```r
model.extract(frame, component)
model.offset(x)
model.response(data, type = "any")
model.weights(x)
```

**Arguments**

- `frame, x, data` A model frame.
- `component` literal character string or name. The name of a component to extract, such as "weights", "subset".
- `type` One of "any", "numeric", "double". Using either of latter two coerces the result to have storage mode "double".
model.frame

Details

model.extract is provided for compatibility with S, which does not have the more specific functions. It is also useful to extract e.g. the etastart and mustart components of a glm fit.

model.offset and model.response are equivalent to model.extract(, "offset") and model.extract(, "response") respectively. model.offset sums any terms specified by offset terms in the formula or by offset arguments in the call producing the model frame: it does check that the offset is numeric.

model.weights is slightly different from model.frame(, "weights") in not naming the vector it returns.

Value

The specified component of the model frame, usually a vector.

See Also

model.frame, offset

Examples

a <- model.frame(cbind(ncases,ncontrols) ~ agegp + tobgp + alcgp, data = esoph)
model.extract(a, "response")
stopifnot(model.extract(a, "response") == model.response(a))

a <- model.frame(ncases/(ncases+ncontrols) ~ agegp + tobgp + alcgp,
data = esoph, weights = ncases+ncontrols)
model.response(a)
model.extract(a, "weights")

a <- model.frame(cbind(ncases, ncontrols) ~ agegp,
                 something = tobgp, data = esoph)
names(a)
stopifnot(model.extract(a, "something") == esoph$tobgp)
Usage

model.frame(formula, ...) 

## Default S3 method:
model.frame(formula, data = NULL,
    subset = NULL, na.action = na.fail,
    drop.unused.levels = FALSE, xlev = NULL, ...)

## S3 method for class 'aovlist'
model.frame(formula, data = NULL, ...)

## S3 method for class 'glm'
model.frame(formula, ...)

## S3 method for class 'lm'
model.frame(formula, ...)

get_all_vars(formula, data, ...)

Arguments

formula a model formula or terms object or an R object.
data a data.frame, list or environment (or object coercible by as.data.frame to a
    data.frame), containing the variables in formula. Neither a matrix nor an array
    will be accepted.
subset a specification of the rows to be used: defaults to all rows. This can be any
    valid indexing vector (see [.data.frame) for the rows of data or if that is not
    supplied, a data frame made up of the variables used in formula.
na.action how NAs are treated. The default is first, any na.action attribute of data, second
    a na.action setting of options, and third na.fail if that is unset. The 'factory-
    fresh' default is na.omit. Another possible value is NULL.
drop.unused.levels should factors have unused levels dropped? Defaults to FALSE.
xlev a named list of character vectors giving the full set of levels to be assumed for
    each factor.
... further arguments such as data, na.action, subset. Any additional argu-
    ments such as offset and weights which reach the default method are used
    to create further columns in the model frame, with parenthesised names such as
    "(offset)".

Details

Exactly what happens depends on the class and attributes of the object formula. If this is an object
of fitted-model class such as "lm", the method will either return the saved model frame used when
fitting the model (if any, often selected by argument model = TRUE) or pass the call used when
fitting on to the default method. The default method itself can cope with rather standard model
objects such as those of class "lqs" from package MASS if no other arguments are supplied.
The rest of this section applies only to the default method.

If either formula or data is already a model frame (a data frame with a “terms” attribute) and the other is missing, the model frame is returned. Unless formula is a terms object, as.formula and then terms is called on it. (If you wish to use the keep.order argument of terms.formula, pass a terms object rather than a formula.)

Row names for the model frame are taken from the data argument if present, then from the names of the response in the formula (or rownames if it is a matrix), if there is one.

All the variables in formula, subset and in ... are looked for first in data and then in the environment of formula (see the help for formula() for further details) and collected into a data frame. Then the subset expression is evaluated, and it is used as a row index to the data frame. Then the na.action function is applied to the data frame (and may well add attributes). The levels of any factors in the data frame are adjusted according to the drop.unused.levels and xlev arguments: if xlev specifies a factor and a character variable is found, it is converted to a factor (as from R 2.10.0).

Unless na.action = NULL, time-series attributes will be removed from the variables found (since they will be wrong if NAs are removed).

Note that all the variables in the formula are included in the data frame, even those preceded by -. Only variables whose type is raw, logical, integer, real, complex or character can be included in a model frame: this includes classed variables such as factors (whose underlying type is integer), but excludes lists.

get_all_vars returns a data.frame containing the variables used in formula plus those specified .... Unlike model.frame.default, it returns the input variables and not those resulting from function calls in formula.

Value

A data.frame containing the variables used in formula plus those specified in .... It will have additional attributes, including "terms" for an object of class "terms" derived from formula, and possibly "na.action" giving information on the handling of NAs (which will not be present if no special handling was done, e.g. by na.pass).

Examples

data.class(model.frame(dist ~ speed, data = cars))
model.matrix

Construct Design Matrices

Description

model.matrix creates a design (or model) matrix.

Usage

model.matrix(object, ...)

## Default S3 method:
model.matrix(object, data = environment(object),
contrasts.arg = NULL, xlev = NULL, ...)

Arguments

object
an object of an appropriate class. For the default method, a model formula or a terms object.

data
a data frame created with model.frame. If another sort of object, model.frame is called first.

contrasts.arg
A list, whose entries are values (numeric matrices or character strings naming functions) to be used as replacement values for the contrasts replacement function and whose names are the names of columns of data containing factors.

xlev
to be used as argument of model.frame if data is such that model.frame is called.

...
further arguments passed to or from other methods.

Details

model.matrix creates a design matrix from the description given in terms(object), using the data in data which must supply variables with the same names as would be created by a call to model.frame(object) or, more precisely, by evaluating attr(terms(object), "variables"). If data is a data frame, there may be other columns and the order of columns is not important. Any character variables are coerced to factors. After coercion, all the variables used on the right-hand side of the formula must be logical, integer, numeric or factor.

If contrasts.arg is specified for a factor it overrides the default factor coding for that variable and any "contrasts" attribute set by C or contrasts.

In an interaction term, the variable whose levels vary fastest is the first one to appear in the formula (and not in the term), so in ~ a + b + b:a the interaction will have a varying fastest.

By convention, if the response variable also appears on the right-hand side of the formula it is dropped (with a warning), although interactions involving the term are retained.
Value
The design matrix for a regression-like model with the specified formula and data.
There is an attribute "assign", an integer vector with an entry for each column in the matrix giving the term in the formula which gave rise to the column. Value 0 corresponds to the intercept (if any), and positive values to terms in the order given by the term.labels attribute of the terms structure corresponding to object.
If there are any factors in terms in the model, there is an attribute "contrasts", a named list with an entry for each factor. This specifies the contrasts that would be used in terms in which the factor is coded by contrasts (in some terms dummy coding may be used), either as a character vector naming a function or as a numeric matrix.

Examples

```r
ff <- log(Volume) ~ log(Height) + log(Girth)
utils::str(m <- model.frame(ff, trees))
mat <- model.matrix(ff, m)

dd <- data.frame(a = gl(3,4), b = gl(4,1,12)) # balanced 2-way
options("contrasts")
model.matrix(~ a + b, dd)
model.matrix(~ a + b, dd, contrasts = list(a = "contr.sum"))
model.matrix(~ a + b, dd, contrasts = list(a = "contr.sum", b = "contr.poly"))
m.orth <- model.matrix(~a+b, dd, contrasts = list(a = "contr.helmert"))
crossprod(m.orth) # m.orth is ALMOST orthogonal
```

---

model.tables

**Compute Tables of Results from an Aov Model Fit**

Description
Computes summary tables for model fits, especially complex aov fits.

Usage

```
model.tables(x, ...)
```

## S3 method for class 'aov'
model.tables(x, type = "effects", se = FALSE, cterms, ...)

---

model.tables

Compute Tables of Results from an Aov Model Fit

Description
Computes summary tables for model fits, especially complex aov fits.

Usage

```
model.tables(x, ...)
```

## S3 method for class 'aov'
model.tables(x, type = "effects", se = FALSE, cterms, ...)
model.tables(x, type = "effects", se = FALSE, ...)

Arguments

x a model object, usually produced by aov
type type of table: currently only "effects" and "means" are implemented.
se should standard errors be computed?
terms A character vector giving the names of the terms for which tables should be computed. The default is all tables.
... further arguments passed to or from other methods.

Details

For type = "effects" give tables of the coefficients for each term, optionally with standard errors.
For type = "means" give tables of the mean response for each combinations of levels of the factors in a term.
The "aov" method cannot be applied to components of a "aovlist" fit.

Value

An object of class "tables.aov", as list which may contain components
tables A list of tables for each requested term.
n The replication information for each term.
se Standard error information.

Warning

monthplot

Plot a Seasonal or other Subseries from a Time Series

Description

These functions plot seasonal (or other) subseries of a time series. For each season (or other category), a time series is plotted.

Usage

monthplot(x, ...)

## S3 method for class 'stl'
monthplot(x, labels = NULL, ylab = choice, choice = "seasonal", ...)

## S3 method for class 'StructTS'
monthplot(x, labels = NULL, ylab = choice, choice = "sea", ...)

## S3 method for class 'ts'
monthplot(x, labels = NULL, times = time(x), phase = cycle(x),
ylab = deparse(substitute(x)), ...)

## Default S3 method:
monthplot(x, labels = 1:12L,
ylab = deparse(substitute(x)),
times = seq_along(x),
phase = (times - 1L)%*%length(labels) + 1L, base = mean,
axes = TRUE, type = c("l", "h"), box = TRUE,
add = FALSE,
col = par("col"), lty = par("lty"), lwd = par("lwd"),
col.base = col, lty.base = lty, lwd.base = lwd, ...)

Arguments

x Time series or related object.
labels Labels to use for each ‘season’.
ylab y label.
times Time of each observation.
phase Indicator for each ‘season’.
base Function to use for reference line for subseries.
choice Which series of an stl or StructTS object?
... Arguments to be passed to the default method or graphical parameters.
axes Should axes be drawn (ignored if add = TRUE)?
type Type of plot. The default is to join the points with lines, and "h" is for histogram-like vertical lines.
box Should a box be drawn (ignored if add = TRUE)?
add Should thus just add on an existing plot.
col, lty, lwd Graphics parameters for the series.
col.base, lty.base, lwd.base Graphics parameters for the segments used for the reference lines.

Details
These functions extract subseries from a time series and plot them all in one frame. The ts, stl, and StructTS methods use the internally recorded frequency and start and finish times to set the scale and the seasons. The default method assumes observations come in groups of 12 (though this can be changed).

If the labels are not given but the phase is given, then the labels default to the unique values of the phase. If both are given, then the phase values are assumed to be indices into the labels array, i.e., they should be in the range from 1 to length(labels).

Value
These functions are executed for their side effect of drawing a seasonal subseries plot on the current graphical window.

mood.test

### Mood Two-Sample Test of Scale

#### Description
Performs Mood’s two-sample test for a difference in scale parameters.

#### Usage
mood.test(x, ...)

### Default S3 method:
mood.test(x, y,
  alternative = c("two.sided", "less", "greater"), ...)

### S3 method for class 'formula'
mood.test(formula, data, subset, na.action, ...)

#### Arguments
- x, y numeric vectors of data values.
- alternative indicates the alternative hypothesis and must be one of "two.sided" (default), "greater" or "less" all of which can be abbreviated.
- formula a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups.
- data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
- subset an optional vector specifying a subset of observations to be used.
- na.action a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").
- ... further arguments to be passed to or from methods.
Details

The underlying model is that the two samples are drawn from \( f(x - l) \) and \( f((x - l)/s)/s \), respectively, where \( l \) is a common location parameter and \( s \) is a scale parameter.

The null hypothesis is \( s = 1 \).

There are more useful tests for this problem.

In the case of ties, the formulation of Mielke (1967) is employed.

Value

A list with class "htest" containing the following components:

- statistic: the value of the test statistic.
- p.value: the p-value of the test.
- alternative: a character string describing the alternative hypothesis.
- method: the character string "Mood two-sample test of scale".
- data.name: a character string giving the names of the data.

References

- `ansari.test` for another rank-based two-sample test for a difference in scale parameters; `var.test` and `bartlett.test` for parametric tests for the homogeneity in variance.

Examples

```r
## Same data as for the Ansari-Bradley test:
## Serum iron determination using Hyland control sera
ramsay <- c(111, 107, 100, 99, 102, 106, 109, 108, 104, 99,
           101, 96, 97, 102, 107, 113, 116, 113, 110, 98)
jung.parekh <- c(107, 108, 106, 98, 105, 103, 110, 105, 104,
mood.test(ramsay, jung.parekh)
## Compare this to ansari.test(ramsay, jung.parekh)
```
The Multinomial Distribution

Description

Generate multinomially distributed random number vectors and compute multinomial probabilities.

Usage

```r
rmultinom(n, size, prob)
dmultinom(x, size = NULL, prob, log = FALSE)
```

Arguments

- `x` vector of length `K` of integers in `0:size`.
- `n` number of random vectors to draw.
- `size` integer, say `N`, specifying the total number of objects that are put into `K` boxes in the typical multinomial experiment. For `dmultinom`, it defaults to `sum(x)`.
- `prob` numeric non-negative vector of length `K`, specifying the probability for the `K` classes; is internally normalized to sum 1.
- `log` logical; if TRUE, log probabilities are computed.

Details

If `x` is a `K`-component vector, `dmultinom(x, prob)` is the probability

\[ P(X_1 = x_1, \ldots, X_K = x_k) = C \times \prod_{j=1}^{K} \pi_j^{x_j} \]

where `C` is the ‘multinomial coefficient’ `C = N!/(x_1! \cdots x_K!)` and `N = \sum_{j=1}^{K} x_j`.

By definition, each component `X_j` is binomially distributed as `Bin(size, prob[j])` for `j = 1, \ldots, K`.

The `rmultinom()` algorithm draws binomials `X_j` from `Bin(n_j, P_j)` sequentially, where `n_1 = N` (\(N := \text{size}\)), `P_1 = \pi_1` (\(\pi\) is prob scaled to sum 1), and for `j \geq 2`, recursively, `n_j = N - \sum_{k=1}^{j-1} X_k` and `P_j = \pi_j/(1 - \sum_{k=1}^{j-1} \pi_k)`.

Value

For `rmultinom()`, an integer `K \times n` matrix where each column is a random vector generated according to the desired multinomial law, and hence summing to `size`. Whereas the transposed result would seem more natural at first, the returned matrix is more efficient because of columnwise storage.

Note

`dmultinom` is currently not vectorized at all and has no C interface (API); this may be amended in the future.
See Also

Distributions for standard distributions, including \texttt{dbinom} which is a special case conceptually.

Examples

\begin{verbatim}
rmultinom(10, size = 12, prob = c(0.1, 0.2, 0.8))

pr <- c(1, 3, 6, 10) # normalization not necessary for generation
rmultinom(10, 20, prob = pr)

## all possible outcomes of Multinom(N = 3, K = 3)
X <- t(as.matrix(expand.grid(0:3, 0:3))); X <- X[, colSums(X) <= 3]
X <- rbind(X, 3:3 - colSums(X)); dimnames(X) <- list(letters[1:3], NULL)
X

round(apply(X, 2, function(x) dmultinom(x, prob = c(1, 2, 5))), 3)
\end{verbatim}

\textbf{na.action} \quad \textit{NA Action}

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Extract information on the NA action used to create an object.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{na.action(object, \ldots)}</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Arguments</th>
</tr>
</thead>
<tbody>
<tr>
<td>\textbf{object} \quad any object whose \texttt{NA} action is given.</td>
</tr>
<tr>
<td>\textbf{\ldots} \quad further arguments special methods could require.</td>
</tr>
</tbody>
</table>

Details

\texttt{na.action} is a generic function, and \texttt{na.action.default} its default method. The latter extracts the "na.action" component of a list if present, otherwise the "na.action" attribute.

When \texttt{model.frame} is called, it records any information on NA handling in a "na.action" attribute. Most model-fitting functions return this as a component of their result.

Value

Information from the action which was applied to object if NAs were handled specially, or \texttt{NULL}.

References

See Also

\texttt{options("na.action"), na.omit, na.fail}, also for \texttt{na.exclude, na.pass}.

Examples

\begin{verbatim}
na.action(na.omit(c(1, NA)))
\end{verbatim}

---

\texttt{na.contiguous} \hspace{3cm} \textit{Find Longest Contiguous Stretch of non-NA}\texttt{s}

Description

Find the longest consecutive stretch of non-missing values in a time series object. (In the event of a tie, the first such stretch.)

Usage

\begin{verbatim}
na.contiguous(object, ...)
\end{verbatim}

Arguments

\begin{verbatim}
object \hspace{1cm} \text{a univariate or multivariate time series.}
...
\text{further arguments passed to or from other methods.}
\end{verbatim}

Value

A time series without missing values. The class of \texttt{object} will be preserved.

See Also

\texttt{na.omit and na.omit.ts; na.fail}

Examples

\begin{verbatim}
na.contiguous(presidents)
\end{verbatim}
These generic functions are useful for dealing with NAs in e.g., data frames. `na.fail` returns the object if it does not contain any missing values, and signals an error otherwise. `na.omit` returns the object with incomplete cases removed. `na.pass` returns the object unchanged.

**Usage**

```r
na.fail(object, ...)  
na.omit(object, ...)  
na.exclude(object, ...)  
na.pass(object, ...)
```

**Arguments**

- `object` an R object, typically a data frame
- `...` further arguments special methods could require.

**Details**

At present these will handle vectors, matrices and data frames comprising vectors and matrices (only).

If `na.omit` removes cases, the row numbers of the cases form the "na.action" attribute of the result, of class "omit".

`na.exclude` differs from `na.omit` only in the class of the "na.action" attribute of the result, which is "exclude". This gives different behaviour in functions making use of `naresid` and `napredict`: when `na.exclude` is used the residuals and predictions are padded to the correct length by inserting NAs for cases omitted by `na.exclude`.

**References**

**See Also**

`na.action`, `options` with argument `na.action` for setting NA actions; and `lm` and `glm` for functions using these. `na.contiguous` as alternative for time series.
Examples

DF <- data.frame(x = c(1, 2, 3), y = c(0, 10, NA))
na.omit(DF)
m <- as.matrix(DF)
na.omit(m)
stopifnot(all(na.omit(1:3) == 1:3)) # does not affect objects with no NA's
try(na.fail(DF))  #> Error: missing values in ...

options("na.action")

---

naprint

Adjust for Missing Values

Description

Use missing value information to report the effects of an na.action.

Usage

naprint(x, ...)

Arguments

x
An object produced by an na.action function.

... further arguments passed to or from other methods.

Details

This is a generic function, and the exact information differs by method. naprint.omit reports the number of rows omitted: naprint.default reports an empty string.

Value

A character string providing information on missing values, for example the number.

---

naresid

Adjust for Missing Values

Description

Use missing value information to adjust residuals and predictions.

Usage

naresid(omit, x, ...)
napredict(omit, x, ...)
Arguments

omit an object produced by an na.action function, typically the "na.action" attribute of the result of na.omit or na.exclude.

x a vector, data frame, or matrix to be adjusted based upon the missing value information.

... further arguments passed to or from other methods.

Details

These are utility functions used to allow predict, fitted and residuals methods for modelling functions to compensate for the removal of NAs in the fitting process. They are used by the default, "lm", "glm" and "nls" methods, and by further methods in packages MASS, rpart and survival. Also used for the scores returned by factanal, prcomp and princomp.

The default methods do nothing. The default method for the na.exclude action is to pad the object with NAs in the correct positions to have the same number of rows as the original data frame.

Currently naresid and napredict are identical, but future methods need not be. naresid is used for residuals, and napredict for fitted values, predictions and weights.

Value

These return a similar object to x.

Note

In the early 2000s, packages rpart and survival5 contained versions of these functions that had an na.omit action equivalent to that now used for na.exclude.

---

NegBinomial

The Negative Binomial Distribution

Description

Density, distribution function, quantile function and random generation for the negative binomial distribution with parameters size and prob.

Usage

dnbinom(x, size, prob, mu, log = FALSE)
pnbinom(q, size, prob, mu, lower.tail = TRUE, log.p = FALSE)
qnbinom(p, size, prob, mu, lower.tail = TRUE, log.p = FALSE)
rnbinom(n, size, prob, mu)
NegBinomial

Arguments

- `x` vector of (non-negative integer) quantiles.
- `q` vector of (non-negative integer) quantiles.
- `p` vector of probabilities.
- `n` number of observations. If `length(n) > 1`, the length is taken to be the number required.
- `size` target for number of successful trials, or dispersion parameter (the shape parameter of the gamma mixing distribution). Must be strictly positive, need not be integer.
- `prob` probability of success in each trial. 0 < `prob` <= 1.
- `mu` alternative parametrization via mean: see ‘Details’.
- `log, log.p` logical; if TRUE, probabilities `p` are given as log(p).
- `lower.tail` logical; if TRUE (default), probabilities are `P[X ≤ x]`, otherwise, `P[X > x].`

Details

The negative binomial distribution with `size = n` and `prob = p` has density

\[ p(x) = \frac{\Gamma(x + n)}{\Gamma(n)x!} p^n(1 - p)^x \]

for `x = 0, 1, 2, …, n > 0` and `0 < p ≤ 1`.

This represents the number of failures which occur in a sequence of Bernoulli trials before a target number of successes is reached. The mean is `n(1 - p)/p` and variance `n(1 - p)/p^2`.

A negative binomial distribution can also arise as a mixture of Poisson distributions with mean distributed as a gamma distribution (see `pgamma`) with scale parameter `(1 - prob)/prob` and shape parameter `size`. (This definition allows non-integer values of `size`.)

An alternative parametrization (often used in ecology) is by the mean `mu`, and `size`, the dispersion parameter, where `prob = size/(size+mu)`. The variance is `mu + mu^2/size` in this parametrization.

If an element of `x` is not integer, the result of `dnbinom` is zero, with a warning.

The quantile is defined as the smallest value `x` such that `F(x) ≥ p`, where `F` is the distribution function.

Value

`dnbinom` gives the density, `pbinom` gives the distribution function, `qbinom` gives the quantile function, and `rbinom` generates random deviates.

Invalid `size` or `prob` will result in return value NaN, with a warning.

The length of the result is determined by `n` for `rbinom`, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than `n` are recycled to the length of the result. Only the first elements of the logical parameters are used.
Source

dnbinom computes via binomial probabilities, using code contributed by Catherine Loader (see dbinom).

pnbinom uses pbeta.

qnbinom uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.

rnbinom uses the derivation as a gamma mixture of Poissons, see

See Also

Distributions for standard distributions, including dbinom for the binomial, dpois for the Poisson and dgeom for the geometric distribution, which is a special case of the negative binomial.

Examples

require(graphics)
x <- seq(0:11)
dnbinom(x, size = 1, prob = 1/2) * 2^(1 + x) # == 1
126 / dnbinom(0:7, size = 2, prob = 1/2) # - theoretically integer

## Cumulative ('p') = Sum of discrete prob.s ('d'); Relative error :
summary(1 - cumsum(dnbinom(x, size = 2, prob = 1/2)) / pnbinom(x, size = 2, prob = 1/2))

x <- seq(0:15)
size <- (1:2)/4
persp(x, size, dnb <- outer(x, size, function(x,s) dnbinom(x, s, prob = 0.4)),
xlab = "x", ylab = "s", zlab = "density", theta = 15)
title(tit <- "negative binomial density(x,s, pr = 0.4) vs. x & s")
image (x, size, log10(dnb), main = paste("log \[", tit, "]\))
contour(x, size, log10(dnb), add = TRUE)

## Alternative parametrization
x1 <- rnbinom(500, mu = 4, size = 1)
x2 <- rnbinom(500, mu = 4, size = 10)
x3 <- rnbinom(500, mu = 4, size = 100)
h1 <- hist(x1, breaks = 20, plot = FALSE)
h2 <- hist(x2, breaks = h1$breaks, plot = FALSE)
h3 <- hist(x3, breaks = h1$breaks, plot = FALSE)
barplot(rbind(h1$counts, h2$counts, h3$counts),
beside = TRUE, col = c("red","blue","cyan"),
names.arg = round(h1$breaks[-length(h1$breaks)]))
**nextn**

*Highly Composite Numbers*

**Description**

`nextn` returns the smallest integer, greater than or equal to `n`, which can be obtained as a product of powers of the values contained in `factors`. `nextn` is intended to be used to find a suitable length to zero-pad the argument of `fft` to so that the transform is computed quickly. The default value for `factors` ensures this.

**Usage**

`nextn(n, factors = c(2,3,5))`

**Arguments**

- `n` an integer.
- `factors` a vector of positive integer factors.

**See Also**

`convolve`, `fft`.

**Examples**

```r
nextn(1/0) # 1/0
table(sapply(599:630, nextn))
```

---

**nlm**

*Non-Linear Minimization*

**Description**

This function carries out a minimization of the function `f` using a Newton-type algorithm. See the references for details.

**Usage**

```r
nlm(f, p, ..., hessian = FALSE, typsize = rep(1, length(p)),
    fscale = 1, print.level = 0, ndigit = 12, gradtol = 1e-6,
    stepmax = max(1000 * sqrt(sum((p/typsize)^2)), 1000),
    steptol = 1e-6, iterlim = 100, check.analyticals = TRUE)
```
Arguments

\( f \)
the function to be minimized, returning a single numeric value. This should be
a function with first argument a vector of the length of \( p \) followed by any other
arguments specified by the \( \ldots \) argument.

If the function value has an attribute called \texttt{gradient} or both \texttt{gradient} and
\texttt{hessian} attributes, these will be used in the calculation of updated parameter
values. Otherwise, numerical derivatives are used. \texttt{deriv} returns a function with
suitable \texttt{gradient} attribute and optionally a \texttt{hessian} attribute.

\( p \)
starting parameter values for the minimization.

\( \ldots \)
additional arguments to be passed to \( f \).

\texttt{hessian}
if \texttt{TRUE}, the hessian of \( f \) at the minimum is returned.

\texttt{typsize}
an estimate of the size of each parameter at the minimum.

\texttt{fscale}
an estimate of the size of \( f \) at the minimum.

\texttt{print.level}
this argument determines the level of printing which is done during the mini-
mization process. The default value of 0 means that no printing occurs, a value
of 1 means that initial and final details are printed and a value of 2 means that
full tracing information is printed.

\texttt{ndigit}
the number of significant digits in the function \( f \).

\texttt{gradtol}
a positive scalar giving the tolerance at which the scaled gradient is considered
close enough to zero to terminate the algorithm. The scaled gradient is a measure
of the relative change in \( f \) in each direction \( p[i] \) divided by the relative change
in \( p[i] \).

\texttt{stepmax}
a positive scalar which gives the maximum allowable scaled step length.
\texttt{stepmax} is used to prevent steps which would cause the optimization function to
overflow, to prevent the algorithm from leaving the area of interest in parameter
space, or to detect divergence in the algorithm. \texttt{stepmax} would be chosen small
enough to prevent the first two of these occurrences, but should be larger than
any anticipated reasonable step.

\texttt{steptol}
A positive scalar providing the minimum allowable relative step length.

\texttt{iterlim}
a positive integer specifying the maximum number of iterations to be performed
before the program is terminated.

\texttt{check.analyticals}
a logical scalar specifying whether the analytic gradients and Hessians, if they
are supplied, should be checked against numerical derivatives at the initial pa-
rameter values. This can help detect incorrectly formulated gradients or Hess-
ians.

Details

Note that arguments after \( \ldots \) must be matched exactly.

If a gradient or hessian is supplied but evaluates to the wrong mode or length, it will be ignored if
\texttt{check.analyticals} = \texttt{TRUE} (the default) with a warning. The hessian is not even checked unless
the gradient is present and passes the sanity checks.
From the three methods available in the original source, we always use method “1” which is line search.

The functions supplied should always return finite (including not NA and not NaN) values: for the function value itself non-finite values are replaced by the maximum positive value with a warning.

The parameter vector passed to \( f \) and \( \text{hessian} \) has special semantics and is shared between calls. The functions should not copy it.

**Value**

A list containing the following components:

- `minimum` the value of the estimated minimum of \( f \).
- `estimate` the point at which the minimum value of \( f \) is obtained.
- `gradient` the gradient at the estimated minimum of \( f \).
- `hessian` the hessian at the estimated minimum of \( f \) (if requested).
- `code` an integer indicating why the optimization process terminated.
  - 1: relative gradient is close to zero, current iterate is probably solution.
  - 2: successive iterates within tolerance, current iterate is probably solution.
  - 3: last global step failed to locate a point lower than \( \text{estimate} \). Either \( \text{estimate} \) is an approximate local minimum of the function or \( \text{steptol} \) is too small.
  - 4: iteration limit exceeded.
  - 5: maximum step size \( \text{stepmax} \) exceeded five consecutive times. Either the function is unbounded below, becomes asymptotic to a finite value from above in some direction or \( \text{stepmax} \) is too small.
- `iterations` the number of iterations performed.

**Source**

The current code is by Saikat DebRoy and the R Core team, using a C translation of Fortran code by Richard H. Jones.

**References**

**See Also**

- `optim` and `nlminb`.
- `constrOptim` for constrained optimization, `optimize` for one-dimensional minimization and `uniroot` for root finding. `deriv` to calculate analytical derivatives.

For nonlinear regression, `nls` may be better.
Examples

\[
f <- \text{function}(x) \sum((x-1:length(x))^2)
\]
\[
nlm(f, c(10,10))
\]
\[
nlm(f, c(10,10), \text{print.level} = 2)
\]
\[
\text{utils::str(nlm(f, c(5), \text{hessian} = \text{TRUE}))}
\]
\[
f <- \text{function}(x, a) \sum((x-a)^2)
\]
\[
nlm(f, c(10,10), a = c(3,5))
\]
\[
f <- \text{function}(x, a)
\]
\[
\{
  \text{res} <- \sum((x-a)^2)
  \text{attr(res, "gradient")} <- 2*(x-a)
  \text{res}
\}
\]
\[
nlm(f, c(10,10), a = c(3,5))
\]

## more examples, including the use of derivatives.
## Not run: demo(nlm)

### nlminb

**Optimization using PORT routines**

**Description**

Unconstrained and box-constrained optimization using PORT routines.

**Usage**

\[
nlminb(\text{start}, \text{objective}, \text{gradient} = \text{NULL}, \text{hessian} = \text{NULL}, ..., \text{scale} = 1, \text{control} = \text{list()}, \text{lower} = -\text{Inf}, \text{upper} = \text{Inf})
\]

**Arguments**

- **start**
  numeric vector, initial values for the parameters to be optimized.

- **objective**
  Function to be minimized. Must return a scalar value. The first argument to objective is the vector of parameters to be optimized, whose initial values are supplied through start. Further arguments (fixed during the course of the optimization) to objective may be specified as well (see ...).

- **gradient**
  Optional function that takes the same arguments as objective and evaluates the gradient of objective at its first argument. Must return a vector as long as start.

- **hessian**
  Optional function that takes the same arguments as objective and evaluates the hessian of objective at its first argument. Must return a square matrix of order length(start). Only the lower triangle is used.

- **...**
  Further arguments to be supplied to objective.

- **scale**
  See PORT documentation (or leave alone).
controls

control A list of control parameters. See below for details.
lower, upper vectors of lower and upper bounds, replicated to be as long as start. If unspecified, all parameters are assumed to be unconstrained.

Details

Any names of start are passed on to objective and where applicable, gradient and hessian. The parameter vector will be coerced to double.

The parameter vector passed to objective, gradient and hessian has special semantics and is shared between calls. The functions should not copy it.

If any of the functions returns NA or NaN the internal code could infinite-loop in `R` prior to 2.15.2: this is now an error for the gradient and Hessian, and such values for function evaluation are replaced by +Inf with a warning.

Value

A list with components:

- par The best set of parameters found.
- objective The value of objective corresponding to par.
- convergence An integer code. 0 indicates successful convergence.
- message A character string giving any additional information returned by the optimizer, or NULL. For details, see PORT documentation.
- iterations Number of iterations performed.
- evaluations Number of objective function and gradient function evaluations.

Control parameters

Possible names in the control list and their default values are:

eval.max Maximum number of evaluations of the objective function allowed. Defaults to 200.
iter.max Maximum number of iterations allowed. Defaults to 150.
trace The value of the objective function and the parameters is printed every trace'th iteration. Defaults to 0 which indicates no trace information is to be printed.
abs.tol Absolute tolerance. As from R 2.12.0, defaults to 0 so the absolute convergence test is not used. If the objective function is known to be non-negative, the previous default of 1e-20 would be more appropriate.
rel.tol Relative tolerance. Defaults to 1e-10.
x.tol X tolerance. Defaults to 1.5e-8.
xf.tol false convergence tolerance. Defaults to 2.2e-14.
step.min, step.max Minimum and maximum step size. Both default to 1.
sing.tol singular convergence tolerance; defaults to rel.tol.
scale.init ...
diff.g an estimated bound on the relative error in the objective function value.

\]

---

**nls**  
*Nonlinear Least Squares*

**Description**

Determine the nonlinear (weighted) least-squares estimates of the parameters of a nonlinear model.

**Usage**

\[
nls(\text{formula}, \text{data}, \text{start}, \text{control}, \text{algorithm}, \\
\text{trace}, \text{subset}, \text{weights}, \text{na.action}, \text{model}, \\
\text{lower}, \text{upper}, \ldots)
\]

**Arguments**

- **formula**: a nonlinear model formula including variables and parameters. Will be coerced to a formula if necessary.
- **data**: an optional data frame in which to evaluate the variables in formula and weights. Can also be a list or an environment, but not a matrix.
- **start**: a named list or named numeric vector of starting estimates. When start is missing, a very cheap guess for start is tried (if algorithm != "plinear").
- **control**: an optional list of control settings. See \text{nls.control} for the names of the settable control values and their effect.
- **algorithm**: character string specifying the algorithm to use. The default algorithm is a Gauss-Newton algorithm. Other possible values are "plinear" for the Golub-Pereyra algorithm for partially linear least-squares models and "port" for the 'nl2sol' algorithm from the Port library – see the references.
- **trace**: logical value indicating if a trace of the iteration progress should be printed. Default is FALSE. If TRUE the residual (weighted) sum-of-squares and the parameter values are printed at the conclusion of each iteration. When the "plinear" algorithm is used, the conditional estimates of the linear parameters are printed after the nonlinear parameters. When the "port" algorithm is used the objective function value printed is half the residual (weighted) sum-of-squares.
subset an optional vector specifying a subset of observations to be used in the fitting process.

weights an optional numeric vector of (fixed) weights. When present, the objective function is weighted least squares.

na.action a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The ‘factory-fresh’ default is na.omit. Value na.exclude can be useful.

model logical. If true, the model frame is returned as part of the object. Default is FALSE.

lower, upper vectors of lower and upper bounds, replicated to be as long as start. If unspecified, all parameters are assumed to be unconstrained. Bounds can only be used with the "port" algorithm. They are ignored, with a warning, if given for other algorithms.

... Additional optional arguments. None are used at present.

Details

An nls object is a type of fitted model object. It has methods for the generic functions anova, coef, confint, deviance, df.residual, fitted, formula, logLik, predict, print, profile, residuals, summary, vcov and weights.

Variables in formula (and weights if not missing) are looked for first in data, then the environment of formula and finally along the search path. Functions in formula are searched for first in the environment of formula and then along the search path.

Arguments subset and na.action are supported only when all the variables in the formula taken from data are of the same length: other cases give a warning.

Note that the anova method does not check that the models are nested: this cannot easily be done automatically, so use with care.

Value

A list of

m an nlsModel object incorporating the model.
data the expression that was passed to nls as the data argument. The actual data values are present in the environment of the m component.
call the matched call with several components, notably algorithm.
na.action the "na.action" attribute (if any) of the model frame.
dataClasses the "dataClasses" attribute (if any) of the "terms" attribute of the model frame.
model if model = TRUE, the model frame.
weights if weights is supplied, the weights.
convInfo a list with convergence information.
control the control list used, see the control argument.
nls

convergence, message
for an algorithm = "port" fit only, a convergence code (0 for convergence) and message.
To use these is deprecated, as they are available from convInfo now.

Warning

Do not use nls on artificial "zero-residual" data.
The nls function uses a relative-offset convergence criterion that compares the numerical imprecision at the current parameter estimates to the residual sum-of-squares. This performs well on data of the form

\[ y = f(x, \theta) + \epsilon \]

(with \( \text{var}(\epsilon) > 0 \)). It fails to indicate convergence on data of the form

\[ y = f(x, \theta) \]

because the criterion amounts to comparing two components of the round-off error. If you wish to test nls on artificial data please add a noise component, as shown in the example below.
The algorithm = "port" code appears unfinished, and does not even check that the starting value is within the bounds. Use with caution, especially where bounds are supplied.

Note

Setting warnOnly = TRUE in the control argument (see nls.control) returns a non-converged object (since R version 2.5.0) which might be useful for further convergence analysis, but not for inference.

```

## If the value of the right side [of formula] has an attribute called
## 'gradient' this should be a matrix with the number of rows equal
## to the length of the response and one column for each parameter.

```r
weighted.MM.grad <- function(resp, conc1, conc.1, Vm, K)
{
  conc <- c(conc1, conc.1)
  K.conc <- K+conc
  dy.dV <- conc/K.conc
  dy.dK <- -Vm*dy.dV/K.conc
  pred <- Vm*dy.dV
  pred.5 <- sqrt(pred)
  dev <- (resp - pred) / pred.5
  Ddev <- -0.5*(resp+pred)/(pred.5*pred)
  attr(dev, "gradient") <- Ddev * cbind(Vm = dy.dV, K = dy.dK)
  dev
}
```

```r
Pur.wt.grad <- nls( ~ weighted.MM.grad(rate, conc1, conc.1, Vm, K),
  data = listTreat, start = list(Vm = 2, K = 1))
```

```
rbind(coef(Pur.wt), coef(Pur.wt1), coef(Pur.wt.grad))
```

## In this example, there seems no advantage to providing the gradient.
## In other cases, there might be.

## The two examples below show that you can fit a model to
## artificial data with noise but not to artificial data
## without noise.

```r
x <- 1:10
y <- 2*x + 3 # perfect fit
yeps <- y + rnorm(length(y), sd = 0.01) # added noise
nls(yeps ~ a + b*x, start = list(a = 0.12345, b = 0.54321))
```

## Not run:

## terminates in an error, because convergence cannot be confirmed:

```r
nls(y ~ a + b*x, start = list(a = 0.12345, b = 0.54321))
```
## End(Not run)

## the nls() internal cheap guess for starting values can be sufficient:

```r
x <- -(1:100)/10
y <- 100 + 10 * exp(x / 2) + rnorm(x)/10
nlmod <- nls(y ~ Const + A * exp(B * x))

plot(x,y, main = "nls(*), data, true function and fit, n=100")
curve(100 + 10 * exp(x / 2), col = 4, add = TRUE)
lines(x, predict(nlmod), col = 2)
```

## The muscle dataset in MASS is from an experiment on muscle
## contraction on 21 animals. The observed variables are Strip
## (identifier of muscle), Conc (Cacl concentration) and Length
## (resulting length of muscle section).
```r
utils::data(muscle, package = "MASS")

## The non linear model considered is
## Length = alpha + beta*exp(-Conc/theta) + error
## where theta is constant but alpha and beta may vary with Strip.
```

```r
with(muscle, table(Strip)) # 2,3 or 4 obs per strip

## We first use the plinear algorithm to fit an overall model,
## ignoring that alpha and beta might vary with Strip.
```n
```r
musc.1 <- nls(Length ~ cbind(1, exp(-Conc/th)), muscle,
    start = list(th = 1), algorithm = "plinear")
summary(musc.1)
```

## Then we use nls' indexing feature for parameters in non-linear
## models to use the conventional algorithm to fit a model in which
## alpha and beta vary with Strip. The starting values are provided
## by the previously fitted model.

```r
musc.2 <- nls(Length ~ a[Strip] + b[Strip]*exp(-Conc/th), muscle,
    start = list(a = rep(b[2], 21), b = rep(b[3], 21), th = b[1]))
summary(musc.2)
```

---------------

### nls.control

**Control the Iterations in nls**

**Description**

Allow the user to set some characteristics of the nls nonlinear least squares algorithm.
Usage

nls.control(maxiter = 50, tol = 1e-05, minFactor = 1/1024, printEval = FALSE, warnOnly = FALSE)

Arguments

maxiter  A positive integer specifying the maximum number of iterations allowed.
tol      A positive numeric value specifying the tolerance level for the relative offset convergence criterion.
minFactor A positive numeric value specifying the minimum step-size factor allowed on any step in the iteration. The increment is calculated with a Gauss-Newton algorithm and successively halved until the residual sum of squares has been decreased or until the step-size factor has been reduced below this limit.
printEval a logical specifying whether the number of evaluations (steps in the gradient direction taken each iteration) is printed.
warnOnly a logical specifying whether nls() should return instead of signalling an error in the case of termination before convergence. Termination before convergence happens upon completion of maxiter iterations, in the case of a singular gradient, and in the case that the step-size factor is reduced below minFactor.

Value

A list with exactly five components:
- maxiter
- tol
- minFactor
- printEval
- warnOnly

with meanings as explained under ‘Arguments’.

NLSstAsymptotic  
Fit the Asymptotic Regression Model

Description
Fits the asymptotic regression model, in the form \( b_0 + b_1 \cdot (1 - \exp(-\exp(lrc) \cdot x) \) to the \( xy \) data. This can be used as a building block in determining starting estimates for more complicated models.

Usage
NLSstAsymptotic(xy)

Arguments
xy a sortedXyData object

Value
A numeric value of length 3 with components labelled \( b_0, b_1, \) and \( lrc \). \( b_0 \) is the estimated intercept on the \( y \)-axis, \( b_1 \) is the estimated difference between the asymptote and the \( y \)-intercept, and \( lrc \) is the estimated logarithm of the rate constant.

print(NLSstAsymptotic(sortedXyData(expression(age),
                                         expression(height),
                                         Lob.329)), digits = 3)
**NLSstClosestX**

**Inverse Interpolation**

**Description**

Use inverse linear interpolation to approximate the x value at which the function represented by xy is equal to yval.

**Usage**

NLSstClosestX(xy, yval)

**Arguments**

- **xy**: a sortedXyData object
- **yval**: a numeric value on the y scale

**Value**

A single numeric value on the x scale.

**Author(s)**

José Pinheiro and Douglas Bates

**See Also**

sortedXyData, NLSstLfAsymptote, NLSstRtAsymptote, selfStart

**Examples**

```r
dNase.2 <- DNase[ DNase$Run == "2", ]
dN.srt <- sortedXyData(expression(log(conc)), expression(density), dNase.2)
NLSstClosestX(dN.srt, 1./zero.noslash)
```

---

**NLSstLfAsymptote**

**Horizontal Asymptote on the Left Side**

**Description**

Provide an initial guess at the horizontal asymptote on the left side (i.e., small values of x) of the graph of y versus x from the xy object. Primarily used within initial functions for self-starting nonlinear regression models.

**Usage**

NLSstLfAsymptote(xy)
**NLSstRtAsymptote**

**Arguments**
- `xy` a sortedXyData object

**Value**
A single numeric value estimating the horizontal asymptote for small x.

**Author(s)**
José Pinheiro and Douglas Bates

DN.srt <- sortedXyData( expression(log(conc)), expression(density), DNase.2 )
NLSstLlAsymptote( DN.srt )
```

---

**NLSstRtAsymptote**  
*Horizontal Asymptote on the Right Side*

**Description**
Provide an initial guess at the horizontal asymptote on the right side (i.e., large values of x) of the graph of y versus x from the xy object. Primarily used within initial functions for self-starting nonlinear regression models.

**Usage**
```
NLSstRtAsymptote(xy)
```

**Arguments**
- `xy` a sortedXyData object

**Value**
A single numeric value estimating the horizontal asymptote for large x.

**Author(s)**
José Pinheiro and Douglas Bates

**See Also**
- `sortedXyData`, `NLSstClosestX`, `NLSstRtAsymptote`, `selfStart`
nobs

Examples

DNase.2 <- DNase[ DNase$Run == "2", ]
DN.srt <- sortedXYData( expression(log(conc)), expression(density), DNase.2 )
NLSstRtAsymptote( DN.srt )

nobs

Extract the Number of Observations from a Fit.

Description

Extract the number of ‘observations’ from a model fit. This is principally intended to be used in computing BIC (see AIC).

Usage

nobs(object, ...)

## Default S3 method:
nobs(object, use.fallback = FALSE, ...)

Arguments

object

A fitted model object.

use.fallback

logical: should fallback methods be used to try to guess the value?

...

Further arguments to be passed to methods.

Details

This is a generic function, with an S4 generic in package stats4. There are methods in this package for objects of classes "lm", "glm", "nls" and "logLik", as well as a default method (which throws an error, unless use.fallback = TRUE when it looks for weights and residuals components – use with care!).

The main usage is in determining the appropriate penalty for BIC, but nobs is also used by the stepwise fitting methods step, add1 and drop1 as a quick check that different fits have been fitted to the same set of data (and not, say, that further rows have been dropped because of NAs in the new predictors).

For lm, glm and nls fits, observations with zero weight are not included.

Value

A single number, normally an integer. Could be NA.

See Also

AIC.
The Normal Distribution

Description

Density, distribution function, quantile function and random generation for the normal distribution with mean equal to \( \text{mean} \) and standard deviation equal to \( \text{sd} \).

Usage

\[
\begin{align*}
\text{dnorm}(x, \text{mean} = 0, \text{sd} = 1, \text{log} = \text{FALSE}) \\
\text{pnorm}(q, \text{mean} = 0, \text{sd} = 1, \text{lower.tail} = \text{TRUE}, \text{log.p} = \text{FALSE}) \\
\text{qnorm}(p, \text{mean} = 0, \text{sd} = 1, \text{lower.tail} = \text{TRUE}, \text{log.p} = \text{FALSE}) \\
\text{rnorm}(n, \text{mean} = 0, \text{sd} = 1)
\end{align*}
\]

Arguments

- \( x, q \) vector of quantiles.
- \( p \) vector of probabilities.
- \( n \) number of observations. If \( \text{length}(n) > 1 \), the length is taken to be the number required.
- \( \text{mean} \) vector of means.
- \( \text{sd} \) vector of standard deviations.
- \( \text{log} \), \( \text{log.p} \) logical; if TRUE, probabilities \( p \) are given as \( \log(p) \).
- \( \text{lower.tail} \) logical; if TRUE (default), probabilities are \( P[X \leq x] \) otherwise, \( P[X > x] \).

Details

If \( \text{mean} \) or \( \text{sd} \) are not specified they assume the default values of 0 and 1, respectively.

The normal distribution has density

\[
f(x) = \frac{1}{\sqrt{2\pi\sigma}} e^{-(x-\mu)^2/2\sigma^2}
\]

where \( \mu \) is the mean of the distribution and \( \sigma \) the standard deviation.

\text{qnorm} \ is based on Wichura’s algorithm AS 241 which provides precise results up to about 16 digits.

Value

\text{dnorm} \ gives the density, \text{pnorm} \ gives the distribution function, \text{qnorm} \ gives the quantile function, and \text{rnorm} \ generates random deviates.

The length of the result is determined by \( n \) for \text{rnorm}, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than \( n \) are recycled to the length of the result. Only the first elements of the logical parameters are used.
Normal

Source

Distributions for other standard distributions, including `dlnorm` for the Lognormal distribution.

Examples

```r
require(graphics)

dnorm(0) == 1/sqrt(2*pi)
dnorm(1) == exp(-1/2)/sqrt(2*pi)
dnorm(1) == 1/sqrt(2*pi*exp(1))

## Using "log = TRUE" for an extended range :
par(mfrow = c(2,1))
plot(function(x) dnorm(x, log = TRUE), -6/2, 5/2,
     main = "log ( Normal density )")
curve(log(dnorm(x)), add = TRUE, col = "red", lwd = 2)
mtext("dnorm(x, log=TRUE)", adj = 0)
mtext("log(dnorm(x))", col = "red", adj = 1)

plot(function(x) pnorm(x, log.p = TRUE), -5/2, 1/2,
     main = "log ( Normal Cumulative )")
curve(log(pnorm(x)), add = TRUE, col = "red", lwd = 2)
mtext("pnorm(x, log=TRUE)", adj = 0)
mtext("log(pnorm(x))", col = "red", adj = 1)

## if you want the so-called 'error function'
erf <- function(x) 2 * pnorm(x * sqrt(2)) - 1
## (see Abramowitz and Stegun 29.2.29)
## and the so-called 'complementary error function'
ecf <- function(x) 2 * pnorm(x * sqrt(2), lower = FALSE)
## and the inverses
erfinv <- function(x) qnorm((1 + x)/2)/sqrt(2)
erfcinv <- function(x) qnorm(x/2, lower = FALSE)/sqrt(2)
```
numericDeriv  Evaluate Derivatives Numerically

Description

numericDeriv numerically evaluates the gradient of an expression.

Usage

numericDeriv(expr, theta, rho = parent.frame(), dir = 1./zero.noslash)

Arguments

- **expr**: The expression to be differentiated. The value of this expression should be a numeric vector.
- **theta**: A character vector of names of numeric variables used in expr.
- **rho**: An environment containing all the variables needed to evaluate expr.
- **dir**: A numeric vector of directions to use for the finite differences.

Details

This is a front end to the C function numeric_deriv, which is described in *Writing R Extensions*. The numeric variables must be of type real and not integer.

Value

The value of eval(expr, envir = rho) plus a matrix attribute called gradient. The columns of this matrix are the derivatives of the value with respect to the variables listed in theta.

Author(s)

Saikat DebRoy <saikat@stat.wisc.edu>

Examples

```r
myenv <- new.env()
assign("mean", 0., envir = myenv)
assign("sd", 1., envir = myenv)
assign("x", seq(-3., 3., len = 31), envir = myenv)
numericDeriv(quote(pnorm(x, mean, sd)), c("mean", "sd"), myenv)
```
offset

Include an Offset in a Model Formula

Description
An offset is a term to be added to a linear predictor, such as in a generalised linear model, with known coefficient 1 rather than an estimated coefficient.

Usage
offset(object)

Arguments
object An offset to be included in a model frame

Details
There can be more than one offset in a model formula, but - is not supported for offset terms (and is equivalent to +).

Value
The input value.

See Also
model.offset, model.frame.
For examples see glm and Insurance in package MASS.

oneway.test
Test for Equal Means in a One-Way Layout

Description
Test whether two or more samples from normal distributions have the same means. The variances are not necessarily assumed to be equal.

Usage
oneway.test(formula, data, subset, na.action, var.equal = FALSE)
Arguments

- **formula**: a formula of the form \( \text{lhs} \sim \text{rhs} \) where \( \text{lhs} \) gives the sample values and \( \text{rhs} \) the corresponding groups.
- **data**: an optional matrix or data frame (or similar; see `model.frame`) containing the variables in the formula. By default the variables are taken from `environment(formula)`.
- **subset**: an optional vector specifying a subset of observations to be used.
- **na.action**: a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.
- **var.equal**: a logical variable indicating whether to treat the variances in the samples as equal. If `TRUE`, then a simple F test for the equality of means in a one-way analysis of variance is performed. If `FALSE`, an approximate method of Welch (1951) is used, which generalizes the commonly known 2-sample Welch test to the case of arbitrarily many samples.

Value

A list with class "htest" containing the following components:

- **statistic**: the value of the test statistic.
- **parameter**: the degrees of freedom of the exact or approximate F distribution of the test statistic.
- **p.value**: the p-value of the test.
- **method**: a character string indicating the test performed.
- **data.name**: a character string giving the names of the data.

References

See Also

The standard t test (`t.test`) as the special case for two samples; the Kruskal-Wallis test `kruskal.test` for a nonparametric test for equal location parameters in a one-way layout.

Examples

```r
## Not assuming equal variances
oneway.test(extra ~ group, data = sleep)
## Assuming equal variances
oneway.test(extra ~ group, data = sleep, var.equal = TRUE)
## which gives the same result as
anova(lm(extra ~ group, data = sleep))
```
optim

General-purpose Optimization

Description

General-purpose optimization based on Nelder–Mead, quasi-Newton and conjugate-gradient algorithms. It includes an option for box-constrained optimization and simulated annealing.

Usage

optim(par, fn, gr = NULL, ..., method = c("Nelder-Mead", "BFGS", "CG", "L-BFGS-B", "SANN", "Brent"), lower = -Inf, upper = Inf, control = list(), hessian = FALSE)

optimHess(par, fn, gr = NULL, ..., control = list())

Arguments

par Initial values for the parameters to be optimized over.
fn A function to be minimized (or maximized), with first argument the vector of parameters over which minimization is to take place. It should return a scalar result.
gr A function to return the gradient for the "BFGS", "CG" and "L-BFGS-B" methods. If it is NULL, a finite-difference approximation will be used. For the "SANN" method it specifies a function to generate a new candidate point. If it is NULL a default Gaussian Markov kernel is used.
...
method The method to be used. See ‘Details’.
lower, upper Bounds on the variables for the "L-BFGS-B" method, or bounds in which to search for method "Brent".
control A list of control parameters. See ‘Details’.
hessian Logical. Should a numerically differentiated Hessian matrix be returned?

Details

Note that arguments after ... must be matched exactly.

By default optim performs minimization, but it will maximize if control$fnscale is negative. optimHess is an auxiliary function to compute the Hessian at a later stage if hessian = TRUE was forgotten.

The default method is an implementation of that of Nelder and Mead (1965), that uses only function values and is robust but relatively slow. It will work reasonably well for non-differentiable functions.
Method "BFGS" is a quasi-Newton method (also known as a variable metric algorithm), specifically that published simultaneously in 1970 by Broyden, Fletcher, Goldfarb and Shanno. This uses function values and gradients to build up a picture of the surface to be optimized.

Method "CG" is a conjugate gradients method based on that by Fletcher and Reeves (1964) (but with the option of Polak–Ribiere or Beale–Sorenson updates). Conjugate gradient methods will generally be more fragile than the BFGS method, but as they do not store a matrix they may be successful in much larger optimization problems.

Method "L-BFGS-B" is that of Byrd et al. (1995) which allows box constraints, that is each variable can be given a lower and/or upper bound. The initial value must satisfy the constraints. This uses a limited-memory modification of the BFGS quasi-Newton method. If non-trivial bounds are supplied, this method will be selected, with a warning.

Nocedal and Wright (1999) is a comprehensive reference for the previous three methods.

Method "SANN" is by default a variant of simulated annealing given in Belisle (1992). Simulated-annealing belongs to the class of stochastic global optimization methods. It uses only function values but is relatively slow. It will also work for non-differentiable functions. This implementation uses the Metropolis function for the acceptance probability. By default the next candidate point is generated from a Gaussian Markov kernel with scale proportional to the actual temperature. If a function to generate a new candidate point is given, method "SANN" can also be used to solve combinatorial optimization problems. Temperatures are decreased according to the logarithmic cooling schedule as given in Belisle (1992, p. 890); specifically, the temperature is set to \[
temp / \log(((t-1) \times tmax) + \exp(1)),
\]
where \( t \) is the current iteration step and \( temp \) and \( tmax \) are specifiable via control, see below. Note that the "SANN" method depends critically on the settings of the control parameters. It is not a general-purpose method but can be very useful in getting to a good value on a very rough surface.

Method "Brent" is for one-dimensional problems only, using optimize(). It can be useful in cases where optim() is used inside other functions where only method can be specified, such as in mle from package stats4.

Function fn can return NA or Inf if the function cannot be evaluated at the supplied value, but the initial value must have a computable finite value of fn. (Except for method "L-BFGS-B" where the values should always be finite.)

optim can be used recursively, and for a single parameter as well as many. It also accepts a zero-length par, and just evaluates the function with that argument.

The control argument is a list that can supply any of the following components:

- trace Non-negative integer. If positive, tracing information on the progress of the optimization is produced. Higher values may produce more tracing information: for method "L-BFGS-B" there are six levels of tracing. (To understand exactly what these do see the source code: higher levels give more detail.)

- fnscale An overall scaling to be applied to the value of fn and gr during optimization. If negative, turns the problem into a maximization problem. Optimization is performed on fn(par)/fnscale.

- parscale A vector of scaling values for the parameters. Optimization is performed on par/parscale and these should be comparable in the sense that a unit change in any element produces about a unit change in the scaled value. Not used (nor needed) for method = "Brent".
ndeps A vector of step sizes for the finite-difference approximation to the gradient, on
par/parscale scale. Defaults to $1e^{-3}$.

maxit The maximum number of iterations. Defaults to 100 for the derivative-based methods, and
500 for "Nelder-Mead".
For "SANN" maxit gives the total number of function evaluations: there is no other stopping
criterion. Defaults to 10000.

abstol The absolute convergence tolerance. Only useful for non-negative functions, as a tolerance
for reaching zero.

reltol Relative convergence tolerance. The algorithm stops if it is unable to reduce the
value by a factor of $\text{realtol} \times (\text{abs(val)} + \text{realtol})$ at a step. Defaults to
$\sqrt{\text{.Machine}$double.eps}$, typically about $1e^{-8}$.

alpha, beta, gamma Scaling parameters for the "Nelder-Mead" method. alpha is the reflection
factor (default 1.0), beta the contraction factor (0.5) and gamma the expansion factor (2.0).

REPORT The frequency of reports for the "BFGS", "L-BFGS-B" and "SANN" methods if
control$trace is positive. Defaults to every 10 iterations for "BFGS" and "L-BFGS-B", or
every 100 temperatures for "SANN".

type for the conjugate-gradients method. Takes value 1 for the Fletcher–Reeves update, 2 for
Polak–Ribiere and 3 for Beale–Sorenson.

lmm is an integer giving the number of BFGS updates retained in the "L-BFGS-B" method. It de-
defaults to 5.

factr controls the convergence of the "L-BFGS-B" method. Convergence occurs when the red-
duction in the objective is within this factor of the machine tolerance. Default is $1e$7, that is a
tolerance of about $1e^{-8}$.

pgtol helps control the convergence of the "L-BFGS-B" method. It is a tolerance on the projected
gradient in the current search direction. This defaults to zero, when the check is suppressed.

temp controls the "SANN" method. It is the starting temperature for the cooling schedule. Defaults
to 10.

tmax is the number of function evaluations at each temperature for the "SANN" method. Defaults to
10.

Any names given to par will be copied to the vectors passed to fn and gr. Note that no other
attributes of par are copied over.

The parameter vector passed to fn has special semantics and may be shared between calls: the
function should not change or copy it.

Value

For optim, a list with components:

par The best set of parameters found.

value The value of fn corresponding to par.

counts A two-element integer vector giving the number of calls to fn and gr respectiv-
ely. This excludes those calls needed to compute the Hessian, if requested,
and any calls to fn to compute a finite-difference approximation to the gradient.
convergence  An integer code. 0 indicates successful completion (which is always the case for "SANN" and "Brent"). Possible error codes are

1  indicates that the iteration limit maxit had been reached.
10  indicates degeneracy of the Nelder–Mead simplex.
51  indicates a warning from the "L-BFGS-B" method; see component message for further details.
52  indicates an error from the "L-BFGS-B" method; see component message for further details.

message  A character string giving any additional information returned by the optimizer, or NULL.

hessian  Only if argument hessian is true. A symmetric matrix giving an estimate of the Hessian at the solution found. Note that this is the Hessian of the unconstrained problem even if the box constraints are active.

For optimHess, the description of the hessian component applies.

Note

optim will work with one-dimensional pars, but the default method does not work well (and will warn). Method "Brent" uses optimize and needs bounds to be available; "BFGS" often works well enough if not.

Source

The code for methods "Nelder-Mead", "BFGS" and "CG" was based originally on Pascal code in Nash (1990) that was translated by p2c and then hand-optimized. Dr Nash has agreed that the code can be made freely available.

The code for method "L-BFGS-B" is based on Fortran code by Zhu, Byrd, Lu-Chen and Nocedal obtained from Netlib (file 'opt/lbfgs_bcm.shar': another version is in 'toms/778').

The code for method "SANN" was contributed by A. Trapletti.

---

**optimize**

One Dimensional Optimization

**Description**

The function `optimize` searches the interval from `lower` to `upper` for a minimum or maximum of the function `f` with respect to its first argument.

`optimise` is an alias for `optimize`. 
Usage

optimize(f = , interval = , ..., lower = min(interval),
          upper = max(interval), maximum = FALSE,
          tol = .Machine$double.eps^/zero.noslash.25)
optimise(f = , interval = , ..., lower = min(interval),
          upper = max(interval), maximum = FALSE,
          tol = .Machine$double.eps^/zero.noslash.25)

Arguments

f the function to be optimized. The function is either minimized or maximized
over its first argument depending on the value of maximum.
interval a vector containing the end-points of the interval to be searched for the mini-
mum.
... additional named or unnamed arguments to be passed to f.
lower the lower end point of the interval to be searched.
upper the upper end point of the interval to be searched.
maximum logical. Should we maximize or minimize (the default)?
tol the desired accuracy.

Details

Note that arguments after ... must be matched exactly.

The method used is a combination of golden section search and successive parabolic interpolation,
and was designed for use with continuous functions. Convergence is never much slower than that
for a Fibonacci search. If f has a continuous second derivative which is positive at the minimum
(which is not at lower or upper), then convergence is superlinear, and usually of the order of about
1.324.

The function f is never evaluated at two points closer together than \( \varepsilon|x_0| + (tol/3) \), where \( \varepsilon \) is
approximately \( \sqrt{\text{.Machine}$double.eps} \) and \( x_0 \) is the final abscissa optimize()$minimum.
If f is a unimodal function and the computed values of f are always unimodal when separated by at
least \( \varepsilon |x| + (tol/3) \), then \( x_0 \) approximates the abscissa of the global minimum of f on the interval
lower,upper with an error less than \( \varepsilon|x_0| + tol \).
If f is not unimodal, then optimize() may approximate a local, but perhaps non-global, minimum
to the same accuracy.

The first evaluation of f is always at \( x_1 = a + (1 - \phi)(b - a) \) where \( (a,b) = (\text{lower, upper}) \)
and \( \phi = (\sqrt{5} - 1)/2 = 0.61803.. \) is the golden section ratio. Almost always, the second evaluation
is at \( x_2 = a + \phi(b - a) \). Note that a local minimum inside \([x_1, x_2]\) will be found as solution, even
when f is constant in there, see the last example.

f will be called as f(x, ...) for a numeric value of x.

The argument passed to f has special semantics and used to be shared between calls. The function
should not copy it.
Value

A list with components minimum (or maximum) and objective which give the location of the minimum (or maximum) and the value of the function at that point.

Source

A C translation of Fortran code http://www.netlib.org/fmm/fmin.f (author(s) unstated) based on the Algol 60 procedure localmin given in the reference.

require(graphics)

f <- function (x, a) (x - a)^2
xmin <- optimize(f, c(0, 1), tol = 0.0001, a = 1/3)
xmin

## See where the function is evaluated:
optimize(function(x) x^2*(print(x)-1), lower = 0, upper = 10)

## "wrong" solution with unlucky interval and piecewise constant f():
f <- function(x) ifelse(x > -1, ifelse(x < 4, exp(-1/abs(x - 1)), 10), 10)
fp <- function(x) { print(x); f(x) }
plot(f, -2,5, ylim = 0:1, col = 2)
optimize(fp, c(-4, 20))  # doesn't see the minimum
optimize(fp, c(-7, 20))  # ok
```

order.dendrogram

Ordering or Labels of the Leaves in a Dendrogram

Description

Theses functions return the order (index) or the "label" attribute for the leaves in a dendrogram. These indices can then be used to access the appropriate components of any additional data.
Usage

order.dendrogram(x)

## S3 method for class 'dendrogram'
labels(object, ...)

Arguments

x, object  a dendrogram (see as.dendrogram).
...  additional arguments

Details

The indices or labels for the leaves in left to right order are retrieved.

Value

A vector with length equal to the number of leaves in the dendrogram is returned. From 
r <- order.dendrogram(), each element is the index into the original data (from which the 
dendrogram was computed).

Author(s)

R. Gentleman (order.dendrogram) and Martin Maechler (labels.dendrogram).

See Also

reorder, dendrogram.

Examples

set.seed(123)
x <- rnorm(10)
hc <- hclust(dist(x))
hc$order
dd <- as.dendrogram(hc)
order.dendrogram(dd) ## the same :
stopifnot(hc$order == order.dendrogram(dd))

d2 <- as.dendrogram(hclust(dist(USArrests)))
labels(d2) ## in this case the same as
stopifnot(identical(labels(d2),
                  rownames(USArrests)[order.dendrogram(d2)]))
Adjust P-values for Multiple Comparisons

Description

Given a set of p-values, returns p-values adjusted using one of several methods.

Usage

```r
p.adjust(p, method = p.adjust.methods, n = length(p))
```

```r
p.adjust.methods
# c("holm", "hochberg", "hommel", "bonferroni", "BH", "BY",
#    "fdr", "none")
```

Arguments

- `p` numeric vector of p-values (possibly with NAs). Any other R is coerced by `as.numeric`.
- `method` correction method
- `n` number of comparisons, must be at least `length(p)`; only set this (to non-default) when you know what you are doing!

Details

The adjustment methods include the Bonferroni correction ("bonferroni") in which the p-values are multiplied by the number of comparisons. Less conservative corrections are also included by Holm (1979) ("holm"), Hochberg (1988) ("hochberg"), Hommel (1988) ("hommel"), Benjamini & Hochberg (1995) ("BH" or its alias "fdr"), and Benjamini & Yekutieli (2001) ("BY"), respectively. A pass-through option ("none") is also included. The set of methods are contained in the `p.adjust.methods` vector for the benefit of methods that need to have the method as an option and pass it on to `p.adjust`.

The first four methods are designed to give strong control of the family-wise error rate. There seems no reason to use the unmodified Bonferroni correction because it is dominated by Holm’s method, which is also valid under arbitrary assumptions.

Hochberg’s and Hommel’s methods are valid when the hypothesis tests are independent or when they are non-negatively associated (Sarkar, 1998; Sarkar and Chang, 1997). Hommel’s method is more powerful than Hochberg’s, but the difference is usually small and the Hochberg p-values are faster to compute.

The "BH" (aka "fdr") and "BY" method of Benjamini, Hochberg, and Yekutieli control the false discovery rate, the expected proportion of false discoveries amongst the rejected hypotheses. The false discovery rate is a less stringent condition than the family-wise error rate, so these methods are more powerful than the others.

Note that you can set `n` larger than `length(p)` which means the unobserved p-values are assumed to be greater than all the observed p for "bonferroni" and "holm" methods and equal to 1 for the other methods.
Value

A numeric vector of corrected p-values (of the same length as \( p \), with names copied from \( p \)).

References

See Also

pairwise.* functions such as `pairwise.t.test`.

Examples

```r
require(graphics)

set.seed(123)
x <- rnorm(50, mean = c(rep(0, 25), rep(3, 25)))
p <- 2*pnorm(sort(-abs(x)))

round(p, 3)
round(p.adjust(p), 3)
round(p.adjust(p, "BH"), 3)

## or all of them at once (dropping the "fdr" alias):
p.adj <- sapply(p.adjust.M, function(meth) p.adjust(p, meth))
p.adj.60 <- sapply(p.adjust.M, function(meth) p.adjust(p, meth, n = 60))
stopifnot(identical(p.adj[,"none"], p), p.adj <= p.adj.60)
round(p.adj, 3)
## or a bit nicer:
```
noquote(apply(p.adj, 2, format.pval, digits = 3))

## and a graphic:
matplot(p, p.adj, ylab="p.adjust(p, meth)", type = "l", asp = 1, lty = 1:6,
       main = "P-value adjustments")
legend(0.7, 0.6, p.adjust.M, col = 1:6, lty = 1:6)

## Can work with NA's:
pN <- p; iN <- c(46, 47); pN[iN] <- NA
pN.a <- sapply(p.adjust.M, function(meth) p.adjust(pN, meth))
## The smallest 20 P-values all affected by the NA's :
round((pN.a / p.adj)[1:20, ], 4)

---

pairwise.prop.test Pairwise comparisons for proportions

### Description

Calculate pairwise comparisons between pairs of proportions with correction for multiple testing

### Usage

```r
pairwise.prop.test(x, n, p.adjust.method = p.adjust.methods, ...)
```

### Arguments

- **x**: Vector of counts of successes or a matrix with 2 columns giving the counts of successes and failures, respectively.
- **n**: Vector of counts of trials; ignored if `x` is a matrix.
- **p.adjust.method**: Method for adjusting p values (see `p.adjust`)
- **...**: Additional arguments to pass to `prop.test`

### Value

Object of class "pairwise.htest"

### See Also

- `prop.test`
- `p.adjust`

### Examples

```r
smokers <- c( 83, 90, 129, 70 )
patients <- c( 86, 93, 136, 82 )
pairwise.prop.test(smokers, patients)
```
pairwise.t.test  

Description  
Calculate pairwise comparisons between group levels with corrections for multiple testing.

Usage  

```r  
pairwise.t.test(x, g, p.adjust.method = p.adjust.methods,  
                pool.sd = !paired, paired = FALSE,  
                alternative = c("two.sided", "less", "greater"),  
                ...)  
```

Arguments  
- `x` response vector.
- `g` grouping vector or factor.
- `p.adjust.method` Method for adjusting p values (see `p.adjust`).
- `pool.sd` switch to allow/disallow the use of a pooled SD.
- `paired` a logical indicating whether you want paired t-tests.
- `alternative` a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less".
- `...` additional arguments to pass to `t.test`.

Details  
The `pool.sd` switch calculates a common SD for all groups and uses that for all comparisons (this can be useful if some groups are small). This method does not actually call `t.test`, so extra arguments are ignored. Pooling does not generalize to paired tests so `pool.sd` and `paired` cannot both be TRUE.

Only the lower triangle of the matrix of possible comparisons is being calculated, so setting `alternative` to anything other than "two.sided" requires that the levels of `g` are ordered sensibly.

Value  
Object of class "pairwise.htest"

See Also  
`t.test`, `p.adjust`
Examples

```
attach(airquality)
Month <- factor(Month, labels = month.abb[5:9])
pairwise.t.test(Ozone, Month)
pairwise.t.test(Ozone, Month, p.adj = "bonf")
pairwise.t.test(Ozone, Month, pool.sd = FALSE)
detach()
```

---

**pairwise.table**

Tabulate p values for pairwise comparisons

Description

Creates table of p values for pairwise comparisons with corrections for multiple testing.

Usage

```
pairwise.table(compare.levels, level.names, p.adjust.method)
```

Arguments

- `compare.levels` Function to compute (raw) p value given indices i and j
- `level.names` Names of the group levels
- `p.adjust.method` Method for multiple testing adjustment

Details

Functions that do multiple group comparisons create separate compare.levels functions (assumed to be symmetrical in i and j) and passes them to this function.

Value

Table of p values in lower triangular form.

See Also

pairwise.t.test, et al.
pairwise.wilcox.test

Pairwise Wilcoxon Rank Sum Tests

Description

Calculate pairwise comparisons between group levels with corrections for multiple testing.

Usage

pairwise.wilcox.test(x, g, p.adjust.method = p.adjust.methods, paired = FALSE, ...)

Arguments

x
response vector.

g
grouping vector or factor.

p.adjust.method
method for adjusting p values (see p.adjust).

paired
a logical indicating whether you want a paired test.

... additional arguments to pass to wilcox.test.

Details

Extra arguments that are passed on to wilcox.test may or may not be sensible in this context. In particular, only the lower triangle of the matrix of possible comparisons is being calculated, so setting alternative to anything other than "two.sided" requires that the levels of g are ordered sensibly.

Value

Object of class "pairwise.htest"

See Also

wilcox.test, p.adjust

Examples

attach(airquality)
Month <- factor(Month, labels = month.abb[5:9])
## These give warnings because of ties :
pairwise.wilcox.test(Ozone, Month)
pairwise.wilcox.test(Ozone, Month, p.adj = "bonf")
detach()
plot.acf  Plot Autocovariance and Autocorrelation Functions

Description

Plot method for objects of class "acf".

Usage

## S3 method for class 'acf'
plot(x, ci = 0.95, type = "h", xlab = "Lag", ylab = NULL,
     ylim = NULL, main = NULL,
     ci.col = "blue", ci.type = c("white", "ma"),
     max.mfrow = 6, ask = Npgs > 1 && dev.interactive(),
     mar = if(nser > 2) c(3,2,2,0.8) else par("mar"),
     oma = if(nser > 2) c(1,1.2,1,1) else par("oma"),
     mgp = if(nser > 2) c(1.5,0.6,0) else par("mgp"),
     xpd = par("xpd"),
     cex.main = if(nser > 2) 1 else par("cex.main"),
     verbose = getOption("verbose"),
     ...)  

Arguments

  x     an object of class "acf".
  ci    coverage probability for confidence interval. Plotting of the confidence interval
         is suppressed if ci is zero or negative.
  type  the type of plot to be drawn, default to histogram like vertical lines.
  xlab  the x label of the plot.
  ylab  the y label of the plot.
  ylim  numeric of length 2 giving the y limits for the plot.
  main  overall title for the plot.
  ci.col colour to plot the confidence interval lines.
  ci.type should the confidence limits assume a white noise input or for lag k an MA(k-1)
         input?
  max.mfrow positive integer; for multivariate x indicating how many rows and columns of
              plots should be put on one page, using par(mfrow = c(m,m)).
  ask    logical; if TRUE, the user is asked before a new page is started.
  mar, oma, mgp, xpd, cex.main
         graphics parameters as in par(*), by default adjusted to use smaller than default
         margins for multivariate x only.
  verbose logical. Should R report extra information on progress?
  ...    graphics parameters to be passed to the plotting routines.
Note

The confidence interval plotted in plot.acf is based on an uncorrelated series and should be treated with appropriate caution. Using ci.type = "ma" may be less potentially misleading.

See Also

acf which calls plot.acf by default.

Examples

require(graphics)

z4 <- ts(matrix(rnorm(400), 100, 4), start = c(1961, 1), frequency = 12)
z7 <- ts(matrix(rnorm(700), 100, 7), start = c(1961, 1), frequency = 12)
acf(z4)
acf(z7, max.mfrow = 7)  # squeeze onto 1 page
acf(z7)  # multi-page
plot.HoltWinters  

Plot function for HoltWinters objects

Description

Produces a chart of the original time series along with the fitted values. Optionally, predicted values (and their confidence bounds) can also be plotted.

Usage

```r
## S3 method for class 'HoltWinters'
plot(x, predicted.values = NA, intervals = TRUE,
     separator = TRUE, col = 1, col.predicted = 2,
     col.intervals = 4, col.separator = 1, lty = 1,
     lty.predicted = 1, lty.intervals = 1, lty.separator = 3,
     ylab = "Observed / Fitted",
     main = "Holt-Winters filtering",
     ylim = NULL, ...)
```

Arguments

- `x`: Object of class "HoltWinters"
- `predicted.values`: Predicted values as returned by `predict.HoltWinters`
- `intervals`: If TRUE, the prediction intervals are plotted (default).
- `separator`: If TRUE, a separating line between fitted and predicted values is plotted (default).
- `col, lty`: Color/line type of original data (default: black solid).
- `col.predicted, lty.predicted`: Color/line type of fitted and predicted values (default: red solid).
- `col.intervals, lty.intervals`: Color/line type of prediction intervals (default: blue solid).
- `col.separator, lty.separator`: Color/line type of observed/predicted values separator (default: black dashed).
- `ylab`: Label of the y-axis.
- `main`: Main title.
- `ylim`: Limits of the y-axis. If NULL, the range is chosen such that the plot contains the original series, the fitted values, and the predicted values if any.
- `...`: Other graphics parameters.

plot.isoreg

*Plot Method for isoreg Objects*

**Description**

The plot and lines method for R objects of class isoreg.

**Usage**

```r
## S3 method for class 'isoreg'
plot(x, plot.type = c("single", "row.wise", "col.wise"),
     main = paste("Isotonic regression", deparse(x$call)),
     main2 = "Cumulative Data and Convex Minorant",
     xlab = "x/0", ylab = "x/y",
     par.fit = list(col = "red", cex = 1.5, pch = 13, lwd = 1.5),
     mar = if (both) /zero.noslash.1 + c(3.5, 2.5, 1, 1) else par("mar"),
     mgp = if (both) c(1.6, 0.7, 0) else par("mgp"),
     grid = length(x$x) < 12, ...)

## S3 method for class 'isoreg'
lines(x, col = "red", lwd = 1.5,
      do.points = FALSE, cex = 1.5, pch = 13, ...)
```

**Arguments**

- `x` an isoreg object.
- `plot.type` character indicating which type of plot is desired. The first (default) only draws the data and the fit, where the others add a plot of the cumulative data and fit.
- `main` main title of plot, see `title`.
- `main2` title for second (cumulative) plot.
- `xlab, ylab` x- and y- axis annotation.
- `par.fit` a list of arguments (for points and lines) for drawing the fit.
- `mar, mgp` graphical parameters, see `par`, mainly for the case of two plots.
grid logical indicating if grid lines should be drawn. If true, `grid()` is used for the first plot, where as vertical lines are drawn at ‘touching’ points for the cumulative plot.

do.points for `lines()`: logical indicating if the step points should be drawn as well (and as they are drawn in `plot()`).

col, lwd, cex, pch graphical arguments for `lines()`, where cex and pch are only used when `do.points` is TRUE.

... further arguments passed to and from methods.

See Also

`isoreg` for computation of `isoreg` objects.

Examples

```r
require(graphics)
utils::example(isoreg) # for the examples there

plot(y3, main = "simple plot(.) + lines(<isoreg>)")
lines(ir3)

## 'same' plot as above, "proving" that only ranks of 'x' are important
plot(isoreg(2^(1:9), c(1,0,4,3,3,5,4,2,0)), plot.type = "row", log = "x")

plot(ir3, plot.type = "row", ylab = "y3")
plot(isoreg(y3 - 4), plot.t="r", ylab = "y3 - 4")
plot(ir4, plot.type = "ro", ylab = "y4", xlab = "x = 1:n")

## experiment a bit with these (C-c C-j):
plot(isoreg(sample(9), y3), plot.type = "row")
plot(isoreg(sample(9), y3), plot.type = "col.wise")

plot(ir <- isoreg(sample(10), sample(10, replace = TRUE)), plot.type = "r")
```

---

**plot.lm**

*Plot Diagnostics for an lm Object*

**Description**

Six plots (selectable by which) are currently available: a plot of residuals against fitted values, a Scale-Location plot of $\sqrt{|residuals|}$ against fitted values, a Normal Q-Q plot, a plot of Cook’s distances versus row labels, a plot of residuals against leverages, and a plot of Cook’s distances against leverage/(1-leverage). By default, the first three and 5 are provided.
Usage

## S3 method for class 'lm'
plot(x, which = c(1:3, 5),
caption = list("Residuals vs Fitted", "Normal Q-Q",
"Scale-Location", "Cook’s distance",
"Residuals vs Leverage",
expression("Cook's dist vs Leverage " * h[ii] / (1 - h[ii]))),
panel = if(add.smooth) panel.smooth else points,
sub.caption = NULL, main = "",
ask = prod(par("mfcol")) < length(which) && dev.interactive(),
...
, id.n = 3, labels.id = names(residuals(x)), cex.id = 0.75,
qqline = TRUE, cook.levels = c(0.5, 1.0),
add.smooth =getOption("add.smooth"), label.pos = c(4,2),
cex.caption = 1)

Arguments

x

1m object, typically result of lm or glm.

which

if a subset of the plots is required, specify a subset of the numbers 1:6.

caption

captions to appear above the plots; character vector or list of valid graphics annotations, see as.graphicsAnnot. Can be set to "" or NA to suppress all captions.

panel

panel function. The useful alternative to points, panel.smooth can be chosen by add.smooth = TRUE.

sub.caption

common title—above the figures if there are more than one; used as sub (s.title) otherwise. If NULL, as by default, a possible abbreviated version of deparse(x$call) is used.

main

title to each plot—in addition to caption.

ask

logical; if TRUE, the user is asked before each plot, see par(ask=.).

... other parameters to be passed through to plotting functions.

id.n

number of points to be labelled in each plot, starting with the most extreme.

labels.id

vector of labels, from which the labels for extreme points will be chosen. NULL uses observation numbers.

cex.id

magnification of point labels.

qqline

logical indicating if a qqline() should be added to the normal Q-Q plot.

cook.levels

levels of Cook’s distance at which to draw contours.

add.smooth

logical indicating if a smoother should be added to most plots; see also panel above.

label.pos

positioning of labels, for the left half and right half of the graph respectively, for plots 1-3.

cex.caption

controls the size of caption.
Details

sub.caption—by default the function call—is shown as a subtitle (under the x-axis title) on each plot when plots are on separate pages, or as a subtitle in the outer margin (if any) when there are multiple plots per page.

The ‘Scale-Location’ plot, also called ‘Spread-Location’ or ‘S-L’ plot, takes the square root of the absolute residuals in order to diminish skewness ($\sqrt{|E|}$) is much less skewed than $|E|$ for Gaussian zero-mean $E$).

The ‘S-L’, the Q-Q, and the Residual-Leverage plot, use standardized residuals which have identical variance (under the hypothesis). They are given as $R_i/(s \times \sqrt{1 - h_{ii}})$ where $h_{ii}$ are the diagonal entries of the hat matrix, influence()$\hat{\text{m}}$ (see also hat), and where the Residual-Leverage plot uses standardized Pearson residuals (residuals.glm(type = "pearson")) for $R[i]$.

The Residual-Leverage plot shows contours of equal Cook’s distance, for values of cook.levels (by default 0.5 and 1) and omits cases with leverage one with a warning. If the leverages are constant (as is typically the case in a balanced aov situation) the plot uses factor level combinations instead of the leverages for the x-axis. (The factor levels are ordered by mean fitted value.)

In the Cook’s distance vs leverage/(1-leverage) plot, contours of standardized residuals that are equal in magnitude are lines through the origin. The contour lines are labelled with the magnitudes.

```

---

**plot.ppr**  
*Plot Ridge Functions for Projection Pursuit Regression Fit*

**Description**
Plot ridge functions for projection pursuit regression fit.

**Usage**
```
## S3 method for class 'ppr'
plot(x, ask, type = "o", ...) 
```

**Arguments**
- **x**  
  A fit of class "ppr" as produced by a call to ppr.
- **ask**  
  the graphics parameter ask: see par for details. If set to TRUE will ask between
  the plot of each cross-section.
- **type**  
  the type of line to draw
- **...**  
  further graphical parameters

**Value**
None

**Side Effects**
A series of plots are drawn on the current graphical device, one for each term in the fit.

ppr.par

Examples

require(graphics)

with(rock, {
  area1 <- area/10000; peri1 <- peri/10000
  par(mfrow = c(3,2)) # maybe: , pty = "s"
  rock.ppr <- ppr(log(perm) ~ area1 + peri1 + shape,
                  data = rock, nterms = 2, max.terms = 5)
  plot(rock.ppr, main = "ppr(log(perm)~ ., nterms=2, max.terms=5)"
  plot(update(rock.ppr, bass = 5), main = "update(..., bass = 5)"
  plot(update(rock.ppr, sm.method = "gcv", gcvpen = 2),
       main = "update(..., sm.method="gcv", gcvpen=2)"
}))

plot.profile.nls  
Plot a profile.nls Object

Description

Displays a series of plots of the profile t function and interpolated confidence intervals for the parameters in a nonlinear regression model that has been fit with nls and profiled with profile.nls.

Usage

## S3 method for class 'profile.nls'
plot(x, levels, conf = c(99, 95, 90, 80, 50)/100,
     absVal = TRUE, ylab = NULL, lty = 2, ...)

Arguments

x  
an object of class "profile.nls"

levels  
levels, on the scale of the absolute value of a t statistic, at which to interpolate intervals. Usually conf is used instead of giving levels explicitly.

conf  
a numeric vector of confidence levels for profile-based confidence intervals on the parameters. Defaults to \(c(0.99, 0.95, 0.90, 0.80, 0.50)\).

absVal  
a logical value indicating whether or not the plots should be on the scale of the absolute value of the profile t. Defaults to TRUE.

lty  
the line type to be used for axis and dropped lines.

ylab, ...  
other arguments to the plot.default function can be passed here (but not xlab, xlim, ylim nor type).
Details

The plots are produced in a set of hard-coded colours, but as these are coded by number their effect can be changed by setting the palette. Colour 1 is used for the axes and 4 for the profile itself. Colours 3 and 6 are used for the axis line at zero and the horizontal/vertical lines dropping to the axes.

```r
require(graphics)

# obtain the fitted object
fm1 <- nls(demand ~ SSasympOrig(Time, A, lrc), data = BOD)
# get the profile for the fitted model
pr1 <- profile(fm1, alpha = .05)
opar <- par(mfrow = c(2,2), oma = c(1.1, 0, 1.1, 0), las = 1)
plot(pr1, conf = c(95, 90, 80, 50)/100)
plot(pr1, conf = c(95, 90, 80, 50)/100, absVal = FALSE)
mtext("Confidence intervals based on the profile sum of squares",
     side = 3, outer = TRUE)
mtext("BOD data - confidence levels of 50%, 80%, 90% and 95%",
     side = 1, outer = TRUE)
par(opar)
```

---

**plot.spec**  

**Plotting Spectral Densities**

Description

Plotting method for objects of class "spec". For multivariate time series it plots the marginal spectra of the series or pairs plots of the coherency and phase of the cross-spectra.
Usage

```r
## S3 method for class 'spec'
plot(x, add = FALSE, ci = 0.95, log = c("yes", "dB", "no"),
     xlab = "frequency", ylab = NULL, type = "l",
     ci.col = "blue", ci.lty = 3,
     main = NULL, sub = NULL,
     plot.type = c("marginal", "coherency", "phase"),
     ...)  
plot.spec.phase(x, ci = 0.95,
     xlab = "frequency", ylab = "phase",
     ylim = c(-pi, pi), type = "l",
     main = NULL, ci.col = "blue", ci.lty = 3, ...)
plot.spec.coherency(x, ci = 0.95,
     xlab = "frequency",
     ylab = "squared coherency",
     ylim = c(0, 1), type = "l",
     main = NULL, ci.col = "blue", ci.lty = 3, ...)
```

Arguments

- **x**: an object of class "spec".
- **add**: logical. If TRUE, add to already existing plot. Only valid for plot.type = "marginal".
- **ci**: coverage probability for confidence interval. Plotting of the confidence bar/limits is omitted unless ci is strictly positive.
- **log**: If "dB", plot on log10 (decibel) scale (as S-PLUS), otherwise use conventional log scale or linear scale. Logical values are also accepted. The default is "yes" unless options(ts.S.compat = TRUE) has been set, when it is "dB". Only valid for plot.type = "marginal".
- **xlab**: the x label of the plot.
- **ylab**: the y label of the plot. If missing a suitable label will be constructed.
- **type**: the type of plot to be drawn, defaults to lines.
- **ci.col**: colour for plotting confidence bar or confidence intervals for coherency and phase.
- **ci.lty**: line type for confidence intervals for coherency and phase.
- **main**: overall title for the plot. If missing, a suitable title is constructed.
- **sub**: a sub title for the plot. Only used for plot.type = "marginal". If missing, a description of the smoothing is used.
- **plot.type**: For multivariate time series, the type of plot required. Only the first character is needed.
- **ylim, ...**: Graphical parameters.
**plot.stepfun**

**Plot Step Functions**

**Description**

Method of the generic `plot` for `stepfun` objects and utility for plotting piecewise constant functions.

**Usage**

```r
## S3 method for class 'stepfun'
plot(x, xval, xlim, ylim = range(c(y, Fn.kn)),
     xlab = "x", ylab = "f(x)", main = NULL,
     add = FALSE, verticals = TRUE, do.points = (n < 1/zero.noslash/zero.noslash/zero.noslash),
     pch = par("pch"), col = par("col"),
     col.points = col, cex.points = par("cex"),
     col.hor = col, col.vert = col,
     lty = par("lty"), lwd = par("lwd"), ...)
## S3 method for class 'stepfun'
lines(x, ...)
```

**Arguments**

- `x`: an R object inheriting from "stepfun".
- `xval`: numeric vector of abscissa values at which to evaluate `x`. Defaults to `knots(x)` restricted to `xlim`.
- `xlim, ylim`: limits for the plot region: see `plot.window`. Both have sensible defaults if omitted.
- `xlab, ylab`: labels for x and y axis.
- `main`: main title.
- `add`: logical; if TRUE only `add` to an existing plot.
- `verticals`: logical; if TRUE, draw vertical lines at steps.
- `do.points`: logical; if TRUE, also draw points at the (xlim restricted) knot locations. Default is true, for sample size < 1000.
- `pch`: character; point character if `do.points`.
- `col`: default color of all points and lines.
- `col.points`: character or integer code; color of points if `do.points`.
- `cex.points`: numeric; character expansion factor if `do.points`.
- `col.hor`: color of horizontal lines.

**See Also**

`spectrum`
col.\_vert \quad \text{color of vertical lines.}

lt, lwd \quad \text{line type and thickness for all lines.}

... \quad \text{further arguments of plot(\_), or if(add) segments(\_).}

\textbf{Value}

A list with two components

\texttt{t} \quad \text{abscissa (x) values, including the two outermost ones.}

\texttt{y} \quad \text{y values ‘in between’ the \texttt{t}.}

\textbf{Author(s)}

Martin Maechler <maechler@stat.math.ethz.ch>, 1990, 1993; ported to \texttt{R}, 1997.

\textbf{See Also}

\texttt{ecdf} for empirical distribution functions as special step functions, \texttt{approxfun} and \texttt{splinefun}.

\textbf{Examples}

\begin{verbatim}
require(graphics)
y0 <- c(1,2,4,3)
sfun0 <- stepfun(1:3, y0, f = 0)
sfun.2 <- stepfun(1:3, y0, f = .2)
sfun1 <- stepfun(1:3, y0, right = TRUE)

tt <- seq(0, 3, by = 0.1)
op <- par(mfrow = c(2,2))
plot(sfun0); plot(sfun0, xval = tt, add = TRUE, col.hor = "bisque")
plot(sfun.2);plot(sfun.2, xval = tt, add = TRUE, col = "orange") # all colors
plot(sfun1);lines(sfun1, xval = tt, col.hor = "coral")

##-- This is revealing:
plot(sfun0, verticals = FALSE,
     main = "stepfun(x, y0, f=f) for f = 0, .2, 1")
for(i in 1:3)
  lines(list(sfun0, sfun.2, stepfun(1:3, y0, f = 1))[[i]], col = i)
legend(2.5, 1.9, paste("f =", c(0, 0.2, 1)), col = 1:3, lty = 1, y.intersp = 1)
par(op)

# Extend and/or restrict 'viewport':
plot(sfun0, xlim = c(0,5), ylim = c(0, 3.5),
     main = "plot(stepfun(*), xlim= . , ylim = .")

##-- this works too (automatic call to \texttt{ecdf(.)):
plot.stepfun(rt(50, df = 3), col.\_vert = "gray20")
\end{verbatim}
**plot.ts**

*Plotting Time-Series Objects*

---

**Description**

Plotting method for objects inheriting from class "ts".

**Usage**

```r
## S3 method for class 'ts'
plot(x, y = NULL, plot.type = c("multiple", "single"),
    xy.labels, xy.lines, panel = lines, nc, yax.flip = FALSE,
    mar.multi = c(0, 5.1, 0, if(yax.flip) 5.1 else 2.1),
    oma.multi = c(6, 0, 5, 0), axes = TRUE, ...)

## S3 method for class 'ts'
lines(x, ...)
```

**Arguments**

- `x, y` time series objects, usually inheriting from class "ts".
- `plot.type` for multivariate time series, should the series be plotted separately (with a common time axis) or on a single plot?
- `xy.labels` logical, indicating if `text()` labels should be used for an x-y plot, or character, supplying a vector of labels to be used. The default is to label for up to 150 points, and not for more.
- `xy.lines` logical, indicating if `lines` should be drawn for an x-y plot. Defaults to the value of `xy.labels` if that is logical, otherwise to TRUE.
- `panel` a function(`x, col, bg, pch, type, ...`) which gives the action to be carried out in each panel of the display for `plot.type = "multiple"`. The default is `lines`.
- `nc` the number of columns to use when `type = "multiple"`. Defaults to 1 for up to 4 series, otherwise to 2.
- `yax.flip` logical indicating if the y-axis (ticks and numbering) should flip from side 2 (left) to 4 (right) from series to series when `type = "multiple"`.
- `mar.multi, oma.multi` the (default) `par` settings for `plot.type = "multiple"`. Modify with care!
- `axes` logical indicating if x- and y- axes should be drawn.
- `...` additional graphical arguments, see `plot.plot.default` and `par`.

**Details**

If `y` is missing, this function creates a time series plot, for multivariate series of one of two kinds depending on `plot.type`.

If `y` is present, both `x` and `y` must be univariate, and a scatter plot `y ~ x` will be drawn, enhanced by using `text` if `xy.labels` is TRUE or character, and `lines` if `xy.lines` is TRUE.
The Poisson Distribution

Description

Density, distribution function, quantile function and random generation for the Poisson distribution with parameter lambda.

Usage

dpois(x, lambda, log = FALSE)
pois(q, lambda, lower.tail = TRUE, log.p = FALSE)
qpois(p, lambda, lower.tail = TRUE, log.p = FALSE)
Rpois(n, lambda)
Arguments

- **x**: vector of (non-negative integer) quantiles.
- **q**: vector of quantiles.
- **p**: vector of probabilities.
- **n**: number of random values to return.
- **lambda**: vector of (non-negative) means.
- **log, log.p**: logical; if TRUE, probabilities p are given as log(p).
- **lower.tail**: logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

The Poisson distribution has density

\[
p(x) = \frac{\lambda^x e^{-\lambda}}{x!}
\]

for \( x = 0, 1, 2, \ldots \). The mean and variance are \( E(X) = Var(X) = \lambda \).

If an element of \( x \) is not integer, the result of `dpois` is zero, with a warning. \( p(x) \) is computed using Loader's algorithm, see the reference in `dbinom`.

The quantile is right continuous: \( qpois(p, \lambda) \) is the smallest integer \( x \) such that \( P(X \leq x) \geq p \).

Setting `lower.tail = FALSE` allows to get much more precise results when the default, `lower.tail = TRUE` would return 1, see the example below.

Value

dpois gives the (log) density, ppois gives the (log) distribution function, qpois gives the quantile function, and rpois generates random deviates.

Invalid lambda will result in return value NaN, with a warning.

The length of the result is determined by n for rpois, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than n are recycled to the length of the result. Only the first elements of the logical parameters are used.

Source

dpois uses C code contributed by Catherine Loader (see `dbinom`).

ppois uses `pgamma`.

qpois uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.

See Also

Distributions for other standard distributions, including `dbinom` for the binomial and `dnbinom` for the negative binomial distribution.

`poisson.test`.

Examples

```r
require(graphics)

-log(dpois(0:7, lambda = 1) * gamma(1 + 0:7)) # == 1
Ni <- rpois(50, lambda = 4); table(factor(Ni, 0:max(Ni))

1 - ppois(10*(15:25), lambda = 100) # becomes 0 (cancellation)
  ppois(10*(15:25), lambda = 100, lower.tail = FALSE) # no cancellation

par(mfrow = c(2, 1))
x <- seq(-0.01, 5, 0.01)
plot(x, ppois(x, 1), type = "s", ylab = "F(x)", main = "Poisson(1) CDF")
plot(x, pbinom(x, 100, 0.01), type = "s", ylab = "F(x)",
     main = "Binomial(100, 0.01) CDF")
```

---

**poisson.test**  
*Exact Poisson tests*

Description

Performs an exact test of a simple null hypothesis about the rate parameter in Poisson distribution, or for the ratio between two rate parameters.

Usage

```r
poisson.test(x, T = 1, r = 1,
             alternative = c("two.sided", "less", "greater"),
             conf.level = 0.95)
```

Arguments

- `x`: number of events. A vector of length one or two.
- `T`: time base for event count. A vector of length one or two.
- `r`: hypothesized rate or rate ratio
- `alternative`: indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter.
- `conf.level`: confidence level for the returned confidence interval.

Details

Confidence intervals are computed similarly to those of `binom.test` in the one-sample case, and using `binom.test` in the two sample case.
poly

Value
A list with class "htest" containing the following components:

- **statistic**: the number of events (in the first sample if there are two.)
- **parameter**: the corresponding expected count
- **p.value**: the p-value of the test.
- **conf.int**: a confidence interval for the rate or rate ratio.
- **estimate**: the estimated rate or rate ratio.
- **null.value**: the rate or rate ratio under the null, \( r \).
- **alternative**: a character string describing the alternative hypothesis.
- **method**: the character string "Exact Poisson test" or "Comparison of Poisson rates" as appropriate.
- **data.name**: a character string giving the names of the data.

Note
The rate parameter in Poisson data is often given based on a “time on test” or similar quantity (person-years, population size, or expected number of cases from mortality tables). This is the role of the \( T \) argument.

The one-sample case is effectively the binomial test with a very large \( n \). The two sample case is converted to a binomial test by conditioning on the total event count, and the rate ratio is directly related to the odds in that binomial distribution.

### SMR, Welsh Nickel workers
poisson.test(137, 24.19893)

### eba1977, compare Fredericia to other three cities for ages 55-59
poisson.test(c(11, 6+8+7), c(8/1, 83+1/878+878))
```

poly

Compute Orthogonal Polynomials

Description
Returns or evaluates orthogonal polynomials of degree 1 to degree over the specified set of points \( x \). These are all orthogonal to the constant polynomial of degree 0. Alternatively, evaluate raw polynomials.
Usage

poly(x, ..., degree = 1, coefs = NULL, raw = FALSE)
polym(..., degree = 1, raw = FALSE)

## S3 method for class 'poly'
predict(object, newdata, ...)

Arguments

x, newdata a numeric vector at which to evaluate the polynomial. x can also be a matrix. Missing values are not allowed in x.
dergree the degree of the polynomial. Must be less than the number of unique points if raw = TRUE.
coefs for prediction, coefficients from a previous fit.
raw if true, use raw and not orthogonal polynomials.
object an object inheriting from class "poly", normally the result of a call to poly with a single vector argument.
... poly, polym: further vectors.
predict.poly: arguments to be passed to or from other methods.

Details

Although formally degree should be named (as it follows ...), an unnamed second argument of length 1 will be interpreted as the degree.

The orthogonal polynomial is summarized by the coefficients, which can be used to evaluate it via the three-term recursion given in Kennedy & Gentle (1980, pp. 343–4), and used in the predict part of the code.

Value

For poly with a single vector argument:
A matrix with rows corresponding to points in x and columns corresponding to the degree, with attributes "degree" specifying the degrees of the columns and (unless raw = TRUE) "coefs" which contains the centering and normalization constants used in constructing the orthogonal polynomials.
The matrix has given class c("poly", "matrix").
Other cases of poly and polym, and predict.poly: a matrix.

Note

This routine is intended for statistical purposes such as contr.poly: it does not attempt to orthogonalize to machine accuracy.

zapsmall(poly(cbind(1:4, c(1, 4:6)), degree = 3))
options(od)

power

Create a Power Link Object

Description

Creates a link object based on the link function \( \eta = \mu^\lambda \).

Usage

power(lambda = 1)

Arguments

lambda a real number.

Details

If lambda is non-positive, it is taken as zero, and the log link is obtained. The default lambda = 1 gives the identity link.

Value

A list with components linkfun, linkinv, mu.eta, and valideta. See make.link for information on their meaning.

References

See Also

make.link, family
To raise a number to a power, see Arithmetic.
To calculate the power of a test, see various functions in the stats package, e.g., power.t.test.
Examples

    power()
    quasi(link = power(1/3))[c("linkfun", "linkinv")]

Description

Compute power of test or determine parameters to obtain target power.

Usage

    power.anova.test(groups = NULL, n = NULL,
                    between.var = NULL, within.var = NULL,
                    sig.level = 0.05, power = NULL)

Arguments

    groups   Number of groups
    n        Number of observations (per group)
    between.var   Between group variance
    within.var   Within group variance
    sig.level   Significance level (Type I error probability)
    power      Power of test (1 minus Type II error probability)

Details

Exactly one of the parameters `groups`, `n`, `between.var`, `power`, `within.var`, and `sig.level` must be passed as `NULL`, and that parameter is determined from the others. Notice that `sig.level` has non-NULL default so `NULL` must be explicitly passed if you want it computed.

Value

Object of class "power.htest", a list of the arguments (including the computed one) augmented with method and note elements.

Note

`uniroot` is used to solve power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given.

Author(s)

Claus Ekstrøm
power.prop.test

See Also
anova, lm, uniroot

Examples

```r
code
```n
## Assume we have prior knowledge of the group means:
groupmeans <- c(120, 130, 140, 150)  
power.anova.test(groups = length(groupmeans),  
                between.var = var(groupmeans),  
                within.var = 500, power = .90)  
# n = 15.18834
```n

power.prop.test

Power Calculations for Two-Sample Test for Proportions

Description

Compute power of test, or determine parameters to obtain target power.

Usage

```r
power.prop.test(n = NULL, p1 = NULL, p2 = NULL, sig.level = 0.05,  
                power = NULL, alternative = c("two.sided", "one.sided"),  
                strict = FALSE)
```n

Arguments

- `n` Number of observations (per group)
- `p1` probability in one group
- `p2` probability in other group
- `sig.level` Significance level (Type I error probability)
- `power` Power of test (1 minus Type II error probability)
- `alternative` One- or two-sided test
- `strict` Use strict interpretation in two-sided case
Details

Exactly one of the parameters n, p1, p2, power, and sig.level must be passed as NULL, and that parameter is determined from the others. Notice that sig.level has a non-NULL default so NULL must be explicitly passed if you want it computed.

If strict = TRUE is used, the power will include the probability of rejection in the opposite direction of the true effect, in the two-sided case. Without this the power will be half the significance level if the true difference is zero.

Value

Object of class "power.htest", a list of the arguments (including the computed one) augmented with method and note elements.

Note

uniroot is used to solve power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given. If one of them is computed p1 < p2 will hold, although this is not enforced when both are specified.

Author(s)

Peter Dalgaard. Based on previous work by Claus Ekstrøm

power.prop.test(n = 50, p1 = .5, power = .90)

power.t.test

Power calculations for one and two sample t tests

Description

Compute power of test, or determine parameters to obtain target power.

Usage

power.t.test(n = NULL, delta = NULL, sd = 1, sig.level = 0.05, power = NULL, type = c("two.sample", "one.sample", "paired"), alternative = c("two.sided", "one.sided"), strict = FALSE)
Arguments

- **n**: Number of observations (per group)
- **delta**: True difference in means
- **sd**: Standard deviation
- **sig.level**: Significance level (Type I error probability)
- **power**: Power of test (1 minus Type II error probability)
- **type**: Type of t test
- **alternative**: One- or two-sided test
- **strict**: Use strict interpretation in two-sided case

Details

Exactly one of the parameters `n`, `delta`, `power`, `sd`, and `sig.level` must be passed as NULL, and that parameter is determined from the others. Notice that the last two have non-NULL defaults so NULL must be explicitly passed if you want to compute them.

If `strict = TRUE` is used, the power will include the probability of rejection in the opposite direction of the true effect, in the two-sided case. Without this the power will be half the significance level if the true difference is zero.

Value

Object of class "power.htest", a list of the arguments (including the computed one) augmented with `method` and `note` elements.

Note

`uniroot` is used to solve power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given.

Author(s)

Peter Dalgaard. Based on previous work by Claus Ekstrøm

See Also

`t.test`, `uniroot`

Examples

```r
power.t.test(n = 20, delta = 1)
power.t.test(power = .90, delta = 1)
power.t.test(power = .90, delta = 1, alternative = "one.sided")
```
**Description**

Computes the Phillips-Perron test for the null hypothesis that \( x \) has a unit root against a stationary alternative.

**Usage**

\[
\text{PP.test}(x, \text{lshort} = \text{TRUE})
\]

**Arguments**

- **x**: a numeric vector or univariate time series.
- **lshort**: a logical indicating whether the short or long version of the truncation lag parameter is used.

**Details**

The general regression equation which incorporates a constant and a linear trend is used and the corrected t-statistic for a first order autoregressive coefficient equals one is computed. To estimate \( \sigma^2 \) the Newey-West estimator is used. If \( \text{lshort} \) is \( \text{TRUE} \), then the truncation lag parameter is set to \( \text{trunc}(4 \times (n/100)^{0.25}) \), otherwise \( \text{trunc}(12 \times (n/100)^{0.25}) \) is used. The p-values are interpolated from Table 4.2, page 103 of Banerjee et al. (1993). Missing values are not handled.

**Value**

A list with class "htest" containing the following components:

- **statistic**: the value of the test statistic.
- **parameter**: the truncation lag parameter.
- **p.value**: the p-value of the test.
- **method**: a character string indicating what type of test was performed.
- **data.name**: a character string giving the name of the data.

**Author(s)**

A. Trapletti

**References**

ppoints

Examples

x <- rnorm(1000)
PP.test(x)
y <- cumsum(x) # has unit root
PP.test(y)

ppoints(n, a = ifelse(n <= 1, 3/8, 1/2))

Arguments

n either the number of points generated or a vector of observations.
a the offset fraction to be used; typically in (0, 1).

Details

If 0 < a < 1, the resulting values are within (0, 1) (excluding boundaries). In any case, the resulting sequence is symmetric in [0, 1], i.e., p + rev(p) == 1.
ppoints() is used in qqplot and qqnorm to generate the set of probabilities at which to evaluate the inverse distribution.
The choice of a follows the documentation of the function of the same name in Becker et al (1988), and appears to have been motivated by results from Blom (1958) on approximations to expect normal order statistics (see also quantile).

ppoints(4) # the same as ppoints(1:4)
ppoints(10)
ppoints(10, a = 1/2)
Projection Pursuit Regression

Description

Fit a projection pursuit regression model.

Usage

ppr(x, ...)

## S3 method for class 'formula'
ppr(formula, data, weights, subset, na.action,
     contrasts = NULL, ..., model = FALSE)

## Default S3 method:
ppr(x, y, weights = rep(1, n),
    ww = rep(1, q), nterms, max.terms = nterms, optlevel = 2,
    sm.method = c("supsmu", "spline", "gcvspine"),
    bass = 0, span = 0, df = 5, gcvpen = 1, ...)

Arguments

formula a formula specifying one or more numeric response variables and the explanatory variables.
x numeric matrix of explanatory variables. Rows represent observations, and columns represent variables. Missing values are not accepted.
y numeric matrix of response variables. Rows represent observations, and columns represent variables. Missing values are not accepted.
nterms number of terms to include in the final model.
data a data frame (or similar: see model.frame) from which variables specified in formula are preferentially to be taken.
weights a vector of weights w_i for each case.
ww a vector of weights for each response, so the fit criterion is the sum over case i and responses j of w_i ww_j (y_ij - fit_ij)^2 divided by the sum of w_i.
subset an index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)
na.action a function to specify the action to be taken if NAs are found. The default action is given by getOption("na.action"). (NOTE: If given, this argument must be named.)
contrasts the contrasts to be used when any factor explanatory variables are coded.
max.terms maximum number of terms to choose from when building the model.
optlevel integer from 0 to 3 which determines the thoroughness of an optimization routine in the SMART program. See the ‘Details’ section.
sm.method  the method used for smoothing the ridge functions. The default is to use Friedman's super smoother \texttt{supsmu}. The alternatives are to use the smoothing spline code underlying \texttt{smooth.spline}, either with a specified (equivalent) degrees of freedom for each ridge functions, or to allow the smoothness to be chosen by GCV.

bass  super smoother bass tone control used with automatic span selection (see \texttt{supsmu}); the range of values is 0 to 10, with larger values resulting in increased smoothing.

span  super smoother span control (see \texttt{supsmu}). The default, 0, results in automatic span selection by local cross validation. span can also take a value in $(0, 1]$.

df  if \texttt{sm.method} is "spline" specifies the smoothness of each ridge term via the requested equivalent degrees of freedom.

gcvpen  if \texttt{sm.method} is "gcv.spline" this is the penalty used in the GCV selection for each degree of freedom used.

model  logical. If true, the model frame is returned.

Details

The basic method is given by Friedman (1984), and is essentially the same code used by S-PLUS's \texttt{ppreg}. This code is extremely sensitive to the compiler used.

The algorithm first adds up to \texttt{max.terms} ridge terms one at a time; it will use less if it is unable to find a term to add that makes sufficient difference. It then removes the least important term at each step until \texttt{nterms} terms are left.

The levels of optimization (argument \texttt{optlevel}) differ in how thoroughly the models are refitted during this process. At level 0 the existing ridge terms are not refitted. At level 1 the projection directions are not refitted, but the ridge functions and the regression coefficients are.

Levels 2 and 3 refit all the terms and are equivalent for one response; level 3 is more careful to re-balance the contributions from each regressor at each step and so is a little less likely to converge to a saddle point of the sum of squares criterion.

Value

A list with the following components, many of which are for use by the method functions.

call  the matched call
p  the number of explanatory variables (after any coding)
q  the number of response variables
mu  the argument \texttt{nterms}
ml  the argument \texttt{max.terms}
gof  the overall residual (weighted) sum of squares for the selected model
gofn  the overall residual (weighted) sum of squares against the number of terms, up to \texttt{max.terms}. Will be invalid (and zero) for less than \texttt{nterms}.
df  the argument \texttt{df}
edf if sm.method is "spline" or "gcv.spline" the equivalent number of degrees of freedom for each ridge term used.
xnames the names of the explanatory variables
ynames the names of the response variables
alpha a matrix of the projection directions, with a column for each ridge term
beta a matrix of the coefficients applied for each response to the ridge terms: the rows are the responses and the columns the ridge terms
yb the weighted means of each response
ys the overall scale factor used: internally the responses are divided by ys to have unit total weighted sum of squares.
fitted.values the fitted values, as a matrix if q > 1.
residuals the residuals, as a matrix if q > 1.
smod internal work array, which includes the ridge functions evaluated at the training set points.
model (only if model = TRUE) the model frame.

Source
Friedman (1984): converted to double precision and added interface to smoothing splines by B. D. Ripley, originally for the MASS package.

prcomp

---

### Description

Performs a principal components analysis on the given data matrix and returns the results as an object of class prcomp.

### Usage

```r
prcomp(x, ...)
```

```
## S3 method for class 'formula'
prcomp(formula, data = NULL, subset, na.action, ...)
```

```
## Default S3 method:
prcomp(x, retx = TRUE, center = TRUE, scale. = FALSE,
       tol = NULL, ...)
```

```
## S3 method for class 'prcomp'
predict(object, newdata, ...)
```
Arguments

- **formula**: a formula with no response variable, referring only to numeric variables.
- **data**: an optional data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- **subset**: an optional vector used to select rows (observations) of the data matrix `x`.
- **na.action**: a function which indicates what should happen when the data contain NAs. The default is set by the `na.action` setting of `options`, and is `na.fail` if that is unset. The ‘factory-fresh’ default is `na.omit`.
- **...**: arguments passed to or from other methods. If `x` is a formula one might specify `scale` or `tol`.
- **x**: a numeric or complex matrix (or data frame) which provides the data for the principal components analysis.
- **retx**: a logical value indicating whether the rotated variables should be returned.
- **center**: a logical value indicating whether the variables should be shifted to be zero centered. Alternately, a vector of length equal the number of columns of `x` can be supplied. The value is passed to `scale`.
- **scale.**: a logical value indicating whether the variables should be scaled to have unit variance before the analysis takes place. The default is `FALSE` for consistency with S, but in general scaling is advisable. Alternatively, a vector of length equal the number of columns of `x` can be supplied. The value is passed to `scale`.
- **tol**: a value indicating the magnitude below which components should be omitted. (Components are omitted if their standard deviations are less than or equal to `tol` times the standard deviation of the first component.) With the default null setting, no components are omitted. Other settings for `tol` could be `tol = 0` or `tol = sqrt(.Machine$double.eps)`, which would omit essentially constant components.
- **object**: Object of class inheriting from "prcomp"
- **newdata**: An optional data frame or matrix in which to look for variables with which to predict. If omitted, the scores are used. If the original fit used a formula or a data frame or a matrix with column names, `newdata` must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order.

Details

The calculation is done by a singular value decomposition of the (centered and possibly scaled) data matrix, not by using `eigen` on the covariance matrix. This is generally the preferred method for numerical accuracy. The `print` method for these objects prints the results in a nice format and the `plot` method produces a scree plot.

Unlike `princomp`, variances are computed with the usual divisor $N - 1$.

Note that `scale = TRUE` cannot be used if there are zero or constant (for `center = TRUE`) variables.
Value

`prcomp` returns a list with class "prcomp" containing the following components:

- **sdev**: the standard deviations of the principal components (i.e., the square roots of the eigenvalues of the covariance/correlation matrix, though the calculation is actually done with the singular values of the data matrix).
- **rotation**: the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors). The function `princomp` returns this in the element `loadings`.
- **x**: if `retx` is true the value of the rotated data (the centred (and scaled if requested) data multiplied by the rotation matrix) is returned. Hence, `cov(x)` is the diagonal matrix `diag(sdev^2)`. For the formula method, `napredict()` is applied to handle the treatment of values omitted by the `na.action`.
- **center, scale**: the centering and scaling used, or `FALSE`.

Note

The signs of the columns of the rotation matrix are arbitrary, and so may differ between different programs for PCA, and even between different builds of R.

References

See Also

- `biplot.prcomp`, `screeplot`, `princomp`, `cor`, `cov`, `svd`, `eigen`.

Examples

```r
## signs are random
require(graphics)

## the variances of the variables in the
## USArrests data vary by orders of magnitude, so scaling is appropriate
prcomp(USArrests)  # inappropriate
prcomp(USArrests, scale = TRUE)
prcomp(~ Murder + Assault + Rape, data = USArrests, scale = TRUE)
plot(prcomp(USArrests))
summary(prcomp(USArrests, scale = TRUE))
biplot(prcomp(USArrests, scale = TRUE))
```
Description

`predict` is a generic function for predictions from the results of various model fitting functions. The function invokes particular methods which depend on the class of the first argument.

Usage

```r
predict (object, ...)```

Arguments

- `object` a model object for which prediction is desired.
- `...` additional arguments affecting the predictions produced.

Details

Most prediction methods which are similar to those for linear models have an argument `newdata` specifying the first place to look for explanatory variables to be used for prediction. Some considerable attempts are made to match up the columns in `newdata` to those used for fitting, for example that they are of comparable types and that any factors have the same level set in the same order (or can be transformed to be so).

Time series prediction methods in package `stats` have an argument `n.ahead` specifying how many time steps ahead to predict.

Many methods have a logical argument `se.fit` saying if standard errors are to returned.

Value

The form of the value returned by `predict` depends on the class of its argument. See the documentation of the particular methods for details of what is produced by that method.

References

See Also

- `SafePrediction` for prediction from polynomial and spline fits.

predict.Arima

Examples

require(utils)

## All the "predict" methods found
## NB most of the methods in the standard packages are hidden.
for(fn in methods("predict"))
  try(
    f <- eval(substitute(getAnywhere(fn)$objs[[1]], list(fn = fn)))
    cat(fn, ".\n\n\t", deparse(args(f)), "\n")
  ), silent = TRUE)

predict.Arima  Forecast from ARIMA fits

Description

Forecast from models fitted by arima.

Usage

## S3 method for class 'Arima'
predict(object, n.ahead = 1, newxreg = NULL,
        se.fit = TRUE, ...)

Arguments

object  The result of an arima fit.
n.ahead The number of steps ahead for which prediction is required.
newxreg New values of xreg to be used for prediction. Must have at least n.ahead rows.
se.fit  Logical: should standard errors of prediction be returned?
...     arguments passed to or from other methods.

Details

Finite-history prediction is used, via KalmanForecast. This is only statistically efficient if the MA part of the fit is invertible, so predict.Arima will give a warning for non-invertible MA models.

The standard errors of prediction exclude the uncertainty in the estimation of the ARMA model and the regression coefficients. According to Harvey (1993, pp. 58–9) the effect is small.

Value

A time series of predictions, or if se.fit = TRUE, a list with components pred, the predictions, and se, the estimated standard errors. Both components are time series.

**predict.glm**  
*Predict Method for GLM Fits*

Description

Obtains predictions and optionally estimates standard errors of those predictions from a fitted generalized linear model object.

Usage

```r
## S3 method for class 'glm'
predict(object, newdata = NULL,
 type = c("link", "response", "terms"),
 se.fit = FALSE, dispersion = NULL, terms = NULL,
 na.action = na.pass, ...)
```

Arguments

- `object`: a fitted object of class inheriting from "glm".
- `newdata`: optionally, a data frame in which to look for variables with which to predict. If omitted, the fitted linear predictors are used.
- `type`: the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. Thus for a default binomial model the default predictions are of log-odds (probabilities on logit scale) and type = "response" gives the predicted probabilities.
predict.glm

The "terms" option returns a matrix giving the fitted values of each term in the model formula on the linear predictor scale. The value of this argument can be abbreviated.

se.fit logical switch indicating if standard errors are required.
dispersion the dispersion of the GLM fit to be assumed in computing the standard errors. If omitted, that returned by summary applied to the object is used.
terms with type = "terms" by default all terms are returned. A character vector specifies which terms are to be returned
na.action function determining what should be done with missing values in newdata. The default is to predict NA.
... further arguments passed to or from other methods.

Details

If newdata is omitted the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit is determined by the na.action argument of that fit. If na.action = na.omit omitted cases will not appear in the residuals, whereas if na.action = na.exclude they will appear (in predictions and standard errors), with residual value NA. See also napredict.

Value

If se.fit = FALSE, a vector or matrix of predictions. For type = "terms" this is a matrix with a column per term, and may have an attribute "constant".

If se.fit = TRUE, a list with components

- fit Predictions, as for se.fit = FALSE.
- se.fit Estimated standard errors.
- residual.scale A scalar giving the square root of the dispersion used in computing the standard errors.

Note

Variables are first looked for in newdata and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in newdata if it was supplied.

predict.HoltWinters  Prediction Function for Fitted Holt-Winters Models

Description

Computes predictions and prediction intervals for models fitted by the Holt-Winters method.

Usage

## S3 method for class 'HoltWinters'
predict(object, n.ahead = 1, prediction.interval = FALSE,
    level = 0.95, ...)

Arguments

object  An object of class HoltWinters.
n.ahead Number of future periods to predict.
prediction.interval  logical. If TRUE, the lower and upper bounds of the corresponding prediction
    intervals are computed.
level  Confidence level for the prediction interval.
...  arguments passed to or from other methods.

Value

A time series of the predicted values. If prediction intervals are requested, a multiple time series is
returned with columns fit, lwr and upr for the predicted values and the lower and upper bounds
respectively.

**predict.lm**

*Predict method for Linear Model Fits*

Description

Predicted values based on linear model object.

Usage

```r
## S3 method for class 'lm'
predict(object, newdata, se.fit = FALSE, scale = NULL, df = Inf,
       interval = c("none", "confidence", "prediction"),
       level = 0.95, type = c("response", "terms"),
       terms = NULL, na.action = na.pass,
       pred.var = res.var/weights, weights = 1, ...)
```

Arguments

- **object**: Object of class inheriting from "lm"
- **newdata**: An optional data frame in which to look for variables with which to predict. If omitted, the fitted values are used.
- **se.fit**: A switch indicating if standard errors are required.
- **scale**: Scale parameter for std.err. calculation
- **df**: Degrees of freedom for scale
- **interval**: Type of interval calculation.
- **level**: Tolerance/confidence level
- **type**: Type of prediction (response or model term).
predict.lm

**terms**
If type = "terms", which terms (default is all terms), a character vector.

**na.action**
function determining what should be done with missing values in newdata. The default is to predict NA.

**pred.var**
the variance(s) for future observations to be assumed for prediction intervals. See ‘Details’.

**weights**
variance weights for prediction. This can be a numeric vector or a one-sided model formula. In the latter case, it is interpreted as an expression evaluated in newdata

... further arguments passed to or from other methods.

**Details**

predict.lm produces predicted values, obtained by evaluating the regression function in the frame newdata (which defaults to model.frame(object)). If the logical se.fit is TRUE, standard errors of the predictions are calculated. If the numeric argument scale is set (with optional df), it is used as the residual standard deviation in the computation of the standard errors, otherwise this is extracted from the model fit. Setting intervals specifies computation of confidence or prediction (tolerance) intervals at the specified level, sometimes referred to as narrow vs. wide intervals.

If the fit is rank-deficient, some of the columns of the design matrix will have been dropped. Prediction from such a fit only makes sense if newdata is contained in the same subspace as the original data. That cannot be checked accurately, so a warning is issued.

If newdata is omitted the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit are handled is determined by the na.action argument of that fit. If na.action = na.omit omitted cases will not appear in the predictions, whereas if na.action = na.exclude they will appear (in predictions, standard errors or interval limits), with value NA. See also napredict.

The prediction intervals are for a single observation at each case in newdata (or by default, the data used for the fit) with error variance(s) pred.var. This can be a multiple of res.var, the estimated value of \( \sigma^2 \); the default is to assume that future observations have the same error variance as those used for fitting. If weights is supplied, the inverse of this is used as a scale factor. For a weighted fit, if the prediction is for the original data frame, weights defaults to the weights used for the model fit, with a warning since it might not be the intended result. If the fit was weighted and newdata is given, the default is to assume constant prediction variance, with a warning.

**Value**

predict.lm produces a vector of predictions or a matrix of predictions and bounds with column names fit, lwr, and upr if interval is set. For type = "terms" this is a matrix with a column per term and may have an attribute "constant".

If se.fit is TRUE, a list with the following components is returned:

- **fit** vector or matrix as above
- **se.fit** standard error of predicted means
- **residual.scale** residual standard deviations
- **df** degrees of freedom for residual
**predict.lm**

Note

Variables are first looked for in newdata and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in newdata if it was supplied.

Notice that prediction variances and prediction intervals always refer to future observations, possibly corresponding to the same predictors as used for the fit. The variance of the residuals will be smaller.

Strictly speaking, the formula used for prediction limits assumes that the degrees of freedom for the fit are the same as those for the residual variance. This may not be the case if res.var is not obtained from the fit.

require(graphics)

## Predictions
x <- rnorm(15)
y <- x + rnorm(15)
predict(lm(y ~ x))
new <- data.frame(x = seq(-3, 3, 0.5))
predict(lm(y ~ x), new, se.fit = TRUE)
pred.w.plim <- predict(lm(y ~ x), new, interval = "prediction")
pred.w.clim <- predict(lm(y ~ x), new, interval = "confidence")
matplot(new$x, cbind(pred.w.clim, pred.w.plim[, -1]),
   lty = c(1, 2, 2, 3, 3), type = "l", ylab = "predicted y")

## Prediction intervals, special cases
## The first three of these throw warnings
w <- 1 + x^2
fit <- lm(y ~ x)
wfit <- lm(y ~ x, weights = w)
predict(fit, interval = "prediction")
predict(wfit, interval = "prediction")
predict(wfit, new, interval = "prediction")
predict(wfit, new, interval = "prediction", weights = (new$x)^2)
predict(wfit, new, interval = "prediction", weights = -x^2)

##-- From aov(.) example ---- predict(.. terms)
utils::data(npk, package = "MASS")
npk.aov <- aov(yield ~ block + N*P*K, npk)
(termL <- attr(terms(npk.aov), "term.labels"))
(pt <- predict(npk.aov, type = "terms"))
(pt. <- predict(npk.aov, type = "terms", terms = termL[1:4])
stopifnot(all.equal(pt[, 1:4], pt.,
   check.attr = FALSE, tol = 1e-12))
```
predict.loess  

*Predict Loess Curve or Surface*

**Description**

Predictions from a `loess` fit, optionally with standard errors.

**Usage**

```r
## S3 method for class 'loess'
predict(object, newdata = NULL, se = FALSE,
          na.action = na.pass, ...)
```

**Arguments**

- `object`  
an object fitted by `loess`.
- `newdata`  
an optional data frame in which to look for variables with which to predict,  
or a matrix or vector containing exactly the variables needs for prediction. If  
missing, the original data points are used.
- `se`  
should standard errors be computed?
- `na.action`  
function determining what should be done with missing values in data frame  
`newdata`. The default is to predict `NA`.
- `...`  
arguments passed to or from other methods.

**Details**

The standard errors calculation is slower than prediction.

When the fit was made using `surface = "interpolate"` (the default), `predict.loess` will not  
extrapolate – so points outside an axis-aligned hypercube enclosing the original data will have  
missing (NA) predictions and standard errors.

The default for `na.action` prior to R 2.12.0 was `na.omit`.

**Value**

If `se = FALSE`, a vector giving the prediction for each row of `newdata` (or the original data). If  
`se = TRUE`, a list containing components

- `fit`  
the predicted values.
- `se`  
an estimated standard error for each predicted value.
- `residual.scale`  
the estimated scale of the residuals used in computing the standard errors.
- `df`  
an estimate of the effective degrees of freedom used in estimating the residual  
scale, intended for use with t-based confidence intervals.

If `newdata` was the result of a call to `expand.grid`, the predictions (and s.e.’s if requested) will be  
an array of the appropriate dimensions.

Predictions from infinite inputs will be NA since `loess` does not support extrapolation.
predict.nls

Note

Variables are first looked for in newdata and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in newdata if it was supplied.

Author(s)

B. D. Ripley, based on the cloess package of Cleveland, Grosse and Shyu.

loess

Examples

cars.lo <- loess(dist ~ speed, cars)
predict(cars.lo, data.frame(speed = seq(5, 30, 1)), se = TRUE)
# to get extrapolation
cars.lo2 <- loess(dist ~ speed, cars,
control = loess.control(surface = "direct"))
predict(cars.lo2, data.frame(speed = seq(5, 30, 1)), se = TRUE)

predict.nls

Predicting from Nonlinear Least Squares Fits

Description

predict.nls produces predicted values, obtained by evaluating the regression function in the frame newdata. If the logical se.fit is TRUE, standard errors of the predictions are calculated. If the numeric argument scale is set (with optional df), it is used as the residual standard deviation in the computation of the standard errors, otherwise this is extracted from the model fit. Setting intervals specifies computation of confidence or prediction (tolerance) intervals at the specified level.

At present se.fit and interval are ignored.

Usage

## S3 method for class 'nls'
predict(object, newdata, se.fit = FALSE, scale = NULL, df = Inf,
interval = c("none", "confidence", "prediction"),
level = 0.95, ...)
Arguments

- **object**: An object that inherits from class `nls`.
- **newdata**: A named list or data frame in which to look for variables with which to predict. If `newdata` is missing the fitted values at the original data points are returned.
- **se.fit**: A logical value indicating if the standard errors of the predictions should be calculated. Defaults to `FALSE`. At present this argument is ignored.
- **scale**: A numeric scalar. If it is set (with optional `df`), it is used as the residual standard deviation in the computation of the standard errors, otherwise this information is extracted from the model fit. At present this argument is ignored.
- **df**: A positive numeric scalar giving the number of degrees of freedom for the `scale` estimate. At present this argument is ignored.
- **interval**: A character string indicating if prediction intervals or a confidence interval on the mean responses are to be calculated. At present this argument is ignored.
- **level**: A numeric scalar between 0 and 1 giving the confidence level for the intervals (if any) to be calculated. At present this argument is ignored.
- **...**: Additional optional arguments. At present no optional arguments are used.

Value

`predict.nls` produces a vector of predictions. When implemented, `interval` will produce a matrix of predictions and bounds with column names `fit`, `lwr`, and `upr`. When implemented, if `se.fit` is `TRUE`, a list with the following components will be returned:

- **fit**: vector or matrix as above
- **se.fit**: standard error of predictions
- **residual.scale**: residual standard deviations
- **df**: degrees of freedom for residual

Note

Variables are first looked for in `newdata` and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in `newdata` if it was supplied.

Examples

```R
require(graphics)

fm <- nls(demand ~ SSasympOrig(Time, A, lrc), data = BOD)
predict(fm) # fitted values at observed times
## Form data plot and smooth line for the predictions
opar <- par(las = 1)
```
predict.smooth.spline

plot(demand ~ Time, data = BOD, col = 4,
     main = "BOD data and fitted first-order curve",
     xlim = c(0,7), ylim = c(0, 20) )

tt <- seq(0, 8, length = 101)
lines(tt, predict(fm, list(Time = tt)))
par(opar)

predict.smooth.spline  Predict from Smoothing Spline Fit

Description

Predict a smoothing spline fit at new points, return the derivative if desired. The predicted fit is linear beyond the original data.

Usage

## S3 method for class 'smooth.spline'
predict(object, x, deriv = 0, ...)

Arguments

object  a fit from smooth.spline.
x        the new values of x.
deriv    integer; the order of the derivative required.
...      further arguments passed to or from other methods.

Value

A list with components

x        The input x.
y        The fitted values or derivatives at x.

See Also

smooth.spline

Examples

require(graphics)

attach(cars)
cars.spl <- smooth.spline(speed, dist, df = 6.4)

## "Proof" that the derivatives are okay, by comparing with approximation
## Difference quotient (central differences where available)

```r
diff.quot <- function(x, y) {
  n <- length(x); i1 <- 1:2; i2 <- (n-1):n
  c(diff(y[i1]) / diff(x[i1]), (y[-i1] - y[-i2]) / (x[-i1] - x[-i2]),
     diff(y[i2]) / diff(x[i2]))
}
```

### Example

```r
xx <- unique(sort(c(seq(0, 3, by = .2), kn <- unique(speed))))
i.kn <- match(kn, xx) # indices of knots within xx
op <- par(mfrow = c(2,2))
plot(speed, dist, xlim = range(xx), main = "Smooth.spline & derivatives")
lines(pp <- predict(cars.spl, xx), col = "red")
points(kn, pp$y[i.kn], pch = 3, col = "dark red")
mtext("s(x)", col = "red")
for(d in 1:3){
  n <- length(pp$x)
  plot(pp$x, diff.quot(pp$x,pp$y), type = "l", xlab = "x", ylab = "",
       col = "blue", col.main = "red",
       main = paste("s",paste(rep("", d), collapse = ""), "(x)"))
mtext("Difference quotient approx.(last)", col = "blue")
  lines(pp <- predict(cars.spl, xx, deriv = d), col = "red")
  points(kn, pp$y[i.kn], pch = 3, col = "dark red")
  abline(h = 0, lty = 3, col = "gray")
}
detach(); par(op)
```

---

**preplot**

*Pre-computations for a Plotting Object*

### Description

Compute an object to be used for plots relating to the given model object.

### Usage

```r
preplot(object, ...)  
```

### Arguments

- **object**
  - a fitted model object.

- **...**
  - additional arguments for specific methods.

### Details

Only the generic function is currently provided in base R, but some add-on packages have methods. Principally here for S compatibility.
**Value**

An object set up to make a plot that describes object.

**Description**

`princomp` performs a principal components analysis on the given numeric data matrix and returns the results as an object of class `princomp`.

**Usage**

```r
princomp(x, ...)  
## S3 method for class 'formula'
princomp(formula, data = NULL, subset, na.action, ...)  
## Default S3 method:
princomp(x, cor = FALSE, scores = TRUE, covmat = NULL,  
        subset = rep(TRUE, nrow(as.matrix(x))), ...)  
## S3 method for class 'princomp'
predict(object, newdata, ...)
```

**Arguments**

- `formula` a formula with no response variable, referring only to numeric variables.
- `data` an optional data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- `subset` an optional vector used to select rows (observations) of the data matrix `x`.
- `na.action` a function which indicates what should happen when the data contain NAs. The default is set by the `na.action` setting of `options`, and is `na.fail` if that is unset. The ‘factory-fresh’ default is `na.omit`.
- `x` a numeric matrix or data frame which provides the data for the principal components analysis.
- `cor` a logical value indicating whether the calculation should use the correlation matrix or the covariance matrix. (The correlation matrix can only be used if there are no constant variables.)
- `scores` a logical value indicating whether the score on each principal component should be calculated.
- `covmat` a covariance matrix, or a covariance list as returned by `cov.wt` (and `cov.mve` or `cov.mcd` from package `MASS`). If supplied, this is used rather than the covariance matrix of `x`. 
... arguments passed to or from other methods. If x is a formula one might specify cor or scores.

object Object of class inheriting from "princomp"

newdata An optional data frame or matrix in which to look for variables with which to predict. If omitted, the scores are used. If the original fit used a formula or a data frame or a matrix with column names, newdata must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order.

Details

princomp is a generic function with "formula" and "default" methods.

The calculation is done using eigen on the correlation or covariance matrix, as determined by cor. This is done for compatibility with the S-PLUS result. A preferred method of calculation is to use svd on x, as is done in prcomp.

Note that the default calculation uses divisor N for the covariance matrix.

The print method for these objects prints the results in a nice format and the plot method produces a scree plot (screeplot). There is also a biplot method.

If x is a formula then the standard NA-handling is applied to the scores (if requested): see napredict.

princomp only handles so-called R-mode PCA, that is feature extraction of variables. If a data matrix is supplied (possibly via a formula) it is required that there are at least as many units as variables. For Q-mode PCA use prcomp.

Value

princomp returns a list with class "princomp" containing the following components:

sdev the standard deviations of the principal components.

loadings the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors). This is of class "loadings": see loadings for its print method.

center the means that were subtracted.

scale the scalings applied to each variable.

n.obs the number of observations.

scores if scores = TRUE, the scores of the supplied data on the principal components. These are non-null only if x was supplied, and if covmat was also supplied if it was a covariance list. For the formula method, napredict() is applied to handle the treatment of values omitted by the na.action.

call the matched call.

na.action If relevant.

Note

The signs of the columns of the loadings and scores are arbitrary, and so may differ between different programs for PCA, and even between different builds of R.

## The variances of the variables in the
## USArrests data vary by orders of magnitude, so scaling is appropriate
(pc.cr <- princomp(USArrests)) # inappropriate
princomp(USArrests, cor = TRUE) # = prcomp(USArrests, scale=TRUE)
## Similar, but different:
## The standard deviations differ by a factor of sqrt(49/50)

summary(pc.cr <- princomp(USArrests, cor = TRUE))
loadings(pc.cr) # note that blank entries are small but not zero
plot(pc.cr) # shows a screeplot.
biplot(pc.cr)

## Formula interface
princomp(~ ., data = USArrests, cor = TRUE)

## NA-handling
USArrests[1, 2] <- NA
pc.cr <- princomp(~ Murder + Assault + UrbanPop,
                  data = USArrests, na.action = na.exclude, cor = TRUE)
pc.cr$scores[1:5, ]

## (Simple) Robust PCA:
## Classical:
(pc.cl <- princomp(stackloss))
## Robust:
(pc.rob <- princomp(stackloss, covmat = MASS::cov.rob(stackloss)))

print.power.htest

Print method for power calculation object

Description

Print object of class "power.htest" in nice layout.

Usage

## S3 method for class 'power.htest'
print(x, ...)
Arguments

- `x`: Object of class "power.htest".
- `...`: further arguments to be passed to or from methods.

Details

A `power.htest` object is just a named list of numbers and character strings, supplemented with method and note elements. The method is displayed as a title, the note as a footnote, and the remaining elements are given in an aligned 'name = value' format.

Value

- `none`

Author(s)

Peter Dalgaard

See Also

`power.t.test, power.prop.test`

Description

Print method for time series objects.

Usage

```r
## S3 method for class 'ts'
print(x, calendar, ...)
```

Arguments

- `x`: a time series object.
- `calendar`: enable/disable the display of information about month names, quarter names or year when printing. The default is `TRUE` for a frequency of 4 or 12, `FALSE` otherwise.
- `...`: additional arguments to `print`.

Details

This is the `print` methods for objects inheriting from class "ts".
See Also

print.ts.

Examples

print(ts(1:10, frequency = 7, start = c(12, 2)), calendar = TRUE)

printCoefmat

Print Coefficient Matrices

Description

Utility function to be used in higher-level print methods, such as print.summary.lm, print.summary.glm and print.anova. The goal is to provide a flexible interface with smart defaults such that often, only x needs to be specified.

Usage

printCoefmat(x, digits = max(3, getOption("digits") - 2),
  signif.stars = getOption("show.signif.stars"),
  signif.legend = signif.stars,
  dig.tst = max(1, min(5, digits - 1)),
  cs.ind = 1L:k, tst.ind = k + 1L,
  zap.ind = integer(), P.values = NULL,
  has.Pvalue = nc >= 4L &&
    substr(colnames(x)[nc], 1L, 3L) == "Pr(",
  eps.Pvalue = .Machine$double.eps,
  na.print = "NA", ...)

Arguments

x a numeric matrix like object, to be printed.

digits minimum number of significant digits to be used for most numbers.

signif.stars logical; if TRUE, P-values are additionally encoded visually as ‘significance stars’ in order to help scanning of long coefficient tables. It defaults to the show.signif.stars slot of options.

signif.legend logical; if TRUE, a legend for the ‘significance stars’ is printed provided signif.stars = TRUE.

dig.tst minimum number of significant digits for the test statistics, see tst.ind.

cs.ind indices (integer) of column numbers which are (like) coefficients and standard errors to be formatted together.

tst.ind indices (integer) of column numbers for test statistics.

zap.ind indices (integer) of column numbers which should be formatted by zapsmall, i.e., by ‘zapping’ values close to 0.
profile

Generic Function for Profiling Models

Description

Investigates behavior of objective function near the solution represented by fitted.

See documentation on method functions for further details.

Usage

profile(fitted, ...)
Arguments

fitted the original fitted model object.

... additional parameters. See documentation on individual methods.

Value

A list with an element for each parameter being profiled. See the individual methods for further details.

See Also

profile.nls, profile.glm in package MASS, ...

For profiling R code, see Rprof.

profile.nls Method for Profiling nls Objects

Description

Investigates the profile log-likelihood function for a fitted model of class "nls".

Usage

## S3 method for class 'nls'
profile(fitted, which = 1:npar, maxpts = 100, alphamax = 0.01, delta.t = cutoff/5, ...)
Value

A list with an element for each parameter being profiled. The elements are data-frames with two variables

par.vals  a matrix of parameter values for each fitted model.
tau   the profile t-statistics.

Author(s)

Of the original version, Douglas M. Bates and Saikat DebRoy

---

proj

Projections of Models

Description

proj returns a matrix or list of matrices giving the projections of the data onto the terms of a linear model. It is most frequently used for aov models.

Usage

```r
proj(object, ...)
```

### S3 method for class 'aov'
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)

### S3 method for class 'aovlist'

```r
```
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)

## Default S3 method:
proj(object, onedf = TRUE, ...)

## S3 method for class 'lm'
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)

Arguments

object  An object of class "lm" or a class inheriting from it, or an object with a similar structure including in particular components qr and effects.

onedf  A logical flag. If TRUE, a projection is returned for all the columns of the model matrix. If FALSE, the single-column projections are collapsed by terms of the model (as represented in the analysis of variance table).

unweighted.scale  If the fit producing object used weights, this determines if the projections correspond to weighted or unweighted observations.

...  Swallow and ignore any other arguments.

Details

A projection is given for each stratum of the object, so for aov models with an Error term the result is a list of projections.

Value

A projection matrix or (for multi-stratum objects) a list of projection matrices.

Each projection is a matrix with a row for each observations and either a column for each term (onedf = FALSE) or for each coefficient (onedf = TRUE). Projection matrices from the default method have orthogonal columns representing the projection of the response onto the column space of the Q matrix from the QR decomposition. The fitted values are the sum of the projections, and the sum of squares for each column is the reduction in sum of squares from fitting that column (after those to the left of it).

The methods for lm and aov models add a column to the projection matrix giving the residuals (the projection of the data onto the orthogonal complement of the model space).

Strictly, when onedf = FALSE the result is not a projection, but the columns represent sums of projections onto the columns of the model matrix corresponding to that term. In this case the matrix does not depend on the coding used.

Author(s)

The design was inspired by the S function of the same name described in Chambers et al. (1992).

proj(npk.aovE)

prop.test

Test of Equal or Given Proportions

Description

prop.test can be used for testing the null that the proportions (probabilities of success) in several groups are the same, or that they equal certain given values.

Usage

prop.test(x, n, p = NULL,
          alternative = c("two.sided", "less", "greater"),
          conf.level = 0.95, correct = TRUE)

Arguments

x a vector of counts of successes, a one-dimensional table with two entries, or a two-dimensional table (or matrix) with 2 columns, giving the counts of successes and failures, respectively.

n a vector of counts of trials; ignored if x is a matrix or a table.

p a vector of probabilities of success. The length of p must be the same as the number of groups specified by x, and its elements must be greater than 0 and less than 1.

alternative a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter. Only used for testing the null that a single proportion equals a given value, or that two proportions are equal; ignored otherwise.
conf.level  confidence level of the returned confidence interval. Must be a single number between 0 and 1. Only used when testing the null that a single proportion equals a given value, or that two proportions are equal; ignored otherwise.

correct  a logical indicating whether Yates’ continuity correction should be applied where possible.

Details

Only groups with finite numbers of successes and failures are used. Counts of successes and failures must be nonnegative and hence not greater than the corresponding numbers of trials which must be positive. All finite counts should be integers.

If p is NULL and there is more than one group, the null tested is that the proportions in each group are the same. If there are two groups, the alternatives are that the probability of success in the first group is less than, not equal to, or greater than the probability of success in the second group, as specified by alternative. A confidence interval for the difference of proportions with confidence level as specified by conf.level and clipped to $[-1, 1]$ is returned. Continuity correction is used only if it does not exceed the difference of the sample proportions in absolute value. Otherwise, if there are more than 2 groups, the alternative is always "two.sided", the returned confidence interval is NULL, and continuity correction is never used.

If there is only one group, then the null tested is that the underlying probability of success is p, or .5 if p is not given. The alternative is that the probability of success is less than, not equal to, or greater than p or 0.5, respectively, as specified by alternative. A confidence interval for the underlying proportion with confidence level as specified by conf.level and clipped to $[0, 1]$ is returned. Continuity correction is used only if it does not exceed the difference between sample and null proportions in absolute value. The confidence interval is computed by inverting the score test.

Finally, if p is given and there are more than 2 groups, the null tested is that the underlying probabilities of success are those given by p. The alternative is always "two.sided", the returned confidence interval is NULL, and continuity correction is never used.

Value

A list with class "htest" containing the following components:

- statistic  the value of Pearson’s chi-squared test statistic.
- parameter  the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- p.value    the p-value of the test.
- estimate   a vector with the sample proportions $x/n$.
- conf.int   a confidence interval for the true proportion if there is one group, or for the difference in proportions if there are 2 groups and p is not given, or NULL otherwise. In the cases where it is not NULL, the returned confidence interval has an asymptotic confidence level as specified by conf.level, and is appropriate to the specified alternative hypothesis.
- null.value the value of p if specified by the null, or NULL otherwise.
- alternative a character string describing the alternative.
prop.trend.test

method a character string indicating the method used, and whether Yates’ continuity correction was applied.
data.name a character string giving the names of the data.

References

See Also

binom.test for an exact test of a binomial hypothesis.

Examples

```r
heads <- rbinom(1, size = 1/zero.noslash/zero.noslash, prob = .5)
prop.test(heads, 1/zero.noslash/zero.noslash) # continuity correction TRUE by default
prop.test(heads, 1/zero.noslash/zero.noslash, correct = FALSE)

## Data from Fleiss (1981), p. 139.
## H/zero.noslash: The null hypothesis is that the four populations from which
## the patients were drawn have the same true proportion of smokers.
## A: The alternative is that this proportion is different in at
## least one of the populations.

smokers <- c( 83, 9/zero.noslash, 129, 7/zero.noslash )
patients <- c( 86, 93, 136, 82 )
prop.test(smokers, patients)
```

prop.trend.test Test for trend in proportions

Description

Performs chi-squared test for trend in proportions, i.e., a test asymptotically optimal for local alternatives where the log odds vary in proportion with score. By default, score is chosen as the group numbers.

Usage

```r
prop.trend.test(x, n, score = seq_along(x))
```
Arguments

- `x` Number of events
- `n` Number of trials
- `score` Group score

Value

An object of class "htest" with title, test statistic, p-value, etc.

Note

This really should get integrated with `prop.test`

prop.trend.test(smokers, patients)
prop.trend.test(smokers, patients, c(0,0,0,1))
```

Description

`qqnorm` is a generic function the default method of which produces a normal QQ plot of the values in `y`. `qqline` adds a line to a "theoretical", by default normal, quantile-quantile plot which passes through the `probs` quantiles, by default the first and third quartiles.

`qqplot` produces a QQ plot of two datasets.

Graphical parameters may be given as arguments to `qqnorm`, `qqplot` and `qqline`. 
Usage

qqnorm(y, ...)

## Default S3 method:
qqnorm(y, ylim, main = "Normal Q-Q Plot",
xlab = "Theoretical Quantiles", ylab = "Sample Quantiles",
plot.it = TRUE, datax = FALSE, ...)

qqline(y, datax = FALSE, distribution = qnorm,
probs = c(0.25, 0.75), qtype = 7, ...)

qqplot(x, y, plot.it = TRUE, xlab = deparse(substitute(x)),
ylab = deparse(substitute(y)), ...)

Arguments

x
The first sample for qqplot.
y
The second or only data sample.
xlab, ylab, main
plot labels. The xlab and ylab refer to the y and x axes respectively if
datax = TRUE.
plot.it
logical. Should the result be plotted?
datax
logical. Should data values be on the x-axis?
distribution
quantile function for reference theoretical distribution.
probs
numeric vector of length two, representing probabilities. Corresponding quantile pairs define the line drawn.
qtype
the type of quantile computation used in quantile.
ylim, ...
graphical parameters.

Value

For qqnorm and qqplot, a list with components

x
The x coordinates of the points that were/would be plotted
y
The original y vector, i.e., the corresponding y coordinates including NAs.

References

See Also

ppoints, used by qqnorm to generate approximations to expected order statistics for a normal distribution.
Examples

require(graphics)

y <- rt(200, df = 5)
qqnorm(y); qqline(y, col = 2)
qqplot(y, rt(300, df = 5))

qqnorm(precip, ylab = "Precipitation [in/yr] for 70 US cities")

## "QQ-Chisquare" : --------------------------
y <- rchisq(500, df = 3)
## Q-Q plot for Chi^2 data against true theoretical distribution:
qqplot(qchisq(ppoints(500), df = 3), y,
       main = expression("Q-Q plot for" ~~ {chi^2}[nu == 3]))
qqline(y, distribution = function(p) qchisq(p, df = 3),
       prob = c(0.1, 0.6), col = 2)
mtext("qqline(*, dist = qchisq(., df=3), prob = c(0.1, 0.6))")

quade.test

Quade Test

Description

Performs a Quade test with unreplicated blocked data.

Usage

quade.test(y, ...)

## Default S3 method:
quade.test(y, groups, blocks, ...)

## S3 method for class 'formula'
quade.test(formula, data, subset, na.action, ...)

Arguments

y

either a numeric vector of data values, or a data matrix.

groups

a vector giving the group for the corresponding elements of y if this is a vector;
 ignored if y is a matrix. If not a factor object, it is coerced to one.

blocks

a vector giving the block for the corresponding elements of y if this is a vector;
 ignored if y is a matrix. If not a factor object, it is coerced to one.

formula

a formula of the form a ~ b | c, where a, b and c give the data values and
corresponding groups and blocks, respectively.

data

an optional matrix or data frame (or similar: see model.frame) containing
the variables in the formula formula. By default the variables are taken from
environment(formula).
subset: an optional vector specifying a subset of observations to be used.

na.action: a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.

... further arguments to be passed to or from methods.

**Details**

`quade.test` can be used for analyzing unreplicated complete block designs (i.e., there is exactly one observation in `y` for each combination of levels of `groups` and `blocks`) where the normality assumption may be violated.

The null hypothesis is that apart from an effect of `blocks`, the location parameter of `y` is the same in each of the `groups`.

If `y` is a matrix, `groups` and `blocks` are obtained from the column and row indices, respectively. NAs are not allowed in `groups` or `blocks`; if `y` contains NAs, corresponding blocks are removed.

**Value**

A list with class "htest" containing the following components:

- `statistic`: the value of Quade's F statistic.
- `parameter`: a vector with the numerator and denominator degrees of freedom of the approximate F distribution of the test statistic.
- `p.value`: the p-value of the test.
- `method`: the character string "Quade test".
- `data.name`: a character string giving the names of the data.

**Examples**

```r
## Conover (1999, p. 375f):
## Numbers of five brands of a new hand lotion sold in seven stores
## during one week.
y <- matrix(c( 5, 4, 7, 10, 12,
  1, 3, 1, 0, 2,
  16, 12, 22, 22, 35,
  5, 4, 3, 5, 4,
  10, 9, 7, 13, 10,
  19, 18, 28, 37, 58,
```
quantile

10, 7, 6, 8, 7),
nrow = 7, byrow = TRUE,
dimnames =
list(Store = as.character(1:7),
     Brand = LETTERS[1:5])

y
quade.test(y)

quantile  Sample Quantiles

Description
The generic function quantile produces sample quantiles corresponding to the given probabilities. The smallest observation corresponds to a probability of 0 and the largest to a probability of 1.

Usage
quantile(x, ...)

## Default S3 method:
quantile(x, probs = seq(0, 1, 0.25), na.rm = FALSE,
names = TRUE, type = 7, ...)

Arguments
x numeric vector whose sample quantiles are wanted, or an object of a class for which a method has been defined (see also ‘details’). NA and NaN values are not allowed in numeric vectors unless na.rm is TRUE.
probs numeric vector of probabilities with values in [0, 1]. (Values up to ‘2e-14’ outside that range are accepted and moved to the nearby endpoint.)
na.rm logical; if true, any NA and NaN’s are removed from x before the quantiles are computed.
names logical; if true, the result has a names attribute. Set to FALSE for speedup with many probs.
type an integer between 1 and 9 selecting one of the nine quantile algorithms detailed below to be used.
...

Details
A vector of length length(probs) is returned; if names = TRUE, it has a names attribute.
NA and NaN values in probs are propagated to the result.
The default method works with classed objects sufficiently like numeric vectors that sort and (not needed by types 1 and 3) addition of elements and multiplication by a number work correctly. Note that as this is in a namespace, the copy of sort in base will be used, not some S4 generic of that.
name. Also note that that is no check on the 'correctly', and so e.g. quantile can be applied to complex vectors which (apart from ties) will be ordered on their real parts.

There is a method for the date-time classes (see "POSIXt"). Types 1 and 3 can be used for class "Date" and for ordered factors.

Types

quantile returns estimates of underlying distribution quantiles based on one or two order statistics from the supplied elements in x at probabilities in probs. One of the nine quantile algorithms discussed in Hyndman and Fan (1996), selected by type, is employed.

All sample quantiles are defined as weighted averages of consecutive order statistics. Sample quantiles of type i are defined by:

\[ Q_i(p) = (1 - \gamma)x_j + \gamma x_{j+1} \]

where 1 \leq i \leq 9, \( \frac{j-m}{n} \leq p < \frac{j-m+1}{n} \), \( x_j \) is the jth order statistic, \( n \) is the sample size, the value of \( \gamma \) is a function of \( j = \lfloor np + m \rfloor \) and \( g = np + m - j \), and \( m \) is a constant determined by the sample quantile type.

Discontinuous sample quantile types 1, 2, and 3

For types 1, 2 and 3, \( Q_i(p) \) is a discontinuous function of \( p \), with \( m = 0 \) when \( i = 1 \) and \( i = 2 \), and \( m = -1/2 \) when \( i = 3 \).

Type 1 Inverse of empirical distribution function. \( \gamma = 0 \) if \( g = 0 \), and 1 otherwise.

Type 2 Similar to type 1 but with averaging at discontinuities. \( \gamma = 0.5 \) if \( g = 0 \), and 1 otherwise.

Type 3 SAS definition: nearest even order statistic. \( \gamma = 0 \) if \( g = 0 \) and \( j \) is even, and 1 otherwise.

Continuous sample quantile types 4 through 9

For types 4 through 9, \( Q_i(p) \) is a continuous function of \( p \), with \( \gamma = g \) and \( m \) given below. The sample quantiles can be obtained equivalently by linear interpolation between the points \((p_k, x_k)\) where \( x_k \) is the \( k \)th order statistic. Specific expressions for \( p_k \) are given below.

Type 4 \( m = 0 \). \( p_k = \frac{k}{n} \). That is, linear interpolation of the empirical cdf.

Type 5 \( m = 1/2 \). \( p_k = \frac{k-0.5}{n} \). That is a piecewise linear function where the knots are the values midway through the steps of the empirical cdf. This is popular amongst hydrologists.

Type 6 \( m = p \). \( p_k = \frac{k}{n+1} \). Thus \( p_k = E[F(x_k)] \). This is used by Minitab and by SPSS.

Type 7 \( m = 1 - p \). \( p_k = \frac{k-1}{n-1} \). In this case, \( p_k = \text{mode}[F(x_k)] \). This is used by S.

Type 8 \( m = (p + 1)/3 \). \( p_k = \frac{k-1/3}{n+1/3} \). Then \( p_k \approx \text{median}[F(x_k)] \). The resulting quantile estimates are approximately median-unbiased regardless of the distribution of \( x \).

Type 9 \( m = p/4 + 3/8 \). \( p_k = \frac{k-3/8}{n+3/8} \). The resulting quantile estimates are approximately unbiased for the expected order statistics if \( x \) is normally distributed.

Further details are provided in Hyndman and Fan (1996) who recommended type 8. The default method is type 7, as used by S and by R < 2.0.0.

**r2dtable**

*Random 2-way Tables with Given Marginals*

Description

Generate random 2-way tables with given marginals using Patefield’s algorithm.

Usage

`r2dtable(n, r, c)`

Arguments

- `n` a non-negative numeric giving the number of tables to be drawn.
- `r` a non-negative vector of length at least 2 giving the row totals, to be coerced to integer. Must sum to the same as `c`.
- `c` a non-negative vector of length at least 2 giving the column totals, to be coerced to integer.

Value

A list of length `n` containing the generated tables as its components.
References

Examples

```r
## Fisher's Tea Drinker data.
TeaTasting <-
  matrix(c(3, 1, 1, 3),
         nrow = 2,
         dimnames = list(Guess = c("Milk", "Tea"),
                         Truth = c("Milk", "Tea")))
## Simulate permutation test for independence based on the maximum
## Pearson residuals (rather than their sum).
rowTotals <- rowSums(TeaTasting)
colTotals <- colSums(TeaTasting)
NOfCases <- sum(rowTotals)
expected <- outer(rowTotals, colTotals, "*") / NOfCases
maxSqResid <- function(x) max((x - expected) ^ 2 / expected)
simMaxSqResid <-
  sapply(r2dtable(1/zero.noslash/zero.noslash/zero.noslash, rowTotals, colTotals), maxSqResid)
sum(simMaxSqResid >= maxSqResid(TeaTasting)) / 1/zero.noslash/zero.noslash/zero.noslash
## Fisher's exact test gives p = 0.4857 ...
```

---

read.ftable  

Manipulate Flat Contingency Tables

Description

Read, write and coerce ‘flat’ contingency tables.

Usage

read.ftable(file, sep = "", quote = "\"",
            row.var.names, col.vars, skip = 0)

write.ftable(x, file = "", quote = TRUE, append = FALSE,
              digits = getOption("digits"), ...)

## S3 method for class 'ftable'
format(x, quote = TRUE, digits = getOption("digits"),
       method = c("non.compact", "row.compact",
                  "col.compact", "compact"),
       lsep = " | ", ...)

## S3 method for class 'ftable'
print(x, digits = getOption("digits"), ...)
Arguments

file either a character string naming a file or a connection which the data are to be read from or written to. "" indicates input from the console for reading and output to the console for writing.

sep the field separator string. Values on each line of the file are separated by this string.

quote a character string giving the set of quoting characters for read.ftable; to disable quoting altogether, use quote="". For write.table, a logical indicating whether strings in the data will be surrounded by double quotes.

row.var.names a character vector with the names of the row variables, in case these cannot be determined automatically.

col.vars a list giving the names and levels of the column variables, in case these cannot be determined automatically.

skip the number of lines of the data file to skip before beginning to read data.

x an object of class "ftable".

append logical. If TRUE and file is the name of a file (and not a connection or "|cmd"), the output from write.ftable is appended to the file. If FALSE, the contents of file will be overwritten.

digits an integer giving the number of significant digits to use for (the cell entries of) x.

method string specifying how the "ftable" object is formatted (and printed if used as in write.ftable() or the print method). Available methods are (see the examples):

"non.compact" the default representation of an "ftable" object.

"row.compact" a row-compact version without empty cells below the column labels.

"col.compact" a column-compact version without empty cells to the right of the row labels.

"compact" a row- and column-compact version. This may imply a row and a column label sharing the same cell. They are then separated by the string lsep.

lsep only for method = "compact", the separation string for row and column labels.

... further arguments to be passed to or from methods; for write() and print(), notably arguments such as method, passed to format().

Details

read.ftable reads in a flat-like contingency table from a file. If the file contains the written representation of a flat table (more precisely, a header with all information on names and levels of column variables, followed by a line with the names of the row variables), no further arguments are needed. Similarly, flat tables with only one column variable the name of which is the only entry in the first line are handled automatically. Other variants can be dealt with by skipping all header information using skip, and providing the names of the row variables and the names and levels of the column variable using row.var.names and col.vars, respectively. See the examples below.
Note that flat tables are characterized by their ‘ragged’ display of row (and maybe also column) labels. If the full grid of levels of the row variables is given, one should instead use `read.table` to read in the data, and create the contingency table from this using `xtabs`.

`write.ftable` writes a flat table to a file, which is useful for generating ‘pretty’ ASCII representations of contingency tables. Different versions are available via the `method` argument, which may be useful, for example, for constructing LaTeX tables.

References

`ftable` for more information on flat contingency tables.

Examples

```r
## Agresti (1990), page 157, Table 5.8.
## Not in ftable standard format, but o.k.
file <- tempfile()
cat(" Intercourse
", "Race Gender Yes No\n", "White Male 43 134\n", " Female 26 149\n", "Black Male 29 23\n", " Female 22 36\n", file = file)
file.show(file)
ft1 <- read.ftable(file)
unlink(file)

## Agresti (1990), page 297, Table 8.16.
## Almost o.k., but misses the name of the row variable.
file <- tempfile()
cat(" "Tonsil Size\n", "Noncarriers 497 560 269\n", "Carriers 19 29 24\n", file = file)
file.show(file)
ft <- read.ftable(file, skip = 2,
row.var.names = "Status",
col.vars = list("Tonsil Size" =
c("Not Enl.", "Enl.", "Greatly Enl.")))
ft
unlink(file)

ft22 <- ftable(Titanic, row.vars = 2:1, col.vars = 4:3)
write.ftable(ft22, quote = FALSE)
write.ftable(ft22, quote = FALSE, method="row.compact")
write.ftable(ft22, quote = FALSE, method="col.compact")
```
**rect.hclust**

Draw Rectangles Around Hierarchical Clusters

**Description**

Draws rectangles around the branches of a dendrogram highlighting the corresponding clusters. First the dendrogram is cut at a certain level, then a rectangle is drawn around selected branches.

**Usage**

```r
rect.hclust(tree, k = NULL, which = NULL, x = NULL, h = NULL, border = 2, cluster = NULL)
```

**Arguments**

- `tree` an object of the type produced by `hclust`.
- `k`, `h` Scalar. Cut the dendrogram such that either exactly `k` clusters are produced or by cutting at height `h`.
- `which`, `x` A vector selecting the clusters around which a rectangle should be drawn. `which` selects clusters by number (from left to right in the tree), `x` selects clusters containing the respective horizontal coordinates. Default is `which = 1:k`.
- `border` Vector with border colors for the rectangles.
- `cluster` Optional vector with cluster memberships as returned by `cutree(hclust.obj, k = k)`, can be specified for efficiency if already computed.

**Value**

(Invisibly) returns a list where each element contains a vector of data points contained in the respective cluster.

**See Also**

`hclust`, `identify.hclust`.

**Examples**

```r
require(graphics)

hca <- hclust(dist(USArrests))
plot(hca)
rect.hclust(hca, k = 3, border = "red")
x <- rect.hclust(hca, h = 50, which = c(2,7), border = 3:4)
x
```
**relevel**  
*Reorder Levels of Factor*

**Description**
The levels of a factor are re-ordered so that the level specified by `ref` is first and the others are moved down. This is useful for `contr.treatment` contrasts which take the first level as the reference.

**Usage**
```r
relevel(x, ref, ...)
```

**Arguments**
- `x`: An unordered factor.
- `ref`: The reference level.
- `...`: Additional arguments for future methods.

**Value**
A factor of the same length as `x`.

**See Also**
`factor`, `contr.treatment`, `levels`, `reorder`.

**Examples**
```r
warpbreaks$tension <- relevel(warpbreaks$tension, ref = "M")
summary(lm(breaks ~ wool + tension, data = warpbreaks))
```

---

**reorder.default**  
*Reorder Levels of a Factor*

**Description**
`reorder` is a generic function. The "default" method treats its first argument as a categorical variable, and reorders its levels based on the values of a second variable, usually numeric.

**Usage**
```r
reorder(x, ...)
```

**## Default S3 method:**
```r
reorder(x, X, FUN = mean, ..., 
        order = is.ordered(x))
```
Arguments

x  An atomic vector, usually a factor (possibly ordered). The vector is treated as a
categorical variable whose levels will be reordered. If x is not a factor, its unique
values will be used as the implicit levels.

X  a vector of the same length as x, whose subset of values for each unique level of
x determines the eventual order of that level.

FUN  a function whose first argument is a vector and returns a scalar, to be applied to
each subset of X determined by the levels of x.

...  optional: extra arguments supplied to FUN

order  logical, whether return value will be an ordered factor rather than a factor.

Value

A factor or an ordered factor (depending on the value of order), with the order of the levels deter-
mined by FUN applied to X grouped by x. The levels are ordered such that the values returned by
FUN are in increasing order. Empty levels will be dropped.

Additionally, the values of FUN applied to the subsets of X (in the original order of the levels of x) is
returned as the "scores" attribute.

Author(s)

Deepayan Sarkar <deepayan.sarkar@r-project.org>

See Also

reorder.dendrogram, levels, relevel.

Examples

require(graphics)

bymedian <- with(InsectSprays, reorder(spray, count, median))
boxplot(count ~ bymedian, data = InsectSprays,
  xlab = "Type of spray", ylab = "Insect count",
  main = "InsectSprays data", varwidth = TRUE,
  col = "lightgray")

Description

A method for the generic function reorder.

There are many different orderings of a dendrogram that are consistent with the structure imposed.
This function takes a dendrogram and a vector of values and reorders the dendrogram in the order
of the supplied vector, maintaining the constraints on the dendrogram.
Usage

```r
## S3 method for class 'dendrogram'
reorder(x, wts, agglo.FUN = sum, ...)
```

Arguments

- `x`: the (dendrogram) object to be reordered
- `wts`: numeric weights (arbitrary values) for reordering.
- `agglo.FUN`: a function for weights agglomeration, see below.
- `...`: additional arguments

Details

Using the weights `wts`, the leaves of the dendrogram are reordered so as to be in an order as consistent as possible with the weights. At each node, the branches are ordered in increasing weights where the weight of a branch is defined as \( f(w_j) \) where \( f \) is `agglo.FUN` and \( w_j \) is the weight of the \( j \)-th sub branch.

Value

A dendrogram where each node has a further attribute `value` with its corresponding weight.

Author(s)

R. Gentleman and M. Maechler

See Also

- `reorder`
- `rev.dendrogram` which simply reverses the nodes’ order; `heatmap`, `cophenetic`.

Examples

```r
require(graphics)

set.seed(123)
x <- rnorm(10)
hc <- hclust(dist(x))
dd <- as.dendrogram(hc)
dd.reorder <- reorder(dd, 10:1)
plot(dd, main = "random dendrogram 'dd'")

op <- par(mfcol = 1:2)
plot(dd.reorder, main = "reorder(dd, 10:1)")
plot(reorder(dd, 10:1, agglo.FUN = mean), main = "reorder(dd, 10:1, mean")
par(op)
```
replications

Description

Returns a vector or a list of the number of replicates for each term in the formula.

Usage

replications(formula, data = NULL, na.action)

Arguments

formula a formula or a terms object or a data frame.
data a data frame used to find the objects in formula.
na.action function for handling missing values. Defaults to a na.action attribute of data, then a setting of the option na.action, or na.fail if that is not set.

Details

If formula is a data frame and data is missing, formula is used for data with the formula ~ ..
Any character vectors in the formula are coerced to factors.

Value

A vector or list with one entry for each term in the formula giving the number(s) of replications for each level. If all levels are balanced (have the same number of replications) the result is a vector, otherwise it is a list with a component for each terms, as a vector, matrix or array as required.
A test for balance is !is.list(replications(formula, data)).

Author(s)

The design was inspired by the S function of the same name described in Chambers et al. (1992).

replications(~ . - yield, npk)

---

**reshape**

### Reshape Grouped Data

**Description**

This function reshapes a data frame between ‘wide’ format with repeated measurements in separate columns of the same record and ‘long’ format with the repeated measurements in separate records.

**Usage**

\[
\text{reshape}(\text{data, varying = NULL, v.names = NULL, timevar = "time", idvar = "id", ids = 1:NROW(\text{data}), times = seq.along(varying[[1]]), drop = NULL, direction, new.row.names = NULL, sep = ".", split = if (sep == ".") { list(regexp = "[A-Za-z][0-9]", include = TRUE) } else { list(regexp = sep, include = FALSE, fixed = TRUE))}
\]

**Arguments**

- **data**: a data frame
- **varying**: names of sets of variables in the wide format that correspond to single variables in long format (‘time-varying’). This is canonically a list of vectors of variable names, but it can optionally be a matrix of names, or a single vector of names. In each case, the names can be replaced by indices which are interpreted as referring to names(data). See ‘Details’ for more details and options.
- **v.names**: names of variables in the long format that correspond to multiple variables in the wide format. See ‘Details’.
- **timevar**: the variable in long format that differentiates multiple records from the same group or individual. If more than one record matches, the first will be taken (with a warning).
idvar  
Names of one or more variables in long format that identify multiple records from the same group/individual. These variables may also be present in wide format.

ids   
the values to use for a newly created idvar variable in long format.

times  
the values to use for a newly created timevar variable in long format. See 'Details'.

drop   
a vector of names of variables to drop before reshaping.

direction  
character string, either "wide" to reshape to wide format, or "long" to reshape to long format.

new.row.names  
character or NULL: a non-null value will be used for the row names of the result.

sep  
A character vector of length 1, indicating a separating character in the variable names in the wide format. This is used for guessing v.names and times arguments based on the names in varying. If sep == "", the split is just before the first numeral that follows an alphabetic character. This is also used to create variable names when reshaping to wide format.

split  
A list with three components, regexp, include, and (optionally) fixed. This allows an extended interface to variable name splitting. See 'Details'.

Details

The arguments to this function are described in terms of longitudinal data, as that is the application motivating the functions. A ‘wide’ longitudinal dataset will have one record for each individual with some time-constant variables that occupy single columns and some time-varying variables that occupy a column for each time point. In ‘long’ format there will be multiple records for each individual, with some variables being constant across these records and others varying across the records. A ‘long’ format dataset also needs a ‘time’ variable identifying which time point each record comes from and an ‘id’ variable showing which records refer to the same person.

If the data frame resulted from a previous reshape then the operation can be reversed simply by reshape(a). The direction argument is optional and the other arguments are stored as attributes on the data frame.

If direction = "wide" and no varying or v.names arguments are supplied it is assumed that all variables except idvar and timevar are time-varying. They are all expanded into multiple variables in wide format.

If direction = "long" the varying argument can be a vector of column names (or a corresponding index). The function will attempt to guess the v.names and times from these names. The default is variable names like x.1, x.2, where sep = "." specifies to split at the dot and drop it from the name. To have alphabetic followed by numeric times use sep = "".

Variable name splitting as described above is only attempted in the case where varying is an atomic vector, if it is a list or a matrix, v.names and times will generally need to be specified, although they will default to, respectively, the first variable name in each set, and sequential times.

Also, guessing is not attempted if v.names is given explicitly. Notice that the order of variables in varying is like x.1.y.1.x.2.y.2.

The split argument should not usually be necessary. The split$regexp component is passed to either strsplit or regexpr, where the latter is used if split$include is TRUE, in which case the splitting occurs after the first character of the matched string. In the strsplit case, the separator is not included in the result, and it is possible to specify fixed-string matching using split$fixed.
The reshaped data frame with added attributes to simplify reshaping back to the original form.

See Also

stack, aperm, relist for reshaping the result of unlist.

Examples

```r
summary(Indometh)
wide <- reshape(Indometh, v.names = "conc", idvar = "Subject",
    timevar = "time", direction = "wide")
wide

reshape(wide, direction = "long")
reshape(wide, idvar = "Subject", varying = list(2:12),
    v.names = "conc", direction = "long")

## times need not be numeric
df <- data.frame(id = rep(1:4, rep(2,4)),
    visit = I(rep(c("Before","After"), 4)),
    x = rnorm(4), y = runif(4))
df
reshape(df, timevar = "visit", idvar = "id", direction = "wide")
## warns that y is really varying
reshape(df, timevar = "visit", idvar = "id", direction = "wide", v.names = "x")

## unbalanced 'long' data leads to NA fill in 'wide' form
df2 <- df[1:7, ]
df2
reshape(df2, timevar = "visit", idvar = "id", direction = "wide")

## Alternative regular expressions for guessing names
df3 <- data.frame(id = 1:4, age = c(40,50,50,50), dose1 = c(1,2,1,2),
    dose2 = c(2,1,2,1), dose4 = c(3,3,3,3))
reshape(df3, direction = "long", varying = 3:5, sep = "")

## an example that isn't longitudinal data
state.x77 <- as.data.frame(state.x77)
long <- reshape(state.x77, idvar = "state", ids = row.names(state.x77),
    times = names(state.x77), timevar = "Characteristic",
    varying = list(names(state.x77)), direction = "long")
reshape(long, direction = "wide")
reshape(long, direction = "wide", new.row.names = unique(long$state))

## multiple id variables
df3 <- data.frame(school = rep(1:3, each = 4), class = rep(9:10, 6),
    time = rep(c(1,1,2,2), 3), score = rnorm(12))
```
residuals <- reshape(df3, idvar = c("school","class"), direction = "wide")
wide
## transform back
reshape(wide)

---

**residuals**  
*Extract Model Residuals*

**Description**

`residuals` is a generic function which extracts model residuals from objects returned by modeling functions.

The abbreviated form `resid` is an alias for `residuals`. It is intended to encourage users to access object components through an accessor function rather than by directly referencing an object slot.

All object classes which are returned by model fitting functions should provide a `residuals` method. (Note that the method is for `residuals` and not `resid`.)

Methods can make use of `naresid` methods to compensate for the omission of missing values. The default, `nls` and `smooth.spline` methods do.

**Usage**

```r
residuals(object, 
\ldots)
resid(object, 
\ldots)
```

**Arguments**

- `object` an object for which the extraction of model residuals is meaningful.
- `\ldots` other arguments.

**Value**

Residuals extracted from the object `object`.

**References**

**See Also**

`coefficients`, `fitted.values`, `glm`, `lm`.  
`influence.measures` for standardized (`rstandard`) and studentized (`rstudent`) residuals.
**Description**

Compute running medians of odd span. This is the ‘most robust’ scatter plot smoothing possible. For efficiency (and historical reason), you can use one of two different algorithms giving identical results.

**Usage**

```r
runmed(x, k, endrule = c("median", "keep", "constant"),
       algorithm = NULL, print.level = 0)
```

**Arguments**

- `x` numeric vector, the ‘dependent’ variable to be smoothed.
- `k` integer width of median window; must be odd. Turlach had a default of
  \( k <- 1 + 2 \times \min((n-1) \div 2, \text{ceiling}(0.1 \times n)) \). Use \( k = 3 \) for ‘minimal’ robust smoothing eliminating isolated outliers.
- `endrule` character string indicating how the values at the beginning and the end (of the data) should be treated. “keep” keeps the first and last \( k_2 \) values at both ends, where \( k_2 = k \div 2 \), i.e., \( y[j] = x[j] \) for \( j \in \{1, \ldots, k_2; n - k_2 + 1, \ldots, n\} \); “constant” copies \( \text{median}(y[1:k_2]) \) to the first values and analogously for the last ones making the smoothed ends constant; “median” the default, smooths the ends by using symmetrical medians of subsequently smaller bandwidth, but for the very first and last value where Tukey’s robust end-point rule is applied, see `smoothEnds`.
- `algorithm` character string (partially matching "Turlach" or "Stuetzle") or the default `NULL`, specifying which algorithm should be applied. The default choice depends on \( n = \text{length}(x) \) and \( k \) where "Turlach" will be used for larger problems.
- `print.level` integer, indicating verboseness of algorithm; should rarely be changed by average users.

**Details**

Apart from the end values, the result \( y = \text{runmed}(x, k) \) simply has \( y[j] = \text{median}(x[(j-k_2):(j+k_2)]) \) (\( k = 2 \times k_2 + 1 \)), computed very efficiently.

The two algorithms are internally entirely different:

"Turlach" is the Härdle–Steiger algorithm (see Ref.) as implemented by Berwin Turlach. A tree algorithm is used, ensuring performance \( O(n \log k) \) where \( n = \text{length}(x) \) which is asymptotically optimal.
"Stuetzle" is the (older) Stuetzle–Friedman implementation which makes use of median updating when one observation enters and one leaves the smoothing window. While this performs as \(O(n \times k)\) which is slower asymptotically, it is considerably faster for small \(k\) or \(n\).

Currently long vectors are only supported for algorithm = "Stuetzle".

**Value**

vector of smoothed values of the same length as \(x\) with an attribute \(k\) containing (the 'oddified') \(k\).

**Author(s)**

Martin Maechler <maechler@stat.math.ethz.ch>, based on Fortran code from Werner Stuetzle and S-PLUS and C code from Berwin Turlach.

**References**

**See Also**

smoothEnds which implements Tukey’s end point rule and is called by default from runmed(*, endrule = "median"). smooth uses running medians of 3 for its compound smoothers.

**Examples**

```r
require(graphics)
utils::example(nhtemp)
myNHT <- as.vector(nhtemp)
plot(myNHT, type = "b", ylim = c(48, 60), main = "Running Medians Example")
lines(runmed(myNHT, 7), col = "red")

## special: multiple y values for one x
plot(cars, main = "'cars' data and runmed(dist, 3)")
lines(cars, col = "light gray", type = "c")
with(cars, lines(speed, runmed(dist, k = 3), col = 2))

## nice quadratic with a few outliers
y <- ys <- (-20:20)^2
y[1, 10, 21, 41] <- c(150, 30, 400, 450)
all(y == runmed(y, 1)) # 1-neighbourhood <=> interpolation
plot(y) # lines(y, lwd = .1, col = "light gray")
```
## Lowess is not robust

```r
y <- ys; y[21] <- 6666; x <- seq(y)
col <- c("black", "brown", "blue")
plot(y, col = col[1])
lines(lowess(x, y, f = 0.3), col = col[2])
lines(runmed(y, 7), lwd = 2, col = col[3])
legend(length(y), max(y), c("data", "lowess(y, f = 0.3)", "runmed(y, 7)"),
xjust = 1, col = col, lty = c(0, 1, 1), pch = c(1, NA, NA))
```

---

### rWishart

**Random Wishart Distributed Matrices**

**Description**

Generate \( n \) random matrices, distributed according to the Wishart distribution with parameters \( \Sigma \) and \( \text{df} \), \( W_p(\Sigma,m) \), \( m = \text{df} \), \( \Sigma = \text{Sigma} \).

**Usage**

```
rWishart(n, df, Sigma)
```

**Arguments**

- \( n \): integer sample size.
- \( \text{df} \): numeric parameter, “degrees of freedom”.
- \( \text{Sigma} \): positive definite \((p \times p)\) “scale” matrix, the matrix parameter of the distribution.

**Details**

If \( X_1,\ldots,X_m, X_i \in \mathbb{R}^p \) is a sample of \( m \) independent multivariate Gaussians with mean (vector) 0, and covariance matrix \( \Sigma \), the distribution of \( M = X'X \) is \( W_p(\Sigma,m) \).

Consequently, the expectation of \( M \) is

\[
E[M] = m \times \Sigma.
\]

Further, if \( \text{Sigma} \) is scalar \((p = 1)\), the Wishart distribution is a scaled chi-squared \((\chi^2)\) distribution with \( \text{df} \) degrees of freedom, \( W_1(\sigma^2,m) = \sigma^2\chi_m^2 \).

The component wise variance is

\[
\text{Var}(M_{ij}) = m(\Sigma_{ij}^2 + \Sigma_{ii} \Sigma_{jj}).
\]
scatter.smooth

Value

A numeric array, say R, of dimension $p \times p \times n$, where each $R[,,i]$ is a positive definite matrix, a realization of the Wishart distribution $W_p(\Sigma, m)$, $m = df, \Sigma = \Sigma$.

Author(s)

Douglas Bates

References

cov, rnorm, rchisq.

Examples

```r
## Artificial
S <- toeplitz((1:10)/10)
set.seed(11)
R <- rWishart(1000, 20, S)
dim(R) # 10 10 1000
mR <- apply(R, 1:2, mean) # \approx E[ Wish(S, 20) ] = 20 * S
stopifnot(all.equal(mR, 20*S, tol = .009))

## See Details, the variance is
Va <- 20*(S^2 + tcrossprod(diag(S)))
vrR <- apply(R, 1:2, var)
stopifnot(all.equal(vrR, Va, tol = 1/16))
```

scatter.smooth

Scatter Plot with Smooth Curve Fitted by Loess

Description

Plot and add a smooth curve computed by loess to a scatter plot.

Usage

```r
scatter.smooth(x, y = NULL, span = 2/3, degree = 1,
family = c("symmetric", "gaussian"),
xlab = NULL, ylab = NULL,
ylim = range(y, pred$y, na.rm = TRUE),
evaluation = 50, ..., lpars = list())
```

```r
loess.smooth(x, y, span = 2/3, degree = 1,
family = c("symmetric", "gaussian"), evaluation = 50, ...)
```
scatter.smooth

Arguments

- **x, y**  
  the x and y arguments provide the x and y coordinates for the plot. Any reasonable way of defining the coordinates is acceptable. See the function `xy.coords` for details.

- **span**  
  smoothness parameter for `loess`.

- **degree**  
  degree of local polynomial used.

- **family**  
  if "gaussian" fitting is by least-squares, and if family = "symmetric" a re-descending M estimator is used.

- **xlab**  
  label for x axis.

- **ylab**  
  label for y axis.

- **ylim**  
  the y limits of the plot.

- **evaluation**  
  number of points at which to evaluate the smooth curve.

- **...**  
  For `scatter.smooth()`, graphical parameters, passed to `plot()` only. For `loess.smooth`, control parameters passed to `loess.control`.

- **lpars**  
  a list of arguments to be passed to `lines()`.

Details

`loess.smooth` is an auxiliary function which evaluates the `loess` smooth at evaluation equally spaced points covering the range of x.

Value

For `scatter.smooth`, none.

For `loess.smooth`, a list with two components, x (the grid of evaluation points) and y (the smoothed values at the grid points).

See Also

`loess`; `smoothScatter` for scatter plots with smoothed density color representation.

Examples

```r
require(graphics)

with(cars, scatter.smooth(speed, dist))
## or with dotted thick smoothed line results :
with(cars, scatter.smooth(speed, dist, lpars = list(col = "red", lwd = 3, lty = 3)))
```
Description

screeplot.default plots the variances against the number of the principal component. This is also the plot method for classes "princomp" and "prcomp".

Usage

## Default S3 method:
screeplot(x, npcs = min(10, length(x$sdev)),
type = c("barplot", "lines"),
main = deparse(substitute(x)), ...)

Arguments

x an object containing a sdev component, such as that returned by princomp() and prcomp().
npcs the number of components to be plotted.
type the type of plot.
main, ... graphics parameters.

References

See Also

princomp and prcomp.

Examples

require(graphics)

## The variances of the variables in the
## USArrests data vary by orders of magnitude, so scaling is appropriate
(pc.cr <- princomp(USArrests, cor = TRUE)) # inappropriate
screeplot(pc.cr)

fit <- princomp(covmat = Harman74.cor)
screeplot(fit)
screeplot(fit, npcs = 24, type = "lines")
sd

**Standard Deviation**

**Description**

This function computes the standard deviation of the values in x. If na.rm is TRUE then missing values are removed before computation proceeds.

**Usage**

`sd(x, na.rm = FALSE)`

**Arguments**

- `x` a numeric vector or an R object which is coercible to one by `as.vector(x, "numeric")`.
- `na.rm` logical. Should missing values be removed?

**Details**

Like `var` this uses denominator $n - 1$.

The standard deviation of a zero-length vector (after removal of NAs if na.rm = TRUE) is not defined and gives an error. The standard deviation of a length-one vector is NA.

Prior to R 2.14.0, `sd(dfrm)` worked directly for a data.frame dfrm. This is now deprecated and you are expected to use `sapply(dfrm, sd)`.

**See Also**

- `var` for its square, and `mad`, the most robust alternative.

**Examples**

`sd(1:2) ^ 2`
## Usage

se.contrast(object, ...)  # S3 method for class 'aov'
se.contrast(object, contrast.obj,
    coef = contr.helmert(ncol(contrast))[, 1],
    data = NULL, ...)

## Arguments

- **object**: A suitable fit, usually from `aov`.
- **contrast.obj**: The contrasts for which standard errors are requested. This can be specified via a list or via a matrix. A single contrast can be specified by a list of logical vectors giving the cells to be contrasted. Multiple contrasts should be specified by a matrix, each column of which is a numerical contrast vector (summing to zero).
- **coef**: used when `contrast.obj` is a list; it should be a vector of the same length as the list with zero sum. The default value is the first Helmert contrast, which contrasts the first and second cell means specified by the list.
- **data**: The data frame used to evaluate `contrast.obj`.
- **...**: further arguments passed to or from other methods.

## Details

Contrasts are usually used to test if certain means are significantly different; it can be easier to use `se.contrast` than compute them directly from the coefficients.

In multistratum models, the contrasts can appear in more than one stratum, in which case the standard errors are computed in the lowest stratum and adjusted for efficiencies and comparisons between strata. (See the comments in the note in the help for `aov` about using orthogonal contrasts.) Such standard errors are often conservative.

Suitable matrices for use with `coef` can be found by calling `contrasts` and indexing the columns by a factor.

## Value

A vector giving the standard errors for each contrast.

## See Also

- `contrasts`, `model.tables`

## Examples

```r
N <- c(0,1,0,1,1,1,0,0,0,1,1,0,1,0,1,0,1,1,0,1,1,0)
P <- c(1,1,0,0,0,1,1,1,1,0,0,1,0,1,1,0,1,1,0,1,1,0)

Construct Self-starting Nonlinear Models

Description

Construct self-starting nonlinear models.

Usage

selfStart(model, initial, parameters, template)

Arguments

- **model**: a function object defining a nonlinear model or a nonlinear formula object of the form ~expression.
- **initial**: a function object, taking three arguments: mCall, data, and LHS, representing, respectively, a matched call to the function model, a data frame in which to interpret the variables in mCall, and the expression from the left-hand side of the model formula in the call to nls. This function should return initial values for the parameters in model.
- **parameters**: a character vector specifying the terms on the right hand side of model for which initial estimates should be calculated. Passed as the namevec argument to the deriv function.
- **template**: an optional prototype for the calling sequence of the returned object, passed as the function.arg argument to the deriv function. By default, a template is generated with the covariates in model coming first and the parameters in model coming last in the calling sequence.

Details

This function is generic; methods functions can be written to handle specific classes of objects.

Value

A function object of class "selfStart", for the formula method obtained by applying deriv to the right hand side of the model formula. An initial attribute (defined by the initial argument) is added to the function to calculate starting estimates for the parameters in the model automatically.

Author(s)

José Pinheiro and Douglas Bates

### Examples

```r
## self-starting logistic model

SSlogis <- selfStart(~ Asym/(1 + exp((xmid - x)/scal)),
  function(mCall, data, LHS)
  {
    xy <- sortedXyData(mCall[["x"]], LHS, data)
    if(nrow(xy) < 4) {
      stop("Too few distinct x values to fit a logistic")
    }
    z <- xy[["y"]]
    if (min(z) <= 0) { z <- z + 0.05 * max(z) } # avoid zeroes
    z <- z/(1.05 * max(z)) # scale to within unit height
    xy[["z"]]<- log(z/(1 - z)) # logit transformation
    aux <- coef(lm(x ~ z, xy))
    parameters(xy) <- list(xmid = aux[1], scal = aux[2])
    pars <- as.vector(coef(nls(y ~ 1/(1 + exp((xmid - x)/scal)),
                             data = xy, algorithm = "plinear")))
    setNames(c(pars[3], pars[1], pars[2]),
              mCall[c("Asym", "xmid", "scal")])
  },
  names = c("Asym", "xmid", "scal"))
```

# 'first.order.log.model' is a function object defining a first order
# compartment model

# 'first.order.log.initial' is a function object which calculates initial
# values for the parameters in 'first.order.log.model'

# self-starting first order compartment model

## Not run:

SSfol <- selfStart(first.order.log.model, first.order.log.initial)

## End(Not run)

## Explore the self-starting models already available in R's "stats":

```r
pos.st <- which("package:stats" == search())
mSS <- apropos("SS..", where = TRUE, ignore.case = FALSE)
(mSS <- unname(mSS[names(mSS) == pos.st]))
fSS <- sapply(mSS, get, pos = pos.st, mode = "function")
all(sapply(fSS, inherits, "selfStart")) # -> TRUE
```

## Show the argument list of each self-starting function:

```r
str(fSS, give.attr = FALSE)
```

---

**setNames**

*Set the Names in an Object*

**Description**

This is a convenience function that sets the names on an object and returns the object. It is most useful at the end of a function definition where one is creating the object to be returned and would prefer not to store it under a name just so the names can be assigned.
Usage

\texttt{setNames(object = nm, nm)}

Arguments

- \texttt{object} an object for which a names attribute will be meaningful
- \texttt{nm} a character vector of names to assign to the object

Value

An object of the same sort as \texttt{object} with the new names assigned.

Author(s)

Douglas M. Bates and Saikat DebRoy

See Also

\texttt{unname} for removing names.

Examples

\begin{verbatim}
setNames( 1:3, c("foo", "bar", "baz") )
# this is just a short form of
tmp <- 1:3
names(tmp) <- c("foo", "bar", "baz")
tmp
## special case of character vector, using default
setNames(nm = c("First", "2nd"))
\end{verbatim}

\begin{description}
\item[shapiro.test] \textit{Shapiro-Wilk Normality Test}
\end{description}

Description

Performs the Shapiro-Wilk test of normality.

Usage

\texttt{shapiro.test(x)}

Arguments

- \texttt{x} a numeric vector of data values. Missing values are allowed, but the number of non-missing values must be between 3 and 5000.
SignRank

Value

A list with class "htest" containing the following components:

- **statistic**: the value of the Shapiro-Wilk statistic.
- **p.value**: an approximate p-value for the test. This is said in Royston (1995) to be adequate for p.value < 0.1.
- **method**: the character string "Shapiro-Wilk normality test".
- **data.name**: a character string giving the name(s) of the data.

Source

The algorithm used is a C translation of the Fortran code described in Royston (1995) and found at [http://lib.stat.cmu.edu/apstat/R94](http://lib.stat.cmu.edu/apstat/R94). The calculation of the p value is exact for \( n = 3 \), otherwise approximations are used, separately for \( 4 \leq n \leq 11 \) and \( n \geq 12 \).

References

See Also

- `qqnorm` for producing a normal quantile-quantile plot.

Examples

```r
shapiro.test(rnorm(100, mean = 5, sd = 3))
shapiro.test(runif(100, min = 2, max = 4))
```

---

SignRank Distribution of the Wilcoxon Signed Rank Statistic

Description

Density, distribution function, quantile function and random generation for the distribution of the Wilcoxon Signed Rank statistic obtained from a sample with size \( n \).

Usage

```r
designrank(x, n, log = FALSE)
pesignrank(q, n, lower.tail = TRUE, log.p = FALSE)
qesignrank(p, n, lower.tail = TRUE, log.p = FALSE)
resignrank(nn, n)
```
Arguments

- `x, q` vector of quantiles.
- `p` vector of probabilities.
- `nn` number of observations. If `length(nn) > 1`, the length is taken to be the number required.
- `n` number(s) of observations in the sample(s). A positive integer, or a vector of such integers.
- `log, log.p` logical; if TRUE, probabilities `p` are given as `log(p)`.
- `lower.tail` logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

This distribution is obtained as follows. Let $x$ be a sample of size $n$ from a continuous distribution symmetric about the origin. Then the Wilcoxon signed rank statistic is the sum of the ranks of the absolute values $x[i]$ for which $x[i]$ is positive. This statistic takes values between 0 and $n(n + 1)/2$, and its mean and variance are $n(n + 1)/4$ and $n(n + 1)(2n + 1)/24$, respectively.

If either of the first two arguments is a vector, the recycling rule is used to do the calculations for all combinations of the two up to the length of the longer vector.

Value

dsignrank gives the density, psignrank gives the distribution function, qsignrank gives the quantile function, and rsignrank generates random deviates.

The length of the result is determined by `nn` for rsignrank, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than `nn` are recycled to the length of the result. Only the first elements of the logical parameters are used.

Author(s)

Kurt Hornik; efficiency improvement by Ivo Ugrina.

See Also

wilcox.test to calculate the statistic from data, find p values and so on.

Distributions for standard distributions, including dwilcox for the distribution of two-sample Wilcoxon rank sum statistic.

Examples

```r
require(graphics)
par(mfrow = c(2,2))
for(n in c(4:5,10,40)) {
  x <- seq(0, n*(n+1)/2, length = 501)
  plot(x, dsignrank(x, n = n), type = "l",
       main = paste0("dsignrank(x, n = ", n, ")")
}
Simulate one or more responses from the distribution corresponding to a fitted model object.

Usage

simulate(object, nsim = 1, seed = NULL, ...)

Arguments

  object     an object representing a fitted model.
  nsim       number of response vectors to simulate. Defaults to 1.
  seed       an object specifying if and how the random number generator should be initialized ("seeded").
              For the "lm" method, either NULL or an integer that will be used in a call to set.seed before simulating the response vectors. If set, the value is saved as the "seed" attribute of the returned value. The default, NULL will not change the random generator state, and return .Random.seed as the "seed" attribute, see "Value".
  ...        additional optional arguments.

Details

This is a generic function. Consult the individual modeling functions for details on how to use this function.

Package stats has a method for "lm" objects which is used for lm and glm fits. There is a method for fits from glm.nb in package MASS, and hence the case of negative binomial families is not covered by the "lm" method.

The methods for linear models fitted by lm or glm(family = "gaussian") assume that any weights which have been supplied are inversely proportional to the error variance. For other GLMs the (optional) simulate component of the family object is used—there is no appropriate simulation method for 'quasi' models as they are specified only up to two moments.

For binomial and Poisson GLMs the dispersion is fixed at one. Integer prior weights \(w_i\) can be interpreted as meaning that observation \(i\) is an average of \(w_i\) observations, which is natural for binomials specified as proportions but less so for a Poisson, for which prior weights are ignored with a warning.

For a gamma GLM the shape parameter is estimated by maximum likelihood (using function gamma.shape in package MASS). The interpretation of weights is as multipliers to a basic shape parameter, since dispersion is inversely proportional to shape.
For an inverse gaussian GLM the model assumed is $IG(\mu_i, \lambda w_i)$ (see http://en.wikipedia.org/wiki/Inverse_Gaussian_distribution) where $\lambda$ is estimated by the inverse of the dispersion estimate for the fit. The variance is $\mu_i^3/(\lambda w_i)$ and hence inversely proportional to the prior weights. The simulation is done by function `rinvGauss` from the `SuppDists` package, which must be installed.

**Value**

Typically, a list of length `nsim` of simulated responses. Where appropriate the result can be a data frame (which is a special type of list). For the "lm" method, the result is a data frame with an attribute "seed". If argument `seed` is `NULL`, the attribute is the value of `.Random.seed` before the simulation was started; otherwise it is the value of the argument with a "kind" attribute with value as.list(RNGkind()).

**See Also**

`RNG` about random number generation in R, `fitted.values` and `residuals` for related methods; `glm`, `lm` for model fitting.

There are further examples in the ‘simulate.R’ tests file in the sources for package `stats`.

**Examples**

```r
x <- 1:5
mod1 <- lm(c(1:3, 7, 6) ~ x)
S1 <- simulate(mod1, nsim = 4)
## repeat the simulation:
.Random.seed <- attr(S1, "seed")
identical(S1, simulate(mod1, nsim = 4))

S2 <- simulate(mod1, nsim = 200, seed = 101)
rowMeans(S2) # should be about the same as fitted(mod1)

## repeat identically:
(sseed <- attr(S2, "seed")) # seed; RNGkind as attribute
stopifnot(identical(S2, simulate(mod1, nsim = 200, seed = sseed)))

## To be sure about the proper RNGkind, e.g., after
RNGversion("2.7.0")
## first set the RNG kind, then simulate
do.call(RNGkind, attr(sseed, "kind"))
identical(S2, simulate(mod1, nsim = 200, seed = sseed))

## Binomial GLM examples
yb1 <- matrix(c(4, 4, 5, 7, 8, 6, 6, 5, 3, 2), ncol = 2)
modb1 <- glm(yb1 ~ x, family = binomial)
S3 <- simulate(modb1, nsim = 4)
# each column of S3 is a two-column matrix.
x2 <- sort(runif(100))
yb2 <- rbinom(100, prob = plogis(2*(x2-1)), size = 1)
```
smooth

Tukey’s (Running Median) Smoothing

Description

Tukey’s smoothers, 3RS3R, 3RSS, 3R, etc.

Usage

smooth(x, kind = c("3RS3R", "3RSS", "3RSR", "3R", "3", "S"),
      twiceit = FALSE, endrule = "Tukey", do.ends = FALSE)

Arguments

x          a vector or time series
kind       a character string indicating the kind of smoother required; defaults to "3RS3R".
twiceit    logical, indicating if the result should be 'twiced'. Twicing a smoother \(S(y)\)
            means \(S(y) + S(y - S(y))\), i.e., adding smoothed residuals to the smoothed
            values. This decreases bias (increasing variance).
endrule    a character string indicating the rule for smoothing at the boundary. Either
            "Tukey" (default) or "copy".
do.ends   logical, indicating if the 3-splitting of ties should also happen at the boundaries
            (ends). This is only used for kind = "S".

Details

3 is Tukey’s short notation for running medians of length 3,
3R stands for Repeated 3 until convergence, and
S for Splitting of horizontal stretches of length 2 or 3.

Hence, 3RS3R is a concatenation of 3R, S and 3R, 3RSS similarly, whereas 3RSR means first 3R and
then (S and 3) Repeated until convergence – which can be bad.

Value

An object of class "tukeysmooth" (which has print and summary methods) and is a vector or time
series containing the smoothed values with additional attributes.
smooth

Note

S and S-PLUS use a different (somewhat better) Tukey smoother in smooth(*). Note that there are other smoothing methods which provide rather better results. These were designed for hand calculations and may be used mainly for didactical purposes.

Since R version 1.2, smooth does really implement Tukey’s end-point rule correctly (see argument endrule).

kind = "3RSR" has been the default till R-1.1, but it can have very bad properties, see the examples.

Note that repeated application of smooth(*) does smooth more, for the "3RS*" kinds.

smooth.spline

Fit a Smoothing Spline

Description

Fits a cubic smoothing spline to the supplied data.

Usage

smooth.spline(x, y = NULL, w = NULL, df, spar = NULL,
            df.offset = 0, penalty = 1,
            control.spar = list(), tol = 1e-6 * IQR(x))

Arguments

  x  a vector giving the values of the predictor variable, or a list or a two-column
      matrix specifying x and y.
  y  responses. If y is missing or NULL, the responses are assumed to be specified by
      x, with x the index vector.
  w  optional vector of weights of the same length as x; defaults to all 1.
  df  the desired equivalent number of degrees of freedom (trace of the smoother ma-
       trix).
  spar  smoothing parameter, typically (but not necessarily) in (0, 1]. The coefficient λ
        of the integral of the squared second derivative in the fit (penalized log likeli-
        hood) criterion is a monotone function of spar, see the details below.
  cv  ordinary (TRUE) or ‘generalized’ cross-validation (GCV) when FALSE; setting it
       to NA skips the evaluation of leverages and any score.
  all.knots  if TRUE, all distinct points in x are used as knots. If FALSE (default), a subset
             of x[] is used, specifically x[j] where the nknots indices are evenly spaced in
             1:n, see also the next argument nknots.
  nknots  integer giving the number of knots to use when all.knots = FALSE. Per default,
           this is less than n, the number of unique x values for n ≥ 49.
  keep.data  logical specifying if the input data should be kept in the result. If TRUE (as per
             default), fitted values and residuals are available from the result.
  df.offset  allows the degrees of freedom to be increased by df.offset in the GCV crite-
             rion.
  penalty  the coefficient of the penalty for degrees of freedom in the GCV criterion.
  control.spar  optional list with named components controlling the root finding when the
                smoothing parameter spar is computed, i.e., missing or NULL, see below.

Note that this is partly experimental and may change with general spar compu-

tation improvements!
low: lower bound for spar; defaults to -1.5 (used to implicitly default to 0 in R versions earlier than 1.4).

high: upper bound for spar; defaults to +1.5.

tol: the absolute precision (tolerance) used; defaults to 1e-4 (formerly 1e-3).

eps: the relative precision used; defaults to 2e-8 (formerly 0.00244).

trace: logical indicating if iterations should be traced.

maxit: integer giving the maximal number of iterations; defaults to 500.

Note that spar is only searched for in the interval \([low, high]\).

tol

A tolerance for same-ness of the x values. The values are binned into bins of size tol and values which fall into the same bin are regarded as the same. Must be strictly positive (and finite).

Details

Neither x nor y are allowed to containing missing or infinite values.

The x vector should contain at least four distinct values. ‘Distinct’ here is controlled by tol: values which are regarded as the same are replaced by the first of their values and the corresponding y and w are pooled accordingly.

The computational \(\lambda\) used (as a function of \(s = spar\)) is \(\lambda = r \ast 256^{3s-1}\) where \(r = tr(X'WX)/tr(\Sigma)\), \(\Sigma\) is the matrix given by \(\Sigma_{ij} = \int B_i'(t)B_j'(t)dt\), \(X\) is given by \(X_{ij} = B_j(x_i)\), \(W\) is the diagonal matrix of weights (scaled such that its trace is \(n\), the original number of observations) and \(B_k(.)\) is the \(k\)-th B-spline.

Note that with these definitions, \(f_i = f(x_i)\), and the B-spline basis representation \(f = Xc\) (i.e., \(c\) is the vector of spline coefficients), the penalized log likelihood is \(L = (y - f)'W(y - f) + \lambda c'\Sigma c\), and hence \(c\) is the solution of the (ridge regression) \((X'WX + \lambda \Sigma)c = X'Wy\).

If spar is missing or NULL, the value of df is used to determine the degree of smoothing. If both are missing, leave-one-out cross-validation (ordinary or ‘generalized’ as determined by cv) is used to determine \(\lambda\). Note that from the above relation,

\[ spar = s0 + 0.0601 \ast \log \lambda \]

which is intentionally different from the S-PLUS implementation of smooth.spline (where spar is proportional to \(\lambda\)). In R’s (\(\log \lambda\)) scale, it makes more sense to vary spar linearly.

Note however that currently the results may become very unreliable for spar values smaller than about -1 or -2. The same may happen for values larger than 2 or so. Don’t think of setting spar or the controls low and high outside such a safe range, unless you know what you are doing!

The ‘generalized’ cross-validation method will work correctly when there are duplicated points in x. However, it is ambiguous what leave-one-out cross-validation means with duplicated points, and the internal code uses an approximation that involves leaving out groups of duplicated points. cv = TRUE is best avoided in that case.

Value

An object of class "smooth.spline" with components

- x: the distinct x values in increasing order, see the ‘Details’ above.
- y: the fitted values corresponding to x.
The weights used at the unique values of \( x \).

the \( y \) values used at the unique \( y \) values.

only if \( \text{keep.data} = \text{TRUE} \): itself a list with components \( x \), \( y \) and \( w \) of the same length. These are the original \( (x_i, y_i, w_i), i = 1, \ldots, n \), values where \( \text{data}\_x \) may have repeated values and hence be longer than the above \( x \) component; see details.

(when \( \text{cv} \) was not \( \text{NA} \)) leverages, the diagonal values of the smoother matrix.

cross-validation score, 'generalized' or true, depending on \( \text{cv} \).

penalized criterion

the criterion value minimized in the underlying \( \text{Fortran} \) routine ‘\text{sslvrg}’. 

equivalent degrees of freedom used. Note that (currently) this value may become quite imprecise when the true \( df \) is between and 1 and 2.

the value of \( \text{spar} \) computed or given.

the value of \( \lambda \) corresponding to \( \text{spar} \), see the details above.

named integer(3) vector where \( \text{..ipars}["\text{iter}"] \) gives number of \( \text{spar} \) computing iterations used.

list for use by \text{predict.smooth.spline}, with components

\( \text{knot} \): the knot sequence (including the repeated boundary knots).

\( \text{nk} \): number of coefficients or number of 'proper' knots plus 2.

\( \text{coef} \): coefficients for the spline basis used.

\( \text{min}, \text{range} \): numbers giving the corresponding quantities of \( x \).

the matched call.

\textbf{Note}

The default \( \text{all.knots} = \text{FALSE} \) and \( \text{n knots} = \text{NULL} \) entails using only \( O(n^{0.2}) \) knots instead of \( n \) for \( n > 49 \). This cuts speed and memory requirements, but not drastically anymore since \( \text{R} \) version 1.5.1 where it is only \( O(n_k) + O(n) \) where \( n_k \) is the number of knots. In this case where not all unique \( x \) values are used as knots, the result is not a smoothing spline in the strict sense, but very close unless a small smoothing parameter (or large \( df \)) is used.

\textbf{Author(s)}

\( \text{R} \) implementation by B. D. Ripley and Martin Maechler (\text{spar}/\text{lambda}, etc).

\textbf{Source}

This function is based on code in the \text{GAMFIT} \( \text{Fortran} \) program by T. Hastie and R. Tibshirani (\text{http://lib.stat.cmu.edu/general/}), which makes use of spline code by Finbarr O'Sullivan. Its design parallels the \text{smooth.spline} function of Chambers & Hastie (1992).

Examples

```r
require(graphics)

attach(cars)
plot(speed, dist, main = "data(cars) & smoothing splines")
cars.spl <- smooth.spline(speed, dist)
(cars.spl)
## This example has duplicate points, so avoid cv = TRUE
lines(cars.spl, col = "blue")
lines(smooth.spline(speed, dist, df = 10), lty = 2, col = "red")
legend(5, 12, c(paste("default [C.V.] => df =", round(cars.spl$df, 1)),
                  "s(*, df = 10)"), col = c("blue", "red"), lty = 1:2,
                  bg = 'bisque')
detach()

## Residual (Tukey Anscombe) plot:
plot(residuals(cars.spl) ~ fitted(cars.spl))
abline(h = 0, col = "gray")

## consistency check:
stopifnot(all.equal(cars$dist,
                     fitted(cars.spl) + residuals(cars.spl)))

##-- artificial example
y18 <- c(1:3, 5, 4, 7:3, 2*(2:5), rep(1, 4))
xx <- seq(1, length(y18), len = 21)
(s2 <- smooth.spline(y18)) # GCV
(s02 <- smooth.spline(y18, spar = 0.2))
(s02. <- smooth.spline(y18, spar = 0.2, cv = NA))
plot(y18, main = deparse(s2$call), col.main = 2)
lines(s2, col = "gray"); lines(predict(s2, xx), col = 2)
lines(predict(s02, xx), col = 3); mtext(deparse(s02$call), col = 3)

## The following shows the problematic behavior of 'spar' searching:
(s2 <- smooth.spline(y18, control =
                     list(trace = TRUE, tol = 1e-6, low = -1.5)))
```
\begin{verbatim}
(s2m <- smooth.spline(y18, cv = TRUE, control =
     list(trace = TRUE, tol = 1e-6, low = -1.5)))
## both above do quite similarly (Df = 8.5 +- 0.2)
\end{verbatim}

smoothEnds

\textit{End Points Smoothing (for Running Medians)}

\textbf{Description}

Smooth end points of a vector \( y \) using subsequently smaller medians and Tukey’s end point rule at the very end. (of odd span).

\textbf{Usage}

```
smoothEnds(y, k = 3)
```

\textbf{Arguments}

- \( y \) dependent variable to be smoothed (vector).
- \( k \) width of largest median window; must be odd.

\textbf{Details}

\( \text{smoothEnds} \) is used to only do the ‘end point smoothing’, i.e., change at most the observations closer to the beginning/end than half the window \( k \). The first and last value are computed using Tukey’s end point rule, i.e., \( \text{sm}[1] = \text{median}(y[1], \text{sm}[2], 3*\text{sm}[2] - 2*\text{sm}[3]) \).

\textbf{Value}

vector of smoothed values, the same length as \( y \).

\textbf{Author(s)}

Martin Maechler

y <- ys <- (-2/zero.noslash:2/zero.noslash)^2
y[c(1,1/zero.noslash,21,41)] <- c(1/zero.noslash/zero.noslash, 3/zero.noslash, 4/zero.noslash/zero.noslash, 47/zero.noslash)
s7k <- runmed(y, 7, endrule = "keep")
s7. <- runmed(y, 7, endrule = "const")
s7m <- runmed(y, 7)
col3 <- c("midnightblue","blue","steelblue")
plot(y, main = "Running Medians -- runmed(*, k=7, end.rule = X)")
lines(ys, col = "light gray")
matlines(cbind(s7k, s7.,s7m), lwd = 1.5, lty = 1, col = col3)
legend(1, 47/zero.noslash, paste("endrule", c("keep","constant","median"), sep = " = "),
       col = col3, lwd = 1.5, lty = 1)
stopifnot(identical(s7m, smoothEnds(s7k, 7)))
```

sortedXyData

Create a sortedXyData Object

Description

This is a constructor function for the class of sortedXyData objects. These objects are mostly used in the initial function for a self-starting nonlinear regression model, which will be of the selfStart class.

Usage

```r
sortedXyData(x, y, data)
```

Arguments

- **x**: a numeric vector or an expression that will evaluate in `data` to a numeric vector
- **y**: a numeric vector or an expression that will evaluate in `data` to a numeric vector
- **data**: an optional data frame in which to evaluate expressions for `x` and `y`, if they are given as expressions

Value

A `sortedXyData` object. This is a data frame with exactly two numeric columns, named `x` and `y`. The rows are sorted so the `x` column is in increasing order. Duplicate `x` values are eliminated by averaging the corresponding `y` values.

Author(s)

José Pinheiro and Douglas Bates
spec.ar

Estimate Spectral Density of a Time Series from AR Fit

Description

Fits an AR model to x (or uses the existing fit) and computes (and by default plots) the spectral density of the fitted model.

Usage

spec.ar(x, n.freq, order = NULL, plot = TRUE, na.action = na.fail, method = "yule-walker", ...)

Arguments

x A univariate (not yet: or multivariate) time series or the result of a fit by ar.
n.freq The number of points at which to plot.
order The order of the AR model to be fitted. If omitted, the order is chosen by AIC.
plot Plot the periodogram?
na.action NA action function.
method method for ar fit.
... Graphical arguments passed to plot.spec.

Value

An object of class "spec". The result is returned invisibly if plot is true.

Warning

Some authors, for example Thomson (1990), warn strongly that AR spectra can be misleading.

Note

The multivariate case is not yet implemented.
spec.pgram

**spec.pgram** Estimate Spectral Density of a Time Series by a Smoothed Periodogram

Description

*spec.pgram* calculates the periodogram using a fast Fourier transform, and optionally smooths the result with a series of modified Daniell smoothers (moving averages giving half weight to the end values).

Usage

```r
spec.pgram(x, spans = NULL, kernel, taper = 0.1,
           pad = 0, fast = TRUE, demean = FALSE, detrend = TRUE,
           plot = TRUE, na.action = na.fail, ...)
```

Arguments

- **x** univariate or multivariate time series.
- **spans** vector of odd integers giving the widths of modified Daniell smoothers to be used to smooth the periodogram.
- **kernel** alternatively, a kernel smoother of class "tskernel".
taper specifies the proportion of data to taper. A split cosine bell taper is applied to this proportion of the data at the beginning and end of the series.

pad proportion of data to pad. Zeros are added to the end of the series to increase its length by the proportion pad.

fast logical; if TRUE, pad the series to a highly composite length.

demean logical. If TRUE, subtract the mean of the series.

detrend logical. If TRUE, remove a linear trend from the series. This will also remove the mean.

plot plot the periodogram?

na.action NA action function.

... graphical arguments passed to plot.spec.

Details

The raw periodogram is not a consistent estimator of the spectral density, but adjacent values are asymptotically independent. Hence a consistent estimator can be derived by smoothing the raw periodogram, assuming that the spectral density is smooth.

The series will be automatically padded with zeros until the series length is a highly composite number in order to help the Fast Fourier Transform. This is controlled by the fast and not the pad argument.

The periodogram at zero is in theory zero as the mean of the series is removed (but this may be affected by tapering): it is replaced by an interpolation of adjacent values during smoothing, and no value is returned for that frequency.

Value

A list object of class "spec" (see spectrum) with the following additional components:

kernel The kernel argument, or the kernel constructed from spans.

df The distribution of the spectral density estimate can be approximated by a (scaled) chi square distribution with df degrees of freedom.

bandwidth The equivalent bandwidth of the kernel smoother as defined by Bloomfield (1976, page 201).

taper The value of the taper argument.

pad The value of the pad argument.

detrend The value of the detrend argument.

demean The value of the demean argument.

The result is returned invisibly if plot is true.

**spec.taper**

Taper a Time Series by a Cosine Bell
spectrum

Description

Apply a cosine-bell taper to a time series.

Usage

spec.taper(x, p = 0.1)

Arguments

x A univariate or multivariate time series
p The proportion to be tapered at each end of the series, either a scalar (giving the proportion for all series) or a vector of the length of the number of series (giving the proportion for each series).

Details

The cosine-bell taper is applied to the first and last \( p[i] \) observations of time series \( x[, i] \).

Value

A new time series object.

See Also

spec.pgram, cpgram

spectrum

Spectral Density Estimation

Description

The spectrum function estimates the spectral density of a time series.

Usage

spectrum(x, ..., method = c("pgram", "ar"))

Arguments

x A univariate or multivariate time series.
method String specifying the method used to estimate the spectral density. Allowed methods are "pgram" (the default) and "ar".
... Further arguments to specific spec methods or plot.spec.
Details

`spectrum` is a wrapper function which calls the methods `spec.pgram` and `spec.ar`.

The spectrum here is defined with scaling $1/\text{frequency}(x)$, following S-PLUS. This makes the spectral density a density over the range $(-\text{frequency}(x)/2, +\text{frequency}(x)/2]$, whereas a more common scaling is $2\pi$ and range $(-0.5, 0.5]$ (e.g., Bloomfield) or 1 and range $(-\pi, \pi]$.

If available, a confidence interval will be plotted by `plot.spec`: this is asymmetric, and the width of the centre mark indicates the equivalent bandwidth.

Value

An object of class "spec", which is a list containing at least the following components:

- `freq`: vector of frequencies at which the spectral density is estimated. (Possibly approximate Fourier frequencies.) The units are the reciprocal of cycles per unit time (and not per observation spacing): see ‘Details’ below.
- `spec`: Vector (for univariate series) or matrix (for multivariate series) of estimates of the spectral density at frequencies corresponding to `freq`.
- `coh`: NULL for univariate series. For multivariate time series, a matrix containing the `squared` coherency between different series. Column $i + (j - 1) * (j - 2)/2$ of `coh` contains the squared coherency between columns $i$ and $j$ of $x$, where $i < j$.
- `phase`: NULL for univariate series. For multivariate time series a matrix containing the cross-spectrum phase between different series. The format is the same as `coh`.
- `series`: The name of the time series.
- `snames`: For multivariate input, the names of the component series.
- `method`: The method used to calculate the spectrum.

The result is returned invisibly if `plot` is true.

Note

The default plot for objects of class "spec" is quite complex, including an error bar and default title, subtitle and axis labels. The defaults can all be overridden by supplying the appropriate graphical parameters.

splinefun

Interpolating Splines

Description

Perform cubic (or Hermite) spline interpolation of given data points, returning either a list of points obtained by the interpolation or a function performing the interpolation.

Usage

splinefun(x, y = NULL,
          method = c("fmm", "periodic", "natural", "monoH.FC", "hyman"),
          ties = mean)
spline(x, y = NULL, n = 3*length(x), method = "fmm",
        xmin = min(x), xmax = max(x), xout, ties = mean)
splinefunH(x, y, m)
Arguments

- **x, y**: vectors giving the coordinates of the points to be interpolated. Alternatively a single plotting structure can be specified: see `xy.coords`. y must be increasing or decreasing for `method = "hyman"`.
- **m**: (for `splinefunH()`): vector of slopes $m_i$ at the points $(x_i, y_i)$; these together determine the Hermite “spline” which is piecewise cubic, (only) once differentiable continuously.
- **method**: specifies the type of spline to be used. Possible values are "fmm", "natural", "periodic", "monoH.FC" and "hyman".
- **n**: if `xout` is left unspecified, interpolation takes place at `n` equally spaced points spanning the interval [xmin, xmax].
- **xmin, xmax**: left-hand and right-hand endpoint of the interpolation interval (when `xout` is unspecified).
- **xout**: an optional set of values specifying where interpolation is to take place.
- **ties**: Handling of tied x values. Either a function with a single vector argument returning a single number result or the string "ordered".

Details

The inputs can contain missing values which are deleted, so at least one complete (x, y) pair is required. If `method = "fmm"`, the spline used is that of Forsythe, Malcolm and Moler (an exact cubic is fitted through the four points at each end of the data, and this is used to determine the end conditions). Natural splines are used when `method = "natural"`, and periodic splines when `method = "periodic"`.

The method "monoH.FC" computes a monotone Hermite spline according to the method of Fritsch and Carlson. It does so by determining slopes such that the Hermite spline, determined by $(x_i, y_i, m_i)$, is monotone (increasing or decreasing) if the data are.

Method "hyman" computes a monotone cubic spline using Hyman filtering of an `method = "fmm"` fit for strictly monotonic inputs. (Added in R 2.15.2.)

These interpolation splines can also be used for extrapolation, that is prediction at points outside the range of x. Extrapolation makes little sense for `method = "fmm"`; for natural splines it is linear using the slope of the interpolating curve at the nearest data point.

Value

`spline` returns a list containing components x and y which give the ordinates where interpolation took place and the interpolated values.

`splinefun` returns a function with formal arguments x and deriv, the latter defaulting to zero. This function can be used to evaluate the interpolating cubic spline (deriv = 0), or its derivatives (deriv = 1, 2, 3) at the points x, where the spline function interpolates the data points originally specified. It uses data stored in its environment when it was created, the details of which are subject to change.

Warning

The value returned by `splinefun` contains references to the code in the current version of R: it is not intended to be saved and loaded into a different R session. This is safer in R >= 3.0.0.

---

SSasymp

Self-Starting Nls Asymptotic Regression Model

Description

This selfStart model evaluates the asymptotic regression function and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters Asym, R0, and lrc for a given set of data.

Usage

SSasymp(input, Asym, R0, lrc)

Arguments

input a numeric vector of values at which to evaluate the model.
Asym a numeric parameter representing the horizontal asymptote on the right side (very large values of input).
R0 a numeric parameter representing the response when input is zero.
lrc a numeric parameter representing the natural logarithm of the rate constant.

Value

a numeric vector of the same length as input. It is the value of the expression
Asym*(R0-Asym)*exp(-exp(lrc)*input). If all of the arguments Asym, R0, and lrc are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

```

---

**SSasympOff**

**Self-Starting Nls Asymptotic Regression Model with an Offset**

### Description

This `selfStart` model evaluates an alternative parametrization of the asymptotic regression function and the gradient with respect to those parameters. It has an initial attribute that creates initial estimates of the parameters `Asym`, `lrc`, and `c0`.

### Usage

```r
SSasympOff(input, Asym, lrc, c0)
```

### Arguments

- **input**: a numeric vector of values at which to evaluate the model.
- **Asym**: a numeric parameter representing the horizontal asymptote on the right side (very large values of `input`).
- **lrc**: a numeric parameter representing the natural logarithm of the rate constant.
- **c0**: a numeric parameter representing the input for which the response is zero.

### Value

A numeric vector of the same length as `input`. It is the value of the expression `Asym*(1 - exp(-exp(lrc)*(input - c0)))`. If all of the arguments `Asym`, `lrc`, and `c0` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSasympOrig

Self-Starting Nls Asymptotic Regression Model through the Origin

Description

This selfStart model evaluates the asymptotic regression function through the origin and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters Asym and lrc for a given set of data.

Usage

SSasympOrig(input, Asym, lrc)

Arguments

- **input**: a numeric vector of values at which to evaluate the model.
- **Asym**: a numeric parameter representing the horizontal asymptote.
- **lrc**: a numeric parameter representing the natural logarithm of the rate constant.

Value

A numeric vector of the same length as input. It is the value of the expression \( Asym*(1 - \exp(-\exp(lrc)*input)) \). If all of the arguments Asym and lrc are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

SSbiexp

Description

This selfStart model evaluates the biexponential model function and its gradient. It has an initial attribute that creates initial estimates of the parameters \(A_1, lrc_1, A_2, \) and \(lrc_2\).

Usage

SSbiexp(input, A1, lrc1, A2, lrc2)

Arguments

input          a numeric vector of values at which to evaluate the model.
A1             a numeric parameter representing the multiplier of the first exponential.
lrc1           a numeric parameter representing the natural logarithm of the rate constant of the first exponential.
A2             a numeric parameter representing the multiplier of the second exponential.
lrc2           a numeric parameter representing the natural logarithm of the rate constant of the second exponential.

Value

a numeric vector of the same length as input. It is the value of the expression \(A_1\exp(-\exp(lrc_1)\times\text{input})+A_2\exp(-\exp(lrc_2)\times\text{input})\). If all of the arguments \(A_1, lrc_1, A_2, \) and \(lrc_2\) are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

SSD

SSD Matrix and Estimated Variance Matrix in Multivariate Models

Description

Functions to compute matrix of residual sums of squares and products, or the estimated variance matrix for multivariate linear models.

Usage

# S3 method for class 'mlm'
SSD(object, ...)

# S3 methods for class 'SSD' and 'mlm'
estVar(object, ...)

Arguments

object object of class "mlm", or "SSD" in the case of estVar.
... Unused

Value

SSD() returns a list of class "SSD" containing the following components

SSD The residual sums of squares and products matrix
df Degrees of freedom
call Copied from object

estVar returns a matrix with the estimated variances and covariances.
### SSfol

**Self-Starting Nls First-order Compartment Model**

**Description**

This `selfStart` model evaluates the first-order compartment function and its gradient. It has an initial attribute that creates initial estimates of the parameters `lKe`, `lKa`, and `lCl`.

**Usage**

```r
SSfol(Dose, input, lKe, lKa, lCl)
```

**Arguments**

- `Dose`: a numeric value representing the initial dose.
- `input`: a numeric vector at which to evaluate the model.
- `lKe`: a numeric parameter representing the natural logarithm of the elimination rate constant.
- `lKa`: a numeric parameter representing the natural logarithm of the absorption rate constant.
- `lCl`: a numeric parameter representing the natural logarithm of the clearance.
Value

a numeric vector of the same length as `input`, which is the value of the expression

\[
\text{Dose} \times \exp(lKe+lKa-lCl) \times (\exp(-\exp(lKe)\times\text{input}) - \exp(-\exp(lKa)\times\text{input})) / (\exp(lKa) - \exp(lKe))
\]

If all of the arguments `lKe`, `lKa`, and `lCl` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

`SSfpl`  
*Self-Starting Nls Four-Parameter Logistic Model*

Description

This `selfStart` model evaluates the four-parameter logistic function and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters `A`, `B`, `xmid`, and `scal` for a given set of data.

Usage

```r
SSfpl(input, A, B, xmid, scal)
```

Arguments

- `input`: a numeric vector of values at which to evaluate the model.
- `A`: a numeric parameter representing the horizontal asymptote on the left side (very small values of `input`).
- `B`: a numeric parameter representing the horizontal asymptote on the right side (very large values of `input`).
SSgompertz

xmid

a numeric parameter representing the input value at the inflection point of the curve. The value of SSfpl will be midway between A and B at xmid.

scal

a numeric scale parameter on the input axis.

Value

a numeric vector of the same length as input. It is the value of the expression \( A + (B - A)/(1 + \exp((xmid - \text{input})/\text{scal})) \). If all of the arguments A, B, xmid, and scal are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

SSgompertz

Self-Starting Nls Gompertz Growth Model

Description

This selfStart model evaluates the Gompertz growth model and its gradient. It has an initial attribute that creates initial estimates of the parameters Asym, b2, and b3.

Usage

```r
SSgompertz(x, Asym, b2, b3)
```

Arguments

x

a numeric vector of values at which to evaluate the model.

Asym

a numeric parameter representing the asymptote.

b2

a numeric parameter related to the value of the function at \( x = 0 \)

b3

a numeric parameter related to the scale the x axis.
SSlogis

Self-Starting Nls Logistic Model

Description

This selfStart model evaluates the logistic function and its gradient. It has an initial attribute that creates initial estimates of the parameters Asym, xmid, and scal.

Usage

SSlogis(input, Asym, xmid, scal)

Arguments

input a numeric vector of values at which to evaluate the model.
Asym a numeric parameter representing the asymptote.
xmid a numeric parameter representing the x value at the inflection point of the curve. The value of SSlogis will be Asym/2 at xmid.
scal a numeric scale parameter on the input axis.
**Value**

a numeric vector of the same length as `input`. It is the value of the expression `Asym/(1+exp((xmid-input)/scal))`. If all of the arguments `Asym`, `xmid`, and `scal` are names of objects the gradient matrix with respect to these names is attached as an attribute named `gradient`.

### SSmicmen

*Self-Starting Nls Michaelis-Menten Model*

**Description**

This `selfStart` model evaluates the Michaelis-Menten model and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters `Vm` and `K`.

**Usage**

`SSmicmen(input, Vm, K)`

**Arguments**

- **input**: a numeric vector of values at which to evaluate the model.
- **Vm**: a numeric parameter representing the maximum value of the response.
- **K**: a numeric parameter representing the input value at which half the maximum response is attained. In the field of enzyme kinetics this is called the Michaelis parameter.
Value

A numeric vector of the same length as input. It is the value of the expression \( Vm \times \text{input}/(K + \text{input}) \). If both the arguments \( Vm \) and \( K \) are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

SSmicmen(PurTrt$conc, Vm, K)     # response and gradient
print(getInitial(rate ~ SSmicmen(conc, Vm, K), data = PurTrt), digits = 3)
## Initial values are in fact the converged values
fm1 <- nls(rate ~ SSmicmen(conc, Vm, K), data = PurTrt)
summary(fm1)
## Alternative call using the subset argument
fm2 <- nls(rate ~ SSmicmen(conc, Vm, K), data = Puromycin, 
            subset = state == "treated")
summary(fm2)
```

SSweibull

Self-Starting Nls Weibull Growth Curve Model

Description

This selfStart model evaluates the Weibull model for growth curve data and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters Asym, Drop, lrc, and pwr for a given set of data.

Usage

```r
SSweibull(x, Asym, Drop, lrc, pwr)
```

Arguments

- `x`: A numeric vector of values at which to evaluate the model.
- `Asym`: A numeric parameter representing the horizontal asymptote on the right side (very small values of \( x \)).
- `Drop`: A numeric parameter representing the change from Asym to the y intercept.
lrc a numeric parameter representing the natural logarithm of the rate constant.
pwr a numeric parameter representing the power to which \( x \) is raised.

Details
This model is a generalization of the SSasymp model in that it reduces to SSasymp when \( pwr \) is unity.

Value
a numeric vector of the same length as \( x \). It is the value of the expression
\[
Asym - Drop \cdot \exp(-\exp(lrc) \cdot x^{pwr}).
\]
If all of the arguments \( Asym, Drop, lrc, \) and \( pwr \) are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

summary(fm1)

---

start  

*Encode the Terminal Times of Time Series*

Description
Extract and encode the times the first and last observations were taken. Provided only for compatibility with S version 2.
Usage

start(x, ...)  
end(x, ...)

Arguments

x           a univariate or multivariate time-series, or a vector or matrix.
...          extra arguments for future methods.

Details

These are generic functions, which will use the tsp attribute of x if it exists. Their default methods decode the start time from the original time units, so that for a monthly series 1995.5 is represented as c(1995, 7). For a series of frequency f, time n+i/f is presented as c(n, i+1) (even for i = 0 and f = 1).

Warning

The representation used by start and end has no meaning unless the frequency is supplied.

stat.anova  GLM Anova Statistics

Description

This is a utility function, used in lm and glm methods for anova(..., test != NULL) and should not be used by the average user.

Usage

stat.anova(table, test = c("Rao", "LRT", "Chisq", "F", "Cp"),  
scale, df.scale, n)

Arguments

table      numeric matrix as results from anova.glm(..., test = NULL).
test       a character string, matching one of "Rao", "LRT", "Chisq", "F" or "Cp".
scale      a residual mean square or other scale estimate to be used as the denominator in an F test.
df.scale   degrees of freedom corresponding to scale.
n          number of observations.
Value

A matrix which is the original table, augmented by a column of test statistics, depending on the test argument.

References

See Also

anova.lm, anova.glm.

Examples

```r
##-- Continued from '?glm':

print(ag <- anova(glm.D93))
stat.anova(ag$table, test = "Cp",
          scale = sum(resid(glm.D93, "pearson")^2)/4,
          df.scale = 4, n = 9)
```

Description

These functions are provided for compatibility with older versions of R only, and may be defunct as soon as the next release.

Details

There are currently no deprecated functions in this package.

See Also

Deprecated
**step**  
*Choose a model by AIC in a Stepwise Algorithm*

**Description**
Select a formula-based model by AIC.

**Usage**
```r
step(object, scope, scale = 0,  
     direction = c("both", "backward", "forward"),  
     trace = 1, keep = NULL, steps = 1000, k = 2, ...)  
```

**Arguments**
- **object**: an object representing a model of an appropriate class (mainly "lm" and "glm"). This is used as the initial model in the stepwise search.
- **scope**: defines the range of models examined in the stepwise search. This should be either a single formula, or a list containing components upper and lower, both formulae. See the details for how to specify the formulae and how they are used.
- **scale**: used in the definition of the AIC statistic for selecting the models, currently only for `lm`, `aov` and `glm` models. The default value, 0, indicates the scale should be estimated: see `extractAIC`.
- **direction**: the mode of stepwise search, can be one of "both", "backward", or "forward", with a default of "both". If the `scope` argument is missing the default for `direction` is "backward".
- **trace**: if positive, information is printed during the running of `step`. Larger values may give more detailed information.
- **keep**: a filter function whose input is a fitted model object and the associated AIC statistic, and whose output is arbitrary. Typically `keep` will select a subset of the components of the object and return them. The default is not to keep anything.
- **steps**: the maximum number of steps to be considered. The default is 1000 (essentially as many as required). It is typically used to stop the process early.
- **k**: the multiple of the number of degrees of freedom used for the penalty. Only `k = 2` gives the genuine AIC: `k = log(n)` is sometimes referred to as BIC or SBC.
- **...**: any additional arguments to `extractAIC`.

**Details**
`step` uses `add1` and `drop1` repeatedly; it will work for any method for which they work, and that is determined by having a valid method for `extractAIC`. When the additive constant can be chosen so that AIC is equal to Mallows’ $C_p$, this is done and the tables are labelled appropriately.

The set of models searched is determined by the `scope` argument. The right-hand-side of its `lower` component is always included in the model, and right-hand-side of the model is included in the
upper component. If scope is a single formula, it specifies the upper component, and the lower model is empty. If scope is missing, the initial model is used as the upper model.

Models specified by scope can be templates to update object as used by `update.formula`. So using . in a scope formula means ‘what is already there’, with .^2 indicating all interactions of existing terms.

There is a potential problem in using `glm` fits with a variable scale, as in that case the deviance is not simply related to the maximized log-likelihood. The "glm" method for function `extractAIC` makes the appropriate adjustment for a gaussian family, but may need to be amended for other cases. (The binomial and poisson families have fixed scale by default and do not correspond to a particular maximum-likelihood problem for variable scale.)

### Value

The stepwise-selected model is returned, with up to two additional components. There is an "anova" component corresponding to the steps taken in the search, as well as a "keep" component if the `keep=` argument was supplied in the call. The "Resid. Dev" column of the analysis of deviance table refers to a constant minus twice the maximized log likelihood: it will be a deviance only in cases where a saturated model is well-defined (thus excluding `lm`, `aov` and `survreg` fits, for example).

### Warning

The model fitting must apply the models to the same dataset. This may be a problem if there are missing values and R’s default of `na.action = na.omit` is used. We suggest you remove the missing values first.

Calls to the function `nobs` are used to check that the number of observations involved in the fitting process remains unchanged.

### Note

This function differs considerably from the function in S, which uses a number of approximations and does not in general compute the correct AIC.

This is a minimal implementation. Use `stepAIC` in package `MASS` for a wider range of object classes.

### Author(s)

B. D. Ripley: step is a slightly simplified version of `stepAIC` in package `MASS` (Venables & Ripley, 2002 and earlier editions).

The idea of a `step` function follows that described in Hastie & Pregibon (1992); but the implementation in R is more general.

**stepfun**

*Step Function Class*

**Description**

Given the vectors \((x_1, \ldots, x_n)\) and \((y_0, y_1, \ldots, y_n)\) (one value more!), \(\text{stepfun}(x, y, \ldots)\) returns an interpolating ‘step’ function, say \(fn\). I.e., \(fn(t) = c_i\) (constant) for \(t \in (x_i, x_{i+1})\) and at the abscissa values, if (by default) \(right = \text{FALSE}\), \(fn(x_i) = y_i\) and for \(right = \text{TRUE}\), \(fn(x_i) = y_{i-1}\), for \(i = 1, \ldots, n\).

The value of the constant \(c_i\) above depends on the ‘continuity’ parameter \(f\). For the default, \(right = \text{FALSE}, f = 0\), \(fn\) is a \texttt{cadlag} function, i.e., continuous at right, limit (‘the point’) at left. In general, \(c_i\) is interpolated in between the neighbouring \(y\) values, \(c_i = (1-f)y_i + f \cdot y_{i+1}\). Therefore, for non-0 values of \(f\), \(fn\) may no longer be a proper step function, since it can be discontinuous from both sides, unless \(right = \text{TRUE}, f = 1\) which is right-continuous.

**Usage**

```r
stepfun(x, y, f = as.numeric(right), ties = "ordered",
right = FALSE)

is.stepfun(x)

knots(Fn, ...)

as.stepfun(x, ...)

## S3 method for class 'stepfun'

print(x, digits = getOption("digits") - 2, ...)

## S3 method for class 'stepfun'

summary(object, ...)
```
Arguments

- **x**: numeric vector giving the knots or jump locations of the step function for `stepfun()`. For the other functions, `x` is as object below.
- **y**: numeric vector one longer than `x`, giving the heights of the function values between the `x` values.
- **f**: a number between 0 and 1, indicating how interpolation outside the given `x` values should happen. See `approxfun`.
- **ties**: Handling of tied `x` values. Either a function or the string "ordered". See `approxfun`.
- **right**: logical, indicating if the intervals should be closed on the right (and open on the left) or vice versa.
- **Fn, object**: an R object inheriting from "stepfun".
- **digits**: number of significant digits to use, see `print`.
- **...**: potentially further arguments (required by the generic).

Value

A function of class "stepfun", say `fn`.

There are methods available for summarizing ("summary(.)"), representing ("print(.)") and plotting ("plot(.)", see `plot.stepfun`) "stepfun" objects.

The environment of `fn` contains all the information needed;

- "x", "y" the original arguments
- "n" number of knots (x values)
- "f" continuity parameter
- "yleft", "yright" the function values outside the knots
- "method" (always == "constant", from `approxfun(.)`).

The knots are also available via `knots(fn)`.

Author(s)

Martin Maechler, <maechler@stat.math.ethz.ch> with some basic code from Thomas Lumley.

stopifnot(identical(y0[-1], sfun0(1:3)), # right = FALSE
          identical(y0[-4], sfun1c(1:3))) # right = TRUE
```

---

**stl**

*Seasonal Decomposition of Time Series by Loess*

**Description**

Decompose a time series into seasonal, trend and irregular components using loess, acronym STL.

**Usage**

```r
stl(x, s.window, s.degree = 0,
    t.window = NULL, t.degree = 1,
    l.window = nextodd(period), l.degree = t.degree,
    s.jump = ceiling(s.window/10),
    t.jump = ceiling(t.window/10),
    l.jump = ceiling(l.window/10),
    robust = FALSE,
    inner = if(robust) 1 else 2,
    outer = if(robust) 15 else 0,
    na.action = na.fail)
```

**Arguments**

- **x**: univariate time series to be decomposed. This should be an object of class "ts" with a frequency greater than one.
- **s.window**: either the character string "periodic" or the span (in lags) of the loess window for seasonal extraction, which should be odd. This has no default.
**s.degree**
degree of locally-fitted polynomial in seasonal extraction. Should be zero or one.

**t.window**
the span (in lags) of the loess window for trend extraction, which should be odd. If NULL, the default, nextodd(ceiling((1.5*period) / (1-(1.5/s.window)))), is taken.

**t.degree**
degree of locally-fitted polynomial in trend extraction. Should be zero or one.

**l.window**
the span (in lags) of the loess window of the low-pass filter used for each subseries. Defaults to the smallest odd integer greater than or equal to \text{frequency}(x) which is recommended since it prevents competition between the trend and seasonal components. If not an odd integer its given value is increased to the next odd one.

**l.degree**
dergee of locally-fitted polynomial for the subseries low-pass filter. Must be 0 or 1.

**s.jump, t.jump, l.jump**
integers at least one to increase speed of the respective smoother. Linear interpolation happens between every \(*.jump^th\) value.

**robust**
logical indicating if robust fitting be used in the \text{loess} procedure.

**inner**
integer; the number of ‘inner’ (backfitting) iterations; usually very few (2) iterations suffice.

**outer**
integer; the number of ‘outer’ robustness iterations.

**na.action**
action on missing values.

**Details**
The seasonal component is found by \text{loess} smoothing the seasonal sub-series (the series of all January values,...); if \text{s.window = "periodic"} smoothing is effectively replaced by taking the mean. The seasonal values are removed, and the remainder smoothed to find the trend. The overall level is removed from the seasonal component and added to the trend component. This process is iterated a few times. The remainder component is the residuals from the seasonal plus trend fit.

Several methods for the resulting class "stl" objects, see, \text{plot.stl}.

**Value**
\text{stl} returns an object of class "stl" with components

- **time.series**
a multiple time series with columns seasonal, trend and remainder.
- **weights**
the final robust weights (all one if fitting is not done robustly).
- **call**
the matched call.
- **win**
integer (length 3 vector) with the spans used for the "s", "t", and "l" smoothers.
- **deg**
integer (length 3) vector with the polynomial degrees for these smoothers.
- **jump**
integer (length 3) vector with the ‘jumps’ (skips) used for these smoothers.
- **ni**
number of inner iterations
- **no**
number of outer robustness iterations
Note

This is similar to but not identical to the \texttt{stl} function in S-PLUS. The remainder component given by S-PLUS is the sum of the trend and remainder series from this function.

plot(stmR, set.pars = NULL)
# mark the 'outliers' :
(i0 <- which(stmR $ weights < 1e-8)) # 10 were considered outliers
sts <- stmR$time.series
points(time(sts)[i0], 0.8* sts[,"remainder"][i0], pch = 4, col = "red")
par(op) # reset
\end{verbatim}
Methods for STL Objects

Description

Methods for objects of class stl, typically the result of stl. The plot method does a multiple figure plot with some flexibility.

There are also (non-visible) print and summary methods.

Usage

```r
## S3 method for class 'stl'
plot(x, labels = colnames(X),
     set.pars = list(mar = c(0, 6, 0, 6), oma = c(6, 0, 4, 0),
                    tck = -0.01, mfrow = c(nplot, 1)),
     main = NULL, range.bars = TRUE, …,
     col.range = "light gray")
```

Arguments

- `x`: `stl` object.
- `labels`: character of length 4 giving the names of the component time-series.
- `set.pars`: settings for `par(.)` when setting up the plot.
- `main`: plot main title.
- `range.bars`: logical indicating if each plot should have a bar at its right side which are of equal heights in user coordinates.
- `…`: further arguments passed to or from other methods.
- `col.range`: colour to be used for the range bars, if plotted. Note this appears after `…` and so cannot be abbreviated.

See Also

- `plot.ts` and `stl`, particularly for examples.

Fit Structural Time Series

Description

Fit a structural model for a time series by maximum likelihood.
Usage

StructTS(x, type = c("level", "trend", "BSM"), init = NULL,
fixed = NULL, optim.control = NULL)

Arguments

x          a univariate numeric time series. Missing values are allowed.
type       the class of structural model. If omitted, a BSM is used for a time series with
frequency(x) > 1, and a local trend model otherwise.
init       initial values of the variance parameters.
fixed      optional numeric vector of the same length as the total number of parameters.
If supplied, only NA entries in fixed will be varied. Probably most useful for
setting variances to zero.
optim.control List of control parameters for optim. Method "L-BFGS-B" is used.

Details

Structural time series models are (linear Gaussian) state-space models for (univariate) time series based on a decomposition of the series into a number of components. They are specified by a set of error variances, some of which may be zero.

The simplest model is the local level model specified by type = "level". This has an underlying level $\mu_t$ which evolves by

$$
\mu_{t+1} = \mu_t + \xi_t, \quad \xi_t \sim N(0, \sigma_\xi^2)
$$

The observations are

$$
x_t = \mu_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma_\epsilon^2)
$$

There are two parameters, $\sigma_\xi^2$ and $\sigma_\epsilon^2$. It is an ARIMA(0,1,1) model, but with restrictions on the parameter set.

The local linear trend model, type = "trend", has the same measurement equation, but with a time-varying slope in the dynamics for $\mu_t$, given by

$$
\mu_{t+1} = \mu_t + \nu_t + \xi_t, \quad \xi_t \sim N(0, \sigma_\xi^2)
$$

$$
\nu_{t+1} = \nu_t + \zeta_t, \quad \zeta_t \sim N(0, \sigma_\zeta^2)
$$

with three variance parameters. It is not uncommon to find $\sigma_\zeta^2 = 0$ (which reduces to the local level model) or $\sigma_\xi^2 = 0$, which ensures a smooth trend. This is a restricted ARIMA(0,2,2) model.

The basic structural model, type = "BSM", is a local trend model with an additional seasonal component. Thus the measurement equation is

$$
x_t = \mu_t + \gamma_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma_\epsilon^2)
$$

where $\gamma_t$ is a seasonal component with dynamics

$$
\gamma_{t+1} = -\gamma_t + \cdots + \gamma_{t-s+2} + \omega_t, \quad \omega_t \sim N(0, \sigma_\omega^2)
$$

The boundary case $\sigma_\omega^2 = 0$ corresponds to a deterministic (but arbitrary) seasonal pattern. (This is sometimes known as the ‘dummy variable’ version of the BSM.)
Value

A list of class "StructTS" with components:

- **coef**: the estimated variances of the components.
- **loglik**: the maximized log-likelihood. Note that as all these models are non-stationary this includes a diffuse prior for some observations and hence is not comparable to *arima* nor different types of structural models.
- **loglik0**: the maximized log-likelihood with the constant used prior to R 3.0.0, for backwards compatibility.
- **data**: the time series $x$.
- **residuals**: the standardized residuals.
- **fitted**: a multiple time series with one component for the level, slope and seasonal components, estimated contemporaneously (that is at time $t$ and not at the end of the series).
- **call**: the matched call.
- **series**: the name of the series $x$.
- **code**: the convergence code returned by *optim*.
- **model, model0**: Lists representing the Kalman Filter used in the fitting. See *KalmanLike*. model0 is the initial state of the filter, model its final state.
- **xtsp**: the tsp attributes of $x$.

Note

Optimization of structural models is a lot harder than many of the references admit. For example, the *AirPassengers* data are considered in Brockwell & Davis (1996): their solution appears to be a local maximum, but nowhere near as good a fit as that produced by StructTS. It is quite common to find fits with one or more variances zero, and this can include $\sigma^2_\epsilon$.

References

See Also

*KalmanLike, tsSmooth; stl* for different kind of (seasonal) decomposition.
Examples

## see also JohnsonJohnson, Nile and AirPassengers
require(graphics)

trees <- window(treering, start = 0)
(fit <- StructTS(trees, type = "level"))
plot(trees)
lines(fitted(fit), col = "green")
tsdiag(fit)

(fit <- StructTS(log10(UKgas), type = "BSM"))
par(mfrow = c(4, 1)) # to give appropriate aspect ratio for next plot.
plot(log10(UKgas))
plot(cbind(fitted(fit), resids=resid(fit)), main = "UK gas consumption")

# keep some parameters fixed; trace optimizer:
StructTS(log10(UKgas), type = "BSM", fixed = c(0.1,0.001,NA,NA),
optim.control = list(trace = TRUE))

summary.aov

Summarize an Analysis of Variance Model

Description

Summarize an analysis of variance model.

Usage

## S3 method for class 'aov'
summary(object, intercept = FALSE, split, expand.split = TRUE, keep.zero.df = TRUE, ...)

## S3 method for class 'aovlist'
summary(object, ...)

Arguments

object An object of class "aov" or "aovlist".
intercept logical: should intercept terms be included?
split an optional named list, with names corresponding to terms in the model. Each component is itself a list with integer components giving contrasts whose contributions are to be summed.
expand.split logical: should the split apply also to interactions involving the factor?
keep.zero.df logical: should terms with no degrees of freedom be included?
... Arguments to be passed to or from other methods, for summary.aovlist including those for summary.aov.
Value

An object of class c("summary.aov", "listof") or "summary.aovlist" respectively.

For fits with a single stratum the result will be a list of ANOVA tables, one for each response (even if there is only one response): the tables are of class "anova" inheriting from class "data.frame". They have columns "Df", "Sum Sq", "Mean Sq", as well as "F value" and "Pr(>F)" if there are non-zero residual degrees of freedom. There is a row for each term in the model, plus one for "Residuals" if there are any.

For multistratum fits the return value is a list of such summaries, one for each stratum.

Note

The use of expand.split = TRUE is little tested: it is always possible to set it to FALSE and specify exactly all the splits required.

aov, summary, model.tables, TukeyHSD

Examples

## For a simple example see example(aov)

# Cochran and Cox (1957, p.164)
# 3x3 factorial with ordered factors, each is average of 12.
CC <- data.frame(
    y = c(449, 413, 326, 409, 358, 291, 341, 278, 312)/12,
    P = ordered(gl(3, 3)),
    N = ordered(gl(3, 1, 9))
)
CC.aov <- aov(y ~ N * P, data = CC , weights = rep(12, 9))
summary(CC.aov)

# Split both main effects into linear and quadratic parts.
summary(CC.aov, split = list(N = list(L = 1, Q = 2),
    P = list(L = 1, Q = 2)))

# Split only the interaction
summary(CC.aov, split = list("N:P" = list(L.L = 1, Q = 2:4)))

# split on just one var
summary(CC.aov, split = list(P = list(lin = 1, quad = 2)),
    expand.split = FALSE)

summary.glm

Summarizing Generalized Linear Model Fits

Description

These functions are all methods for class glm or summary.glm objects.
Usage

## S3 method for class 'glm'
summary(object, dispersion = NULL, correlation = FALSE,
        symbolic.cor = FALSE, ...)

## S3 method for class 'summary.glm'
print(x, digits = max(3, getOption("digits") - 3),
      symbolic.cor = x$symbolic.cor,
      signif.stars = getOption("show.signif.stars"), ...)

Arguments

object               an object of class "glm", usually, a result of a call to glm.
x                   an object of class "summary.glm", usually, a result of a call to summary.glm.
dispersion          the dispersion parameter for the family used. Either a single numerical value or
                    NULL (the default), when it is inferred from object (see 'Details').
correlation        logical; if TRUE, the correlation matrix of the estimated parameters is returned
                    and printed.
digits             the number of significant digits to use when printing.
symbolic.cor       logical. If TRUE, print the correlations in a symbolic form (see symnum) rather
                    than as numbers.
signif.stars        logical. If TRUE, 'significance stars' are printed for each coefficient.
...                  further arguments passed to or from other methods.

Details

print.summary.glm tries to be smart about formatting the coefficients, standard errors, etc. and
additionally gives 'significance stars' if signif.stars is TRUE. The coefficients component of
the result gives the estimated coefficients and their estimated standard errors, together with their
ratio. This third column is labelled t ratio if the dispersion is estimated, and z ratio if the
dispersion is known (or fixed by the family). A fourth column gives the two-tailed p-value corre-
sponding to the t or z ratio based on a Student t or Normal reference distribution. (It is possible that
the dispersion is not known and there are no residual degrees of freedom from which to estimate it.
In that case the estimate is NaN.)

Aliased coefficients are omitted in the returned object but restored by the print method.
Correlations are printed to two decimal places (or symbolically): to see the actual correlations print
summary(object)$correlation directly.

The dispersion of a GLM is not used in the fitting process, but it is needed to find standard errors.
If dispersion is not supplied or NULL, the dispersion is taken as 1 for the binomial and Poisson
families, and otherwise estimated by the residual Chisquared statistic (calculated from cases with
non-zero weights) divided by the residual degrees of freedom.

summary can be used with Gaussian glm fits to handle the case of a linear regression with known
error variance, something not handled by summary.lm.
Value

summary.glm returns an object of class "summary.glm", a list with components

call the component from object.
family the component from object.
deviance the component from object.
contrasts the component from object.
df.residual the component from object.
null.deviance the component from object.
df.null the component from object.
deviance.resid the deviance residuals: see residuals.glm.
coefficients the matrix of coefficients, standard errors, z-values and p-values. Aliased coefficients are omitted.
aliased named logical vector showing if the original coefficients are aliased.
dispersion either the supplied argument or the inferred/estimated dispersion if the latter is NULL.
df a 3-vector of the rank of the model and the number of residual degrees of freedom, plus number of coefficients (including aliased ones).
cov.unscaled the unscaled (dispersion = 1) estimated covariance matrix of the estimated coefficients.
cov.scaled ditto, scaled by dispersion.
correlation (only if correlation is true.) The estimated correlations of the estimated coefficients.
symbolic.cor (only if correlation is true.) The value of the argument symbolic.cor.

See Also

glm, summary.

Examples

## For examples see example(glm)
## Usage

### S3 method for class 'lm'

```r
summary(object, correlation = FALSE, symbolic.cor = FALSE, ...)```

### S3 method for class 'summary.lm'

```r
print(x, digits = max(3, getOption("digits") - 3),
     symbolic.cor = x$symbolic.cor,
     signif.stars = getOption("show.signif.stars"), ...)```

## Arguments

- `object`: an object of class "lm", usually, a result of a call to `lm`
- `x`: an object of class "summary.lm", usually, a result of a call to `summary.lm`
- `correlation`: logical; if `TRUE`, the correlation matrix of the estimated parameters is returned and printed.
- `digits`: the number of significant digits to use when printing.
- `symbolic.cor`: logical. If `TRUE`, print the correlations in a symbolic form (see `symnum`) rather than as numbers.
- `signif.stars`: logical. If `TRUE`, 'significance stars' are printed for each coefficient.
- `...`: further arguments passed to or from other methods.

## Details

`print.summary.lm` tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives 'significance stars' if `signif.stars` is `TRUE`.

Aliased coefficients are omitted in the returned object but restored by the `print` method.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print `summary(object)$correlation` directly.

## Value

The function `summary.lm` computes and returns a list of summary statistics of the fitted linear model given in `object`, using the components (list elements) "call" and "terms" from its argument, plus

- residuals: the weighted residuals, the usual residuals rescaled by the square root of the weights specified in the call to `lm`.
- coefficients: a $p \times 4$ matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding (two-sided) p-value. Aliased coefficients are omitted.
- aliased: named logical vector showing if the original coefficients are aliased.
- sigma: the square root of the estimated variance of the random error

$$
\hat{\sigma}^2 = \frac{1}{n - p} \sum_i w_i R_i^2,
$$

where $R_i$ is the $i$-th residual, `residuals[i]`.
df
degrees of freedom, a 3-vector \((p, n - p, p^*)\), the first being the number of non-aliased coefficients, the last being the total number of coefficients.

fstatistic
(for models including non-intercept terms) a 3-vector with the value of the F-statistic with its numerator and denominator degrees of freedom.

r.squared
\(R^2\), the ‘fraction of variance explained by the model’,

\[ R^2 = 1 - \frac{\sum_i R_i^2}{\sum_i (y_i - y^*)^2}, \]

where \(y^*\) is the mean of \(y_i\) if there is an intercept and zero otherwise.

adj.r.squared
the above \(R^2\) statistic ‘adjusted’, penalizing for higher \(p\).

cov.unscaled
a \(p \times p\) matrix of (unscaled) covariances of the \(\hat{\beta}_j, j = 1, \ldots, p\).

correlation
the correlation matrix corresponding to the above cov.unscaled, if correlation = TRUE is specified.

symbolic.cor
(only if correlation is true.) The value of the argument symbolic.cor.

na.action
from object, if present there.

See Also
The model fitting function lm, summary.

Function coef will extract the matrix of coefficients with standard errors, t-statistics and p-values.

Examples

```r
##-- Continuing the lm(.) example:
coef(lm.D9) \# the bare coefficients
sld9 <- summary(lm.D9 <- lm(weight ~ group -1)) \# omitting intercept
sld9
coef(sld9) \# much more

## model with *aliased* coefficient:
lm.D9. <- lm(weight ~ group + I(group != "Ctl"))
Sm.D9. <- summary(lm.D9.)
Sm.D9. \# shows the NA NA NA NA line
stopifnot(length(cc <- coef(lm.D9.)) == 3, is.na(cc[3]),
          dim(coef(Sm.D9.)) == c(2,4), Sm.D9.$df == c(2, 18, 3))
```

---

**summary.manova**

Summary Method for Multivariate Analysis of Variance

**Description**

A summary method for class "manova".
Usage

```r
## S3 method for class 'manova'
summary(object,
    test = c("Pillai", "Wilks", "Hotelling-Lawley", "Roy"),
    intercept = FALSE, tol = 1e-7, ...)
```

Arguments

- `object`: An object of class "manova" or an `aov` object with multiple responses.
- `test`: The name of the test statistic to be used. Partial matching is used so the name can be abbreviated.
- `intercept`: logical. If `TRUE`, the intercept term is included in the table.
- `tol`: tolerance to be used in deciding if the residuals are rank-deficient: see `qr`.
- `...`: further arguments passed to or from other methods.

Details

The `summary.manova` method uses a multivariate test statistic for the summary table. Wilks’ statistic is most popular in the literature, but the default Pillai–Bartlett statistic is recommended by Hand and Taylor (1987).

The table gives a transformation of the test statistic which has approximately an F distribution. The approximations used follow S-PLUS and SAS (the latter apart from some cases of the Hotelling–Lawley statistic), but many other distributional approximations exist: see Anderson (1984) and Krzanowski and Marriott (1994) for further references. All four approximate F statistics are the same when the term being tested has one degree of freedom, but in other cases that for the Roy statistic is an upper bound.

The tolerance `tol` is applied to the QR decomposition of the residual correlation matrix (unless some response has essentially zero residuals, when it is unscaled). Thus the default value guards against very highly correlated responses: it can be reduced but doing so will allow rather inaccurate results and it will normally be better to transform the responses to remove the high correlation.

Value

An object of class "summary.manova". If there is a positive residual degrees of freedom, this is a list with components

- `row.names`: The names of the terms, the row names of the `stats` table if present.
- `SS`: A named list of sums of squares and product matrices.
- `Eigenvalues`: A matrix of eigenvalues.
- `stats`: A matrix of the statistics, approximate F value, degrees of freedom and P value.

otherwise components `row.names`, `SS` and `Df` (degrees of freedom) for the terms (and not the residuals).

`manova`, `aov`

Examples

```r
## Example on producing plastic film from Krzanowski (1998, p. 381)

tear <- c(6.5, 6.2, 5.8, 6.5, 6.5, 6.9, 7.2, 6.9, 6.1, 6.3,
          6.7, 6.6, 7.2, 7.1, 6.8, 7.1, 7.0, 7.2, 7.5, 7.6)
gloss <- c(9.5, 9.9, 9.6, 9.6, 9.2, 9.1, 10.0, 9.9, 9.5, 9.4,
          9.1, 9.3, 8.3, 8.4, 8.5, 9.2, 8.8, 9.7, 10.1, 9.2)
opacity <- c(4.4, 6.4, 3.0, 4.1, 0.8, 5.7, 2.0, 3.9, 1.9, 5.7,
            2.8, 4.1, 3.8, 1.6, 3.4, 8.4, 5.2, 6.9, 2.7, 1.9)

Y <- cbind(tear, gloss, opacity)
rate <- factor(gl(2, 1), labels = c("Low", "High"))
additive <- factor(gl(2, 5, length = 20), labels = c("Low", "High"))

fit <- manova(Y ~ rate * additive)
summary.aov(fit)  # univariate ANOVA tables
summary(fit, test = "Wilks")  # ANOVA table of Wilks' lambda
summary(fit)      # same F statistics as single-df terms
```

summary.nls

**Summarizing Non-Linear Least-Squares Model Fits**

**Description**

summary method for class "nls".

**Usage**

```r
## S3 method for class 'nls'
summary(object, correlation = FALSE, symbolic.cor = FALSE, ...)
```

```r
## S3 method for class 'summary.nls'
print(x, digits = max(3, getOption("digits") - 3),
      symbolic.cor = x$symbolic.cor,
      signif.stars = getOption("show.signif.stars"), ...)
```
Arguments

object  an object of class "nls".
x        an object of class "summary.nls", usually the result of a call to summary.nls.
correlation  logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.
digits    the number of significant digits to use when printing.
symbolic.cor  logical. If TRUE, print the correlations in a symbolic form (see \texttt{symnum}) rather than as numbers.
signif.stars  logical. If TRUE, ‘significance stars’ are printed for each coefficient.
...    further arguments passed to or from other methods.

Details

The distribution theory used to find the distribution of the standard errors and of the residual standard error (for t ratios) is based on linearization and is approximate, maybe very approximate. print.summary.nls tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives ‘significance stars’ if \texttt{signif.stars} is \texttt{TRUE}.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print \texttt{summary(object)$correlation} directly.

Value

The function \texttt{summary.nls} computes and returns a list of summary statistics of the fitted model given in \texttt{object}, using the component "formula" from its argument, plus

residuals     the \textit{weighted} residuals, the usual residuals rescaled by the square root of the weights specified in the call to \texttt{nls}.
coefficients a \( p \times 4 \) matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding (two-sided) p-value.
sigma        the square root of the estimated variance of the random error

\[
\hat{\sigma}^2 = \frac{1}{n - p} \sum_i R_i^2,
\]

where \( R_i \) is the \( i \)-th weighted residual.
df         degrees of freedom, a 2-vector \((p, n - p)\). (Here and elsewhere \( n \) omits observations with zero weights.)
cov.unscaled a \( p \times p \) matrix of (unscaled) covariances of the parameter estimates.
correlation the correlation matrix corresponding to the above \texttt{cov.unscaled}, if correlation = \texttt{TRUE} is specified and there are a non-zero number of residual degrees of freedom.
symbolic.cor (only if correlation is true.) The value of the argument \texttt{symbolic.cor}.

See Also

The model fitting function \texttt{nls}, \texttt{summary}.

Function \texttt{coef} will extract the matrix of coefficients with standard errors, t-statistics and p-values.
The \texttt{summary} method for class "princomp".

### Usage

```r
## S3 method for class 'princomp'
summary(object, loadings = FALSE, cutoff = 0.1, ...)

## S3 method for class 'summary.princomp'
print(x, digits = 3, loadings = x$print.loadings,
cutoff = x$cutoff, ...)
```

### Arguments

- \texttt{object} an object of class "princomp", as from \texttt{princomp}().
- \texttt{loadings} logical. Should loadings be included?
- \texttt{cutoff} numeric. Loadings below this cutoff in absolute value are shown as blank in the output.
- \texttt{x} an object of class "summary.princomp".
- \texttt{digits} the number of significant digits to be used in listing loadings.
- \texttt{...} arguments to be passed to or from other methods.

### Value

\texttt{object} with additional components \texttt{cutoff} and \texttt{print.loadings}.

### See Also

\texttt{princomp}

### Examples

```r
summary(pc.cr <- princomp(USArrests, cor = TRUE))
print(summary(princomp(USArrests, cor = TRUE),
  loadings = TRUE, cutoff = 0.2), digits = 2)
```
Friedman’s SuperSmoother

Description

Smooth the (x, y) values by Friedman’s ‘super smoother’.

Usage

\texttt{supsmu(x, y, wt, span = “cv”, periodic = FALSE, bass = 0)}

Arguments

\begin{itemize}
  \item \texttt{x} \quad x \text{ values for smoothing}
  \item \texttt{y} \quad y \text{ values for smoothing}
  \item \texttt{wt} \quad \text{case weights, by default all equal}
  \item \texttt{span} \quad \text{the fraction of the observations in the span of the running lines smoother, or}
    \text{“cv” to choose this by leave-one-out cross-validation.}
  \item \texttt{periodic} \quad \text{if TRUE, the x values are assumed to be in [0, 1] and of period 1.}
  \item \texttt{bass} \quad \text{controls the smoothness of the fitted curve. Values of up to 10 indicate increasing smoothness.}
\end{itemize}

Details

\texttt{supsmu} is a running lines smoother which chooses between three spans for the lines. The running lines smoothers are symmetric, with $k/2$ data points each side of the predicted point, and values of $k$ as $0.5 \times n$, $0.2 \times n$ and $0.05 \times n$, where $n$ is the number of data points. If \texttt{span} is specified, a single smoother with span $\texttt{span} \times n$ is used.

The best of the three smoothers is chosen by cross-validation for each prediction. The best spans are then smoothed by a running lines smoother and the final prediction chosen by linear interpolation.

The FORTRAN code says: “For small samples ($n < 40$) or if there are substantial serial correlations between observations close in x-value, then a pre-specified fixed span smoother ($\texttt{span} > 0$) should be used. Reasonable span values are 0.2 to 0.4.”

Cases with non-finite values of \texttt{x}, \texttt{y} or \texttt{wt} are dropped, with a warning.

Value

A list with components

\begin{itemize}
  \item \texttt{x} \quad \text{the input values in increasing order with duplicates removed.}
  \item \texttt{y} \quad \text{the corresponding y values on the fitted curve.}
\end{itemize}
symnum

References

ppr

Examples

```
require(graphics)

with(cars, {
  plot(speed, dist)
  lines(supsmu(speed, dist))
  lines(supsmu(speed, dist, bass = 7), lty = 2)
})
```

symnum

Symbolic Number Coding

Description

Symbolically encode a given numeric or logical vector or array. Particularly useful for visualization of structured matrices, e.g., correlation, sparse, or logical ones.

Usage

```
symnum(x, cutpoints = c(0.3, 0.6, 0.8, 0.9, 0.95),
   symbols = if(numeric.x) c("", ".", ",", "+", "*", "B")
   else c(".", "|"),
   legend = length(symbols) >= 3,
   na = "?", eps = 1e-5, numeric.x = is.numeric(x),
   corr = missing(cutpoints) && numeric.x,
   show.max = if(corr) "1", show.min = NULL,
   abbr.colnames = has.colnames,
   lower.triangular = corr && is.numeric(x) && is.matrix(x),
   diag.lower.tri = corr && !is.null(show.max))
```

Arguments

- `x` numeric or logical vector or array.
- `cutpoints` numeric vector whose values `cutpoints[j] = c_j` (after augmentation, see `corr` below) are used for intervals.
symbols character vector, one shorter than (the augmented, see corr below) cutpoints. symbols[j]= s_j are used as 'code' for the (half open) interval (c_j, c_{j+1}]. When numeric.x is FALSE, i.e., by default when argument x is logical, the default is c("."",""") (graphical 0 / 1 s).

legend logical indicating if a "legend" attribute is desired.

na character or logical. How NAs are coded. If na == FALSE, NAs are coded invisibly, including the "legend" attribute below, which otherwise mentions NA coding.

eps absolute precision to be used at left and right boundary.

numeric.x logical indicating if x should be treated as numbers, otherwise as logical.

corr logical. If TRUE, x contains correlations. The cutpoints are augmented by 0 and 1 and abs(x) is coded.

show.max if TRUE, or of mode character, the maximal cutpoint is coded especially.

show.min if TRUE, or of mode character, the minimal cutpoint is coded especially.

abbr.colnames logical, integer or NULL indicating how column names should be abbreviated (if they are); if NULL (or FALSE and x has no column names), the column names will all be empty, i.e., ":"; otherwise if abbr.colnames is false, they are left unchanged. If TRUE or integer, existing column names will be abbreviated to abbreviate(*, minlength = abbr.colnames).

lower.triangular logical. If TRUE and x is a matrix, only the lower triangular part of the matrix is coded as non-blank.

diag.lower.tri logical. If lower.triangular and this are TRUE, the diagonal part of the matrix is shown.

Value

An atomic character object of class noquote and the same dimensions as x.

If legend is TRUE (as by default when there are more than two classes), the result has an attribute "legend" containing a legend of the returned character codes, in the form
c_1s_1c_2s_2 \ldots s_n c_{n+1}

where c_j = cutpoints[j] and s_j = symbols[j].

Note

The optional (mostly logical) arguments all try to use smart defaults. Specifying them explicitly may lead to considerably improved output in many cases.

```r
ii <- setNames(0:8, 0:8)
symnum(ii, cut = 2*(0:4), sym = c(" ", "-", "+", "\$"))
symnum(ii, cut = 2*(0:4), sym = c(" ", "-", "+", "\$"), show.max = TRUE)

symnum(1:12 %% 3 == 0) # --> | = TRUE, . = FALSE for logical

## Pascal's Triangle modulo 2 -- odd and even numbers:
N <- 38
pascal <- t(sapply(N, function(n) round(choose(N, N - (N-n)%/%2))))
rownames(pascal) <- rep("", 1+N) # <-- to improve "graphic"
symnum(pascal %% 2, symbols = c(" ", "A"), numeric = FALSE)

##-- Symbolic correlation matrices:
symnum(cor(attitude), diag = FALSE)
symnum(cor(attitude), abbr. = NULL)
symnum(cor(attitude), abbr. = FALSE)
symnum(cor(attitude), abbr. = 2)

symnum(cor(rbind(1, rnorm(25), rnorm(25)^2)))
symnum(cor(matrix(rexp(3, 1), 5, 18))) # <<-- PATTERN ! --
symnum(cm1 <- cor(matrix(rnorm(9), 5, 18))) # < White Noise SMALL n
symnum(cm1, diag = FALSE)

## NA's:
Cm <- cor(matrix(rnorm(6), 1, 6)); Cm[c(3,6), 2] <- NA
symnum(Cm, show.max = NULL)

## Graphical P-values (aka "significance stars"):
pval <- rev(sort(c(outer(1:6, 10^-1:3))))
symp <- symnum(pval, corr = FALSE,
    cutpoints = c(0, .001,.01,.05,.1, 1),
    symbols = c("***","**","*","."," "))
noquote(cbind(P.val = format(pval), Signif = symp))
```

### Description

Performs one and two sample t-tests on vectors of data.

### Usage

```r
t.test(x, ...)
```

## Default S3 method:
t.test(x, y = NULL,
    alternative = c("two.sided", "less", "greater"),
    mu = 0, paired = FALSE, var.equal = FALSE,
    conf.level = 0.95, ...)

## S3 method for class 'formula'
t.test(formula, data, subset, na.action, ...)

Arguments

x a (non-empty) numeric vector of data values.
y an optional (non-empty) numeric vector of data values.
alternative a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.
mu a number indicating the true value of the mean (or difference in means if you are performing a two sample test).
paired a logical indicating whether you want a paired t-test.
var.equal a logical variable indicating whether to treat the two variances as being equal. If TRUE then the pooled variance is used to estimate the variance otherwise the Welch (or Satterthwaite) approximation to the degrees of freedom is used.
conf.level confidence level of the interval.
formula a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups.
data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset an optional vector specifying a subset of observations to be used.
na.action a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").
... further arguments to be passed to or from methods.

Details

The formula interface is only applicable for the 2-sample tests.

alternative = "greater" is the alternative that x has a larger mean than y.

If paired is TRUE then both x and y must be specified and they must be the same length. Missing values are silently removed (in pairs if paired is TRUE). If var.equal is TRUE then the pooled estimate of the variance is used. By default, if var.equal is FALSE then the variance is estimated separately for both groups and the Welch modification to the degrees of freedom is used.

If the input data are effectively constant (compared to the larger of the two means) an error is generated.
Value

A list with class "htest" containing the following components:

- **statistic**: the value of the t-statistic.
- **parameter**: the degrees of freedom for the t-statistic.
- **p.value**: the p-value for the test.
- **conf.int**: a confidence interval for the mean appropriate to the specified alternative hypothesis.
- **estimate**: the estimated mean or difference in means depending on whether it was a one-sample test or a two-sample test.
- **null.value**: the specified hypothesized value of the mean or mean difference depending on whether it was a one-sample test or a two-sample test.
- **alternative**: a character string describing the alternative hypothesis.
- **method**: a character string indicating what type of t-test was performed.
- **data.name**: a character string giving the name(s) of the data.

See Also

prop.test

Examples

```r
require(graphics)

# t.test(1:10, y = c(7:20))  # P = .00001855
# t.test(1:10, y = c(7:20, 200))  # P = .1245  -- NOT significant anymore

## Classical example: Student's sleep data
plot(extra ~ group, data = sleep)
## Traditional interface
with(sleep, t.test(extra[group == 1], extra[group == 2]))
## Formula interface
t.test(extra ~ group, data = sleep)
```

---

**TDist**

The Student t Distribution

Description

Density, distribution function, quantile function and random generation for the t distribution with df degrees of freedom (and optional non-centrality parameter ncp).

Usage

```r
dt(x, df, ncp, log = FALSE)
pt(q, df, ncp, lower.tail = TRUE, log.p = FALSE)
qt(p, df, ncp, lower.tail = TRUE, log.p = FALSE)
rt(n, df, ncp)
```
Arguments

- **x**, **q** vector of quantiles.
- **p** vector of probabilities.
- **n** number of observations. If `length(n) > 1`, the length is taken to be the number required.
- **df** degrees of freedom (> 0, maybe non-integer). `df = Inf` is allowed.
- **ncp** non-centrality parameter `δ`; currently except for `rt()`, only for `abs(ncp) <= 37.62`. If omitted, use the central t distribution.
- **log**, **log.p** logical; if TRUE, probabilities `p` are given as log(`p`).
- **lower.tail** logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

The \( t \) distribution with \( df = ν \) degrees of freedom has density

\[
f(x) = \frac{Γ((ν + 1)/2)}{\sqrt{πν}Γ(ν/2)} (1 + x^2/ν)^{-(ν+1)/2}
\]

for all real \( x \). It has mean \( 0 \) (for \( ν > 1 \)) and variance \( \frac{ν}{ν-2} \) (for \( ν > 2 \)).

The general **non-central** \( t \) with parameters \((ν, δ) = (df, ncp)\) is defined as the distribution of \( T_ν(δ) := (U + δ)/√(V/ν) \) where \( U \) and \( V \) are independent random variables, \( U \sim N(0, 1) \) and \( V \sim \chi^2_ν \) (see Chisquare).

The most used applications are power calculations for \( t \)-tests:

Let \( T = \frac{\bar{X} - µ_0}{S/√n} \) where \( \bar{X} \) is the mean and \( S \) the sample standard deviation (sd) of \( X_1, X_2, \ldots, X_n \) which are i.i.d. \( N(µ, σ^2) \) Then \( T \) is distributed as non-central \( t \) with \( df = n - 1 \) degrees of freedom and non-centrality parameter \( ncp = (µ - µ_0)√n/σ \).

Value

- **dt** gives the density, **pt** gives the distribution function, **qt** gives the quantile function, and **rt** generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by \( n \) for **rt**, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than \( n \) are recycled to the length of the result. Only the first elements of the logical parameters are used.

Note

Supplying \( ncp = 0 \) uses the algorithm for the non-central distribution, which is not the same algorithm used if \( ncp \) is omitted. This is to give consistent behaviour in extreme cases with values of \( ncp \) very near zero.

The code for non-zero \( ncp \) is principally intended to be used for moderate values of \( ncp \): it will not be highly accurate, especially in the tails, for large values.
Source

The central dt is computed via an accurate formula provided by Catherine Loader (see the reference in dbinom).

For the non-central case of dt, C code contributed by Claus Ekstrøm based on the relationship (for \( x \neq 0 \)) to the cumulative distribution.

For the central case of pt, a normal approximation in the tails, otherwise via pbeta.

For the non-central case of pt based on a C translation of

This computes the lower tail only, so the upper tail suffers from cancellation and a warning will be given when this is likely to be significant.

For central qt, a C translation of

altered to take account of

The non-central case is done by inversion.

Distributions for other standard distributions, including df for the F distribution.

Examples

```r
require(graphics)

1 - pt(1:5, df = 1)
qt(.975, df = c(1:10,20,50,100,1000))

tt <- seq(0, 10, len = 21)
necp <- seq(0, 6, len = 31)
ptn <- outer(tt, ncp, function(t, d) pt(t, df = 3, ncp = d))
t.tit <- "Non-central t - Probabilities"
image(tt, ncp, ptn, zlim = c(0,1), main = t.tit)
persp(tt, ncp, ptn, zlim = 0:1, r = 2, phi = 20, theta = 200, main = t.tit, xlab = "t", ylab = "non-centrality parameter", zlab = "Pr(T <= t)")
```
termplot

Plot Regression Terms

Description

Plots regression terms against their predictors, optionally with standard errors and partial residuals added.

Usage

termplot(model, data = NULL, envir = environment(formula(model)),
partial.resid = FALSE, rug = FALSE,
terms = NULL, se = FALSE,
xislabs = NULL, ylabs = NULL, main = NULL,
col.term = 2, lwd.term = 1.5,
col.se = "orange", lty.se = 2, lwd.se = 1,
col.res = "gray", cex = 1, pch = par("pch"),
col.smth = "darkred", lty.smth = 2, span.smth = 2/3,
ask = dev.interactive() && nb.fig < n.tms,
use.factor.levels = TRUE, smooth = NULL, ylim = "common",
plot = TRUE, ...)

Arguments

model fitted model object
data data frame in which variables in model can be found
envir environment in which variables in model can be found
partial.resid logical; should partial residuals be plotted?
rug add rugplots (jittered 1-d histograms) to the axes?
terms which terms to plot (default NULL means all terms); a character vector, passed
to predict(..., term = "terms", terms = *).
se plot pointwise standard errors?
xlabs vector of labels for the x axes
ylabs vector of labels for the y axes
main logical, or vector of main titles; if TRUE, the model’s call is taken as main title,
NULL or FALSE mean no titles.
col.term, lwd.term color and line width for the ‘term curve’, see lines.
col.se, lty.se, lwd.se color, line type and line width for the ‘twice-standard-error curve’ when se = TRUE.
termplot

col.res, cex, pch
  color, plotting character expansion and type for partial residuals, when partial.resid = TRUE, see points.
ask
  logical; if TRUE, the user is asked before each plot, see par(ask=.)
use.factor.levels
  Should x-axis ticks use factor levels or numbers for factor terms?
smooth
  NULL or a function with the same arguments as panel.smooth to draw a smooth through the partial residuals for non-factor terms
lty.smth, col.smth, span.smth
  Passed to smooth
ylim
  an optional range for the y axis, or "common" when a range sufficient for all the plot will be computed, or "free" when limits are computed for each plot.
plot
  if set to FALSE plots are not produced: instead a list is returned containing the data that would have been plotted.
...
  other graphical parameters.

Details

The model object must have a predict method that accepts type = terms, e.g., glm in the stats package, coxph and survreg in the survival package.

For the partial.resid = TRUE option model must have a residuals method that accepts type = "partial", which lm and glm do.

The data argument should rarely be needed, but in some cases termplot may be unable to reconstruct the original data frame. Using na.action=na.exclude makes these problems less likely.

Nothing sensible happens for interaction terms, and they may cause errors.

The plot = FALSE option is useful when some special action is needed, e.g. to overlay the results of two different models or to plot confidence bands.

Value

For plot = FALSE, a list with one element for each plot which would have been produced. Each element of the list is a data frame with variables x, y, and optionally the pointwise standard errors se. For continuous predictors x will contain the ordered unique values and for a factor it will be a factor containing one instance of each level. The list has attribute "constant" copied from the predicted terms object.

Otherwise, the number of terms, invisibly.

if(!had.splines) rs <- require(splines)
x <- 1:100
z <- factor(rep(LETTERS[1:4], 25))
y <- rnorm(100, sin(x/10)+as.numeric(z))
model <- glm(y ~ ns(x, 6) + z)

par(mfrow = c(2,2)) ## 2 x 2 plots for same model :
termplot(model, main = paste("termplot( ", deparse(model$call)," ...)"))
termplot(model, rug = TRUE)
termplot(model, partial.resid = TRUE, se = TRUE, main = TRUE)
termplot(model, partial.resid = TRUE, smooth = panel.smooth, span.smth = 1/4)
if(!had.splines & rs) detach("package:splines")

---

terms

<table>
<thead>
<tr>
<th>Model Terms</th>
</tr>
</thead>
</table>

**Description**

The function `terms` is a generic function which can be used to extract *terms* objects from various kinds of R data objects.

**Usage**

`terms(x, ...)`

**Arguments**

- `x` object used to select a method to dispatch.
- `...` further arguments passed to or from other methods.

**Details**

There are methods for classes "aovlist", and "terms" "formula" (see `terms.formula`): the default method just extracts the `terms` component of the object, or failing that a "terms" attribute (as used by `model.frame`).

There are `print` and `labels` methods for class "terms": the latter prints the term labels (see `terms.object`).

**Value**

An object of class c("terms", "formula") which contains the *terms* representation of a symbolic model. See `terms.object` for its structure.

**References**

See Also

terms.object, terms.formula, lm, glm, formula.

---

**terms.formula**

*Construct a terms Object from a Formula*

**Description**

This function takes a formula and some optional arguments and constructs a terms object. The terms object can then be used to construct a model.matrix.

**Usage**

```r
## S3 method for class 'formula'
terms(x, specials = NULL, abb = NULL, data = NULL, neg.out = TRUE,
keep.order = FALSE, simplify = FALSE, ...,
allowDotAsName = FALSE)
```

**Arguments**

- `x` a formula.
- `specials` which functions in the formula should be marked as special in the terms object? A character vector or NULL.
- `abb` Not implemented in R.
- `data` a data frame from which the meaning of the special symbol . can be inferred. It is unused if there is no . in the formula.
- `neg.out` Not implemented in R.
- `keep.order` a logical value indicating whether the terms should keep their positions. If FALSE the terms are reordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on. Effects of a given order are kept in the order specified.
- `simplify` should the formula be expanded and simplified, the pre-1.7.0 behaviour?
- `...` further arguments passed to or from other methods.
- `allowDotAsName` normally . in a formula refers to the remaining variables contained in data. Exceptionally, . can be treated as a name for non-standard uses of formulae.

**Details**

Not all of the options work in the same way that they do in S and not all are implemented.

**Value**

A terms.object object is returned. The object itself is the re-ordered (unless keep.order = TRUE) formula. In all cases variables within an interaction term in the formula are re-ordered by the ordering of the "variables" attribute, which is the order in which the variables occur in the formula.
See Also

terms, terms.object

---

terms.object Description of Terms Objects

Description

An object of class `terms` holds information about a model. Usually the model was specified in terms of a `formula` and that formula was used to determine the terms object.

Value

The object itself is simply the formula supplied to the call of `terms.formula`. The object has a number of attributes and they are used to construct the model frame:

- **factors**: A matrix of variables by terms showing which variables appear in which terms. The entries are 0 if the variable does not occur in the term, 1 if it does occur and should be coded by contrasts, and 2 if it occurs and should be coded via dummy variables for all levels (as when an intercept or lower-order term is missing). If there are no terms other than an intercept and offsets, this is `numeric(0)`.

- **term.labels**: A character vector containing the labels for each of the terms in the model, except for offsets. Note that these are after possible re-ordering of terms. Non-syntactic names will be quoted by backticks: this makes it easier to reconstruct the formula from the term labels.

- **variables**: A call to `list` of the variables in the model.

- **intercept**: Either 0, indicating no intercept is to be fit, or 1 indicating that an intercept is to be fit.

- **order**: A vector of the same length as `term.labels` indicating the order of interaction for each term.

- **response**: The index of the variable (in `variables`) of the response (the left hand side of the formula). Zero, if there is no response.

- **offset**: If the model contains `offset` terms there is an `offset` attribute indicating which variable(s) are offsets.

- **specials**: If a specials argument was given to `terms.formula` there is a `specials` attribute, a pairlist of vectors (one for each specified special function) giving numeric indices of the arguments of the list returned as the `variables` attribute which contain these special functions.

- **dataClasses**: optional. A named character vector giving the classes (as given by `.MFclass`) of the variables used in a fit.

The object has class `c("terms", "formula")`. 
Note
These objects are different from those found in S. In particular there is no `formula` attribute: instead the object is itself a formula. (Thus, the mode of a terms object is different.)

Examples of the specials argument can be seen in the `aov` and `coxph` functions, the latter from package `survival`.

See Also
`terms`, `formula`.

Examples
```r
## use of specials (as used for gam() in packages mgcv and gam)
(tf <- terms(y ~ x + x:z + s(x), specials = "s"))
## Note that the "factors" attribute has variables as row names
## and term labels as column names, both as character vectors.
attr(tf, "specials")  # index 's' variable(s)
rownames(attr(tf, "factors"))[attr(tf, "specials")$s]

## we can keep the order by
terms(y ~ x + x:z + s(x), specials = "s", keep.order = TRUE)
```

### time

Sampling Times of Time Series

description

time creates the vector of times at which a time series was sampled.
cycle gives the positions in the cycle of each observation.
frequency returns the number of samples per unit time and `deltat` the time interval between observations (see `ts`).

Usage

time(x, ...)
## Default S3 method:
time(x, offset = /zero.noslash, ...)

cycle(x, ...)
frequency(x, ...)
deltat(x, ...)

Arguments

x a univariate or multivariate time-series, or a vector or matrix.
offset can be used to indicate when sampling took place in the time unit. 0 (the default) indicates the start of the unit, 0.5 the middle and 1 the end of the interval.
... extra arguments for future methods.
Details
These are all generic functions, which will use the `tsp` attribute of `x` if it exists. `time` and `cycle` have methods for class `ts` that coerce the result to that class.

References

See Also
- `ts`, `start`, `tsp`, `window`.
- `date` for clock time, `system.time` for CPU usage.

Examples
```r
require(graphics)
cycle(presidents)
# a simple series plot
plot(as.vector(time(presidents)), as.vector(presidents), type = "l")
```

---

**toeplitz**

*Form Symmetric Toeplitz Matrix*

Description
Forms a symmetric Toeplitz matrix given its first row.

Usage
```
toeplitz(x, ...)
```

Arguments
- `x` the first row to form the Toeplitz matrix.
- `...` potential further arguments (for methods); none here.

Value
The Toeplitz matrix.

Author(s)
A. Trapletti
Examples

```r
x <- 1:5
toeplitz(x)
```

---

**ts**  
*Time-Series Objects*

**Description**

The function `ts` is used to create time-series objects.  

`as.ts` and `is.ts` coerce an object to a time-series and test whether an object is a time series.

**Usage**

```r
ts(data = NA, start = 1, end = numeric(), frequency = 1, 
deltat = 1, ts.eps = getOption("ts.eps"), class = , names = )
```

**Arguments**

- `data` a numeric vector or matrix of the observed time-series values. A data frame will be coerced to a numeric matrix via `data.matrix`.
- `start` the time of the first observation. Either a single number or a vector of two integers, which specify a natural time unit and a (1-based) number of samples into the time unit. See the examples for the use of the second form.
- `end` the time of the last observation, specified in the same way as `start`.
- `frequency` the number of observations per unit of time.
- `deltat` the fraction of the sampling period between successive observations; e.g., 1/12 for monthly data. Only one of `frequency` or `deltat` should be provided.
- `ts.eps` time series comparison tolerance. Frequencies are considered equal if their absolute difference is less than `ts.eps`.
- `class` class to be given to the result, or none if `NULL` or "none". The default is "ts" for a single series, c("mts", "ts", "matrix") for multiple series.
- `names` a character vector of names for the series in a multiple series: defaults to the colnames of `data`, or Series 1, Series 2,....
- `x` an arbitrary R object.
- `...` arguments passed to methods (unused for the default method).
Details

The function \texttt{ts} is used to create time-series objects. These are vector or matrices with class of "ts" (and additional attributes) which represent data which has been sampled at equispaced points in time. In the matrix case, each column of the matrix data is assumed to contain a single (univariate) time series. Time series must have at least one observation, and although they need not be numeric there is very limited support for non-numeric series.

Class "ts" has a number of methods. In particular arithmetic will attempt to align time axes, and subsetting to extract subsets of series can be used (e.g., \texttt{EuStockMarkets[, "DAX"]}). However, subsetting the first (or only) dimension will return a matrix or vector, as will matrix subsetting. Subassignment can be used to replace values but not to extend a series (see \texttt{window}). There is a method for \texttt{t} that transposes the series as a matrix (a one-column matrix if a vector) and hence returns a result that does not inherit from class "ts".

The value of argument \texttt{frequency} is used when the series is sampled an integral number of times in each unit time interval. For example, one could use a value of 7 for \texttt{frequency} when the data are sampled daily, and the natural time period is a week, or 12 when the data are sampled monthly and the natural time period is a year. Values of 4 and 12 are assumed in (e.g.) \texttt{print} methods to imply a quarterly and monthly series respectively.

\texttt{as.ts} is generic. Its default method will use the \texttt{tsp} attribute of the object if it has one to set the start and end times and frequency.

\texttt{is.ts} tests if an object is a time series. It is generic: you can write methods to handle specific classes of objects, see \texttt{InternalMethods}.

Examples

require(graphics)

\texttt{ts(1:10, frequency = 4, start = c(1959, 2)) \# 2nd Quarter of 1959}
\texttt{print( ts(1:10, frequency = 7, start = c(12, 2)), calendar = TRUE)}
\texttt{# print.ts(.)}
\texttt{## Using July 1954 as start date:}
\texttt{gnp <- ts(cumsum(1 + round(rnorm(100), 2)),}
\texttt{ start = c(1954, 7), frequency = 12)}
\texttt{plot(gnp) \# using ‘plot.ts’ for time-series plot}
\texttt{## Multivariate}
\texttt{z <- ts(matrix(rnorm(300), 100, 3), start = c(1961, 1), frequency = 12)}
\texttt{class(z)}
\texttt{head(z) \# as “matrix”}
\texttt{plot(z)}
plot(z, plot.type = "single", lty = 1:3)

## A phase plot:
plot(nhtemp, c(nhtemp[-1], NA), cex = .8, col = "blue",
     main = "Lag plot of New Haven temperatures")
## a clearer way to do this would be
## Not run:
plot(nhtemp, lag(nhtemp, 1), cex = .8, col = "blue",
     main = "Lag plot of New Haven temperatures")
## End(Not run)

### Methods for Time Series Objects

**Description**

Methods for objects of class "ts", typically the result of `ts`.

**Usage**

```r
## S3 method for class 'ts'
diff(x, lag = 1, differences = 1, ...)

## S3 method for class 'ts'
na.omit(object, ...)
```

**Arguments**

- `x` an object of class "ts" containing the values to be differenced.
- `lag` an integer indicating which lag to use.
- `differences` an integer indicating the order of the difference.
- `object` a univariate or multivariate time series.
- `...` further arguments to be passed to or from methods.

**Details**

The `na.omit` method omits initial and final segments with missing values in one or more of the series. ‘Internal’ missing values will lead to failure.

**Value**

For the `na.omit` method, a time series without missing values. The class of `object` will be preserved.

**See Also**

`diff`, `na.omit`, `na.fail`, `na.contiguous`. 
ts.plot  

Plot Multiple Time Series

Description

Plot several time series on a common plot. Unlike `plot.ts` the series can have a different time bases, but they should have the same frequency.

Usage

```r
ts.plot(..., gpars = list())
```

Arguments

- `...`: one or more univariate or multivariate time series.
- `gpars`: list of named graphics parameters to be passed to the plotting functions. Those commonly used can be supplied directly in . . .

Value

None.

Note

Although this can be used for a single time series, `plot` is easier to use and is preferred.

See Also

- `plot.ts`

Examples

```r
require(graphics)

ts.plot(ldeaths, mdeaths, fdeaths,
        gpars=list(xlab="year", ylab="deaths", lty=c(1:3)))
```
ts.union  

**Bind Two or More Time Series**

**Description**

Bind time series which have a common frequency. `ts.union` pads with NAs to the total time coverage, `ts.intersect` restricts to the time covered by all the series.

**Usage**

```r
ts.intersect(..., dframe = FALSE)
```

```r
ts.union(..., dframe = FALSE)
```

**Arguments**

- `...`: two or more univariate or multivariate time series, or objects which can coerced to time series.
- `dframe`: logical; if TRUE return the result as a data frame.

**Details**

As a special case, `...` can contain vectors or matrices of the same length as the combined time series of the time series present, as well as those of a single row.

**Value**

A time series object if `dframe` is FALSE, otherwise a data frame.

**See Also**

- `cbind`

**Examples**

```r
ts.union(mdeaths, fdeaths)
```

```r
cbind(mdeaths, fdeaths) # same as the previous line
```

```r
ts.intersect(window(mdeaths, 1976), window(fdeaths, 1974, 1978))
```

```r
sales1 <- ts.union(BJsales, lead = BJsales.lead)
```

```r
ts.intersect(sales1, lead3 = lag(BJsales.lead, -3))
```
Description
A generic function to plot time-series diagnostics.

Usage

```r
tsdia\text{g}(object, gof.lag, \ldots)
```

Arguments

- `object`: a fitted time-series model
- `gof.lag`: the maximum number of lags for a Portmanteau goodness-of-fit test
- `\ldots`: further arguments to be passed to particular methods

Details
This is a generic function. It will generally plot the residuals, often standardized, the autocorrelation function of the residuals, and the p-values of a Portmanteau test for all lags up to `gof.lag`.

The methods for `arima` and `StructTS` objects plots residuals scaled by the estimate of their (individual) variance, and use the Ljung–Box version of the portmanteau test.

Value
None. Diagnostics are plotted.

See Also

- `arima`
- `StructTS`
- `Box.test`

Examples

```r
## Not run: require(graphics)
fit <- arima(lh, c(1,0,0))
tsdia\text{g}(fit)
## see also examples(arima)
(fit <- StructTS(log10(JohnsonJohnson), type = "BSM"))
tsdia\text{g}(fit)
## End(Not run)
```
tsp

Tsp Attribute of Time-Series-like Objects

Description

tsp returns the tsp attribute (or NULL). It is included for compatibility with S version 2. tsp<- sets the tsp attribute. hasTsp ensures x has a tsp attribute, by adding one if needed.

Usage

tsp(x)
tsp(x) <- value
hasTsp(x)

Arguments

x a vector or matrix or univariate or multivariate time-series.
value a numeric vector of length 3 or NULL.

Details

The tsp attribute was previously described here as c(start(x), end(x), frequency(x)), but this is incorrect. It gives the start time in time units, the end time and the frequency.
Assignments are checked for consistency.
Assigning NULL which removes the tsp attribute and any "ts" (or "mts") class of x.

References

See Also

ts, time, start.

tsSmooth

Use Fixed-Interval Smoothing on Time Series

Description

Performs fixed-interval smoothing on a univariate time series via a state-space model. Fixed-interval smoothing gives the best estimate of the state at each time point based on the whole observed series.

Usage

tsSmooth(object, ...)

Arguments

object a time-series fit. Currently only class "StructTS" is supported
... possible arguments for future methods.

Value

A time series, with as many dimensions as the state space and results at each time point of the original series. (For seasonal models, only the current seasonal component is returned.)

Author(s)

B. D. Ripley

References

See Also

KalmanSmooth, StructTS.

For examples consult AirPassengers, JohnsonJohnson and Nile.

Tukey The Studentized Range Distribution

Description

Functions of the distribution of the studentized range, \( R/s \), where \( R \) is the range of a standard normal sample and \( df \times s^2 \) is independently distributed as chi-squared with \( df \) degrees of freedom, see pchisq.

Usage

ptukey(q, nmeans, df, nranges = 1, lower.tail = TRUE, log.p = FALSE)
qtukey(p, nmeans, df, nranges = 1, lower.tail = TRUE, log.p = FALSE)

Arguments

q vector of quantiles.
p vector of probabilities.
nmeans sample size for range (same for each group).
ndf degrees of freedom for \( s \) (see below).
nranges number of groups whose maximum range is considered.
log.p logical; if TRUE, probabilities \( p \) are given as log(p).
lower.tail logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).
Details

If $n_g = \text{nranges}$ is greater than one, $R$ is the maximum of $n_g$ groups of $n_{\text{means}}$ observations each.

Value

ptukey gives the distribution function and qtukey its inverse, the quantile function.

The length of the result is the maximum of the lengths of the numerical parameters. The other numerical parameters are recycled to that length. Only the first elements of the logical parameters are used.

Note

A Legendre 16-point formula is used for the integral of ptukey. The computations are relatively expensive, especially for qtukey which uses a simple secant method for finding the inverse of ptukey. qtukey will be accurate to the 4th decimal place.

Source

qtukey is in part adapted from Odeh and Evans (1974).

References

See Also

Distributions for standard distributions, including pnorm and qnorm for the corresponding functions for the normal distribution.

Examples

```r
if(interactive())
curve(ptukey(x, nm = 6, df = 5), from = -1, to = 8, n = 101)
(ptt <- ptukey(0:10, 2, df = 5))
(qtt <- qtukey(.95, 2, df = 2:11))
## The precision may be not much more than about 8 digits:
summary(abs(.95 - ptukey(qtt, 2, df = 2:11)))
```
TukeyHSD

Compute Tukey Honest Significant Differences

Description

Create a set of confidence intervals on the differences between the means of the levels of a factor with the specified family-wise probability of coverage. The intervals are based on the Studentized range statistic, Tukey’s ‘Honest Significant Difference’ method.

Usage

TukeyHSD(x, which, ordered = FALSE, conf.level = 0.95, ...)

Arguments

x A fitted model object, usually an aov fit.
which A character vector listing terms in the fitted model for which the intervals should be calculated. Defaults to all the terms.
ordered A logical value indicating if the levels of the factor should be ordered according to increasing average in the sample before taking differences. If ordered is true then the calculated differences in the means will all be positive. The significant differences will be those for which the lwr end point is positive.
conf.level A numeric value between zero and one giving the family-wise confidence level to use.
... Optional additional arguments. None are used at present.

Details

When comparing the means for the levels of a factor in an analysis of variance, a simple comparison using t-tests will inflate the probability of declaring a significant difference when it is not in fact present. This because the intervals are calculated with a given coverage probability for each interval but the interpretation of the coverage is usually with respect to the entire family of intervals.

John Tukey introduced intervals based on the range of the sample means rather than the individual differences. The intervals returned by this function are based on this Studentized range statistics.

The intervals constructed in this way would only apply exactly to balanced designs where there are the same number of observations made at each level of the factor. This function incorporates an adjustment for sample size that produces sensible intervals for mildly unbalanced designs.

If which specifies non-factor terms these will be dropped with a warning: if no terms are left this is an error.

In R 2.15.2 and earlier the results were NA for fits with na.action methods such as na.exclude.
Value

A list of class c("multicomp", "TukeyHSD"), with one component for each term requested in which. Each component is a matrix with columns diff giving the difference in the observed means, lwr giving the lower end point of the interval, upr giving the upper end point and p adj giving the p-value after adjustment for the multiple comparisons.

There are print and plot methods for class "TukeyHSD". The plot method does not accept xlab, ylab or main arguments and creates its own values for each plot.

Author(s)

Douglas Bates

References

See Also

aov, qtukey, model.tables, glht in package multcomp.

Examples

require(graphics)

summary(fm1 <- aov(breaks ~ wool + tension, data = warpbreaks))
TukeyHSD(fm1, "tension", ordered = TRUE)
plot(TukeyHSD(fm1, "tension"))

The Uniform Distribution

Description

These functions provide information about the uniform distribution on the interval from min to max.
dunif gives the density, punif gives the distribution function qunif gives the quantile function and runif generates random deviates.

Usage

dunif(x, min = 0, max = 1, log = FALSE)
punif(q, min = 0, max = 1, lower.tail = TRUE, log.p = FALSE)
qunif(p, min = 0, max = 1, lower.tail = TRUE, log.p = FALSE)
runif(n, min = 0, max = 1)
Arguments

- **x, q**: vector of quantiles.
- **p**: vector of probabilities.
- **n**: number of observations. If length(n) > 1, the length is taken to be the number required.
- **min, max**: lower and upper limits of the distribution. Must be finite.
- **log, log.p**: logical; if TRUE, probabilities p are given as log(p).
- **lower.tail**: logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

If min or max are not specified they assume the default values of 0 and 1 respectively.

The uniform distribution has density

\[
 f(x) = \frac{1}{max - min}
\]

for \( min \leq x \leq max \).

For the case of \( u := min == max \), the limit case of \( X \equiv u \) is assumed, although there is no density in that case and dunif will return NaN (the error condition).

runif will not generate either of the extreme values unless max = min or max-min is small compared to min, and in particular not for the default arguments.

Value

dunif gives the density, punif gives the distribution function, qunif gives the quantile function, and runif generates random deviates.

The length of the result is determined by n for runif, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than n are recycled to the length of the result. Only the first elements of the logical parameters are used.

Note

The characteristics of output from pseudo-random number generators (such as precision and periodicity) vary widely. See `.Random.seed` for more information on R’s random number generation algorithms.

References

See Also

RNG about random number generation in R.

Distributions for other standard distributions.
Examples

u <- runif(20)

## The following relations always hold :
punif(u) == u
dunif(u) == 1

var(runif(10000)) # ~ 1/12 = .08333

uniroot

One Dimensional Root (Zero) Finding

Description

The function uniroot searches the interval from lower to upper for a root (i.e., zero) of the function f with respect to its first argument.

Usage

uniroot(f, interval, ..., lower = min(interval), upper = max(interval),
        f.lower = f(lower, ...), f.upper = f(upper, ...),
        tol = .Machine$double.eps^0.25, maxiter = 1000)

Arguments

f the function for which the root is sought.
interval a vector containing the end-points of the interval to be searched for the root.
... additional named or unnamed arguments to be passed to f
lower, upper the lower and upper end points of the interval to be searched.
f.lower, f.upper the same as f(upper) and f(lower), respectively. Passing these values from the caller where they are often known is more economical as soon as f() contains non-trivial computations.
tol the desired accuracy (convergence tolerance).
maxiter the maximum number of iterations.

Details

Note that arguments after ... must be matched exactly.

Either interval or both lower and upper must be specified: the upper endpoint must be strictly larger than the lower endpoint. The function values at the endpoints must be of opposite signs (or zero).

The function uses Fortran subroutine "zeroin" (from Netlib) based on algorithms given in the reference below. They assume a continuous function (which then is known to have at least one root in the interval).
Convergence is declared either if \( f(x) = 0 \) or the change in \( x \) for one step of the algorithm is less than \( \text{tol} \) (plus an allowance for representation error in \( x \)).

If the algorithm does not converge in \( \text{maxiter} \) steps, a warning is printed and the current approximation is returned.

\( f \) will be called as \( f(x, \ldots) \) for a numeric value of \( x \).

The argument passed to \( f \) has special semantics and used to be shared between calls. The function should not copy it.

**Value**

A list with four components: root and \( f \).root give the location of the root and the value of the function evaluated at that point. iter and estim.prec give the number of iterations used and an approximate estimated precision for root. (If the root occurs at one of the endpoints, the estimated precision is NA.)

**Source**

**References**

**See Also**

polyroot for all complex roots of a polynomial; optimize, nlm.

**Examples**

```r
require(utils) # for str

## some platforms hit zero exactly on the first step:
## if so the estimated precision is 2/3.
\( f \) <- function (x, a) x - a
str(xmin <- uniroot(f, c(\( \text{zero} \), 1), tol = \( \text{zero}/100 \), a = 1/3))

## handheld calculator example: fixed point of \( \cos(\cdot) \):
uniroot(function(x) \cos(x) - x, lower = -pi, upper = pi, tol = 1e-9)$root

str(uniroot(function(x) x*(x^2-1) + .5, lower = -2, upper = 2, tol = \( \text{zero}/100 \)))

str(uniroot(function(x) x*(x^2-1) + .5, lower = -2, upper = 2, tol = 1e-10)))

## Find the smallest value \( x \) for which \( \exp(x) > \text{zero} \) (numerically):
\( r \) <- uniroot(function(x) 1e80*exp(x) - 1e-300, c(-1000, 0), tol = 1e-15)
str(r, digits.d = 15) # around -745, depending on the platform.

exp(r$root) # = 0, but not for r$root * 0.999...
```
update <- r$root * (1 - 10*.Machine$double.eps)
exp(minexp)  # typically denormalized

---

**update**

**Update and Re-fit a Model Call**

**Description**

`update` will update and (by default) re-fit a model. It does this by extracting the call stored in the object, updating the call and (by default) evaluating that call. Sometimes it is useful to call `update` with only one argument, for example if the data frame has been corrected.

“Extracting the call” in `update()` and similar functions uses `getCall()` which itself is a (S3) generic function with a default method that simply gets `x$call`.

Because of this, `update()` will often work (via its default method) on new model classes, either automatically, or by providing a simple `getCall()` method for that class.

**Usage**

```r
update(object, ...) 
## Default S3 method: 
update(object, formula., ..., evaluate = TRUE) 
getCall(x, ...) 
```

**Arguments**

- `object, x` An existing fit from a model function such as `lm`, `glm` and many others.
- `formula.` Changes to the formula – see `update.formula` for details.
- `...` Additional arguments to the call, or arguments with changed values. Use `name = NULL` to remove the argument name.
- `evaluate` If true evaluate the new call else return the call.

**Value**

If `evaluate = TRUE` the fitted object, otherwise the updated call.

**References**

**See Also**

`update.formula`
Examples

```r
oldcon <- options(contrasts = c("contr.treatment", "contr.poly"))
## Annette Dobson (1990) "An Introduction to Generalized Linear Models".
## Page 9: Plant Weight Data.
ctl <- c(4.17, 5.58, 5.18, 6.11, 4.61, 5.17, 5.53, 5.33, 5.14)
trt <- c(4.81, 4.17, 4.41, 3.59, 5.87, 3.83, 6.03, 4.89, 4.69)
group <- gl(2, 10, 20, labels = c("Ctl", "Trt"))
weight <- c(ctl, trt)

lm.D9 <- lm(weight ~ group)

summary(lm.D9 <- update(lm.D9, . ~ . - 1))
options(contrasts = c("contr.helmert", "contr.poly"))
update(lm.D9)
getCall(lm.D9) # "through the origin"

options(oldcon)
```

update.formula

---

### Model Updating

#### Description

update.formula is used to update model formulae. This typically involves adding or dropping terms, but updates can be more general.

#### Usage

```r
## S3 method for class 'formula'
update(old, new, ...)
```

#### Arguments

- `old` a model formula to be updated.
- `new` a formula giving a template which specifies how to update.
- `...` further arguments passed to or from other methods.

#### Details

Either or both of `old` and `new` can be objects such as length-one character vectors which can be coerced to a formula via `as.formula`.

The function works by first identifying the left-hand side and right-hand side of the `old` formula. It then examines the new formula and substitutes the `lhs` of the `old` formula for any occurrence of `.` on the left of `new`, and substitutes the `rhs` of the `old` formula for any occurrence of `.` on the right of `new`. The result is then simplified via `terms.formula(simplify = TRUE)`.

#### Value

The updated formula is returned. The environment of the result is that of `old`. 
var.test

F Test to Compare Two Variances

Perform an F test to compare the variances of two samples from normal populations.

Usage

var.test(x, ...)

## Default S3 method:
var.test(x, y, ratio = 1,
  alternative = c("two.sided", "less", "greater"),
  conf.level = 0.95, ...)

## S3 method for class 'formula'
var.test(formula, data, subset, na.action, ...)

Arguments

x, y            numeric vectors of data values, or fitted linear model objects (inheriting from class "lm").
ratio           the hypothesized ratio of the population variances of x and y.
alternative     a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.
conf.level      confidence level for the returned confidence interval.
formula         a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups.
data             an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset          an optional vector specifying a subset of observations to be used.
na.action       a function which indicates what should happen when the data contain NAs. Defaults togetOption("na.action").
...             further arguments to be passed to or from methods.

See Also

terms, model.matrix.

Examples

update(y ~ x, ~ . + x2) #> y ~ x + x2
update(y ~ x, log(.) ~ . ) #> log(y) ~ x
Details

The null hypothesis is that the ratio of the variances of the populations from which \( x \) and \( y \) were drawn, or in the data to which the linear models \( x \) and \( y \) were fitted, is equal to \( \text{ratio} \).

Value

A list with class "htest" containing the following components:

- **statistic**: the value of the F test statistic.
- **parameter**: the degrees of the freedom of the F distribution of the test statistic.
- **p.value**: the p-value of the test.
- **conf.int**: a confidence interval for the ratio of the population variances.
- **estimate**: the ratio of the sample variances of \( x \) and \( y \).
- **null.value**: the ratio of population variances under the null.
- **alternative**: a character string describing the alternative hypothesis.
- **method**: the character string "F test to compare two variances".
- **data.name**: a character string giving the names of the data.

See Also

- **bartlett.test** for testing homogeneity of variances in more than two samples from normal distributions; **ansari.test** and **mood.test** for two rank based (nonparametric) two-sample tests for difference in scale.

Examples

```r
x <- rnorm(50, mean = 0, sd = 2)
y <- rnorm(30, mean = 1, sd = 1)
var.test(x, y) # Do x and y have the same variance?
var.test(lm(x ~ 1), lm(y ~ 1)) # The same.
```

Description

These functions 'rotate' loading matrices in factor analysis.

Usage

```r
varimax(x, normalize = TRUE, eps = 1e-5)
promax(x, m = 4)
```
Arguments

- **x** A loadings matrix, with \( p \) rows and \( k < p \) columns
- **m** The power used the target for **promax**. Values of 2 to 4 are recommended.
- **normalize** logical. Should Kaiser normalization be performed? If so the rows of \( x \) are re-scaled to unit length before rotation, and scaled back afterwards.
- **eps** The tolerance for stopping: the relative change in the sum of singular values.

Details

These seek a ‘rotation’ of the factors \( x \ %*% T \) that aims to clarify the structure of the loadings matrix. The matrix \( T \) is a rotation (possibly with reflection) for **varimax**, but a general linear transformation for **promax**, with the variance of the factors being preserved.

Value

A list with components

- **loadings** The ‘rotated’ loadings matrix, \( x \ %*% \text{rotmat} \), of class "loadings".
- **rotmat** The ‘rotation’ matrix.

References

See Also

- **factanal**, **Harman74.cor**.

Examples

```r
## varimax with normalize = TRUE is the default
fa <- factanal(~., 2, data = swiss)
varimax(loadings(fa), normalize = FALSE)
promax(loadings(fa))
```
vcov

*Calculate Variance-Covariance Matrix for a Fitted Model Object*

**Description**

Returns the variance-covariance matrix of the main parameters of a fitted model object.

**Usage**

\[
\text{vcov(object, ...)}
\]

**Arguments**

- `object`: a fitted model object, typically. Sometimes also a `summary()` object of such a fitted model.
- `...`: additional arguments for method functions. For the `glm` method this can be used to pass a dispersion parameter.

**Details**

This is a generic function. Functions with names beginning in `vcov` will be methods for this function. Classes with methods for this function include: `lm`, `mlm`, `glm`, `nls`, `summary.lm`, `summary.glm`, `negbin`, `polr`, `rlm` (in package `MASS`), `multinom` (in package `nnet`), `gls`, `lme` (in package `nlme`), `coxph` and `survreg` (in package `survival`).

(\text{vcov()} \text{ methods for summary objects allow more efficient and still encapsulated access when both summary(mod) and vcov(mod) are needed.})

**Value**

A matrix of the estimated covariances between the parameter estimates in the linear or non-linear predictor of the model. This should have row and column names corresponding to the parameter names given by the \text{coef} method.

---

**Weibull**

**The Weibull Distribution**

**Description**

Density, distribution function, quantile function and random generation for the Weibull distribution with parameters shape and scale.

**Usage**

\[
\begin{align*}
\text{dweibull}(x, \text{shape}, \text{scale} = 1, \text{log} = \text{FALSE}) \\
\text{pweibull}(q, \text{shape}, \text{scale} = 1, \text{lower.tail} = \text{TRUE}, \text{log.p} = \text{FALSE}) \\
\text{qweibull}(p, \text{shape}, \text{scale} = 1, \text{lower.tail} = \text{TRUE}, \text{log.p} = \text{FALSE}) \\
\text{rweibull}(n, \text{shape}, \text{scale} = 1)
\end{align*}
\]
Weibull

Arguments

- **x, q**: vector of quantiles.
- **p**: vector of probabilities.
- **n**: number of observations. If `length(n) > 1`, the length is taken to be the number required.
- **shape, scale**: shape and scale parameters, the latter defaulting to 1.
- **log, log.p**: logical; if TRUE, probabilities p are given as log(p).
- **lower.tail**: logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

The Weibull distribution with shape parameter $a$ and scale parameter $\sigma$ has density given by

$$f(x) = \left(\frac{a}{\sigma}\right)(x/\sigma)^{a-1}\exp(-(x/\sigma)^a)$$

for $x > 0$. The cumulative distribution function is $F(x) = 1 - \exp(-(x/\sigma)^a)$ on $x > 0$, the mean is $E(X) = \sigma\Gamma(1 + 1/a)$, and the $Var(X) = \sigma^2(\Gamma(1 + 2/a) - (\Gamma(1 + 1/a))^2)$.

Value

dweibull gives the density, pweibull gives the distribution function, qweibull gives the quantile function, and rweibull generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by n for rweibull, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than n are recycled to the length of the result. Only the first elements of the logical parameters are used.

Note

The cumulative hazard $H(t) = -\log(1 - F(t))$ is

$$-\text{pweibull}(t, a, b, \text{lower} = \text{FALSE}, \text{log} = \text{TRUE})$$

which is just $H(t) = (t/b)^a$.

Source

[dpq]weibull are calculated directly from the definitions. rweibull uses inversion.

References

See Also

Distributions for other standard distributions, including the Exponential which is a special case of the Weibull distribution.

Examples

```r
x <- c(0, rlnorm(50))
all.equal(dweibull(x, shape = 1), dexp(x))
all.equal(pweibull(x, shape = 1, scale = pi), pexp(x, rate = 1/pi))
## Cumulative hazard H():
all.equal(pweibull(x, 2.5, pi, lower.tail = FALSE, log.p = TRUE),
  -(x/pi)^2.5, tol = 1e-15)
all.equal(qweibull(x/11, shape = 1, scale = pi), qexp(x/11, rate = 1/pi))
```

---

**weighted.mean**

Weighted Arithmetic Mean

Description

Compute a weighted mean.

Usage

```r
weighted.mean(x, w, ...)
```

## Default S3 method:

```r
weighted.mean(x, w, ..., na.rm = FALSE)
```

Arguments

- `x`: an object containing the values whose weighted mean is to be computed.
- `w`: a numerical vector of weights the same length as `x` giving the weights to use for elements of `x`.
- `...`: arguments to be passed to or from methods.
- `na.rm`: a logical value indicating whether NA values in `x` should be stripped before the computation proceeds.

Details

This is a generic function and methods can be defined for the first argument `x`: apart from the default methods there are methods for the date-time classes "POSIXct", "POSIXlt", "difftime" and "Date". The default method will work for any numeric-like object for which `[`, multiplication, division and `sum` have suitable methods, including complex vectors.

If `w` is missing then all elements of `x` are given the same weight, otherwise the weights coerced to numeric by `as.numeric` and normalized to sum to one (if possible: if their sum is zero or infinite the value is likely to be NaN).
Missing values in \( w \) are not handled specially and so give a missing value as the result. However, as from \( \text{R 2.11.0} \) zero weights are handled specially and the corresponding \( x \) values are omitted from the sum.

**Value**

For the default method, a length-one numeric vector.

**See Also**

*mean*

**Examples**

```r
## GPA from Siegel 1994
wt <- c(5, 5, 4, 1)/15
x <- c(3.7, 3.3, 3.5, 2.8)
xm <- weighted.mean(x, wt)
```

---

**weighted.residuals**

*Compute Weighted Residuals*

**Description**

Computed weighted residuals from a linear model fit.

**Usage**

```r
weighted.residuals(obj, drop0 = TRUE)
```

**Arguments**

- `obj` \( \text{R object, typically of class } \text{lm or glm}. \)
- `drop0` \( \text{logical. If TRUE, drop all cases with } \text{weights } == 0. \)

**Details**

Weighted residuals are based on the deviance residuals, which for a \( \text{lm} \) fit are the raw residuals \( R_i \) multiplied by \( \sqrt{w_i} \), where \( w_i \) are the weights as specified in \( \text{lm}'s call. \)

Dropping cases with weights zero is compatible with \text{influence} and related functions.

**Value**

Numeric vector of length \( n' \), where \( n' \) is the number of of non-0 weights \( (\text{drop0 } == \text{TRUE}) \) or the number of observations, otherwise.

**See Also**

*residuals, lm.influence, etc.*
Examples

```r
## following on from example(lm)

all.equal(weighted.residuals(lm.D9),
residuals(lm.D9))
x <- 1:10
w <- 0:9
y <- rnorm(x)
weighted.residuals(lmxy <- lm(y ~ x, weights = w))
weighted.residuals(lmxy, drop0 = FALSE)
```

weights

*Extract Model Weights*

Description

weights is a generic function which extracts fitting weights from objects returned by modeling functions.

Methods can make use of `napredict` methods to compensate for the omission of missing values. The default methods does so.

Usage

```r
weights(object, ...)
```

Arguments

- `object`: an object for which the extraction of model weights is meaningful.
- `...`: other arguments passed to methods.

Value

Weights extracted from the object object: the default method looks for component "weights" and if not NULL calls `napredict` on it.

References

See Also

- `weights.glm`
Description

Performs one- and two-sample Wilcoxon tests on vectors of data; the latter is also known as 'Mann-Whitney' test.

Usage

wilcox.test(x, ...)

## Default S3 method:
wilcox.test(x, y = NULL,
    alternative = c("two.sided", "less", "greater"),
    mu = 0, paired = FALSE, exact = NULL, correct = TRUE,
    conf.int = FALSE, conf.level = 0.95, ...)

## S3 method for class 'formula'
wilcox.test(formula, data, subset, na.action, ...)

Arguments

x numeric vector of data values. Non-finite (e.g. infinite or missing) values will be omitted.

y an optional numeric vector of data values: as with x non-finite values will be omitted.

alternative a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.

mu a number specifying an optional parameter used to form the null hypothesis. See 'Details'.

paired a logical indicating whether you want a paired test.

exact a logical indicating whether an exact p-value should be computed.

correct a logical indicating whether to apply continuity correction in the normal approximation for the p-value.

conf.int a logical indicating whether a confidence interval should be computed.

conf.level confidence level of the interval.

formula a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups.

data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset an optional vector specifying a subset of observations to be used.
na.action a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").

... further arguments to be passed to or from methods.

Details

The formula interface is only applicable for the 2-sample tests.

If only x is given, or if both x and y are given and paired is TRUE, a Wilcoxon signed rank test of the null that the distribution of x (in the one sample case) or of x - y (in the paired two sample case) is symmetric about mu is performed.

Otherwise, if both x and y are given and paired is FALSE, a Wilcoxon rank sum test (equivalent to the Mann-Whitney test: see the Note) is carried out. In this case, the null hypothesis is that the distributions of x and y differ by a location shift of mu and the alternative is that they differ by some other location shift (and the one-sided alternative "greater" is that x is shifted to the right of y).

By default (if exact is not specified), an exact p-value is computed if the samples contain less than 50 finite values and there are no ties. Otherwise, a normal approximation is used.

Optionally (if argument conf.int is true), a nonparametric confidence interval and an estimator for the pseudomedian (one-sample case) or for the difference of the location parameters x-y is computed. (The pseudomedian of a distribution F is the median of the distribution of (u + v)/2, where u and v are independent, each with distribution F. If F is symmetric, then the pseudomedian and median coincide. See Hollander & Wolfe (1973), page 34.) Note that in the two-sample case the estimator for the difference in location parameters does not estimate the difference in medians (a common misconception) but rather the median of the difference between a sample from x and a sample from y.

If exact p-values are available, an exact confidence interval is obtained by the algorithm described in Bauer (1972), and the Hodges-Lehmann estimator is employed. Otherwise, the returned confidence interval and point estimate are based on normal approximations. These are continuity-corrected for the interval but not the estimate (as the correction depends on the alternative).

With small samples it may not be possible to achieve very high confidence interval coverages. If this happens a warning will be given and an interval with lower coverage will be substituted.

Value

A list with class "htest" containing the following components:

  statistic the value of the test statistic with a name describing it.
  parameter the parameter(s) for the exact distribution of the test statistic.
  p.value the p-value for the test.
  null.value the location parameter mu.
  alternative a character string describing the alternative hypothesis.
  method a character string describing the type of test applied.
  data.name a character string giving the names of the data.
  conf.int a confidence interval for the location parameter. (Only present if argument conf.int = TRUE.)
  estimate an estimate of the location parameter. (Only present if argument conf.int = TRUE.)
Warning

This function can use large amounts of memory and stack (and even crash R if the stack limit is exceeded) if exact = TRUE and one sample is large (several thousands or more).

Note

The literature is not unanimous about the definitions of the Wilcoxon rank sum and Mann-Whitney tests. The two most common definitions correspond to the sum of the ranks of the first sample with the minimum value subtracted or not: R subtracts and S-PLUS does not, giving a value which is larger by \( m(m+1)/2 \) for a first sample of size \( m \). (It seems Wilcoxon's original paper used the unadjusted sum of the ranks but subsequent tables subtracted the minimum.)

R's value can also be computed as the number of all pairs \((x[i], y[j])\) for which \( y[j] \) is not greater than \( x[i] \), the most common definition of the Mann-Whitney test.

References

## Hamilton depression scale factor measurements in 9 patients with
## mixed anxiety and depression, taken at the first (x) and second
## (y) visit after initiation of a therapy (administration of a
## tranquilizer).

x <- c(1.83, 0.50, 1.62, 2.48, 1.68, 1.88, 1.55, 3.6, 1.3)
y <- c(0.878, 0.647, 0.598, 2.5, 1.29, 1.29)
wilcox.test(x, y, paired = TRUE, alternative = "greater")
wilcox.test(y - x, alternative = "less") # The same.
wilcox.test(y - x, alternative = "less", exact = FALSE, correct = FALSE) # H&W large sample

## Two-sample test.
## Hollander & Wolfe (1973), 69f.
```
Permeability constants of the human chorioamnion (a placental membrane) at term (x) and between 12 to 26 weeks gestational age (y). The alternative of interest is greater permeability of the human chorioamnion for the term pregnancy.

```
x <- c(0.80, 0.83, 1.89, 1.04, 1.45, 1.38, 1.91, 1.64, 0.73, 1.46)
y <- c(1.15, 0.88, 0.97, 0.73, 1.21)
wilcox.test(x, y, alternative = "g")  # greater
wilcox.test(x, y, alternative = "greater", 
            exact = FALSE, correct = FALSE) # H&W large sample
            # approximation
wilcox.test(rnorm(10), rnorm(10, 2), conf.int = TRUE)
```

## Wilcoxon

### Distribution of the Wilcoxon Rank Sum Statistic

**Description**

Density, distribution function, quantile function and random generation for the distribution of the Wilcoxon rank sum statistic obtained from samples with size \(m\) and \(n\), respectively.

**Usage**

```
dwilcox(x, m, n, log = FALSE)
pwilcox(q, m, n, lower.tail = TRUE, log.p = FALSE)
qwilcox(p, m, n, lower.tail = TRUE, log.p = FALSE)
rwilcox(nn, m, n)
```

**Arguments**

- `x, q` vector of quantiles.
- `p` vector of probabilities.
- `nn` number of observations. If `length(nn) > 1`, the length is taken to be the number required.
- `m, n` numbers of observations in the first and second sample, respectively. Can be vectors of positive integers.
- `log, log.p` logical; if TRUE, probabilities p are given as log(p).
- `lower.tail` logical; if TRUE (default), probabilities are \(P[X \leq x]\), otherwise, \(P[X > x]\).
Wilcoxon

Details

This distribution is obtained as follows. Let \( x \) and \( y \) be two random, independent samples of size \( m \) and \( n \). Then the Wilcoxon rank sum statistic is the number of all pairs \( (x[i], y[j]) \) for which \( y[j] \) is not greater than \( x[i] \). This statistic takes values between 0 and \( m \times n \), and its mean and variance are \( m \times n / 2 \) and \( m \times n \times (m + n + 1) / 12 \), respectively.

If any of the first three arguments are vectors, the recycling rule is used to do the calculations for all combinations of the three up to the length of the longest vector.

Value

dwilcoxon gives the density, pwilcoxon gives the distribution function, qwilcoxon gives the quantile function, and rwilcoxon generates random deviates.

The length of the result is determined by \( nn \) for rwilcoxon, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than \( nn \) are recycled to the length of the result. Only the first elements of the logical parameters are used.

Warning

These functions can use large amounts of memory and stack (and even crash R if the stack limit is exceeded and stack-checking is not in place) if one sample is large (several thousands or more).

Note

S-PLUS uses a different (but equivalent) definition of the Wilcoxon statistic: see wilcox.test for details.

Author(s)

Kurt Hornik

Source

These are calculated via recursion, based on cwilcoxon(k, m, n), the number of choices with statistic \( k \) from samples of size \( m \) and \( n \), which is itself calculated recursively and the results cached. Then dwilcoxon and pwilcoxon sum appropriate values of cwilcoxon, and qwilcoxon is based on inversion.

rwilcoxon generates a random permutation of ranks and evaluates the statistic.

See Also

wilcox.test to calculate the statistic from data, find p values and so on.

Distributions for standard distributions, including dsignrank for the distribution of the one-sample Wilcoxon signed rank statistic.
Examples

```r
require(graphics)

x <- -1:(4*6 + 1)
fx <- dwilcox(x, 4, 6)
Fx <- pwilcox(x, 4, 6)

layout(rbind(1,2), widths = 1, heights = c(3,2))
plot(x, fx, type = "h", col = "violet",
     main = "Probabilities (density) of Wilcoxon-Statist.(n=6, m=4)"
)
plot(x, Fx, type = "s", col = "blue",
     main = "Distribution of Wilcoxon-Statist.(n=6, m=4)"
)
abline(h = 0:1, col = "gray20", lty = 2)
layout(1) # set back

N <- 200
hist(U <- rwilcox(N, m = 4, n = 6), breaks = 0:25 - 1/2,
     border = "red", col = "pink", sub = paste("N =",N))

mtext("N * f(x), f() = true \"density\"", side = 3, col = "blue")
lines(x, N*fx, type = "h", col = "blue", lwd = 2)
points(x, N*fx, cex = 2)

## Better is a Quantile-Quantile Plot
qqplot(U, qw <- qwilcox((1:N - 1/2)/N, m = 4, n = 6),
       main = paste("Q-Q-Plot of empirical and theoretical quantiles",
                    "Wilcoxon Statistic, (m=4, n=6)"))
n <- as.numeric(names(print(tU <- table(U))))
text(n+.2, n+.5, labels = tU, col = "red")
```

Description

`window` is a generic function which extracts the subset of the object `x` observed between the times `start` and `end`. If a frequency is specified, the series is then re-sampled at the new frequency.

Usage

```r
window(x, ...)
## S3 method for class 'ts'
window(x, ...)
## Default S3 method:
window(x, start = NULL, end = NULL,
       frequency = NULL, deltat = NULL, extend = FALSE, ...)

window(x, ...) <- value
## S3 replacement method for class 'ts'
window(x, start, end, frequency, deltat, ...) <- value
```
Arguments

- **x**: a time-series (or other object if not replacing values).
- **start**: the start time of the period of interest.
- **end**: the end time of the period of interest.
- **frequency, deltat**: the new frequency can be specified by either (or both if they are consistent).
- **extend**: logical. If true, the start and end values are allowed to extend the series. If false, attempts to extend the series give a warning and are ignored.
- **...**: further arguments passed to or from other methods.
- **value**: replacement values.

Details

The start and end times can be specified as for `ts`. If there is no observation at the new start or end, the immediately following (start) or preceding (end) observation time is used. The replacement function has a method for `ts` objects, and is allowed to extend the series (with a warning). There is no default method.

Value

The value depends on the method. `window.default` will return a vector or matrix with an appropriate `tsp` attribute. `window.ts` differs from `window.default` only in ensuring the result is a `ts` object. If `extend = TRUE` the series will be padded with NAs if needed.

References

See Also

- `time`, `ts`.

Examples

```r
window(presidents, 1960, c(1969,4)) # values in the 1960's
window(presidents, deltat = 1) # All Qtr1s
window(presidents, start = c(1945,3), deltat = 1) # All Qtr3s
window(presidents, 1944, c(1979,2), extend = TRUE)

pres <- window(presidents, 1945, c(1949,4)) # values in the 1940's
window(pres, 1945.25, 1945.5) <- c(6, 7) # will generate a warning
window(pres, c(1945,4), c(1949,4), frequency = 1) <- 85:89
pres
```
xtabs  

Cross Tabulation

Description

Create a contingency table (optionally a sparse matrix) from cross-classifying factors, usually contained in a data frame, using a formula interface.

Usage

xtabs(formula = ~., data = parent.frame(), subset, sparse = FALSE, na.action, exclude = c(NA, NaN), drop.unused.levels = FALSE)

Arguments

- **formula**: a formula object with the cross-classifying variables (separated by +) on the right hand side (or an object which can be coerced to a formula). Interactions are not allowed. On the left hand side, one may optionally give a vector or a matrix of counts; in the latter case, the columns are interpreted as corresponding to the levels of a variable. This is useful if the data have already been tabulated, see the examples below.

- **data**: an optional matrix or data frame (or similar; see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.

- **subset**: an optional vector specifying a subset of observations to be used.

- **sparse**: logical specifying if the result should be a sparse matrix, i.e., inheriting from `sparseMatrix` Only works for two factors (since there are no higher-order sparse array classes yet).

- **na.action**: a function which indicates what should happen when the data contain NAs.

- **exclude**: a vector of values to be excluded when forming the set of levels of the classifying factors.

- **drop.unused.levels**: a logical indicating whether to drop unused levels in the classifying factors. If this is FALSE and there are unused levels, the table will contain zero marginals, and a subsequent chi-squared test for independence of the factors will not work.

Details

There is a summary method for contingency table objects created by `table` or `xtabs(*, sparse = FALSE)`, which gives basic information and performs a chi-squared test for independence of factors (note that the function `chisq.test` currently only handles 2-d tables).

If a left hand side is given in `formula`, its entries are simply summed over the cells corresponding to the right hand side; this also works if the lhs does not give counts.

For variables in `formula` which are factors, `exclude` must be specified explicitly; the default exclusions will not be used.
xtabs

Value

By default, when sparse = FALSE, a contingency table in array representation of S3 class c("xtabs", "table"), with a "call" attribute storing the matched call.

When sparse = TRUE, a sparse numeric matrix, specifically an object of S4 class dgTMatrix from package Matrix.

See Also

table for traditional cross-tabulation, and as.data.frame.table which is the inverse operation of xtabs (see the DF example below).

sparseMatrix on sparse matrices in package Matrix.

Examples

## 'esoph' has the frequencies of cases and controls for all levels of
## the variables 'agegp', 'alcp', and 'tobgp'.
xtabs(cbind(ncases, ncontrols) ~ ., data = esoph)
## Output is not really helpful ... flat tables are better:
ftable(xtabs(cbind(ncases, ncontrols) ~ ., data = esoph))
## In particular if we have fewer factors ...
ftable(xtabs(cbind(ncases, ncontrols) ~ agegp, data = esoph))

## This is already a contingency table in array form.
DF <- as.data.frame(UCBAdmissions)
## Now 'DF' is a data frame with a grid of the factors and the counts
## in variable 'Freq'.
DF
## Nice for taking margins ...
xtabs(Freq ~ Gender + Admit, DF)
## And for testing independence ...
summary(xtabs(Freq ~ ., DF))

## Create a nice display for the warp break data.
warpbreaks$replicate <- rep(1:9, len = 54)
ftable(xtabs(breaks ~ wool + tension + replicate, data = warpbreaks))

### ---- Sparse Examples ----
if(require("Matrix")) {
  ## similar to "nlme"'s 'ergoStool':
d.ergo <- data.frame(Type = paste(0("T", rep(1:4, 9*4)),
                        Subj = gl(9, 4, 36*4))
print(xtabs(~ Type + Subj, data = d.ergo)) # 4 replicates each
set.seed(15) # a subset of cases:
print(xtabs(~ Type + Subj, data = d.ergo[sample(36, 1, replace = TRUE)])

## Hypothetical two level setup:
inner <- factor(sample(letters[1:25], 100, replace = TRUE))
inout <- factor(sample(LETTERS[1:5], 25, replace = TRUE))
fr <- data.frame(inner = inner, outer = inout[as.integer(inner)])
print(xtabs(~ inner + outer, fr, sparse = TRUE))

xtabs

)
Chapter 12

The `tcltk` package

---

tcltk-package  

Tcl/Tk Interface

---

**Description**

Interface and language bindings to Tcl/Tk GUI elements.

**Details**

This package provides access to the platform-independent Tcl scripting language and Tk GUI elements. See `TkWidgets` for a list of supported widgets, `TkWidgetcmds` for commands to work with them, and references in those files for more.

The Tcl/Tk documentation is in the system man pages.

For a complete list of functions, use `ls("package:tcltk")`.

Note that Tk will not be initialized if there is no `DISPLAY` variable set, but Tcl can still be used. This is most useful to allow the loading of a package which depends on `tcltk` in a session that does not actually use it (e.g. during installation).

**Author(s)**

R Core Team

Maintainer: R Core Team <R-core@r-project.org>
TclInterface

Low-level Tcl/Tk Interface

Description

These functions and variables provide the basic glue between R and the Tcl interpreter and Tk GUI toolkit. Tk windows may be represented via R objects. Tcl variables can be accessed via objects of class tclVar and the C level interface to Tcl objects is accessed via objects of class tclObj.

Usage

.Tcl(...)  
.Tcl.objv(objv)  
.Tcl.args(...)  
.Tcl.args.objv(...)  
.Tcl.callback(...)  
.Tk.ID(win)  
.Tk.newwin(ID)  
.Tk.subwin(parent)  
.TkRoot

tkdestroy(win)  
is.tkwin(x)

tclvalue(x)  
tclvalue(x) <- value

tclVar(init = "")  
## S3 method for class 'tclVar'  
as.character(x, ...)  
## S3 method for class 'tclVar'  
tclvalue(x)  
## S3 replacement method for class 'tclVar'  
tclvalue(x) <- value

tclArray()  
## S3 method for class 'tclArray'  
x[[...]]  
## S3 replacement method for class 'tclArray'  
x[[...]] <- value  
## S3 method for class 'tclArray'  
x$i  
## S3 replacement method for class 'tclArray'  
x$i <- value

## S3 method for class 'tclArray'  
names(x)
## S3 method for class 'tclArray'
length(x)

tclObj(x)
tclObj(x) <- value
## S3 method for class 'tclVar'
tclObj(x)
## S3 replacement method for class 'tclVar'
tclObj(x) <- value

as.tclObj(x, drop = FALSE)
is.tclObj(x)

## S3 method for class 'tclObj'
as.character(x, ...)
## S3 method for class 'tclObj'
as.integer(x, ...)
## S3 method for class 'tclObj'
as.double(x, ...)
## S3 method for class 'tclObj'
as.logical(x, ...)
## S3 method for class 'tclObj'
as.raw(x, ...)
## S3 method for class 'tclObj'
tclvalue(x)

## Default S3 method:
tclvalue(x)
## Default S3 replacement method:
tclvalue(x) <- value

addTclPath(path = ".")
tclRequire(package, warn = TRUE)

### Arguments

- **objv**
  - a named vector of Tcl objects

- **win**
  - a window structure

- **x**
  - an object

- **i**
  - character or (unquoted) name

- **drop**
  - logical. Indicates whether a single-element vector should be made into a simple Tcl object or a list of length one

- **value**
  - For tclvalue assignments, a character string. For tclObj assignments, an object of class tclObj

- **ID**
  - a window ID

- **parent**
  - a window which becomes the parent of the resulting window
path path to a directory containing Tcl packages
package a Tcl package name
warn logical. Warn if not found?
... Additional arguments. See below.
init initialization value

Details

Many of these functions are not intended for general use but are used internally by the commands that create and manipulate Tk widgets and Tcl objects. At the lowest level, .Tcl sends a command as a text string to the Tcl interpreter and returns the result as an object of class tclObj (see below). A newer variant .Tcl.objv accepts arguments in the form of a named list of tclObj objects.

.Tcl.args converts an R argument list of tag = value pairs to the Tcl -option value style, thus enabling a simple translation between the two languages. To send a value with no preceding option flag to Tcl, just use an untagged argument. In the rare case one needs an option with no subsequent value tag = NULL can be used. Most values are just converted to character mode and inserted in the command string, but window objects are passed using their ID string, and callbacks are passed via the result of .Tcl.callback. Tags are converted to option flags simply by prepending a -

.Tcl.args.objv serves a similar purpose as .Tcl.args but produces a list of tclObj objects suitable for passing to .Tcl.objv. The names of the list are converted to Tcl option style internally by .Tcl.objv.

Callbacks can be either atomic callbacks handled by .Tcl.callback or expressions. An expression is treated as a list of atomic callbacks, with the following exceptions: if an element is a name, it is first evaluated in the callers frame, and likewise if it is an explicit function definition; the break expression is translated directly to the Tcl counterpart. .Tcl.callback converts R functions and unevaluated calls to Tcl command strings. The argument must be either a function closure or an object of mode "call" followed by an environment. The return value in the first case is of the form R_call 0x408b94d4 in which the hexadecimal number is the memory address of the function. In the second case it will be of the form R_call_lang 0x8a95904 0x819bf0. For expressions, a sequence of similar items is generated, separated by semicolons. .Tcl.args takes special precautions to ensure that functions or calls will continue to exist at the specified address by assigning the callback into the relevant window environment (see below).

Tk windows are represented as objects of class tkwin which are lists containing a ID field and an env field which is an R environments, enclosed in the global environment. The value of the ID field is identical to the Tk window name. The env environment contains a parent variable and a num.subwin variable. If the window obtains sub-windows and callbacks, they are added as variables to the environment. .TkRoot is the top window with ID "."; this window is not displayed in order to avoid ill effects of closing it via window manager controls. The parent variable is undefined for .TkRoot.

.Tk.ID extracts the ID of a window, .Tk.newwin creates a new window environment with a given ID and .Tk.subwin creates a new window which is a sub-window of a given parent window.

tkdestroy destroys a window and also removes the reference to a window from its parent.
is.tkwin can be used to test whether a given object is a window environment.
tclVar creates a new Tcl variable and initializes it to init. An R object of class tclVar is created to represent it. Using as.character on the object returns the Tcl variable name. Accessing the Tcl
variable from R is done using the `tclvalue` function, which can also occur on the left-hand side of assignments. If `tclvalue` is passed an argument which is not a `tclVar` object, then it will assume that it is a character string explicitly naming global Tcl variable. Tcl variables created by `tclVar` are uniquely named and automatically unset by the garbage collector when the representing object is no longer in use.

`tclArray` creates a new Tcl array and initializes it to the empty array. An R object of class `tclArray` and inheriting from class `tclVar` is created to represent it. You can access elements of the Tcl array using indexing with `[ ]` or `$`, which also allow replacement forms. Notice that Tcl arrays are associative by nature and hence unordered; indexing with a numeric index `i` refers to the element with the `name` `as.character(i)`. Multiple indices are pasted together separated by commas to form a single name. You can query the length and the set of names in an array using methods for `length` and `names`, respectively; these cannot meaningfully be set so assignment forms exist only to print an error message.

It is possible to access Tcl’s ‘dual-ported’ objects directly, thus avoiding parsing and deparsing of their string representation. This works by using objects of class `tclObj`. The string representation of such objects can be extracted (but not set) using `tclvalue` and conversion to vectors of mode "character", "double", "integer", "logical", and "raw" is performed using the standard coercion functions `as.character`, etc. Conversely, such vectors can be converted using `as.tclObj`. There is an ambiguity as to what should happen for length one vectors, controlled by the `drop` argument; there are cases where the distinction matters to Tcl, although mostly it treats them equivalently. Notice that `tclvalue` and `as.character` differ on an object whose string representation has embedded spaces, the former is sometimes to be preferred, in particular when applied to the result of `tclread`, `tkgetOpenFile`, and similar functions. The `as.raw` method returns a raw vector or a list of raw vectors and can be used to return binary data from Tcl.

The object behind a `tclVar` object is extracted using `tclObj(x)` which also allows an assignment form, in which the right hand side of the assignment is automatically converted using `as.tclObj`. There is a print method for `tclObj` objects; it prints `<Tcl>` followed by the string representation of the object. Notice that `as.character` on a `tclVar` object is the `name` of the corresponding Tcl variable and not the value.

Tcl packages can be loaded with `tclRequire`; it may be necessary to add the directory where they are found to the Tcl search path with `addTclPath`. The return value is a class "tclObj" object if it succeeds, or `FALSE` if it fails (when a warning is issued). To see the current search path as an R character vector, use

```r
strsplit(tclvalue('auto_path'), " ")[[1]]
```

**Note**

Strings containing unbalanced braces are currently not handled well in many circumstances.

**See Also**

`TkWidgets`, `TkCommands`, `TkWidgetcmds`.

`capabilities("tcltk")` to see if Tcl/Tk support was compiled into this build of R.
Examples

```r
## Not run:
## These cannot be run by example() but should be OK when pasted
## into an interactive R session with the tcltk package loaded
.Tcl("format \"%s\n\" \"Hello, World!\"\")
f <- function()cat("HI\n")
.Tcl.callback(f)
.Tcl.args(text = "Push!", command = f) # NB: Different address

xyzzy <- tclVar(7913)
tclvalue(xyzzy)
tclvalue(xyzzy) <- "foo"
as.character(xyzzy)
tcl("set", as.character(xyzzy))

top <- tkplevel() # a Tk widget, see Tk-widgets
ls(envir = top$env, all = TRUE)
ls(envir = .TkRoot$env, all = TRUE) # .Tcl.args put a callback ref in here

## End(Not run)
```

description

This function controls or reports on the Tcl service mode, i.e. whether Tcl will respond to events.

Usage

tclServiceMode(on = NULL)

Arguments

- **on** (logical) Whether event servicing is turned on.

Details

If called with on == NULL (the default), no change is made.

Note that this blocks all Tcl/Tk activity, including for widgets from other packages. It may be better to manage mapping of windows individually.

Value

The value of the Tcl service mode before the call.
TkCommands

Examples

```r
## see demo(tkcanvas) for an example
## Not run:
oldmode <- tclServiceMode(FALSE)
# Do some work to create a nice picture.
# Nothing will be displayed until...
tclServiceMode(oldmode)

## End(Not run)
## another idea is to use tkwm.withdraw() ... tkwm.deiconify()
```

---

**TkCommands**

*Tk non-widget commands*

**Description**

These functions interface to Tk non-widget commands, such as the window manager interface commands and the geometry managers.

**Usage**

- `tcl(...)`
- `tktitle(x)`
  ```r
tkttitle(x) <- value
  ```
- `tkbell(...)`
- `tkbind(...)`
- `tkbindtags(...)`
- `tkfocus(...)`
- `tklower(...)`
- `tkraise(...)`
- `tkclipboard.append(...)`
- `tkclipboard.clear(...)`
- `tkevent.add(...)`
- `tkevent.delete(...)`
- `tkevent.generate(...)`
- `tkevent.info(...)`
- `tkfont.actual(...)`
- `tkfont.configure(...)`
- `tkfont.create(...)`
- `tkfont.delete(...)`
- `tkfont.families(...)`
- `tkfont.measure(...)`

## Standard dialogs

tkgetOpenFile(...)  tkgetSaveFile(...)  tkchooseDirectory(...)  tkmessageBox(...)
tkdialog(...
 tkpopup(....)

## File handling functions
 tclfile.tail(...)
 tclfile.dir(...)
 tclopen(...)
 tclclose(...)
 tclputs(...)
 tclread(...)

Arguments

x
A window object
value
For tktitle assignments, a character string.
...
Handled via .Tcl.args

Details

tcl provides a generic interface to calling any Tk or Tcl command by simply running .Tcl.args.objv on the argument list and passing the result to .Tcl.objv. Most of the other commands simply call tcl with a particular first argument and sometimes also a second argument giving the subcommand.
tktitle and its assignment form provides an alternate interface to Tk's wm title

There are far too many of these commands to describe them and their arguments in full. Please refer to the Tcl/Tk documentation for details. With a few exceptions, the pattern is that Tk subcommands like pack configure are converted to function names like tkpack.configure, and Tcl subcommands are like tclfile.dir.

See Also

tclfile.tail

Examples

## Not run:
## These cannot be run by examples() but should be OK when pasted
## into an interactive R session with the tcltk package loaded

   tt <- tktoplevel()
   tkpack(l1 <- tklabel(tt, text = "Heave"), l2<- tklabel(tt, text = "Ho"))
   tkpack.configure(l1, side = "left")

   ## Try stretching the window and then

   tkdestroy(tt)

   ## End(Not run)
tkpager

Page file using Tk text widget

Description
This plugs into file.show, showing files in separate windows.

Usage
tkpager(file, header, title, delete.file)

Arguments
  file character vector containing the names of the files to be displayed
  header headers to use for each file
  title common title to use for the window(s). Pasted together with the header to form
         actual window title.
  delete.file logical. Should file(s) be deleted after display?

Note
  The "\b_" string used for underlining is currently quietly removed. The font and background colour
  are currently hardcoded to Courier and gray90.

See Also
  file.show

tkProgressBar

Progress Bars via Tk

Description
Put up a Tk progress bar widget.

Usage
tkProgressBar(title = "R progress bar", label = "",
              min = 0, max = 1, initial = 0, width = 300)

getTkProgressBar(pb)
setTkProgressBar(pb, value, title = NULL, label = NULL)
## S3 method for class 'tkProgressBar'
close(con, ...)

Arguments

- `title, label` character strings, giving the window title and the label on the dialog box respectively.
- `min, max` (finite) numeric values for the extremes of the progress bar.
- `initial, value` initial or new value for the progress bar.
- `width` the width of the progress bar in pixels: the dialog box will be 40 pixels wider (plus frame).
- `pb, con` an object of class "tkProgressBar".
- `...` for consistency with the generic.

Details

tkProgressBar will display a widget containing a label and progress bar.

`setTkProgressbar` will update the value and for non-NULL values, the title and label (provided there was one when the widget was created). Missing (NA) and out-of-range values of value will be (silently) ignored.

The progress bar should be closed when finished with.

This will use the ttk::progressbar widget for Tk version 8.5 or later, otherwise R’s copy of BWidget’s progressbar.

Value

For tkProgressBar an object of class "tkProgressBar".

For `getTkProgressbar` and `setTkProgressbar`, a length-one numeric vector giving the previous value (invisibly for `setTkProgressbar`).

See Also

- `txtProgressBar`

Examples

```r
pb <- tkProgressBar("test progress bar", "Some information in %",
                    0, 100, 50)
Sys.sleep(0.5)
u <- c(0, sort(runif(20, 0, 100)), 100)
for(i in u) {
  Sys.sleep(0.1)
  info <- sprintf("%d%% done", round(i))
  setTkProgressbar(pb, i, sprintf("test (%s)", info), info)
}
Sys.sleep(5)
close(pb)
```
**tkStartGUI**  
*Tcl/Tk GUI startup*

**Description**
Starts up the Tcl/Tk GUI

**Usage**
```
tkStartGUI()
```

**Details**
Starts a GUI console implemented via a Tk text widget. This should probably be called at most once per session. Also redefines the file pager (as used by `help()`) to be the Tk pager.

**Note**
tkStartGUI() saves its evaluation environment as `.GUIenv`. This means that the user interface elements can be accessed in order to extend the interface. The three main objects are named `Term`, `Menu`, and `Toolbar`, and the various submenus and callback functions can be seen with `ls(envir = .GUIenv)`.

**Author(s)**
Peter Dalgaard

**TkWidgetcmds**  
*Tk widget commands*

**Description**
These functions interface to Tk widget commands.

**Usage**
```
tkactivate(widget, ...)  
tkadd(widget, ...)  
tkadetag(widget, ...)  
tbbox(widget, ...)  
tkcanvasx(widget, ...)  
tkcanvasy(widget, ...)  
tkcget(widget, ...)  
tkcompare(widget, ...)  
tkconfigure(widget, ...)  
tkcoords(widget, ...)  
```
tkcreate(widget, ...)
tkcreateselection(widget, ...)
tkdchars(widget, ...)
tkdebug(widget, ...)
tkdelete(widget, ...)
tkdeletein(widget, ...)
tkdeselect(widget, ...)
tkdlineinfo(widget, ...)
tkdtag(widget, ...)
tkdump(widget, ...)
tkentrycget(widget, ...)
tkentryconfigure(widget, ...)
tkfind(widget, ...)
tkflash(widget, ...)
tkfraction(widget, ...)

tktoggle(widget, ...)  
tktag.add(widget, ...)  
tktag.bind(widget, ...)  
tktag.cget(widget, ...)  
tktag.configure(widget, ...)  
tktag.delete(widget, ...)  
tktag.lower(widget, ...)  
tktag.names(widget, ...)  
tktag.nextrange(widget, ...)  
tktag.prevrange(widget, ...)  
tktag.raise(widget, ...)  
tktag.ranges(widget, ...)  
tktag.remove(widget, ...)  
tktype(widget, ...)  
tkunpost(widget, ...)  
tkwindow.cget(widget, ...)  
tkwindow.configure(widget, ...)  
tkwindow.create(widget, ...)  
tkwindow.names(widget, ...)  
tkxview(widget, ...)  
tkxview.moveto(widget, ...)  
tkxview.scroll(widget, ...)  
tkyposition(widget, ...)  
tkyview(widget, ...)  
tkyview.moveto(widget, ...)  
tkyview.scroll(widget, ...)

Arguments

widget The widget this applies to
...

Handled via .Tcl.args

Details

There are far too many of these commands to describe them and their arguments in full. Please refer to the Tcl/Tk documentation for details. Except for a few exceptions, the pattern is that Tcl widget commands possibly with subcommands like .a.b selection clear are converted to function names like tkselection.clear and the widget is given as the first argument.

Examples

```r
## Not run:
## These cannot be run by examples() but should be OK when pasted
## into an interactive R session with the tcltk package loaded

tt <- tktoplevel()
tkpack(txt.w <- tktext(tt))
tkinsert(txt.w, "0.0", "plot(1:10)"

# callback function
eval.txt <- function()
eval(parse(text = tclvalue(tkget(txt.w, "0.0", "end"))))
tkpack(but.w <- tkbutton(tt, text = "Submit", command = eval.txt))

## Try pressing the button, edit the text and when finished:
tkdestroy(tt)

## End(Not run)
```

---

TkWidgets  

## Tk widgets

Description

Create Tk widgets and associated R objects.

Usage

```r
tkwidget(parent, type, ...)
tkbutton(parent, ...)
tkcanvas(parent, ...)
tkcheckbutton(parent, ...)
tkentry(parent, ...)
ttkentry(parent, ...)
tkframe(parent, ...)
tklabel(parent, ...)
tklistbox(parent, ...)
tklistbox(parent, ...)
tkmenu(parent, ...)
tkmenubutton(parent, ...)
tkmessage(parent, ...)
tkradiobutton(parent, ...)
```
TkWidgets

 tkscale(parent, ...)  
 tkscrollbar(parent, ...)  
 tktext(parent, ...)  
 tktoplevel(parent = .TkRoot, ...)

 ttkbutton(parent, ...)  
 ttkcheckbutton(parent, ...)  
 ttkcombobox(parent, ...)  
 ttkframe(parent, ...)  
 ttkimage(parent, ...)  
 ttklabel(parent, ...)  
 ttklabelframe(parent, ...)  
 ttkmenubutton(parent, ...)  
 ttknotebook(parent, ...)  
 ttkpanedwindow(parent, ...)  
 ttkprogressbar(parent, ...)  
 ttkradiobutton(parent, ...)  
 ttk scrollbar(parent, ...)  
 ttkseparator(parent, ...)  
 ttksizegrip(parent, ...)  
 ttktreeview(parent, ...)

Arguments

parent  Parent of widget window.
type  string describing the type of widget desired.
...  handled via .Tcl.args.

Details

These functions create Tk widgets. tkwidget creates a widget of a given type, the others simply call tkwidget with the respective type argument.

The functions starting ttk are for the themed widget set for Tk 8.5 or later. A tutorial can be found at http://www.tkdocs.com.

It is not possible to describe the widgets and their arguments in full. Please refer to the Tcl/Tk documentation.

TclInterface, TkCommands, TkWidgetcmds

Examples

## Not run:
## These cannot be run by examples() but should be OK when pasted
## into an interactive R session with the tcltk package loaded

```
tt <- tktoplevel()
label.widget <- ttklabel(tt, text = "Hello, World!")
```
button.widget <- tkbutton(tt, text = "Push",
command = function()cat("OW!\n"))
tkpack(label.widget, button.widget) # geometry manager
# see Tk-commands

## Push the button and then...

tkdestroy(tt)

## test for themed widgets
if(as.character(tcl("info", "tclversion")) >= "8.5") {
  # make use of themed widgets
  # list themes
  as.character(tcl("ttk::style", "theme", "names"))
  # select a theme -- here pre-XP windows
  tcl("ttk::style", "theme use", "winnative")
} else {
  # use Tk 8.0 widgets
}

## End(Not run)

---

**tk_choose.dir**  
*Choose a Folder Interactively*

---

**Description**

Use a Tk widget to choose a directory interactively.

**Usage**

`tk_choose.dir(default = "", caption = "Select directory")`

**Arguments**

- **default**: which directory to show initially.
- **caption**: the caption on the selection dialog.

**Value**

A length-one character vector, character `NA` if ‘Cancel’ was selected.

**See Also**

`tk_choose.files`
tk_choose.files

Examples

```r
## Not run:
tk_choose.dir(getwd(), "Choose a suitable folder")

## End(Not run)
```

---

### Description

Use a Tk file dialog to choose a list of zero or more files interactively.

### Usage

```r
tk_choose.files(default = ",", caption = "Select files",
               multi = TRUE, filters = NULL, index = 1)
```

### Arguments

- `default`: which filename to show initially.
- `caption`: the caption on the file selection dialog.
- `multi`: whether to allow multiple files to be selected.
- `filters`: two-column character matrix of filename filters.
- `index`: unused.

### Details

Unlike `file.choose`, `tk_choose.files` will always attempt to return a character vector giving a list of files. If the user cancels the dialog, then zero files are returned, whereas `file.choose` would signal an error.

The format of `filters` can be seen from the example. File patterns are specified via extensions, with "*" meaning any file, and "" any file without an extension (a filename not containing a period). (Other forms may work on specific platforms.) Note that the way to have multiple extensions for one file type is to have multiple rows with the same name in the first column, and that whether the extensions are named in file chooser widget is platform-specific. **The format may change before release.**

### Value

A character vector giving zero or more file paths.

### Note

A bug in Tk 8.5.0–8.5.4 prevented multiple selections being used.
See Also

`file.choose`, `tk_choose.dir`

Examples

```r
Filters <- matrix(c("R code", ".R", "R code", ".s", "Text", ".txt", "All files", "*"),
                 4, 2, byrow = TRUE)

if(interactive()) tk_choose.files(filter = Filters)
```

---

**tk_messageBox**

*Tk Message Box*

**Description**

An implementation of a generic message box using Tk

**Usage**

```r
tk_messageBox(type = c("ok", "okcancel", "yesno", "yesnocancel",
                     "retrycancel", "aburtretrycancel"),
               message, caption = "", default = "", ...)  
```

**Arguments**

- `type` character. The type of dialog box. It will have the buttons implied by its name.
- `message` character. The information field of the dialog box.
- `caption` character. The caption on the widget displayed.
- `default` character. The name of the button to be used as the default.
- `...` additional named arguments to be passed to the Tk function of this name. An example is `icon = "warning"`.

**Value**

A character string giving the name of the button pressed.

**See Also**

`tkmessageBox` for a ‘raw’ interface.
Select Items from a List

Description

Select item(s) from a character vector using a Tk listbox.

Usage

\[ \text{tk_select.list}(\text{choices}, \text{preselect} = \text{NULL}, \text{multiple} = \text{FALSE}, \text{title} = \text{NULL}) \]

Arguments

- \textbf{choices} a character vector of items.
- \textbf{preselect} a character vector, or \text{NULL}. If non-null and if the string(s) appear in the list, the item(s) are selected initially.
- \textbf{multiple} logical: can more than one item be selected?
- \textbf{title} optional character string for window title, or \text{NULL} for no title.

Details

This is a version of \text{select.list} implemented as a Tk list box plus \text{OK} and \text{Cancel} buttons. There will be a scrollbar if the list is too long to fit comfortably on the screen.

The dialog box is modal, so a selection must be made or cancelled before the \text{R} session can proceed.

As from \text{R} 2.10.1 double-clicking on an item is equivalent to selecting it and then clicking \text{OK}.

If Tk is version 8.5 or later, themed widgets will be used.

Value

A character vector of selected items. If \text{multiple} is false and no item was selected (or \text{Cancel} was used), "" is returned. If \text{multiple} is true and no item was selected (or \text{Cancel} was used) then a character vector of length 0 is returned.

See Also

\text{select.list} (a text version except on Windows and the OS X GUI), \text{menu} (whose \text{graphics} = \text{TRUE} mode uses this on most Unix-alikes).
Chapter 13

The tools package

---

**tools-package**  
*Tools for Package Development*

---

**Description**

Tools for package development, administration and documentation.

**Details**

This package contains tools for manipulating R packages and their documentation. For a complete list of functions, use `library(help = "tools")`.

**Author(s)**

Kurt Hornik and Friedrich Leisch  
Maintainer: R Core Team <R-core@r-project.org>

---

**.print.via.format**  
*Printing Utilities*

---

**Description**

`.print.via.format` is a “prototype” `print()` method, useful, at least as a start, by a simple

```
pivot.<myS3class> <- .print.via.format
```

**Usage**

```
.print.via.format(x, ...)
```
### add_datalist

**Add a 'datalist' File to a Package**

#### Description

The `data()` command with no arguments lists all the datasets available via `data` in attached packages, and to do so a per-package list is installed. Creating that list at install time can be slow for packages with huge datasets, and can be expedited by a supplying 'data/datalist' file.

#### Usage

```r
add_datalist(pkgpath, force = FALSE)
```

#### Arguments

- **pkgpath**  
The path to a (source) package.
- **force**  
  logical: can an existing 'data/datalist' file be over-written?

#### Details

`R CMD build` will call this function to add a data list to packages with 1MB or more of data.

It is also helpful to give a ‘data/datalist’ file in packages whose datasets have many dependencies, including loading the packages itself (and maybe others).
bibstyle

Select or define a bibliography style.

Description

This function defines and registers styles for rendering `bibentry` objects into ‘Rd’ format, for later conversion to text, HTML, etc.

Usage

```r
bibstyle(style, envir, ..., .init = FALSE, .default = TRUE)
getBibstyle(all = FALSE)
```

Arguments

- `style`: A character string naming the style.
- `envir`: (optional) An environment holding the functions to implement the style.
- `...`: Named arguments to add to the environment.
- `.init`: Whether to initialize the environment from the default style "JSS".
- `.default`: Whether to set the specified style as the default style.
- `all`: Whether to return the names of all registered styles.

Details

Rendering of `bibentry` objects may be done using routines modelled after those used by BibTeX. This function allows environments to be created and manipulated to contain those routines.

There are two ways to create a new style environment. The easiest is to set `.init = TRUE`, in which case the environment will be initialized with a copy of the default "JSS" environment. (This style is modelled after the ‘jss.bst’ style used by the *Journal of Statistical Software.*) Alternatively, the `envir` argument can be used to specify a completely new style environment.

To find the name of the default style, use `getBibstyle()`. To retrieve an existing style without setting it as the default, use `bibstyle(style, .default = FALSE)`. To modify an existing style, specify `style` and some named entries via `...`. (Modifying the default "JSS" style is discouraged.) Setting `style` to `NULL` or leaving it missing will retrieve the default style, but modifications will not be allowed.

At a minimum, the environment should contain routines to render each of the 12 types of bibliographic entry supported by `bibentry` as well as several other routines described below. The former must be named `formatArticle`, `formatBook`, `formatInbook`, `formatIncollection`, `formatInProceedings`, `formatManual`, `formatMastersthesis`, `formatMisc`, `formatPhdthesis`, `formatProceedings`, `formatTechreport` and

See Also

data.
The ‘Writing R Extensions’ manual.
formatUnpublished. Each of these takes one argument, a single unclass'ed entry from the 
bibentry vector passed to the renderer, and should produce a single element character vector 
(possibly containing newlines).

The other routines are as follows. sortKeys, a function to produce a sort key to sort the entries, 
is passed the original bibentry vector and should produce a sortable vector of the same length to 
define the sort order. Finally, the optional function cite should have the same argument list as 
utils::cite, and should produce a citation to be used in text.

The format method for "bibentry" objects adds a field named ".index" to each entry after sorting 
and before formatting. This is a 1-based index within the complete object that can be used in styles 
that require numbering. Although the "JSS" style doesn't use numbers, it includes a fmtPrefix() 
stub function that may be used to display them. See the example below.

Value

bibstyle returns the environment which has been selected or created.

getBibstyle returns the name of the default style, or all style names.

  .init = TRUE)
print(refs, .bibstyle = "unsorted")
List and Build Package Vignettes

Description

Run Sweave (or other custom weave function) and texi2dvi on all vignettes of a package.

Usage

\begin{verbatim}
buildVignettes(package, dir, lib.loc = NULL, quiet = TRUE,
clean = TRUE, tangle = FALSE)
pkgVignettes(package, dir, subdirs = NULL, lib.loc = NULL,
output = FALSE, source = FALSE)
\end{verbatim}

Arguments

- **package**: a character string naming an installed package. If given, Sweave files are searched in subdirectory 'doc'.
- **dir**: a character string specifying the path to a package’s root source directory. This subdirectory ‘vignettes’ (or if it does not exist ‘inst/doc’) is searched for Sweave files.
- **lib.loc**: a character vector of directory names of \texttt{R} libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.
- **quiet**: logical. Weave and run \texttt{texi2pdf} in quiet mode.
- **clean**: Remove all files generated by the build, even if there were copies there before.
- **tangle**: logical. Do tangling as well as weaving.
- **subdirs**: a character vector of subdirectories of dir in which to look for vignettes. Ignored if package is used.
- **output**: logical. If TRUE, the output filename for each vignette in the result.
- **source**: logical. If TRUE, include the tangled output filename for each vignette in the result.

Details

\texttt{buildVignettes} is used by \texttt{R CMD build} and \texttt{R CMD check} to (re-)build vignette PDFs from their (typically Sweave) sources.

Value

\texttt{buildVignettes} is called for its side effect of creating the PDF versions of all vignettes, and if \texttt{tangle = TRUE}, extracting the \texttt{R} code. \texttt{pkgVignettes} returns an object of class "pkgVignettes" if a vignette directory is found, otherwise NULL.
Description

charset_to_Unicode is a matrix of Unicode points with columns for the common 8-bit encodings.

Adobe_glyphs is a dataframe which gives Adobe glyph names for Unicode points. It has two character columns, "adobe" and "unicode" (a 4-digit hex representation).

Usage

charset_to_Unicode
Adobe_glyphs

Details

charset_to_Unicode is an integer matrix of class c("noquote", "hexmode") so prints in hexadecimal. The mappings are those used by libiconv: there are differences in the way quotes and minus/hyphen are mapped between sources (and the postscript encoding files use a different mapping).

Adobe_glyphs include all the Adobe glyph names which correspond to single Unicode characters. It is sorted by Unicode point and within a point alphabetically on the glyph (there can be more than one name for a Unicode point). The data are in the file 'R_HOME/share/encodings/Adobe_glyphlist'.

Source

Examples

```r
## find Adobe names for ISOLatin2 chars.
latin2 <- charset_to_Unicode[, "ISOLatin2"]
aUnicode <- as.numeric(paste0("0x", Adobe_glyphs$unicode))
keep <- aUnicode %in% latin2
aUnicode <- aUnicode[keep]
aAdobe <- Adobe_glyphs[keep, 1]
## first match
aLatin2 <- aAdobe[match(latin2, aUnicode)]
## all matches
bLatin2 <- lapply(1:256, function(x) aAdobe[aUnicode == latin2[x]])
format(bLatin2, justify = "none")
```
Description

Performs checks on calls to compiled code from R code. Currently only checks whether the interface functions such as `.C` and `.Fortran` are called with a "NativeSymbolInfo" first argument or with argument PACKAGE specified, which is highly recommended to avoid name clashes in foreign function calls.

Usage

```r
checkFF(package, dir, file, lib.loc = NULL,
        verbose = getOption("verbose"))
```

Arguments

- **package**: a character string naming an installed package. If given, the installed R code of the package is checked.
- **dir**: a character string specifying the path to a package’s root source directory. This should contain the subdirectory ‘R’ (for R code). Only used if package is not given.
- **file**: the name of a file containing R code to be checked. Used if neither package nor dir are given.
- **lib.loc**: a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.
- **verbose**: a logical. If TRUE, additional diagnostics are printed (and the result is returned invisibly).

Details

Note that we can only check if the name argument is a symbol or a character string, not what class of object the symbol resolves to at run-time.

If the package has a namespace which contains a `useDynLib` directive, calls in top-level functions in the package are not reported as their symbols will be preferentially looked up in the DLL named in the first `useDynLib` directive.

As from R 2.15.2, this also checks that calls with PACKAGE specified are to the same package, and reports separately those which are in base packages and those which are in other packages (and if those packages are specified in the ‘DESCRIPTION’ file). Direct calls to the FORTRAN entry points for LINPACK in R itself are not reported (but this does not include modifications of LINPACK routines such as `dqrls`).
checkMD5sums

Value
An object of class "checkFF", which currently is a list of the (parsed) foreign function calls with a character first argument and no PACKAGE argument.
There is a print method to display the information contained in such objects.

See Also
.C., Fortran; Foreign.

Examples
# order is pretty much random
checkFF(package = "stats", verbose = TRUE)

checkMD5sums package, dir)

Arguments
package the name of an installed package
dir the path to the top-level directory of an installed package.

Details
The file 'MD5' which is created is in a format which can be checked by md5sum -c MD5 if a suitable command-line version of md5sum is available. (For Windows, one is supplied in the bundle at http://www.murdoch-sutherland.com/Rtools.)
If dir is missing, an installed package of name package is searched for.
The private function tools:::.installMD5sums is used to create MD5 files in the Windows build.

Value
checkMD5sums returns a logical, NA if there is no 'MD5' file to be checked.

See Also
md5sum
checkPoFiles  

Check translation files for inconsistent format strings.

Description

These functions compare formats embedded in English messages with translated strings to check for consistency. checkPoFile checks one file, while checkPoFiles checks all files for a specified language.

Usage

```r
checkPoFile(f, strictPlural = FALSE)
checkPoFiles(language, dir = ".")
```

Arguments

- `f` a character string giving a single filepath.
- `strictPlural` whether to compare formats of singular and plural forms in a strict way.
- `language` a character string giving a language code.
- `dir` a path to a directory in which to check files.

Details

Part of R’s internationalization depends on translations of messages in ‘.po’ files. In these files an ‘English’ message taken from the R sources is followed by a translation into another language. Many of these messages are format strings for C or R `sprintf` and related functions. In these cases, the translation must give a compatible format or an error will be generated when the message is displayed.

The rules for compatibility differ between C and R in several ways. C supports several conversions not supported by R, namely c, u, p, n. It is allowed in C’s `sprintf()` function to have more arguments than are needed by the format string, but in R the counts must match exactly. R requires types of arguments to match, whereas C will do the display whether it makes sense or not.

These functions compromise on the testing as follows. The additional formats allowed in C are accepted, and all differences in argument type or count are reported. As a consequence some reported differences are not errors.

If the `strictPlural` argument is `TRUE`, then argument lists must agree exactly between singular and plural forms of messages; if `FALSE`, then translations only need to match one or the other of the two forms. When checkPoFiles calls checkPoFile, the `strictPlural` argument is set to `TRUE` for files with names starting ‘R-’, and to `FALSE` otherwise.

Items marked as ‘fuzzy’ in the ‘.po’ file are not processed (as they are ignored by the message compiler).

If a difference is found, the translated string is checked for variant percent signs (e.g. the wide percent sign “\uFF05”). Such signs will not be recognized as format specifiers, and are likely to be errors.
checkRd

Check an Rd Object

Description

Check an help file or the output of the parse_Rd function.

Usage

checkRd(Rd, defines = .Platform$OS.type, stages = "render",
         unknownOK = TRUE, listOK = TRUE, ..., def_enc = FALSE)

Arguments

Rd  a filename or Rd object to use as input.
defines  string(s) to use in #ifdef tests.
stages  at which stage ("build", "install", or "render") should \Sexpr macros be executed? See the notes below.
unknownOK  unrecognized macros are treated as errors if FALSE, otherwise warnings.
listOK  unnecessary non-empty braces (e.g., around text, not as an argument) are treated as errors if FALSE, otherwise warnings.
additional parameters to pass to `parse_Rd` when Rd is a filename. One that is often useful is `encoding`.

```r
def_enc logical: has the package declared an encoding, so tests for non-ASCII text are suppressed?
```

### Details

`checkRd` performs consistency checks on an Rd file, confirming that required sections are present, etc.

It accepts a filename for an Rd file, and will use `parse_Rd` to parse it before applying the checks. If so, warnings from `parse_Rd` are collected, together with those from the internal function `prepare_Rd`, which does the `#ifdef` and `\Sexpr` processing, drops sections that would not be rendered or are duplicated (and should not be) and removes empty sections.

An Rd object is passed through `prepare_Rd`, but it may already have been (and installed Rd objects have).

Warnings are given a `level`: those from `prepare_Rd` have level 0. These include

```
All text must be in a section
Only one `tag name` section is allowed: the first will be used
Section `name` is unrecognized and will be dropped
Dropping empty section `name`
```

`checkRd` itself can show

```r
7 Tag `tag name` not recognized
7 `\tabular` format must be simple text
7 Unrecognized `\tabular` format: ...
7 Only `n` columns allowed in this table
7 Must have a `tag name`
7 Only one `tag name` is allowed
7 Tag `tag name` must not be empty
7 `\docType` must be plain text
5 Tag `\method` is only valid in `\usage`
5 Tag `\dontrun` is only valid in `\examples`
5 Tag `tag name` is invalid in a `block name` block
5 Title of `\section` must be non-empty plain text
5 `\title` content must be plain text
3 Empty section `tag name`
3 `\synopsis` will be removed in R 3.1.0
-1 Non-ASCII contents without declared encoding
-1 Non-ASCII contents in second part of `\enc`
-3 Tag ... is not valid in a code block
-3 Apparent non-ASCII contents without declared encoding
-3 Apparent non-ASCII contents in second part of `\enc`
-3 Unnecessary braces at ...
-3 `\method` not valid outside a code block
```
and variations with \method replaced by \S3method or \S4method.

Note that both prepare_Rd and checkRd have tests for an empty section: that in checkRd is stricter (essentially that nothing is output).

Value

This may fail through an R error, but otherwise warnings are collected as returned as an object of class "checkRd", a character vector of messages. This class has a print method which only prints unique messages, and has argument minlevel that can be used to select only more serious messages. (This is set to -1 in \texttt{R CMD check}.)

Possible fatal errors are those from running the parser (e.g. a non-existent file, unclosed quoted string, non-ASCII input without a specified encoding) or from prepare_Rd (multiple \Rdversion declarations, invalid \encoding or \docType or \name sections, and missing or duplicate \name or \title sections).

checkRdaFiles Report on Details of Saved Images or Re-saves them

Description

This reports for each of the files produced by save the size, if it was saved in ASCII or XDR binary format, and if it was compressed (and if so in what format).

Usually such files have extension `.rda` or `.RData`, hence the name of the function.

Usage

```r

checkRdaFiles(paths)
resaveRdaFiles(paths, compress = c("auto", "gzip", "bzip2", "xz"),
               compression_level)
```

Arguments

- `paths` A character vector of paths to save files. If this specifies a single directory, it is taken to refer to all `.rda` and `.RData` files in that directory.
- `compress`, `compression_level` type and level of compression: see `save`.

---
checkTnF

Details

compress = "auto" asks R to choose the compression and ignores compression_level. It will try "gzip", "bzip2" and if the "gzip" compressed size is over 10Kb, "xz" and choose the smallest compressed file (but with a 10% bias towards "gzip"). This can be slow.

Value

For checkRdaFiles, a data frame with rows names paths and columns

size numeric: file size in bytes, NA if the file does not exist.
ASCII logical: true for save(ASCII = TRUE), NA if the format is not that of an R save file.
compress character: type of compression. One of "gzip", "bzip2", "xz", "none" or "unknown" (which means that if this is an R save file it is from a later version of R).
version integer: the version of the save – usually 2 but 1 for very old files, and NA for other files.

Examples

## Not run:
## from a package top-level source directory
paths <- sort(Sys.glob(c("data/*.rda", "data/*.RData")))
(res <- checkRdaFiles(paths))
## pick out some that may need attention
bad <- is.na(res$ASCII) | res$ASCII | (res$size > 1e4 & res$compress == "none")
res[bad,]

## End(Not run)

checkTnF

Check R Packages or Code for T/F

Description

Checks the specified R package or code file for occurrences of T or F, and gathers the expression containing these. This is useful as in R T and F are just variables which are set to the logicals TRUE and FALSE by default, but are not reserved words and hence can be overwritten by the user. Hence, one should always use TRUE and FALSE for the logicals.

Usage

checkTnF(package, dir, file, lib.loc = NULL)
Arguments

package

da character string naming an installed package. If given, the installed R code and the examples in the documentation files of the package are checked. R code installed as an image file cannot be checked.

dir

da character string specifying the path to a package’s root source directory. This must contain the subdirectory ‘R’ (for R code), and should also contain ‘man’ (for documentation). Only used if package is not given. If used, the R code files and the examples in the documentation files are checked.

file

the name of a file containing R code to be checked. Used if neither package nor dir are given.

lib.loc

a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.

Value

An object of class "checkTnF" which is a list containing, for each file where occurrences of T or F were found, a list with the expressions containing these occurrences. The names of the list are the corresponding file names.

There is a print method for nicely displaying the information contained in such objects.

Description

Check all Sweave files of a package by running Sweave and/or Stangle on them. All R source code files found after the tangling step are sourced to check whether all code can be executed without errors.

Usage

checkVignettes(package, dir, lib.loc = NULL,
tangle = TRUE, weave = TRUE, latex = FALSE,
workdir = c("tmp", "src", "cur"),
keepfiles = FALSE)

Arguments

package

da character string naming an installed package. If given, Sweave files are searched in subdirectory ‘doc’.

dir

da character string specifying the path to a package’s root source directory. This subdirectory ‘inst/doc’ is searched for Sweave files.

lib.loc

a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.
check_packages_in_dir

**Description**

Check source packages in a given directory, optionally with their reverse dependencies.
Usage

```r
check_packages_in_dir(dir,
  check_args = character(),
  check_args_db = list(),
  reverse = NULL,
  check_env = character(),
  xvfb = FALSE,
  Ncpus = getOption("Ncpus", 1L),
  clean = TRUE,
  ...
)
```

```r
summarize_check_packages_in_dir_results(dir, all = TRUE)
summarize_check_packages_in_dir_timings(dir, all = FALSE,
                                        full = FALSE)
summarize_check_packages_in_dir_depends(dir, all = FALSE)
```

Arguments

- **dir** a character string giving the path to the directory with the source `'.tar.gz'` files to be checked.
- **check_args** a character vector with arguments to be passed to R CMD check, or a list of length two of such character vectors to be used for checking packages and reverse dependencies, respectively.
- **check_args_db** a named list of character vectors with arguments to be passed to R CMD check, with names the respective package names.
- **reverse** a list with names partially matching "repos", "which", or "recursive", giving the repositories to use for locating reverse dependencies (default: `getOption("repos")`), the types of reverse dependencies (default: c("Depends", "Imports", "LinkingTo")), and indicating whether to also check reverse dependencies of reverse dependencies (and so on), or NULL (default), in which case no reverse dependencies are checked.
- **check_env** a character vector of name=value strings to set environment variables for checking, or a list of length two of such character vectors to be used for checking packages and reverse dependencies, respectively.
- **xvfb** a logical indicating whether to perform checking inside a virtual framebuffer X server (Unix only), or a character vector of Xvfb options for doing so.
- **Ncpus** the number of parallel processes to use for parallel installation and checking.
- **clean** a logical indicating whether to remove the downloaded reverse dependency sources.
- **all** a logical indicating whether to also summarize the reverse dependencies checked.
- **full** a logical indicating whether to also summarize check example timings (if available).
Details

check_packages_in_dir allows to conveniently check source package `.tar.gz` files in the given directory `dir`, along with their reverse dependencies as controlled by `reverse`.

If needed, the source `.tar.gz` files of the reverse dependencies to be checked as well are downloaded into `dir` (and removed at the end if `clean` is true). Next, all packages (additionally) needed for checking are installed to the ‘Library’ subdirectory of `dir`. Then, all `.tar.gz` files are checked using the given arguments and environment variables, with outputs and messages to files in the ‘Outputs’ subdirectory of `dir`. The ‘*.Rcheck’ directories with the check results of the reverse dependencies are renamed by prefixing their base names with ‘rdepends_’.

Results and timings can conveniently be summarized using `summarize_check_packages_in_dir_results` and `summarize_check_packages_in_dir_timings`, respectively.

Installation and checking is performed in parallel if `Ncpus` is greater than one: this will use `mclapply` on Unix and `parLapply` on Windows.

Note

This functionality is still experimental: interfaces may change in future versions.

codoc  
Check Code/Documentation Consistency

Description

Find inconsistencies between actual and documented ‘structure’ of R objects in a package. codoc compares names and optionally also corresponding positions and default values of the arguments of functions. codocClasses and codocData compare slot names of S4 classes and variable names of data sets, respectively.

Usage

codoc(package, dir, lib.loc = NULL, 
use.values = NULL, verbose = getOption("verbose"))
codocClasses(package, lib.loc = NULL)
codocData(package, lib.loc = NULL)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>package</td>
<td>a character string naming an installed package.</td>
</tr>
<tr>
<td>dir</td>
<td>a character string specifying the path to a package’s root source directory. This must contain the subdirectories ‘man’ with R documentation sources (in Rd format) and ‘R’ with R code. Only used if package is not given.</td>
</tr>
<tr>
<td>lib.loc</td>
<td>a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.</td>
</tr>
</tbody>
</table>
use.values  if FALSE, do not use function default values when comparing code and docs. Otherwise, compare all default values if TRUE, and only the ones documented in the usage otherwise (default).

verbose    a logical. If TRUE, additional diagnostics are printed.

Details

The purpose of codoc is to check whether the documented usage of function objects agrees with their formal arguments as defined in the R code. This is not always straightforward, in particular as the usage information for methods to generic functions often employs the name of the generic rather than the method.

The following algorithm is used. If an installed package is used, it is loaded (unless it is the base package), after possibly detaching an already loaded version of the package. Otherwise, if the sources are used, the R code files of the package are collected and sourced in a new environment. Then, the usage sections of the Rd files are extracted and parsed ‘as much as possible’ to give the formals documented. For interpreted functions in the code environment, the formals are compared between code and documentation according to the values of the argument use.values. Synopsis sections are used if present; their occurrence is reported if verbose is true.

If a package has a namespace both exported and unexported objects are checked, as well as registered S3 methods. (In the unlikely event of differences the order is exported objects in the package, registered S3 methods and finally objects in the namespace and only the first found is checked.)

Currently, the R documentation format has no high-level markup for the basic ‘structure’ of classes and data sets (similar to the usage sections for function synopses). Variable names for data frames in documentation objects obtained by suitably editing ‘templates’ created by prompt are recognized by codocData and used provided that the documentation object is for a single data frame (i.e., only has one alias). codocClasses analogously handles slot names for classes in documentation objects obtained by editing shells created by promptClass.

Help files named ‘pkgname-defunct.Rd’ for the appropriate pkgname are checked more loosely, as they may have undocumented arguments.

Value

codoc returns an object of class "codoc". Currently, this is a list which, for each Rd object in the package where an inconsistency was found, contains an element with a list of the mismatches (which in turn are lists with elements code and docs, giving the corresponding arguments obtained from the function’s code and documented usage).

codocClasses and codocData return objects of class "codocClasses" and "codocData", respectively, with a structure similar to class "codoc".

There are print methods for nicely displaying the information contained in such objects.

Note

The default for use.values has been changed from FALSE to NULL, for R versions 1.9.0 and later.

See Also

undoc, QC
compactPDF

Compact PDF Files

Description
Re-save PDF files (especially vignettes) more compactly. Support function for \texttt{R CMD build --compact-vignettes}.

Usage
\begin{verbatim}
compactPDF(paths, 
  qpdf = Sys.which(Sys.getenv("R_QPDF", "qpdf")), 
  gs_cmd = Sys.getenv("R_GSCMD", ""), 
  gs_quality = Sys.getenv("GS_QUALITY", "none"), 
  gs_extras = character())
\end{verbatim}

## S3 method for class 'compactPDF'
format(x, ratio = 1/0.9, diff = 1e4, ...)

Arguments
\begin{itemize}
  \item \textbf{paths} A character vector of paths to PDF files, or a length-one character vector naming a directory, when all `*.pdf` files in that directory will be used.
  \item \textbf{qpdf} Character string giving the path to the qpdf command. If empty, qpdf will not be used.
  \item \textbf{gs_cmd} Character string giving the path to the GhostScript executable, if that is to be used. On Windows this is the path to `gswin32c.exe` or `gswin64c.exe`. If `""`, the function will try to find a platform-specific path to GhostScript.
  \item \textbf{gs_quality} A character string indicating the quality required: the options are "none" (so GhostScript is not used), "printer" (300dpi), "ebook" (150dpi) and "screen" (72dpi).
  \item \textbf{gs_extras} An optional character vector of further options to be passed to GhostScript.
  \item \textbf{x} An object of class "compactPDF".
  \item \textbf{ratio, diff} Limits for reporting: files are only reported whose sizes are reduced both by a factor of \texttt{ratio} and by \texttt{diff} bytes.
  \item \textbf{...} Further arguments to be passed to or from other methods.
\end{itemize}

Details
This by default makes use of qpdf, available from \url{http://qpdf.sourceforge.net/} (including as a Windows binary) and included with the CRAN Mac OS X distribution of R. If \texttt{gs_cmd} is non-empty and \texttt{gs_quality} \neq "none", GhostScript will used first, then qpdf if it is available. If \texttt{gs_quality} \neq "none" and \texttt{gs_cmd} is empty, an attempt will be made to find a GhostScript executable.
qpdf and/or gs_cmd are run on all PDF files found, and those which are reduced in size by at least 10% and 10Kb are replaced.

The strategy of our use of qpdf is to (losslessly) compress both PDF streams and objects. Ghostscript compresses streams and more (including downsampling and compressing embedded images) and consequently is much slower and may lose quality (but can also produce much smaller PDF files). However, quality "ebook" is perfectly adequate for screen viewing and printing on laser printers.

Where PDF files are changed they will become PDF version 1.5 files: these have been supported by Acrobat Reader since version 6 in 2003, so this is very unlikely to cause difficulties.

Stream compression is what most often has large gains: R’s pdf device prior to R 2.14.0 did not use it, and older vignette PDFs often benefit from being re-generated. Most PDF documents are generated with object compression, but this does not seem to be the default for MiKTeX’s pdflatex. For some PDF files (and especially package vignettes), using GhostScript can dramatically reduce the space taken by embedded images (often screenshots).

Where both Ghostscript and qpdf are selected (when gs_quality != "none" and both executables are found), they are run in that order and the size reductions apply to the total compression achieved.

Value

An object of class c("compactPDF", "data.frame"). This has two columns, the old and new sizes in bytes for the files that were changed.

There are format and print methods: the latter passes ... to the format method, so will accept ratio and diff arguments.

Note

The external tools used may change in future releases.

See Also

resaveRdaFiles.

Many other (and sometimes more effective) tools to compact PDF files are available, including Adobe Acrobat (not Reader). See the ‘Writing R Extensions’ manual.

delimMatch

Delimited Pattern Matching

Description

Match delimited substrings in a character vector, with proper nesting.

Usage

delimMatch(x, delim = c("\{", "\}"), syntax = "Rd")
dependsOnPkgs

Arguments

- **x**: a character vector.
- **delim**: a character vector of length 2 giving the start and end delimiters. Future versions might allow for arbitrary regular expressions.
- **syntax**: currently, always the string "Rd" indicating Rd syntax (i.e., ‘%’ starts a comment extending till the end of the line, and ‘\’ escapes). Future versions might know about other syntax, perhaps via ‘syntax tables’ allowing to flexibly specify comment, escape, and quote characters.

Value

An integer vector of the same length as x giving the starting position (in characters) of the first match, or −1 if there is none, with attribute "match.length" giving the length (in characters) of the matched text (or −1 for no match).

See Also

regexpr for ‘simple’ pattern matching.

Examples

```r
x <- c("\value{foo}", "function(bar)")
delimMatch(x)
delimMatch(x, c("",""))
```

dependsOnPkgs  Find Reverse Dependencies

Description

Find ‘reverse’ dependencies of packages, that is those packages which depend on this one, and (optionally) so on recursively.

Usage

```r
dependsOnPkgs(pkgs,
dependencies = c("Depends", "Imports", "LinkingTo"),
recursive = TRUE, lib.loc = NULL,
installed =
installed.packages(lib.loc, fields = "Enhances"))
```
Arguments

pkgs  a character vector of package names.
dependencies  a character vector listing the types of dependencies, a subset of c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances"). Character string "all" is shorthand for that vector.
recursive  logical: should reverse dependencies of reverse dependencies (and so on) be included?
lib.loc  a character vector of R library trees, or NULL for all known trees (see .libPaths).
installed  a result of calling installed.packages.

Value

A character vector of package names, which does not include any from pkgs.

Examples

## there are few dependencies in a vanilla R installation
dependsOnPkgs("lattice")

encoded_text_to_latex  Translate non-ASCII Text to LaTeX Escapes

Description

Translate non-ASCII characters in text to LaTeX escape sequences.

Usage

encoded_text_to_latex(x,
  encoding = c("latin1", "latin2", "latin9",
                "UTF-8", "utf8"))

Arguments

  x  a character vector.
  encoding  the encoding to be assumed. "latin9" is officially ISO-8859-15 or Latin-9, but known as latin9 to LaTeX's inputenc package.

Details

Non-ASCII characters in x are replaced by an appropriate LaTeX escape sequence, or '?' if there is no appropriate sequence.

Even if there is an appropriate sequence, it may not be supported by the font in use. Hyphen is mapped to '\-'.

encoded_text_to_latex  Translate non-ASCII Text to LaTeX Escapes

Description

Translate non-ASCII characters in text to LaTeX escape sequences.

Usage

encoded_text_to_latex(x,
  encoding = c("latin1", "latin2", "latin9",
                "UTF-8", "utf8"))

Arguments

  x  a character vector.
  encoding  the encoding to be assumed. "latin9" is officially ISO-8859-15 or Latin-9, but known as latin9 to LaTeX’s inputenc package.

Details

Non-ASCII characters in x are replaced by an appropriate LaTeX escape sequence, or ‘?’ if there is no appropriate sequence.

Even if there is an appropriate sequence, it may not be supported by the font in use. Hyphen is mapped to ‘\-’. 
Value

A character vector of the same length as x.

close(con)

# End(Not run)
Description

Utilities for listing files, and manipulating file paths.

Usage

```r
file_ext(x)
file_path_as_absolute(x)
file_path_sans_ext(x, compression = FALSE)

list_files_with_exts(dir, exts, all.files = FALSE,
                     full.names = TRUE)
list_files_with_type(dir, type, all.files = FALSE,
                     full.names = TRUE, OS_subdirs = .OS_type())
```

Arguments

- `x` character vector giving file paths.
- `compression` logical: should compression extension `.gz`, `.bz2` or `.xz` be removed first?
- `dir` a character string with the path name to a directory.
- `exts` a character vector of possible file extensions.
- `all.files` a logical. If `FALSE` (default), only visible files are considered; if `TRUE`, all files are used.
- `full.names` a logical indicating whether the full paths of the files found are returned (default), or just the file names.
- `type` a character string giving the ‘type’ of the files to be listed, as characterized by their extensions. Currently, possible values are "code" (R code), "data" (data sets), "demo" (demos), "docs" (R documentation), and "vignette" (vignettes).
- `OS_subdirs` a character vector with the names of OS-specific subdirectories to possibly include in the listing of R code and documentation files. By default, the value of the environment variable R_OSTYPE, or if this is empty, the value of .Platform$OS.type, is used.

Details

- `file_ext` returns the file (name) extensions. (Only purely alphanumeric extensions are recognized.)
- `file_path_as_absolute` turns a possibly relative file path absolute, performing tilde expansion if necessary. As from R 2.13.0 this is a wrapper for `normalizePath`. Currently, x must be a single existing path.
- `file_path_sans_ext` returns the file paths without extensions. (Only purely alphanumeric extensions are recognized.)
list_files_with_exts returns the paths or names of the files in directory dir with extension matching one of the elements of exts. Note that by default, full paths are returned, and that only visible files are used.

dir <- file.path(R.home(), "library", "stats")
list_files_with_exts(file.path(dir, "demo"), "R")
list_files_with_type(file.path(dir, "demo"), "demo") # the same
file_path_sans_ext(list.files(file.path(R.home("modules"))))

list_files_with_type returns the paths of the files in dir of the given 'type', as determined by the extensions recognized by R. When listing R code and documentation files, files in OS-specific subdirectories are included if present according to the value of OS_subdirs. Note that by default, full paths are returned, and that only visible files are used.

Examples

getDepList

Functions to Retrieve Dependency Information

Description

Given a dependency matrix, will create a DependsList object for that package which will include the dependencies for that matrix, which ones are installed, which unresolved dependencies were found online, which unresolved dependencies were not found online, and any R dependencies.

Usage

gdepDepList(depMtrx, instPkgs, recursive = TRUE, local = TRUE, reduce = TRUE, lib.loc = NULL)

pkgDepends(pkg, recursive = TRUE, local = TRUE, reduce = TRUE, lib.loc = NULL)

Arguments

depMtrx
pkg
instPkgs
recursive
local
reduce
lib.loc

A dependency matrix as from package.dependencies
The name of the package
A matrix specifying all packages installed on the local system, as from installed.packages
Whether or not to include indirect dependencies
Whether or not to search only locally
Whether or not to collapse all sets of dependencies to a minimal value
What libraries to use when looking for installed packages. NULL indicates all library directories in the user’s .libPaths().
Details

The function pkgDepends is a convenience function which wraps getDepList and takes as input a package name. It will then query `installed.packages` and also generate a dependency matrix, calling getDepList with this information and returning the result.

These functions will retrieve information about the dependencies of the matrix, resulting in a `DependsList` object. This is a list with four elements:

**Depends**  A vector of the dependencies for this package.

**Installed**  A vector of the dependencies which have been satisfied by the currently installed packages.

**Found**  A list representing the dependencies which are not in `Installed` but were found online. This list has element names which are the URLs for the repositories in which packages were found and the elements themselves are vectors of package names which were found in the respective repositories. If `local = TRUE`, the `Found` element will always be empty.

**R**  Any R version dependencies.

If `recursive` is `TRUE`, any package that is specified as a dependency will in turn have its dependencies included (and so on), these are known as indirect dependencies. If `recursive` is `FALSE`, only the dependencies directly stated by the package will be used.

If `local` is `TRUE`, the system will only look at the user's local install and not online to find unresolved dependencies.

If `reduce` is `TRUE`, the system will collapse the fields in the `DependsList` object such that a minimal set of dependencies are specified (for instance if there was `foo, foo (>= 1.0.0), foo (>= 1.3.0)`, it would only return `foo (>= 1.3.0)`).

Value

An object of class "DependsList".

Examples

```r
tools
```
**HTMLheader**  

Generate a standard HTML header for R help

---

**Description**

This function generates the standard HTML header used on R help pages.

**Usage**

```r
HTMLheader(title = "R", logo = TRUE, up = NULL,
    top = file.path(Rhome, "doc/html/index.html"),
    Rhome = ",",
    css = file.path(Rhome, "doc/html/R.css"),
    headerTitle = paste("R:\", title),
    outputEncoding = "UTF-8")
```

**Arguments**

- `title`   
  The title to display and use in the HTML headers. Should have had any HTML escaping already done.
- `logo`    
  Whether to display the R logo after the title.
- `up`      
  Which page (if any) to link to on the “up” button.
- `top`     
  Which page (if any) to link to on the “top” button.
- `Rhome`   
  A relative path to the R home directory. See the ‘Details’.
- `css`     
  The relative URL for the Cascading Style Sheet.
- `headerTitle`  
  The title used in the headers.
- `outputEncoding`  
  The declared encoding for the whole page.

**Details**

The `up` and `top` links should be relative to the current page. The `Rhome` path default works with dynamic help; for static help, a relative path (e.g. `../..`) to it should be used.

**Value**

A character vector containing the lines of an HTML header which can be used to start a page in the R help system.

**Examples**

```r
cat(HTMLheader("This is a sample header"), sep="\n")
```
Collect HTML Links from Package Documentation

Description

Compute relative file paths for URLs to other package’s installed HTML documentation.

Usage

```r
findHTMLlinks(pkgDir = "", lib.loc = NULL, level = 0:2)
```

Arguments

- **pkgDir**: the top-level directory of an installed package. The default indicates no package.
- **lib.loc**: character vector describing the location of R library trees to scan: the default indicates `.libPaths()`.
- **level**: Which level(s) to include.

Details

`findHTMLlinks` tries to resolve links from one help page to another. It uses in decreasing priority:

- The package in `pkgDir`: this is used when converting HTML help for that package (level 0).
- The base and recommended packages (level 1).
- Other packages found in the library trees specified by `lib.loc` in the order of the trees and alphabetically within a library tree (level 2).

Value

A named character vector of file paths, relative to the ‘html’ directory of an installed package. So these are of the form ""./../somepkg/html/sometopic.html"".

Author(s)

Duncan Murdoch, Brian Ripley
installFoundDepends  A function to install unresolved dependencies

Description

This function will take the Found element of a pkgDependsList object and attempt to install all of the listed packages from the specified repositories.

Usage

installFoundDepends(depPkgList, ...)

Arguments

depPkgList A Found element from a pkgDependsList object
...
Arguments to pass on to install.packages

Details

This function takes as input the Found list from a pkgDependsList object. This list will have element names being URLs corresponding to repositories and the elements will be vectors of package names. For each element, install.packages is called for that URL to install all packages listed in the vector.

pkgDepends, install.packages

Examples

## Set up a temporary directory to install packages to
tmp <- tempfile()
dir.create(tmp)

pDL <- pkgDepends("tools", local = FALSE)
installFoundDepends(pDL$Found, destdir = tmp)
make_translations_pkg  Package the Current Translations in the \texttt{R} sources

Description

A utility for R Core members to prepare a package of updated translations.

Usage

\begin{verbatim}
make_translations_pkg(srcdir, outDir = ".", append = "-1")
\end{verbatim}

Arguments

\begin{verbatim}
srcdir The \texttt{R} source directory.
outDir The directory into which to place the prepared package.
append The suffix for the package version number, e.g. 3.0.0-1 will be the default in \texttt{R} 3.0.0.
\end{verbatim}

Details

This extracts the translations in a current \texttt{R} source distribution and packages them as a source package called \texttt{translations} which can be distributed on CRAN and installed by \texttt{update.packages}. This allows e.g. the translations shipped in \texttt{R} 3.x.y to be updated to those currently in \texttt{"R-patched"}, even by a user without administrative privileges.

The package has a `Depends` field which restricts it to versions 3.x.* for a single x.

md5sum  Compute MD5 Checksums

Description

Compute the 32-byte MD5 checksums of one or more files.

Usage

\begin{verbatim}
md5sum(files)
\end{verbatim}

Arguments

\begin{verbatim}
files character. The paths of file(s) to be check-summed.
\end{verbatim}
package.dependencies

Value
A character vector of the same length as files, with names equal to files. The elements will be
NA for non-existent or unreadable files, otherwise a 32-character string of hexadecimal digits.
On Windows all files are read in binary mode (as the md5sum utilities there do): on other OSes the
files are read in the default way.

See Also
checkMD5sums

Examples
as.vector(md5sum(dir(R.home(), pattern = "^COPY", full.names = TRUE)))

package.dependencies Check Package Dependencies

Description
Parses and checks the dependencies of a package against the currently installed version of R (and
other packages).

Usage
package.dependencies(x, check = FALSE,
           depLevel =
           c("Depends", "Imports", "Suggests"))

Arguments
x A matrix of package descriptions as returned by available.packages.
check If TRUE, return logical vector of check results. If FALSE, return parsed list of
dependencies.
depLevel Whether to look for Depends or Suggests level dependencies.

Details
Currently we only check if the package conforms with the currently running version of R. In the
future we might add checks for inter-package dependencies.

See Also
update.packages
Description

Find (recursively) dependencies or reverse dependencies of packages.

Usage

package_dependencies(packages = NULL, db,
                     which = c("Depends", "Imports", "LinkingTo"),
                     recursive = FALSE, reverse = FALSE)

Arguments

packages a character vector of package names.
db character matrix as from available.packages(), or data frame variants thereof. Alternatively, a package database like the one available from http://cran.R-project.org/web/packages/packages.rds.
which a character vector listing the types of dependencies, a subset of c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances"). Character string "all" is shorthand for that vector, character string "most" for the same vector without "Enhances".
recursive logical: should (reverse) dependencies of (reverse) dependencies (and so on) be included?
reverse logical: if FALSE (default), regular dependencies are calculated, otherwise reverse dependencies.

Value

Named list with one element for each package in argument packages, each consists of a character vector naming the (recursive) (reverse) dependencies of that package.

For given packages which are not found in the db, NULL entries are returned, as opposed to character(0) entries which indicate no dependencies.

See Also

dependsOnPkg, and package_dependencies for checking dependencies

Examples

## Not run:
pdb <- available.packages()
deps <- package_dependencies(packages = "MASS", pdb,
                             which = c("Depends", "Imports", "LinkingTo", "Suggests"),
                             recursive = TRUE, reverse = TRUE)
These experimental functions work with a subset of LaTeX code.

Description

The \texttt{parseLatex} function parses LaTeX source, producing a structured object; \texttt{deparseLatex} reverses the process. The \texttt{latexToUtf8} function takes a LaTeX object, and processes a number of different macros to convert them into the corresponding UTF-8 characters.

Usage

\begin{verbatim}
parseLatex(text, filename = deparse(substitute(text)),
    verbose = FALSE,
    verbatim = c("verbatim", "verbatim*",
                "Sinput", "Soutput")

deparseLatex(x, dropBraces = FALSE)
latexToUtf8(x)
\end{verbatim}

Arguments

- **text**: A character vector containing LaTeX source code.
- **filename**: A filename to use in syntax error messages.
- **verbose**: If TRUE, print debug error messages.
- **verbatim**: A character vector containing the names of LaTeX environments holding verbatim text.
- **x**: A "LaTeX" object.
- **dropBraces**: Drop unnecessary braces when displaying a "LaTeX" object.

Details

The parser does not recognize all legal LaTeX code, only relatively simple examples. It does not associate arguments with macros, that needs to be done after parsing, with knowledge of the definitions of each macro. The main intention for this function is to process simple LaTeX code used in bibliographic references, not fully general LaTeX documents.

Verbose text is allowed in two forms: the \verb macro (with single character delimiters), and environments whose names are listed in the \texttt{verbatim} argument.
Value

The `parseLatex()` function returns a recursive object of class "LaTeX". Each of the entries in this object will have a "latex_tag" attribute identifying its syntactic role.

The `deparseLatex()` function returns a single element character vector, possibly containing embedded newlines.

The `latexToUtf8()` function returns a modified version of the "LaTeX" object that was passed to it.

Author(s)

Duncan Murdoch

Examples

```r
latex <- parseLatex("fa\c{c}ile")
deparseLatex(latexToUtf8(latex))
```

Description

This function reads an R documentation (Rd) file and parses it, for processing by other functions.

Usage

```r
parse_Rd(file, srcfile = NULL, encoding = "unknown",
    verbose = FALSE, fragment = FALSE, warningCalls = TRUE)
```

Arguments

- `file`: A filename or text-mode connection. At present filenames work best.
- `srcfile`: NULL, or a "srcfile" object. See the ‘Details’ section.
- `encoding`: Encoding to be assumed for input strings.
- `verbose`: Logical indicating whether detailed parsing information should be printed.
- `fragment`: Logical indicating whether file represents a complete Rd file, or a fragment.
- `warningCalls`: Logical: should parser warnings include the call?
- `x`: An object of class Rd.
- `deparse`: If TRUE, attempt to reinstate the escape characters so that the resulting characters will parse to the same object.
- `...`: Further arguments to be passed to or from other methods.
**Details**

This function parses `Rd` files according to the specification given in http://developer.r-project.org/parseRd.pdf.

It generates a warning for each parse error and attempts to continue parsing. In order to continue, it is generally necessary to drop some parts of the file, so such warnings should not be ignored.

**Value**

`parse_Rd` returns an object of class "Rd". The internal format of this object is subject to change. The `as.character()` and `print()` methods defined for the class return character vectors and print them, respectively.

Files without a marked encoding are by default assumed to be in the native encoding. An alternate default can be set using the `encoding` argument. All text in files is translated to the UTF-8 encoding in the parsed object.

`Rd2HTML` for the converters that use the output of `parse_Rd()`.

---

**pskill**

**Kill a Process**

**Description**

`pskill` sends a signal to a process, usually to terminate it.

**Usage**

`pskill(pid, signal = SIGTERM)`

SIGHUP
SIGINT
SIGQUIT
SICKILL
SIGTERM
SIGSTOP
SIGTSTP
SIGCHLD
SIGUSR1
SIGUSR2
Arguments

- **pid**: positive integers: one or more process IDs as returned by `Sys.getpid`.
- **signal**: integer, most often one of the symbolic constants.

Details

Signals are a C99 concept, but only a small number are required to be supported (of those listed, only SIGINT and SIGTERM). They are much more widely used on POSIX operating systems (which should define all of those listed here), which also support a `kill` system call to send a signal to a process, most often to terminate it. Function `pskill` provides a wrapper: it silently ignores invalid values of its arguments, including zero or negative pids.

In normal use on a Unix-alike, Ctrl-C sends SIGINT, Ctrl-\ sends SIGQUIT and Ctrl-Z sends SIGTSTP: that and SIGSTOP suspend a process which can be resumed by SIGCONT.

The signals are small integers, but the actual numeric values are not standardized (and most do differ between OSes). The `SIG*` objects contain the appropriate integer values for the current platform (or `NA_INTEGER_` if the signal is not defined).

Only SIGINT and SIGKILL will be defined on Windows, and `pskill` will always use the Windows system call `TerminateProcess`.

Value

A logical vector of the same length as `pid`, TRUE (for success) or FALSE, invisibly.

See Also

Package **parallel** has several means to launch child processes which record the process IDs.

**psnice**

Examples

```r
## Not run:
pshall(c(237, 245), SIGKILL)
```

## End(Not run)

---

**psnice** *Get or Set the Priority (Niceness) of a Process*

Description

Get or set the ‘niceness’ of the current process, or one or more other processes.

Usage

```r
psnice(pid = Sys.getpid(), value = NA_integer_)
```
Arguments

pid  positive integers: the process IDs of one of more processes: defaults to the R session process.

value  The niceness to be set, or NA for an enquiry.

Details

POSIX operating systems have a concept of process priorities, usually from 0 to 39 (or 40) with 20
being a normal priority and (somewhat confusingly) larger numeric values denoting lower priority.
To add to the confusion, there is a ‘niceness’ value, the amount by which the priority numerically
exceeds 20 (which can be negative). Processes with high niceness will receive less CPU time than
those with normal priority. On some OSes, processes with niceness +19 are only run when the
system would otherwise be idle.

On many OSes utilities such as top report the priority and not the niceness. Niceness is used by the
utility ‘/usr/bin/renice’: ‘/usr/bin/nice’ (and /usr/bin/renice -n) specifies an increment
in niceness.

Only privileged users (usually super-users) can lower the niceness.

Windows has a slightly different concept of ‘priority classes’. We have mapped the idle priority to
niceness 19, ‘below normal’ to 15, normal to 0, ‘above normal’ to −5 and ‘realtime’ to −10. Unlike
Unix-alikes, a non-privileged user can increase the priority class on Windows (but using ‘realtime’
is inadvisable).

Value

An integer vector of previous niceness values, NA if unknown for any reason.

See Also

Various functions in package parallel create child processes whose priority may need to be changed.
pskill.
Arguments

package     a character string naming an installed package.
dir         a character string specifying the path to a package’s root source directory. This should contain the subdirectories ‘R’ (for R code) and ‘man’ with R documentation sources (in Rd format). Only used if package is not given.
lib.loc     a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.

Details

checkDocFiles checks, for all Rd files in a package, whether all arguments shown in the usage sections of the Rd file are documented in its arguments section. It also reports duplicated entries in the arguments section, and ‘over-documented’ arguments which are given in the arguments section but not in the usage. Note that the match is for the usage section and not a possibly existing synopsis section, as the usage is what gets displayed.

checkDocStyle investigates how (S3) methods are shown in the usages of the Rd files in a package. It reports the methods shown by their full name rather than using the Rd method markup for indicating S3 methods. Earlier versions of R also reported about methods shown along with their generic, which typically caused problems for the documentation of the primary argument in the generic and its methods. With \method now being expanded in a way that class information is preserved, joint documentation is no longer necessarily a problem. (The corresponding information is still contained in the object returned by checkDocStyle.)

checkReplaceFuns checks whether replacement functions or S3/S4 replacement methods in the package R code have their final argument named value.

checkS3methods checks whether all S3 methods defined in the package R code have all arguments of the corresponding generic, with positional arguments of the generics in the same positions for the method. As an exception, the first argument of a formula method may be called formula even if this is not the name used by the generic. The rules when ... is involved are subtle: see the source code. Functions recognized as S3 generics are those with a call to useMethod in their body, internal S3 generics (see InternalMethods), and S3 group generics (see Math). Possible dispatch under a different name is not taken into account. The generics are sought first in the given package, then in the base package and (currently) the packages graphics, stats, and utils added in R 1.9.0 by splitting the former base, and, if an installed package is tested, also in the loaded namespaces/packages listed in the package’s ‘DESCRIPTION’ Depends field.

If using an installed package, the checks needing access to all R objects of the package will load the package (unless it is the base package), after possibly detaching an already loaded version of the package.

Value

The functions return objects of class the same as the respective function names containing the information about problems detected. There are print methods for nicely displaying the information contained in such objects.
Description

These functions take the output of the `parse_Rd` function and produce a help page from it. As they are mainly intended for internal use, their interfaces are subject to change.

Usage

```
Rd2HTML(Rd, out = "", package = "", defines = .Platform$OS.type,
         Links = NULL, Links2 = NULL,
         stages = "render", outputEncoding = "UTF-8",
         dynamic = FALSE, no_links = FALSE, fragment = FALSE,
         stylesheet = "R.css", ...)
```

```
Rd2txt(Rd, out = "", package = "", defines = .Platform$OS.type,
        stages = "render", outputEncoding = "",
        fragment = FALSE, options, ...)
```

```
Rd2latex(Rd, out = "", defines = .Platform$OS.type,
          stages = "render", outputEncoding = "ASCII",
          fragment = FALSE, ..., writeEncoding = TRUE)
```

```
Rd2ex(Rd, out = "", defines = .Platform$OS.type,
       stages = "render", outputEncoding = "UTF-8", ...)
```

Arguments

- `Rd` a filename or Rd object to use as input.
- `out` a filename or connection object to which to write the output.
- `package` the package to list in the output.
- `defines` string(s) to use in #ifdef tests.
- `stages` at which stage ("build", "install", or "render") should \Sexpr macros be executed? See the notes below.
- `outputEncoding` see the ‘Encodings’ section below.
- `dynamic` logical: set links for render-time resolution by dynamic help system.
- `no_links` logical: suppress hyperlinks to other help topics. Used by R CMD Rdconv.
- `fragment` logical: should fragments of Rd files be accepted? See the notes below.
- `stylesheet` character: a URL for a stylesheet to be used in the header of the HTML output page.
- `Links, Links2` NULL or a named (by topics) character vector of links, as returned by findHTMLlinks.
- `options` An optional named list of options to pass to Rd2txt_options.
additional parameters to pass to `parse_Rd` when Rd is a filename.

`writeEncoding` should `\inputencoding` lines be written in the file for non-ASCII encodings?

**Details**

These functions convert help documents: `Rd2HTML` produces HTML, `Rd2txt` produces plain text, `Rd2latex` produces LaTeX. `Rd2ex` extracts the examples in the format used by `example` and R utilities.

Each of the functions accepts a filename for an Rd file, and will use `parse_Rd` to parse it before applying the conversions or checks.

The difference between arguments `Link` and `Link2` is that links are looked in them in turn, so lazy-evaluation can be used to only do a second-level search for links if required.

Note that the default for `Rd2latex` is to output ASCII, including using the second option of `\enc` markup. This was chosen because use of UTF-8 in LaTeX requires version ‘2005/12/01’ or later, and even with that version the coverage of UTF-8 glyphs is not extensive (and not even as complete as Latin-1).

`Rd2txt` will format text paragraphs to a width determined by `width`, with appropriate margins. The default is to be close to the rendering in versions of R < 2.10.0.

`Rd2txt` will use directional quotes (see `sQuote`) if option "useFancyQuotes" is true (the default) and the current encoding is UTF-8.

Various aspects of formatting by `Rd2txt` are controlled by the options argument, documented with the `Rd2txt_options` function. Changes made using options are temporary, those made with `Rd2txt_options` are persistent.

When `fragment = TRUE`, the Rd file will be rendered with no processing of \Sexpr elements or conditional defines using `#ifdef` or `#ifndef`. Normally a fragment represents text within a section, but if the first element of the fragment is a section macro, the whole fragment will be rendered as a series of sections, without the usual sorting.

**Value**

These functions are executed mainly for the side effect of writing the converted help page. Their value is the name of the output file (invisibly). For `Rd2latex`, the output name is given an attribute "latexEncoding" giving the encoding of the file in a form suitable for use with the LaTeX `\inputenc` package.

**Encodings**

Rd files are normally intended to be rendered on a wide variety of systems, so care must be taken in the encoding of non-ASCII characters. In general, any such encoding should be declared using the ‘encoding’ section for there to be any hope of correct rendering.

For output, the `outputEncoding` argument will be used: `outputEncoding = ""` will choose the native encoding for the current system.

If the text cannot be converted to the `outputEncoding`, byte substitution will be used (see `iconv`): `Rd2latex` and `Rd2ex` give a warning.
Note

The \Sexpr macro is a new addition to Rd files. It includes R code that will be executed at one of three times: build time (when a package’s source code is built into a tarball), install time (when the package is installed or built into a binary package), and render time (when the man page is converted to a readable format).

For example, this man page was:

1. built on 2013-08-08 at 18:20:26,
2. installed on 2013-08-08 at 18:20:26, and
3. rendered on 2013-08-08 at 18:42:07.

Examples

## Not run:
## Simulate install and rendering of this page in HTML and text format:

Rd <- file.path("src/library/tools/man/Rd2HTML.Rd")

outfile <- tempfile(fileext = ".html")
browseURL(Rd2HTML(Rd, outfile, package = "tools", stages = c("install", "render")))

outfile <- tempfile(fileext = ".txt")
file.show(Rd2txt(Rd, outfile, package = "tools", stages = c("install", "render")))

checkRd(Rd) # A stricter test than Rd2HTML uses

## End(Not run)
Description

This function sets various options for displaying text help.

Usage

Rd2txt_options(...)

Arguments

... A list containing named options, or options passed as individual named arguments. See below for currently defined ones.

Details

This function persistently sets various formatting options for the Rd2txt function which is used in displaying text format help. Currently defined options are:

- `width` (default 80): The width of the output page.
- `minIndent` (default 10): The minimum indent to use in a list.
- `extraIndent` (default 4): The extra indent to use in each level of nested lists.
- `sectionIndent` (default 5): The indent level for a section.
- `sectionExtra` (default 2): The extra indentation for each nested section level.
- `itemBullet` (default "* ", with the asterisk replaced by a Unicode bullet in UTF-8 and most Windows locales): The symbol to use as a bullet in itemized lists.
- `enumFormat` : A function to format item numbers in enumerated lists.
- `showURLs` (default FALSE): Whether to show URLs when expanding \href tags.
- `code_quote` (default TRUE): Whether to render \code and similar with single quotes.
- `underline_titles` default TRUE): Whether to render section titles with underlines (via backspacing).

Value

If called with no arguments, returns all option settings in a list. Otherwise, it changes the named settings and invisibly returns their previous values.

saveOpts
Rd2txt_options(minIndent = 4)
Rd2txt_options()
Rd2txt_options(saveOpts)
Rd2txt_options()
```

Rdiff

**Difference R Output Files**

Description

Given two R output files, compute differences ignoring headers, footers and some other differences.

Usage

```r
Rdiff(from, to, useDiff = FALSE, forEx = FALSE, 
      nullPointers = TRUE, Log = FALSE)
```

Arguments

- `from, to` filepaths to be compared
- `useDiff` should `diff` always be used to compare results?
- `forEx` logical: extra pruning for `-Ex.Rout` files to exclude the header.
- `nullPointers` logical: should the displayed addresses of pointers be set to `0x00000000` before comparison?
- `Log` logical: should the returned value include a log of differences found?

Details

The R startup banner and any timing information from `R CMD BATCH` are removed from both files, together with lines about loading packages. UTF-8 fancy quotes (see `sQuote`) and on Windows, Windows' so-called `smart quotes`, are mapped to a simple quote. Addresses of environments, compiled bytecode and other exotic types expressed as hex addresses (e.g. `<environment: 0x12345678>`) are mapped to `0x00000000`. The files are then compared line-by-line. If there are the same number of lines and `useDiff` is false, a simple `diff`-like display of differences is printed (which ignores differences in consecutive spaces), otherwise `diff -bw` is called on the edited files. (This tries to ignore all differences in whitespace: note that flag `'-w'` is not required by POSIX but is supported by GNU, Solaris and FreeBSD versions.)

This can compare uncompressed PDF files, ignoring differences in creation and modification dates.

Value

If `Log` is true, a list with components `status` (see below) and `out`, a character vector of descriptions of differences, possibly of zero length.

Otherwise, a status indicator, `0L` if and only if no differences were found.
1804

Rdindex

See Also
The shell script run as R CMD Rdiff.

Rdindex

Generate Index from Rd Files

Description
Print a 2-column index table with names and titles from given R documentation files to a given
output file or connection. The titles are nicely formatted between two column positions (typically
25 and 72, respectively).

Usage
Rdindex(RdFiles, outFile = "", type = NULL,
width = 0.9 * getOption("width"), indent = NULL)
Arguments
RdFiles

a character vector specifying the Rd files to be used for creating the index, either
by giving the paths to the files, or the path to a single directory with the sources
of a package.

outFile

a connection, or a character string naming the output file to print to. "" (the
default) indicates output to the console.

type

a character string giving the documentation type of the Rd files to be included in
the index, or NULL (the default). The type of an Rd file is typically specified via
the \docType tag; if type is "data", Rd files whose only keyword is datasets
are included as well.

width

a positive integer giving the target column for wrapping lines in the output.

indent

a positive integer specifying the indentation of the second column. Must not be
greater than width/2, and defaults to width/3.

Details
If a name is not a valid alias, the first alias (or the empty string if there is none) is used instead.


RdTextFilter

Select text in an Rd file.

Description

This function blanks out all non-text in an Rd file, for spell checking or other uses.

Usage

RdTextFilter(ifile, encoding = "unknown", keepSpacing = TRUE, 
drop = character(), keep = character())

Arguments

ifile An input file specified as a filename or connection, or an "Rd" object from parse_Rd.
encoding An encoding name to pass to parse_Rd.
keepSpacing Whether to try to leave the text in the same lines and columns as in the original file.
drop Additional sections of the Rd to drop.
keep Sections of the Rd file to keep.

Details

This function parses the Rd file, then walks through it, element by element. Items with tag "TEXT" are kept in the same position as they appeared in the original file, while other parts of the file are replaced with blanks, so a spell checker such as aspell can check only the text and report the position in the original file. (If keepSpacing is FALSE, blank filling will not occur, and text will not be output in its original location.)

By default, the tags \S3method, \S4method, \command, \docType, \email, \encoding, \file, \keyword, \link, \linkS4class, \method, \pkg, and \var are skipped. Additional tags can be skipped by listing them in the drop argument; listing tags in the keep argument will stop them from being skipped. It is also possible to keep any of the c("RCODE", "COMMENT", "VERB") tags, which correspond to R-like code, comments, and verbatim text respectively, or to drop "TEXT".

Value

A character vector which if written to a file, one element per line, would duplicate the text elements of the original Rd file.

Note

The filter attempts to merge text elements into single words when markup in the Rd file is used to highlight just the start of a word.
Rdutils

Description

Utilities for computing on the information in Rd objects.

Usage

Rd_db(package, dir, lib.loc = NULL)

Arguments

package a character string naming an installed package.
dir a character string specifying the path to a package’s root source directory. This should contain the subdirectory ‘man’ with R documentation sources (in Rd format). Only used if package is not given.
lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.

Details

Rd_db builds a simple database of all Rd objects in a package, as a list of the results of running parse_Rd on the Rd source files in the package and processing platform conditionals.

See Also

parse_Rd

Examples

## Build the Rd db for the (installed) base package.
db <- Rd_db("base")

## Keyword metadata per Rd object.
keywords <- lapply(db, tools:::.Rd_get_metadata, "keyword")
## Tabulate the keyword entries.
kw_table <- sort(table(unlist(keywords)))
## The 5 most frequent ones:
rev(kw_table)[1:5]
## The "most informative" ones:

kw_table[kw_table == 1]

## Concept metadata per Rd file.

concepts <- lapply(db, tools:::.Rd_get_metadata, "concept")

## How many files already have \concept metadata?

sum(sapply(concepts, length) > 0)

## How many concept entries altogether?

length(unlist(concepts))

---

### read.00Index

**Read 00Index-style Files**

**Description**

Read item/description information from ‘00Index’-like files. Such files are description lists rendered in tabular form, and currently used for the ‘INDEX’ and ‘demo/00Index’ files of add-on packages.

**Usage**

read.00Index(file)

**Arguments**

- **file**
  
  the name of a file to read data values from. If the specified file is "", then input is taken from the keyboard (in this case input can be terminated by a blank line). Alternatively, file can be a **connection**, which will be opened if necessary, and if so closed at the end of the function call.

**Value**

A character matrix with 2 columns named "Item" and "Description" which hold the items and descriptions.

**See Also**

formatDL for the inverse operation of creating a 00Index-style file from items and their descriptions.
Description

Read/check R’s ‘NEWS’ file or a similarly formatted one. This was an experimental feature added in R 2.4.0: as from R 2.12.0 the preferred format is ‘NEWS.Rd’.

Usage

readNEWS(file = file.path(R.home(), "NEWS"), trace = FALSE, chop = c("first", "1", "par1", "keepAll"))
checkNEWS(file = file.path(R.home(), "NEWS"))

Arguments

file the name of the file which the data are to be read from. Alternatively, file can be a connection, which will be opened if necessary, and can also be a complete URL. For more details, see the file argument of read.table.
trace logical indicating if the recursive reading should be traced, i.e., print what it is doing.
chop a character string specifying how the news entries should be chopped; chop = "keepAll" saves the full entries.

Details

readNEWS() reads a pre-R-2.12.0-style ‘NEWS’ file; checkNEWS() checks for common errors in formatting. Currently it detects an incorrect number of spaces before the "o" item marker.

If non-ASCII characters are needed, the ‘NEWS’ file may be encoded in UTF-8 with a byte-order mark (BOM) at the beginning, which readNEWS() will recognize. Other encodings will display incorrectly on some systems. However, BOMs are discouraged on many systems and not all editors recognize them, so ‘NEWS’ files should normally be written in ASCII.

Value

readNEWS() returns an (S3) object of class "newsTree"; effectively a list of lists which is a tree of NEWS entries.
checkNEWS() returns TRUE if no suspected errors are found, or prints a message for each suspected error and returns FALSE.

Note that this was only ever experimental and may be removed soon, since the NEWS-file format is not longer supported (but there are examples ‘ONEWS’, ‘OONWS’ and perhaps in packages).
showNonASCII

Examples

```r
NEWStr <- readNEWS(trace = TRUE)  # chop = "first" (= "first non-empty")
## keep the full NEWS entry text i.e. "no chopping":
NEWStrA <- readNEWS(chop = "keepAll")
object.size(NEWStr)
object.size(NEWStrA)  # (no chopping) ==> about double the size

str(NEWStr, max.level = 3)
str(NEWStr[[c("2.3", "2.3.1")]], max.level = 2, vec.len = 1)

NEWStr [[c("2.3", "2.3.1", "NEW FEATURES")]]
NEWStrA[[c("2.4", "2.4.0", "NEW FEATURES")]]

# Check the current NEWS file
stopifnot(checkNEWS())
```

showNonASCII  Pick Out Non-ASCII Characters

Description

This function prints elements of a character vector which contain non-ASCII bytes, printing such bytes as a escape like ‘<fc>’.

Usage

```r
showNonASCII(x)
showNonASCIIfile(file)
```

Arguments

- `x`  a character vector.
- `file`  path to a file.

Details

This was originally written to help detect non-portable text in files in packages.

It prints all element of `x` which contain non-ASCII characters, preceded by the element number and with non-ASCII bytes highlighted via `iconv(sub = "byte")`.

Value

The elements of `x` containing non-ASCII characters will be returned invisibly.
Examples

```r
out <- c(  
  "fa\xE7ile test of showNonASCII():",  
  \"\"\"\"\details{  
  " This is a good line",  
  " This has an \xfcmlaut in it.",  
  " OK again.",  
  \"}\"
  )

f <- tempfile()
cat(out, file = f, sep = "\n")

showNonASCIIfile(f)
unlink(f)
```

---

**startDynamicHelp**  
*Start the Dynamic HTML Help System*

**Description**

This function starts the internal help server, so that HTML help pages are rendered when requested.

**Usage**

```r
startDynamicHelp(start = TRUE)
```

**Arguments**

- start: logical; whether to start or shut down the dynamic help system.

**Details**

This function starts the internal HTTP server, which runs on the loopback interface (127.0.0.1). If `options("help.ports")` is set to a vector of integer values, `startDynamicHelp` will try those ports in order; otherwise, it tries up to 10 random ports to find one not in use. It can be disabled by setting the environment variable `R_DISABLE_HTTPD` to a non-empty value.

`startDynamicHelp` is called by functions that need to use the server, so would rarely be called directly by a user.

Note that `options(help_type = "html")` must be set to actually make use of HTML help, although it might be the default for an R installation.

If the server cannot be started or is disabled, `help.start` will be unavailable and requests for HTML help will give text help (with a warning).

The browser in use does need to be able to connect to the loopback interface: occasionally it is set to use a proxy for HTTP on all interfaces, which will not work – the solution is to add an exception for 127.0.0.1.
Value

The chosen port number is returned invisibly (which will be 0 if the server has been stopped).

See Also

help.start and help(help_type = "html") will attempt to start the HTTP server if required
Rd2HTML is used to render the package help pages.

---

SweaveTeXFilter  Strip R code out of Sweave file

Description

This function blanks out code chunks and Noweb markup in an Sweave input file, for spell checking
or other uses.

Usage

SweaveTeXFilter(ifile, encoding = "unknown")

Arguments

ifile Input file or connection.
encoding Text encoding to pass to readLines.

Details

This function blanks out all Noweb markup and code chunks from an Sweave input file, leaving
behind the LaTeX source, so that a LaTeX-aware spelling checker can check it and report errors in
their original locations.

Value

A character vector which if written to a file, one element per line, would duplicate the text elements
of the original Rd file.

Author(s)

Duncan Murdoch

See Also

aspell, for which this is used with filter = "Sweave".
testInstalledPackage  Test Installed Packages

Description

These functions allow an installed package to be tested, or all base and recommended packages.

Usage

```r
testInstalledPackage(pkg, lib.loc = NULL, outDir = ".",
                    types = c("examples", "tests", "vignettes"),
                    srcdir = NULL, Ropts = "")

testInstalledPackages(outDir = ".", errorsAreFatal = TRUE,
                       scope = c("both", "base", "recommended"),
                       types = c("examples", "tests", "vignettes"),
                       srcdir = NULL, Ropts = "")

testInstalledBasic(scope = c("basic", "devel", "both"))
```

Arguments

- `pkg`: name of an installed package.
- `lib.loc`: library path(s) in which to look for the package. See `library`.
- `outDir`: the directory into which to write the output files: this should already exist.
- `types`: type(s) of tests to be done.
- `errorsAreFatal`: logical: should testing terminate at the first error?
- `srcdir`: Optional directory to look for `.save` files.
- `Ropts`: Additional options such as `--d valgrind` to be passed to `R CMD BATCH` when running examples or tests.
- `scope`: Which set(s) should be tested?

Details

These tests depend on having the package example files installed (which is the default). If package-specific tests are found in a 'tests' directory they can be tested: these are not installed by default, but will be if `R CMD INSTALL --install-tests` was used. Finally, the R code in any vignettes can be extracted and tested.

Package tests are run in a 'pkg-tests' subdirectory of 'outDir', and leave their output there.

testInstalledBasic runs the basic tests, if installed. This should be run with `LC_COLLATE=C` set: the function tries to set this by it may not work on all OSes. For non-English locales it may be desirable to set environment variables `LANGUAGE` to `en` and `LC_TIME` to `C` to reduce the number of differences from reference results.

The package-specific tests for the base and recommended packages are not normally installed, but `make install-tests` is provided to do so (as well as the basic tests).
Value

Invisibly 0L for success, 1L for failure.

---

\textit{texi2dvi} \quad \textit{Compile LaTeX Files}

**Description**

Run \texttt{latex} and \texttt{bibtex} until all cross-references are resolved and create either a dvi or PDF file.

**Usage**

\begin{verbatim}
texi2dvi(file, pdf = FALSE, clean = FALSE, quiet = TRUE, 
texi2dvi = getOption("texi2dvi"), 
texinputs = NULL, index = TRUE)
texipdf(file, clean = FALSE, quiet = TRUE, 
texi2dvi = getOption("texi2dvi"), 
texinputs = NULL, index = TRUE)
\end{verbatim}

**Arguments**

- \textbf{file} \quad character. Name of LaTeX source file.
- \textbf{pdf} \quad logical. If \texttt{TRUE}, a PDF file is produced instead of the default dvi file (\texttt{texi2dvi} command line option `--pdf`).
- \textbf{clean} \quad logical. If \texttt{TRUE}, all auxiliary files are removed (\texttt{texi2dvi} command line option `--clean`). May not work on some platforms.
- \textbf{quiet} \quad logical. No output unless an error occurs. Ignored if emulation (see the \texttt{texi2dvi} argument) is used.
- \textbf{texi2dvi} \quad character (or \texttt{NULL}). Script or program used to compile a TeX file to dvi or PDF, respectively. The default (selected by `""` or \texttt{NULL}) is to look for an executable on the search path and otherwise emulate the script with \texttt{system} calls.
- \textbf{texinputs} \quad \texttt{NULL} or a character vector of paths to add to the LaTeX and \texttt{bibtex} input search paths.
- \textbf{index} \quad logical: should indices be prepared?

**Details**

texi2pdf is a wrapper for the common case of \texttt{texi2dvi(pdf = TRUE)}.

Despite the name, this is used in \texttt{R} to compile LaTeX files, specifically those generated from vignettes. It ensures that the `\texttt{R_HOME/share/texmf}` directory is in the TEXINPUTS path, so \texttt{R} style files such as `Sweave` and `Rd` will be found. The search path used is first the existing TEXINPUTS setting (or the current directory if unset), then elements of texinputs, then `\texttt{R_HOME/share/texmf}` and finally the default path. Analogous changes are made to BIBINPUTS and BSTINPUTS settings.
MiKTeX has a \texttt{texi2dvi} executable but no other Windows TeX installation that we know of does, so emulation is used on e.g. TeXLive installations on Windows.

Occasionally indices contain special characters which cause indexing to fail (particularly when using the \texttt{hyperref} LaTeX package) even on valid input. The argument \texttt{index = FALSE} is provided to allow package manuals to be made when this happens: it uses emulation.

**Value**

Invisible \texttt{NULL}. Used for the side effect of creating a dvi or PDF file in the current working directory (and maybe other files, especially if \texttt{clean = FALSE}).

**Note**

There are various versions of the \texttt{texi2dvi} script on Unix-alikes and quite a number of bugs have been seen, some of which this \texttt{R} wrapper works around.

One that is current is that it may not work correctly for paths which contain spaces, nor even if the absolute path to a file would contain spaces.

The three possible approaches all have their quirks. For example the Unix-alike \texttt{texi2dvi} script removes ancillary files that already exist but the other two approaches do not (and may get confused by such files).

**Author(s)**

Originally Achim Zeileis but largely rewritten by R-core.

---

**toHTML**

*Display an object in HTML.*

**Description**

This generic function generates a complete HTML page from an object.

**Usage**

```r
\texttt{toHTML(x, \ldots)}
```

---

**Arguments**

- \texttt{x} An object to display.
- \texttt{\ldots} Optional parameters for methods; the \texttt{"packageIQR"} and \texttt{"news\_db"} methods pass these to \texttt{HTMLheader}. 
tools-deprecated

Value
A character vector to display the object x. The "packageIQR" method is designed to display lists in the R help system.

See Also
HTMLheader

Examples
cat(toHTML(demo(package = "base"), sep = "\n")

deprecated

Description
The functions or variables listed here are provided for compatibility with older versions of R only, and may be defunct as soon as of the next release.

See Also
Deprecated, Defunct

toRd

Generic function to convert object to a fragment of Rd code.

Description
Methods for this function render their associated classes as a fragment of Rd code, which can then be rendered into text, HTML, or LaTeX.

Usage
toRd(obj, ...
## S3 method for class ‘bibentry’
toRd(obj, style = NULL, ...)

Arguments
obj The object to be rendered.
style The style to be used in converting a bibentry object.
... Additional arguments used by methods.
Details

See bibstyle for a discussion of styles. The default style = NULL value gives the default style.

Value

Returns a character vector containing a fragment of Rd code that could be parsed and rendered. The default method converts obj to mode character, then escapes any Rd markup within it. The bibentry method converts an object of that class to markup appropriate for use in a bibliography.

Description

Finds the objects in a package which are undocumented, in the sense that they are visible to the user (or data objects or S4 classes provided by the package), but no documentation entry exists.

Usage

undoc(package, dir, lib.loc = NULL)

Arguments

package a character string naming an installed package.
dir a character string specifying the path to a package's root source directory. This must contain the subdirectory 'man' with R documentation sources (in Rd format), and at least one of the 'R' or 'data' subdirectories with R code or data objects, respectively.
lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.

Details

This function is useful for package maintainers mostly. In principle, all user-level R objects should be documented.

The base package is special as it contains the primitives and these do not have definitions available at code level. We provide equivalent closures in environments .ArgsEnv and .GenericArgsEnv in the base package that are used for various purposes: undoc("base") checks that all the primitives that are not language constructs are prototyped in those environments and no others are.

Value

An object of class "undoc" which is a list of character vectors containing the names of the undocumented objects split according to documentation type.

There is a print method for nicely displaying the information contained in such objects.
**update_pkg_po**

**See Also**

codoc, QC

**Examples**

```r
undoc("tools")  # Undocumented objects in 'tools'
```

---

**Description**

Prepare the `po` directory of a package and compile and install the translations.

**Usage**

```r
update_pkg_po(pkgdir, pkg = NULL, version = NULL, copyright, bugs)
```

**Arguments**

- `pkgdir` The path to the package directory.
- `pkg` The package name: if NULL it is read from the package’s `DESCRIPTION` file.
- `version` The package version: if NULL it is read from the package’s `DESCRIPTION` file.
- `copyright`, `bugs` optional character strings for the ‘Copyright’ and ‘Report-Msgid-Bugs-To’ details in the template files.

**Details**

This performs a series of steps to prepare or update messages in the package.

- If the package sources do not already have a `po` directory, one is created.
- `xgettext2pot` is called to create/update a file `po/R-pkgname.pot` containing the translatable messages in the package.
- All existing files in directory `po` with names `R-lang.po` are updated from `R-pkgname.pot`, `checkPoFile` is called on the updated file, and if there are no problems the file is compiled and installed under `inst/po`.
- In a UTF-8 locale, a ‘translation’ `R-en@quot.po` is created with UTF-8 directional quotes, compiled and installed under `inst/po`.
- The remaining steps are done only if file `po/pkname.pot` already exists. The `src/*.c,cc,cpp,m,mm` files in the package are examined to create a file `po/pkname.pot` containing the translatable messages in the C/C++ files. If there is a `src/windows` directory, files within it are also examined.
- All existing files in directory `po` with names `lang.po` are updated from `pkname.pot`, `checkPoFile` is called on the updated file, and if there are no problems the file is compiled and installed under `inst/po`.
• In a UTF-8 locale, a ‘translation’ ‘en@quot.po’ is created with UTF-8 directional quotes, compiled and installed under ‘inst/po’.

Note that C/C++ messages are not automatically prepared for translation as they need to be explicitly marked for translation in the source files. Once that has been done, create an empty file ‘po/pkgname.pot’ in the package sources and run this function again.

pkg = "base" is special (and for use by R developers only): the C files are not in the package directory but in the main sources.

System requirements

This function requires the following tools from the GNU gettext-tools: xgettext, msgmerge, msgfmt, msginit and msgconv. These are part of most Linux distributions and easily compiled from the sources on Unix-alikes (including OS X). Pre-compiled versions for Windows are available in http://www.stats.ox.ac.uk/pub/Rtools/goodies/gettext-tools.zip.

It will probably not work correctly for en@quot translations except in a UTF-8 locale, so these are skipped elsewhere.

See Also

xgettext2pot.

vignetteDepends

Retrieve Dependency Information for a Vignette

Description

Given a vignette name, will create a DependsList object that reports information about the packages the vignette depends on.

Usage

vignetteDepends(vignette, recursive = TRUE, reduce = TRUE,
local = TRUE, lib.loc = NULL)

Arguments

columns | type | description
---|---|---
vignette | string | The path to the vignette source
recursive | logical | Whether or not to include indirect dependencies
reduce | logical | Whether or not to collapse all sets of dependencies to a minimal value
local | logical | Whether or not to search only locally
lib.loc | character | What libraries to search in locally
vignetteEngine

Details

If recursive is TRUE, any package that is specified as a dependency will in turn have its dependencies included (and so on), these are known as indirect dependencies. If recursive is FALSE, only the dependencies directly named by the vignette will be used.

If local is TRUE, the system will only look at the user’s local machine and not online to find dependencies.

If reduce is TRUE, the system will collapse the fields in the DependsList object such that a minimal set of dependencies are specified (for instance if there was ‘foo, foo (>= 1.0.0), foo (>= 1.3.0’), it would only return ‘foo (>= 1.3.0’).

Value

An object of class "DependsList".

pkgDepends

Examples

## This may not be installed
gridEx <- system.file("doc", "grid.Rnw", package = "grid")
vignetteDepends(gridEx)

Description

Vignettes are normally processed by Sweave, but package writers may choose to use a different engine (e.g. one provided by the knitr, noweb or R.rsp packages). This function is used by those packages to register their engines, and internally by R to retrieve them.

Usage

vignetteEngine(name, weave, tangle, pattern = NULL,
          package = NULL)
Arguments

name
weave
tangle
pattern
package

details

If `weave` is missing, `vignetteEngine` will return the currently registered engine matching `name` and `package`.

If `weave` is `NULL`, the specified engine will be deleted.

Other settings define a new engine. The `weave` and `tangle` functions must be defined with argument lists compatible with `function(file, ...)`. Currently the `...` arguments may include logical argument `quiet` and character argument `encoding`; others may be added in future. These are described in the documentation for `Sweave` and `Stangle`.

The `weave` and `tangle` functions should return the filename of the output file that has been produced. Currently the `weave` function, when operating on a file named `<name> <pattern>` must produce a file named `<name>.[.](tex|pdf|html)`. The `*.tex` files will be processed by `pdflatex` to produce `*.pdf` output for display to the user; the others will be displayed as produced. The `tangle` function must produce a file named `<name>.[rRsS]` containing the executable R code from the vignette. The `tangle` function may support a `split = TRUE` argument, and then it should produce files named `<name>.*[.](rRsS)`.

The `pattern` argument gives a regular expression to match the extensions of files which are to be processed as vignette input files. If set to `NULL`, the default pattern `".[RrSs](nw|tex)$"` is used.

Value

If the engine is being deleted, `NULL`. Otherwise a list containing components

name
package
pattern
weave
tangle

Author(s)

Duncan Murdoch and Henrik Bengtsson.

teckfileBuild(your_url)

teckfileBuild("http://example.com")

teckfileBuild(files = "http://example.com")

Description

Generate ‘PACKAGES’ and ‘PACKAGES.gz’ files for a repository of source or Mac/Windows binary packages.

Usage

write_PACKAGES(dir = ".", fields = NULL,
    type = c("source", "mac.binary", "win.binary"),
    verbose = FALSE, unpacked = FALSE, subdirs = FALSE,
    latestOnly = TRUE, addFiles = FALSE)

Arguments

dir Character vector describing the location of the repository (directory including source or binary packages) to generate the ‘PACKAGES’ and ‘PACKAGES.gz’ files from and write them to.

fields a character vector giving the fields to be used in the ‘PACKAGES’ and ‘PACKAGES.gz’ files in addition to the default ones, or NULL (default). The default corresponds to the fields needed by available.packages: "Package", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "Enhances", "OS_type", "License" and "Archs", and those fields will always be included, plus the file name in field "File" if addFile = TRUE and the path to the subdirectory in field "Path" if subdirectories are used.

type Type of packages: currently source ‘.tar.gz’ archives, and Mac or Windows binary (‘.tgz’ or ‘.zip’, respectively) packages are supported. Defaults to "win.binary" on Windows and to "source" otherwise.

verbose logical. Should packages be listed as they are processed?

unpacked a logical indicating whether the package contents are available in unpacked form or not (default).

subdirs either logical (to indicate if subdirectories should be included, recursively) or a character vector of name of subdirectories to include.

latestOnly logical: if multiple versions of a package are available should only the latest version be included?

addFiles logical: should the filenames be included as field ‘File’ in the ‘PACKAGES’ file.
write_PACKAGES

Details

write_PACKAGES scans the named directory for R packages, extracts information from each package’s ‘DESCRIPTION’ file, and writes this information into the ‘PACKAGES’ and ‘PACKAGES.gz’ files.

Including non-latest versions of packages is only useful if they have less constraining version requirements, so for example `latestOnly = FALSE` could be used for a source repository when ‘foo_1.0’ depends on ‘R >= 2.15.0’ but ‘foo_0.9’ is available which depends on ‘R >= 2.11.0’.

Support for repositories with subdirectories and hence for `subdirs != FALSE` was added in R 2.7.0: this depends on recording a "Path" field in the ‘PACKAGES’ file.

Support for more general file names (e.g. other types of compression) via a “File” field in the ‘PACKAGES’ file was added in R 2.10.0 and can be used by `download.packages`. If the file names are not of the standard form, use `addFiles = TRUE`.

type = "win.binary" uses `unz` connections to read all ‘DESCRIPTION’ files contained in the (zipped) binary packages for Windows in the given directory `dir`, and builds files ‘PACKAGES’ and ‘PACKAGES.gz’ files from this information.

Value

Invisibly returns the number of packages described in the resulting ‘PACKAGES’ and ‘PACKAGES.gz’ files. If 0, no packages were found and no files were written.

Note

Processing ‘.tar.gz’ archives to extract the ‘DESCRIPTION’ files is quite slow.

This function can be useful on other OSes to prepare a repository to be accessed by Windows machines, so type = "win.binary" should work on all OSes.

Author(s)

Uwe Ligges and R-core.

See Also

See `read.dcf` and `write.dcf` for reading ‘DESCRIPTION’ files and writing the ‘PACKAGES’ and ‘PACKAGES.gz’ files.

Examples

```r
## Not run:
write_PACKAGES("c:/myFolder/myRepository") # on Windows
write_PACKAGES("/pub/RWin/bin/windows/contrib/2.9",
              type = "win.binary") # on Linux

## End(Not run)
```
xgettext  

**Extract Translatable Messages from R Files in a Package**

**Description**

For each file in the ‘R’ directory (including system-specific subdirectories) of a package, extract the unique arguments passed to `stop`, `warning`, `message`, `gettext` and `gettextf`, or to `ngettext`.

**Usage**

```r
xgettext(dir, verbose = FALSE, asCall = TRUE)

xngettext(dir, verbose = FALSE)

xgettext2pot(dir, potFile, name = "R", version, bugs)
```

**Arguments**

- `dir`: the directory of a source package.
- `verbose`: logical: should each file be listed as it is processed?
- `asCall`: logical: if TRUE each argument is returned whole, otherwise the strings within each argument are extracted.
- `potFile`: name of po template file to be produced. Defaults to ‘R-pkgname.pot’ where `pkgname` is the basename of ‘dir’.
- `name`, `version`, `bugs`: as recorded in the template file: version defaults the version number of the currently running R, and bugs to "bugs.r-project.org".

**Details**

Leading and trailing white space (space, tab and linefeed) is removed for calls to `gettext`, `gettextf`, `stop`, `warning`, and `message`, as it is by the internal code that passes strings for translation.

We look to see if these functions were called with `domain = NA` and if so omit the call if `asCall = TRUE`: note that the call might contain a call to `gettext` which would be visible if `asCall = FALSE`.

`xgettext2pot` calls `xgettext` and then `xngettext`, and writes a PO template file for use with the GNU Gettext tools. This ensures that the strings for simple translation are unique in the file (as GNU Gettext requires), but does not do so for `ngettext` calls (and the rules are not stated in the Gettext manual, but `msgfmt` complains if there is duplication between the sets.).

If applied to the **base** package, this also looks in the `.R` files in ‘R_HOME/share/R’.
Value

For `xgettext`, a list of objects of class "xgettext" (which has a print method), one per source file that potentially contains translatable strings.

For `xngettext`, a list of objects of class "xngettext", which are themselves lists of length-2 character strings.

Examples

```r
## Not run: ## in a source-directory build of R:
xgettext(file.path(R.home(), "src", "library", "splines"))

## End(Not run)
```

adist  Approximate String Distances

Description

Compute the approximate string distance between character vectors. The distance is a generalized
Levenshtein (edit) distance, giving the minimal possibly weighted number of insertions, deletions
and substitutions needed to transform one string into another.

Usage

adist(x, y = NULL, costs = NULL, counts = FALSE, fixed = TRUE,
       partial = !fixed, ignore.case = FALSE, useBytes = FALSE)
Arguments

- **x**: a character vector. **Long vectors** are not supported.
- **y**: a character vector, or **NULL** (default) indicating taking x as y.
- **costs**: a numeric vector or list with names partially matching 'insertions', 'deletions' and 'substitutions' giving the respective costs for computing the Levenshtein distance, or **NULL** (default) indicating using unit cost for all three possible transformations.
- **counts**: a logical indicating whether to optionally return the transformation counts (numbers of insertions, deletions and substitutions) as the "counts" attribute of the return value.
- **fixed**: a logical. If **TRUE** (default), the x elements are used as string literals. Otherwise, they are taken as regular expressions and **partial** = **TRUE** is implied (corresponding to the approximate string distance used by **agrep** with **fixed** = **FALSE**.
- **partial**: a logical indicating whether the transformed x elements must exactly match the complete y elements, or only substrings of these. The latter corresponds to the approximate string distance used by **agrep** (by default).
- **ignore.case**: a logical. If **TRUE**, case is ignored for computing the distances.
- **useBytes**: a logical. If **TRUE** distance computations are done byte-by-byte rather than character-by-character.

Details

The (generalized) Levenshtein (or edit) distance between two strings s and t is the minimal possibly weighted number of insertions, deletions and substitutions needed to transform s into t (so that the transformation exactly matches t). This distance is computed for **partial** = **FALSE**, currently using a dynamic programming algorithm (see, e.g., [http://en.wikipedia.org/wiki/Levenshtein_distance](http://en.wikipedia.org/wiki/Levenshtein_distance)) with space and time complexity $O(mn)$, where $m$ and $n$ are the lengths of s and t, respectively. Additionally computing the transformation sequence and counts is $O(\max(m, n))$.

The generalized Levenshtein distance can also be used for approximate (fuzzy) string matching, in which case one finds the substring of t with minimal distance to the pattern s (which could be taken as a regular expression, in which case the principle of using the leftmost and longest match applies), see, e.g., [http://en.wikipedia.org/wiki/Approximate_string_matching](http://en.wikipedia.org/wiki/Approximate_string_matching). This distance is computed for **partial** = **TRUE** using 'tre' by Ville Laurikari ([http://http://laurikari.net/tre/](http://http://laurikari.net/tre/)) and corresponds to the distance used by **agrep**. In this case, the given cost values are coerced to integer.

Note that the costs for insertions and deletions can be different, in which case the distance between s and t can be different from the distance between t and s.

Value

A matrix with the approximate string distances of the elements of x and y, with rows and columns corresponding to x and y, respectively.

If counts is **TRUE**, the transformation counts are returned as the "counts" attribute of this matrix, as a 3-dimensional array with dimensions corresponding to the elements of x, the elements of y, and the type of transformation (insertions, deletions and substitutions), respectively. Additionally,
if partial = FALSE, the transformation sequences are returned as the "trafos" attribute of the return value, as character strings with elements 'M', 'I', 'D' and 'S' indicating a match, insertion, deletion and substitution, respectively. If partial = FALSE, the offsets (positions of the first and last element) of the matched substrings are returned as the "offsets" attribute of the return value (with both offsets −1 in case of no match).

See Also

agrep for approximate string matching (fuzzy matching) using the generalized Levenshtein distance.

Examples

```r
adist("kitten", "sitting")
## To see the transformation counts for the Levenshtein distance:
drop(attr(adist("kitten", "sitting", counts = TRUE), "counts"))
## To see the transformation sequences:
attr(adist(c("kitten", "sitting"), counts = TRUE), "trafos")

## Cf. the examples for agrep:
adist("lasy", "1 lazy 2")
## For a "partial approximate match" (as used for agrep):
adist("lasy", "1 lazy 2", partial = TRUE)
```

### Description

**alarm**

Alert the User

Gives an audible or visual signal to the user.

#### Usage

```r
alarm()
```

#### Details

alarm() works by sending a "\a" character to the console. On most platforms this will ring a bell, beep, or give some other signal to the user (unless standard output has been redirected).

As from R 2.14.0 it attempts to flush the console (see flush.console).

#### Value

No useful value is returned.

#### Examples

```r
alarm()
```
Description

`apropos()` returns a character vector giving the names of all objects in the search list matching what.

`find()` is a different user interface to the same task.

Usage

```r
apropos(what, where = FALSE, ignore.case = TRUE, mode = "any")
find(what, mode = "any", numeric = FALSE, simple.words = TRUE)
```

Arguments

- `what`: character string with name of an object, or more generally a regular expression to match against.
- `where`: a logical indicating whether positions in the search list should also be returned.
- `ignore.case`: logical indicating if the search should be case-insensitive, TRUE by default. Note that in R versions prior to 2.5.0, the default was implicitly `ignore.case = FALSE`.
- `mode`: character; if not "any", only objects whose `mode` equals `mode` are searched.
- `simple.words`: logical; if TRUE, the `what` argument is only searched as whole word.

Details

If `mode` !="any" only those objects which are of mode `mode` are considered. If `where` is TRUE, the positions in the search list are returned as the names attribute.

`find` is a different user interface for the same task as `apropos`. However, by default (`simple.words == TRUE`), only full words are searched with `grep(fixed = TRUE)`.

Value

For `apropos` character vector, sorted by name, possibly with names giving the (numerical) positions on the search path.

For `find`, either a character vector of environment names, or for `numeric = TRUE`, a numerical vector of positions on the search path, with names giving the names of the corresponding environments.

Author(s)

Kurt Hornik and Martin Maechler (May 1997).
See Also

glob2rx to convert wildcard patterns to regular expressions.

objects for listing objects from one place, help.search for searching the help system, search for the search path.

Examples

require(stats)

## Not run: apropos("lm")
apropos("GLM") # more than a dozen
## that may include internal objects starting '.__C__' if
## methods is attached
apropos("GLM", ignore.case = FALSE) # not one
apropos("lq")

cor <- 1:pi
find("cor") #>.GlobalEnv "package:stats"
find("cor", numeric = TRUE) # numbers with these names
find("cor", numeric = TRUE, mode = "function") # only the second one
rm(cor)

## Not run: apropos(".", mode="list") # a long list

# need a DOUBLE backslash '\" (in case you don’t see it anymore)
apropos("\"\")

## Not run: # everything
length(apropos("."))

# those starting with 'pr'
apropos("^pr")

# the 1-letter things
apropos("^.\$")
# the 1-2-letter things
apropos(".^?\$")
# the 2-to-4 letter things
apropos(".^\.(2,4)$")

# the 8-and-more letter things
apropos(".^\.(8,)$")
table(nchar(apropos("^\.(8,)$")))

## End(Not run)
Description

Determine positions of approximate string matches.

Usage

```r
aregexec(pattern, text, max.distance = 0.1, costs = NULL,
           ignore.case = FALSE, fixed = FALSE, useBytes = FALSE)
```  
Arguments

- **pattern**: a non-empty character string or a character string containing a regular expression (for `fixed = FALSE`) to be matched. Coerced by `as.character` to a string if possible.
- **text**: character vector where matches are sought. Coerced by `as.character` to a character vector if possible.
- **max.distance**: maximum distance allowed for a match. See `agrep`.
- **costs**: cost of transformations. See `agrep`.
- **ignore.case**: a logical. If `TRUE`, case is ignored for computing the distances.
- **fixed**: If `TRUE`, the pattern is matched literally (as is). Otherwise (default), it is matched as a regular expression.
- **useBytes**: a logical. If `TRUE` comparisons are byte-by-byte rather than character-by-character.

Details

`aregexec` provides a different interface to approximate string matching than `agrep` (along the lines of the interfaces to exact string matching provided by `regexec` and `grep`).

Note that by default, `agrep` performs literal matches, whereas `aregexec` performs regular expression matches.

See `agrep` and `adist` for more information about approximate string matching and distances.

Comparisons are byte-by-byte if `pattern` or any element of `text` is marked as "bytes".

Value

A list of the same length as `text`, each element of which is either −1 if there is no match, or a sequence of integers with the starting positions of the match and all substrings corresponding to parenthesized subexpressions of `pattern`, with attribute "match.length" an integer vector giving the lengths of the matches (or −1 for no match).

See Also

- `regmatches` for extracting the matched substrings.
Examples

```r
## Cf. the examples for agrep.
x <- c("1 lazy", "1", "1 LAZY")
aregexec("laysy", x, max.distance = 2)
aregexec("(lay)(sy)", x, max.distance = 2)
aregexec("(lay)(sy)", x, max.distance = 2, ignore.case = TRUE)
m <- aregexec("(lay)(sy)", x, max.distance = 2)
regmatches(x, m)
```

Description

Spell check given files via Aspell, Hunspell or Ispell.

Usage

```r
aspell(files, filter, control = list(), encoding = "unknown",
program = NULL, dictionaries = character())
```

Arguments

- **files**: a character vector with the names of files to be checked.
- **filter**: an optional filter for processing the files before spell checking, given as either a function (with formals `ifile` and `encoding`), or a character string specifying a built-in filter, or a list with the name of a built-in filter and additional arguments to be passed to it. See Details for available filters. If missing or NULL, no filtering is performed.
- **control**: a list or character vector of control options for the spell checker.
- **encoding**: the encoding of the files. Recycled as needed.
- **program**: a character string giving the name (if on the system path) or full path of the spell check program to be used, or NULL (default). By default, the system path is searched for aspell, hunspell and ispell (in that order), and the first one found is used.
- **dictionaries**: a character vector of names or file paths of additional R level dictionaries to use. Elements with no path separator specify R system dictionaries (in subdirectory `share/dictionaries` of the R home directory). The file extension (currently, only `.rds`) can be omitted.
Details

The spell check programs employed must support the so-called Ispell pipe interface activated via command line option `-a`. In addition to the programs, suitable dictionaries need to be available. See http://aspell.net, http://hunspell.sourceforge.net/ and http://lasr.cs.ucla.edu/geoff/ispell.html, respectively, for obtaining the Aspell, Hunspell and (International) Ispell programs and dictionaries.

The currently available built-in filters are "Rd" (corresponding to RdTextFilter), "Sweave" (corresponding to SweaveTeXFilter), "R", "pot" and "dcf".

Filter "R" is for R code and extracts the message string constants in calls to message, warning, stop, packageStartupMessage, gettext, gettextf, and ngettext (the unnamed string constants for the first five, and fmt and msg1/msg2 string constants, respectively, for the latter two). Filter "pot" is for message string catalog `.pot` files. Both have an argument ignore allowing to give regular expressions for parts of message strings to be ignored for spell checking: e.g., using "[ \t'][^']*[ \t[:punct:]]" ignores all text inside single quotes.

Filter "dcf" is for files in Debian Control File format. The fields to keep can be controlled by argument keep (a character vector with the respective field names). By default, 'Title' and 'Description' fields are kept.

The print method has for the objects returned by aspell has an indent argument controlling the indentation of the positions of possibly mis-spelled words. The default is 2; Emacs users may find it useful to use an indentation of 0 and visit output in grep-mode. It also has a verbose argument: when this is true, suggestions for replacements are shown as well.

It is possible to employ additional R level dictionaries. Currently, these are files with extension `*.rds` obtained by serializing character vectors of word lists using saveRDS. If such dictionaries are employed, they are combined into a single word list file which is then used as the spell checker’s personal dictionary (option ‘-p’): hence, the default personal dictionary is not used in this case.

Value

A data frame inheriting from aspell (which has a useful print method) with the information about possibly mis-spelled words.

See Also

aspell-utils for utilities for spell checking packages.

Package Aspell on Omegahat (http://www.omegahat.org/Aspell) for a fine-grained R interface to the Aspell library.

Examples

```r
## Not run:
## To check all Rd files in a directory, (additonally) skipping the
## 'references' sections.
files <- Sys.glob("*.Rd")
aspell(files, filter = list("Rd", drop = "\references"))

## To check all Sweave files
files <- Sys.glob(c("*.Rnw", "*.Snw", "*.rnw", "*.snw"))
```
aspell(files, filter = "Sweave", control = "-t")

## To check all Texinfo files (Aspell only)
files <- Sys.glob("*.texi")
aspell(files, control = "--mode=texinfo")

## End(Not run)

## List the available R system dictionaries.
Sys.glob(file.path(R.home("share"), "dictionaries", "*.rds"))

---

**aspell-utils**

*Spell Check Utilities*

### Description

Utilities for spell checking packages via Aspell, Hunspell or Ispell.

### Usage

```r
aspell_package_Rd_files(dir, drop = c("\author", "\references"),
control = list(), program = NULL,
dictionaries = character())
aspell_package_vignettes(dir,
control = list(), program = NULL,
dictionaries = character())
aspell_package_R_files(dir, ignore = character(), control = list(),
program = NULL, dictionaries = character())
aspell_package_C_files(dir, ignore = character(), control = list(),
program = NULL, dictionaries = character())
aspell_write_personal_dictionary_file(x, out, language = "en",
program = NULL)
```

### Arguments

- **dir**
  - a character string specifying the path to a package’s root directory.
- **drop**
  - a character vector naming additional Rd sections to drop when selecting text via RdTextFilter.
- **control**
  - a list or character vector of control options for the spell checker.
- **program**
  - a character string giving the name (if on the system path) or full path of the spell check program to be used, or NULL (default). By default, the system path is searched for aspell, hunspell and ispell (in that order), and the first one found is used.
- **dictionaries**
  - a character vector of names or file paths of additional R level dictionaries to use. See aspell.
ignore     a character vector with regular expressions to be replaced by blanks when filtering the message strings.
x         a character vector, or the result of a call to aspell().
out        a character string naming the personal dictionary file to write to.
language   a character string indicating a language as used by Aspell.

Details

Functions aspell_package_Rd_files, aspell_package_vignettes, aspell_package_R_files and aspell_package_C_files perform spell checking on the Rd files, vignettes, R files, and C-level messages of the package with root directory dir. They determine the respective files, apply the appropriate filters, and run the spell checker. See aspell for details on filters.

The C-level message string are obtained from the ‘po/PACKAGE.pot’ message catalog file, with PACKAGE the basename of dir. See the section on “C-level messages” in “Writing R Extensions” for more information.

When using Aspell, the vignette checking skips parameters and/or options of commands \Sexpr, \citep, \code, \pkg, \proglang and \samp. Further commands can be skipped by adding --add-tex-command options to the control argument. E.g., to skip both option and parameter of \mycmd, add --add-tex-command='mycmd op'.

Suitable values for control, program, dictionaries, drop and ignore can also be specified using a package defaults file which should go as ‘defaults.R’ into the ‘.aspell’ subdirectory of dir, and provides defaults via assignments of suitable named lists, e.g.,

  vignettes <- list(control = "--add-tex-command='mycmd op'")

for vignettes (when using Aspell) and similarly assigning to Rd_files, R_files and C_files for Rd files, R files and C level message defaults.

Maintainers of packages using both English and American spelling will find it convenient to pass control options ‘--master=en_US’ and ‘--add-extra-dicts=en_GB’ to Aspell and control options ‘-d en_US,en_GB’ to Hunspell (provided that the corresponding dictionaries are installed).

Older versions of R had no support for R level dictionaries, and hence provided the function aspell_write_personal_dictionary_file to create (spell check) program-specific personal dictionary files from words to be accepted. The new mechanism is to use R level dictionaries, i.e., `.rds’ files obtained by serializing character vectors of such words using saveRDS. For such dictionaries specified via the package defaults mechanism, elements with no path separator can be R system dictionaries or dictionaries in the ‘.aspell’ subdirectory.

See Also

aspell
available.packages  List Available Packages at CRAN-like Repositories

Description

available.packages returns a matrix of details corresponding to packages currently available at one or more repositories. The current list of packages is downloaded over the internet (or copied from a local mirror).

Usage

```r
available.packages(contriburl =
  contrib.url(getOption("repos"), type),
  method, fields = NULL,
  type = getOption("pkgType"),
  filters = NULL)
```

Arguments

- `contriburl` URL(s) of the ‘contrib’ sections of the repositories. Specify this argument only if your repository mirror is incomplete, e.g., because you burned only the ‘contrib’ section on a CD.
- `method` download method, see `download.file`.
- `type` character string, indicate which type of packages: see `install.packages`.
- `fields` a character vector giving the fields to extract from the ‘PACKAGES’ file(s) in addition to the default ones, or NULL (default). Unavailable fields result in NA values.
- `filters` a character vector or list or NULL (default). See ‘Details’.

Details

The list is either copied from a local mirror (specified by a ‘file://’ URI) or downloaded. If downloaded, the list is cached for the R session in a per-repository file in `tempdir()` with a name like

```r
repos_http%3a%2f%2fcran.r-project.org%2fsrc%2fcontrib.rds
```

By default, the report includes only packages whose version and OS requirements are met by the running version of R, and only gives information on the latest versions of packages.

Argument `filters` can be used to select which of the packages on the repositories are reported. It is called with its default value (NULL) by functions such as `install.packages`: this value corresponds to `getOption("available_packages_filters")` and to `c("R_version", "OS_type", "subarch", "duplicates")` if that is unset or set to NULL. The built-in filters are

"R_version" exclude packages whose R version requirements are not met
"OS_type" exclude packages whose OS requirement is incompatible with this version of R: that is exclude Windows-only packages on a Unix-alike platform and vice versa.

"subarch" for binary packages, exclude those with compiled code that is not available for the current sub-architecture, e.g. exclude packages only compiled for 32-bit Windows on a 64-bit Windows R.

"duplicates" only report the latest version where more than one version is available, and only report the first-named repository (in contriburl) with the latest version if that is in more than one repository.

"license/FOSS" include only packages for which installation can proceed solely based on packages which can be verified as Free or Open Source Software (FOSS, e.g., http://en.wikipedia.org/wiki/FOSS) employing the available license specifications. Thus both the package and any packages that it depends on to load need to be known to be FOSS.

Note that this does depend on the repository supplying license information.

"license/restricts_use" include only packages for which installation can proceed solely based on packages which are guaranteed not to restrict use.

"CRAN" use CRAN versions in preference to versions from other repositories (even if these have a higher version number).

If all the filters are from this set they can be specified as a character vector; otherwise filters should be a list with elements which are character strings, user-defined functions or add = TRUE (see below).

User-defined filters are functions which take a single argument, a matrix of the form returned by available.packages, and return a matrix consisting of a subset of the rows of the argument.

The special ‘filter’ add = TRUE appends the other elements of the filter list to the default filters.

Value

A matrix with one row per package, row names the package names and column names including "Package", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "Enhances", "File" and "Repository". Additional columns can be specified using the fields argument.

Where provided by the repository, fields "OS_type", "License", "License_is_FOSS", "License_restricts_use", "Archs", "MD5sum" and "NeedsCompilation" are reported for use by the filters and package management tools, including install.packages.

See Also

install.packages, download.packages, contrib.url.

The ‘R Installation and Administration’ manual for how to set up a repository.

Examples

## Not run:
## restrict install.packages() (etc) to known-to-be-FOSS packages
options(available_packages_filters =
  c("R_version", "OS_type", "subarch", "duplicates", "license/FOSS"))
## or
### Description

Run R non-interactively with input from infile and send output (stdout/stderr) to another file.

### Usage

```
R CMD BATCH [options] infile [outfile]
```

### Arguments

- **infile**: the name of a file with R code to be executed.
- **options**: a list of R command line options, e.g., for setting the amount of memory available and controlling the load/save process. If infile starts with a `-`, use `--` as the final option. The default options are `--restore --save --no-readline`.
- **outfile**: the name of a file to which to write output. If not given, the name used is that of infile, with a possible `.R` extension stripped, and `.Rout` appended.

### Details

Use `R CMD BATCH --help` to be reminded of the usage.

By default, the input commands are printed along with the output. To suppress this behavior, add `options(echo = FALSE)` at the beginning of infile, or use option `--slave`.

The infile can have end of line marked by LF or CRLF (but not just CR), and files with an incomplete last line (missing end of line (EOL) mark) are processed correctly.

A final expression `proc.time()` will be executed after the input script unless the latter calls `q(runLast = FALSE)` or is aborted. This can be suppressed by the option `--no-timing`.

Additional options can be set by the environment variable `R_BATCH_OPTIONS`: these come after `--restore --save --no-readline` and before any options given on the command line.

### Note

Unlike Splus BATCH, this does not run the R process in the background. In most shells, `R CMD BATCH [options] infile [outfile] &` will do so.
bibentry

Bibliography Entries

Description

Functionality for representing and manipulating bibliographic information in enhanced BibTeX style.

Usage

bibentry(bibtype, textVersion = NULL, header = NULL, footer = NULL,
key = NULL, ..., other = list(),
mheader = NULL, mfooter = NULL)

## S3 method for class 'bibentry'
print(x, style = "text", .bibstyle, ...)

Arguments

bibtype a character string with a BibTeX entry type. See Entry Types for details.
textVersion a character string with a text representation of the reference to optionally be employed for printing.
header a character string with optional header text.
footer a character string with optional footer text.
key a character string giving the citation key for the entry.
... for bibentry: arguments of the form tag=value giving the fields of the entry, with tag and value the name and value of the field, respectively. Arguments with empty values are dropped. See Entry Fields for details.
For the print method, extra parameters to pass to the renderer.
other a list of arguments as in ... (useful in particular for fields named the same as formals of bibentry).
mheader a character string with optional “outer” header text.
mfooter a character string with optional “outer” footer text.
x an object inheriting from class "bibentry".
style an optional character string specifying the print style. If present, must be a unique abbreviation (with case ignored) of the available styles, see Details.
.bibstyle a character string naming a bibliography style.

Details

The bibentry objects created by bibentry can represent an arbitrary positive number of references. One can use c() to combine bibentry objects, and hence in particular build a multiple reference object from single reference ones. Alternatively, one can use bibentry to directly create a multiple reference object by “vectorizing” the given arguments, i.e., use character vectors instead of character strings.
The `print` method for `bibentry` objects provides a choice between seven different styles: plain text (style "text"), BibTeX ("Bibtex"), a mixture of plain text and BibTeX as traditionally used for citations ("citation"), HTML ("html"), LaTeX ("latex"), R code ("R"), and a simple copy of the `textVersion` elements (style "textVersion"). The "text", "html" and "latex" styles make use of the `.bibstyle` argument using the `bibstyle` function. When printing `bibentry` objects in citation style, a header/footer for each item can be displayed as well as a `mheader/mfooter` for the whole vector of references.

The `print` method is based on a `format` method which provides the same styles, and for formatting as R code a choice between giving a character vector with one `bibentry()` call for each `bibentry` (as commonly used in ‘CITATION’ files), or a character string with one collapsed call, obtained by combining the individual calls with `c()` if there is more than one `bibentry`. This can be controlled by setting the option `collapse` to `FALSE` (default) or `TRUE`, respectively. (Printing in R style always collapses to a single call.) Further, for the "citation" style, `format()`’s optional argument `citation.bibtex.max` (with default `getOption("citation.bibtex.max")` which defaults to 1) determines for up to how many citation `bibentries` text style is shown together with bibtex, automatically.

It is possible to subscript `bibentry` objects by their keys (which are used for character subscripts if the names are `NULL`).

There is also a `toBibtex` method for direct conversion to BibTeX.

**Value**

`bibentry` produces an object of class "bibentry".

**Entry Types**

`bibentry` creates "bibentry" objects, which are modeled after BibTeX entries. The entry should be a valid BibTeX entry type, e.g.,

*Article:* An article from a journal or magazine.

*Book:* A book with an explicit publisher.

*InBook:* A part of a book, which may be a chapter (or section or whatever) and/or a range of pages.

*InCollection:* A part of a book having its own title.

*InProceedings:* An article in a conference proceedings.

*Misc:* Use this type when nothing else fits.

*Proceedings:* The proceedings of a conference.

*TechReport:* A report published by a school or other institution, usually numbered within a series.

*Unpublished:* A document having an author and title, but not formally published.
Entry Fields

The ... argument of bibentry can be any number of BibTeX fields, including

- **address**: The address of the publisher or other type of institution.
- **author**: The name(s) of the author(s), either as a character string in the format described in the LaTeX book, or a person object.
- **booktitle**: Title of a book, part of which is being cited.
- **chapter**: A chapter (or section or whatever) number.
- **editor**: Name(s) of editor(s), same format as author.
- **institution**: The publishing institution of a technical report.
- **journal**: A journal name.
- **note**: Any additional information that can help the reader. The first word should be capitalized.
- **number**: The number of a journal, magazine, technical report, or of a work in a series.
- **pages**: One or more page numbers or range of numbers.
- **publisher**: The publisher’s name.
- **school**: The name of the school where a thesis was written.
- **series**: The name of a series or set of books.
- **title**: The work’s title.
- **volume**: The volume of a journal or multi-volume book.
- **year**: The year of publication.

See Also

- **person**

    publisher = "Cambridge University Press",
    address = "Cambridge",
    isbn = "0-521-57391-2",
    url = "http://statwww.epfl.ch/davison/BMA/",
    key = "boot-book"
  )
)

## Combining and subsetting
c(rref, bref)
bref[2]
bref["boot-book"]

## Extracting fields
bref$author
bref[1]$author

## Convert to BibTeX
toBibtex(bref)

## Format in R style
## One bibentry() call for each bibentry:
writelines(paste(format(bref, "R"), collapse = "\n\n"))
## One collapsed call:
writelines(format(bref, "R", collapse = TRUE))
The browseEnv function opens a browser with a list of objects currently in \texttt{sys.frame()} environment.

**Usage**

\begin{verbatim}
browseEnv(envir = .GlobalEnv, pattern,
   excludepatt = "^last\.\.warning",
   html = .Platform$GUI != "AQUA",
   expanded = TRUE, properties = NULL,
   main = NULL, debugMe = FALSE)
\end{verbatim}

**Arguments**

- **envir** an \texttt{environment} the objects of which are to be browsed.
- **pattern** a regular expression for object subselection is passed to the internal \texttt{ls()} call.
- **excludepatt** a regular expression for dropping objects with matching names.
- **html** is used to display the workspace on a HTML page in your favorite browser. The default except when running from \texttt{R.app} on OS X.
- **expanded** whether to show one level of recursion. It can be useful to switch it to \texttt{FALSE} if your workspace is large. This option is ignored if \texttt{html} is set to \texttt{FALSE}.
- **properties** a named list of global properties (of the objects chosen) to be showed in the browser; when \texttt{NULL} (as per default), user, date, and machine information is used.
- **main** a title string to be used in the browser; when \texttt{NULL} (as per default) a title is constructed.
- **debugMe** logical switch; if true, some diagnostic output is produced.

**Details**

Very experimental code: displays a static HTML page on all platforms except \texttt{R.app} on OS X.

Only allows one level of recursion into object structures.

It can be generalized. See sources for details. Most probably, this should rather work through using the `tkWidget` package (from \url{www.Bioconductor.org}).

**See Also**

\texttt{str}, \texttt{ls}.

**Examples**

\begin{verbatim}
if(interactive()) {
   ## create some interesting objects :
ofa <- ordered(4:1)
ex1 <- expression(1+ /zero.noslash:9)
ex3 <- expression(u, v, 1+ /zero.noslash:9)
example(factor, echo = FALSE)
\end{verbatim}
browseURL

Load URL into a WWW Browser

Description

Load a given URL into a WWW browser.

Usage

browseURL(url, browser = getOption("browser"),
           encodeIfNeeded = FALSE)

Arguments

url  a non-empty character string giving the URL to be loaded.
browser  a non-empty character string giving the name of the program to be used as hyper-
text browser. It should be in the PATH, or a full path specified. Alternatively, an R function to be called to invoke the browser.
Under Windows NULL is also allowed (and is the default), and implies that the file association mechanism will be used.
encodeIfNeeded  Should the URL be encoded by URLencode before passing to the browser? This is not needed (and might be harmful) if the browser program/function itself does encoding, and can be harmful for ‘file://’ URLs on some systems and for ‘http://’ URLs passed to some CGI applications. Fortunately, most URLs do not need encoding.

Details

The default browser is set by option "browser", in turn set by the environment variable R_BROWSER which is by default set in file ‘R_HOME/etc/Renviron’ to a choice made manually or automatically when R was configured. (See Startup for where to override that default value.) To suppress showing URLs altogether, use the value "false".

If browser supports remote control and R knows how to perform it, the URL is opened in any already running browser or a new one if necessary. This mechanism currently is available for browsers
which support the "-remote openURL(...)" interface (which includes Mozilla >= 0.9.5 and Mozilla Firefox), Galeon, KDE konqueror (via kfmclient) and the GNOME interface to Mozilla. Note that the type of browser is determined from its name, so this mechanism will only be used if the browser is installed under its canonical name.

Because "-remote" will use any browser displaying on the X server (whatever machine it is running on), the remote control mechanism is only used if DISPLAY points to the local host. This may not allow displaying more than one URL at a time from a remote host.

It is the caller’s responsibility to encode url if necessary (see \url{URLencode}). This can be tricky for file URLs, where the format accepted can depend on the browser and OS.

To suppress showing URLs altogether, set \texttt{browser = "false"}.

Examples

```r
## Not run: ## for KDE users who want to open files in a new tab
options(browser = "kfmclient newTab")
browseURL("http://www.r-project.org")

## End(Not run)
```

\begin{tabular}{ll}
\textbf{browseVignettes} & \textit{List Vignettes in an HTML Browser} \\
\end{tabular}

Description

List available vignettes in an HTML browser with links to PDF, LaTeX/noweb source, and (tangled) R code (if available).

Usage

```
browseVignettes(package = NULL, lib.loc = NULL, all = TRUE)
```

## S3 method for class 'browseVignettes'
```
print(x, \ldots)
```

Arguments

- \texttt{package} a character vector with the names of packages to search through, or \texttt{NULL} in which "all" packages (as defined by argument \texttt{all}) are searched.
- \texttt{lib.loc} a character vector of directory names of \texttt{R} libraries, or \texttt{NULL}. The default value of \texttt{NULL} corresponds to all libraries currently known.
- \texttt{all} logical; if \texttt{TRUE} search all available packages in the library trees specified by \texttt{lib.loc}, and if \texttt{FALSE}, search only attached packages.
- \texttt{x} Object of class \texttt{browseVignettes}.
- \texttt{\ldots} Further arguments, ignored by the \texttt{print} method.
bug.report

Details

Function `browseVignettes` returns an object of the same class; the print method displays it as an HTML page in a browser (using `browseURL`).

See Also

`browseURL`, `vignette`

Examples

```r
## Not run:
## List vignettes from all *attached* packages
browseVignettes(all = FALSE)

## List vignettes from a specific package
browseVignettes("grid")
## End(Not run)
```

Description

Invokes an editor or email program to write a bug report or opens a web page for bug submission. Some standard information on the current version and configuration of R are included automatically.

Usage

```r
bug.report(subject = "", address, file = "R.bug.report", package = NULL, lib.loc = NULL, ...)
```

Arguments

- `subject`: Subject of the email.
- `address`: Recipient's email address, where applicable: for package bug reports sent by email this defaults to the address of the package maintainer (the first if more than one is listed).
- `file`: filename to use (if needed) for setting up the email.
- `package`: Optional character vector naming a single package which is the subject of the bug report.
- `lib.loc`: A character vector describing the location of R library trees in which to search for the package, or NULL. The default value of NULL corresponds to all libraries currently known.
- `...`: additional named arguments such as `method` and `ccaddress` to pass to `create.post`.

Details

If package is NULL or a base package, this opens the R bugs tracker at http://bugs.r-project.org/.

If package is specified, it is assumed that the bug report is about that package, and parts of its ‘DESCRIPTION’ file are added to the standard information. If the package has a BugReports field in the ‘DESCRIPTION’ file, that URL will be opened using browseURL, otherwise an email directed to the package maintainer will be generated using create.post.

Value

Nothing useful.

When is there a bug?

If R executes an illegal instruction, or dies with an operating system error message that indicates a problem in the program (as opposed to something like “disk full”), then it is certainly a bug.

Taking forever to complete a command can be a bug, but you must make certain that it was really R’s fault. Some commands simply take a long time. If the input was such that you KNOW it should have been processed quickly, report a bug. If you don’t know whether the command should take a long time, find out by looking in the manual or by asking for assistance.

If a command you are familiar with causes an R error message in a case where its usual definition ought to be reasonable, it is probably a bug. If a command does the wrong thing, that is a bug. But be sure you know for certain what it ought to have done. If you aren’t familiar with the command, or don’t know for certain how the command is supposed to work, then it might actually be working right. Rather than jumping to conclusions, show the problem to someone who knows for certain.

Finally, a command’s intended definition may not be best for statistical analysis. This is a very important sort of problem, but it is also a matter of judgement. Also, it is easy to come to such a conclusion out of ignorance of some of the existing features. It is probably best not to complain about such a problem until you have checked the documentation in the usual ways, feel confident that you understand it, and know for certain that what you want is not available. The mailing list r-devel@r-project.org is a better place for discussions of this sort than the bug list.

If you are not sure what the command is supposed to do after a careful reading of the manual this indicates a bug in the manual. The manual’s job is to make everything clear. It is just as important to report documentation bugs as program bugs.

If the online argument list of a function disagrees with the manual, one of them must be wrong, so report the bug.

How to report a bug

When you decide that there is a bug, it is important to report it and to report it in a way which is useful. What is most useful is an exact description of what commands you type, from when you start R until the problem happens. Always include the version of R, machine, and operating system that you are using; type version in R to print this. To help us keep track of which bugs have been fixed and which are still open please send a separate report for each bug.

The most important principle in reporting a bug is to report FACTS, not hypotheses or categorizations. It is always easier to report the facts, but people seem to prefer to strain to posit explanations
and report them instead. If the explanations are based on guesses about how \( R \) is implemented, they will be useless; we will have to try to figure out what the facts must have been to lead to such speculations. Sometimes this is impossible. But in any case, it is unnecessary work for us.

For example, suppose that on a data set which you know to be quite large the command `data.frame(x, y, z, monday, tuesday)` never returns. Do not report that `data.frame()` fails for large data sets. Perhaps it fails when a variable name is a day of the week. If this is so then when we got your report we would try out the `data.frame()` command on a large data set, probably with no day of the week variable name, and not see any problem. There is no way in the world that we could guess that we should try a day of the week variable name.

Or perhaps the command fails because the last command you used was a \( R \) method that had a bug causing \( R \)'s internal data structures to be corrupted and making the `data.frame()` command fail from then on. This is why we need to know what other commands you have typed (or read from your startup file).

It is very useful to try and find simple examples that produce apparently the same bug, and somewhat useful to find simple examples that might be expected to produce the bug but actually do not. If you want to debug the problem and find exactly what caused it, that is wonderful. You should still report the facts as well as any explanations or solutions.

Invoking \( R \) with the ‘--vanilla’ option may help in isolating a bug. This ensures that the site profile and saved data files are not read.

A bug report can be generated using the function `bug.report()`. For reports on \( R \) this will open the Web page at \url{http://bugs.R-project.org/}: for a contributed package it will open the package’s bug tracker Web page or help you compose an email to the maintainer.

Bug reports on **contributed packages** should not be sent to the \( R \) bug tracker: rather make use of the package argument.

**Author(s)**

This help page is adapted from the Emacs manual and the \( R \) FAQ

**See Also**

`help.request` which you possibly should try before `bug.report`.

`create.post`, which handles emailing reports.

The \( R \) FAQ, also `sessionInfo()` from which you may add to the bug report.

---

**capture.output**

**Send Output to a Character String or File**

**Description**

Evaluates its arguments with the output being returned as a character string or sent to a file. Related to `sink` in the same way that `with` is related to `attach`. 
chooseBioCmirror

Select a Bioconductor Mirror

Description

Interact with the user to choose a Bioconductor mirror.

Usage

chooseBioCmirror(graphics = getOption("menu.graphics"), ind = NULL)
chooseCRANmirror

Arguments

graphics  logical. If true, use a graphical list: on Windows or the OS X GUI use a list box, and on a Unix-alike if package tcltk and an X server are available, use a Tk widget. Otherwise use a text menu.

ind  Optional numeric value giving which entry to select.

Details

This sets the option "BioC_mirror": it needs to be used before a call to setRepositories.

In addition to the Bioconductor master site (in Seattle, USA), there currently are mirrors in Bethesda (USA), Dortmund (Germany), Bergen (Norway) and Cambridge (UK).

Value

None: this function is invoked for its side effect of updating options("BioC_mirror").

See Also

setRepositories, chooseCRANmirror.

chooseCRANmirror  Select a CRAN Mirror

Description

Interact with the user to choose a CRAN mirror.

Usage

chooseCRANmirror(graphics = getOption("menu.graphics"), ind = NULL)

getCRANmirrors(all = FALSE, local.only = FALSE)

Arguments

graphics  Logical. If true, use a graphical list: on Windows or the OS X GUI use a list box, and on a Unix-alike if package tcltk and an X server are available, use a Tk widget. Otherwise use a text menu.

ind  Optional numeric value giving which entry to select.

all  Logical, get all known mirrors or only the ones flagged as OK.

local.only  Logical, try to get most recent list from CRAN or use file on local disk only.
Details

A list of mirrors is stored in file ‘R_HOME/doc/CRAN_mirrors.csv’, but first an on-line list of current mirrors is consulted, and the file copy used only if the on-line list is inaccessible.

This function was originally written to support a Windows GUI menu item, but is also called by contrib.url if it finds the initial dummy value of options("repos").

Value

None for chooseCRANmirror(), this function is invoked for its side effect of updating options("repos").

getCRANmirrors() returns a data frame with mirror information.

See Also

setRepositories, chooseBioCmirror, contrib.url.

citation

Citing R and R Packages in Publications

Description

How to cite R and R packages in publications.

Usage

citation(package = "base", lib.loc = NULL, auto = NULL)
readCitationFile(file, meta = NULL)

Arguments

package a character string with the name of a single package. An error occurs if more than one package name is given.

lib.loc a character vector with path names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.

auto a logical indicating whether the default citation auto-generated from the package ‘DESCRIPTION’ metadata should be used or not, or NULL (default), indicating that a ‘CITATION’ file is used if it exists, or an object of class "packageDescription" with package metadata (see below).

file a file name.

meta a list of package metadata as obtained by packageDescription, or NULL (the default).
Details

The R core development team and the very active community of package authors have invested a lot of time and effort in creating R as it is today. Please give credit where credit is due and cite R and R packages when you use them for data analysis.

Execute function citation() for information on how to cite the base R system in publications. If the name of a non-base package is given, the function either returns the information contained in the ‘CITATION’ file of the package or auto-generates citation information. In the latter case the package ‘DESCRIPTION’ file is parsed, the resulting citation object may be arbitrarily bad, but is quite useful (at least as a starting point) in most cases.

In R >= 2.14.0, one can use a ‘Authors@R’ field in ‘DESCRIPTION’ to provide (R code giving) a person object with a refined, machine-readable description of the package “authors” (in particular specifying their precise roles). Only those with an author role will be included in the auto-generated citation.

If only one reference is given, the print method for the object returned by citation() shows both a text version and a BibTeX entry for it, if a package has more than one reference then only the text versions are shown. The BibTeX versions can be obtained using function toBibtex() (see the examples below).

The ‘CITATION’ file of an R package should be placed in the ‘inst’ subdirectory of the package source. The file is an R source file and may contain arbitrary R commands including conditionals and computations. Function readCitationFile() is used by citation() to extract the information in ‘CITATION’ files. The file is source()ed by the R parser in a temporary environment and all resulting bibliographic objects (specifically, of class “bibentry”) are collected.

Traditionally, the ‘CITATION’ file contained zero or more calls to citHeader, then one or more calls to citEntry, and finally zero or more calls to citFooter, where in fact citHeader and citFooter are simply wrappers to paste, with their ... argument passed on to paste as is. R 2.12.0 adds a new "bibentry" class for improved representation and manipulation of bibliographic information (in fact, the old mechanism is implemented using the new one), and one can write ‘CITATION’ files using the unified bibentry interface. Such files are not usable with versions of R prior to 2.12.0.

In R >= 2.14.0, one can include an auto-generated package citation in the ‘CITATION’ file via citation(auto = meta).

readCitationFile makes use of the Encoding element (if any) of meta to determine the encoding of the file.

Value

An object inheriting from class "bibentry".

See Also

bibentry

Examples

```r
## the basic R reference
citation()

## references for a package -- might not have these installed
```
if(nchar(system.file(package = "lattice"))) citation("lattice")
if(nchar(system.file(package = "foreign"))) citation("foreign")

## extract the bibtex entry from the return value
x <- citation()
toBibtex(x)

---

cite  

Cite a bibliography entry.

description

Cite a bibentry object in text. The cite() function uses the cite() function from the default 
bibstyle if present, or citeNatbib() if not. citeNatbib() uses a style similar to that used by 
the LaTeX package natbib.

usage

cite(keys, bib, ...)  
citeNatbib(keys, bib, textual = FALSE, before = NULL, after = NULL, 
  mode = c("authoryear", "numbers", "super"), 
  abbreviate = TRUE, longnamesfirst = TRUE, 
  bibpunct = c("("", ",", ";", "a", ",", ",", ), previous)

arguments

keys  A character vector of keys of entries to cite. May contain multiple keys in a 
  single entry, separated by commas.

bib  A "bibentry" object containing the list of documents in which to find the keys.

...  Additional arguments to pass to the cite() function for the default style.

textual  Produce a "textual" style of citation, i.e. what \cite{t} would produce in LaTeX.

before  Optional text to display before the citation.

after  Optional text to display after the citation.

mode  The "mode" of citation.

abbreviate  Whether to abbreviate long author lists.

longnamesfirst  If abbreviate == TRUE, whether to leave the first citation long.

bibpunct  A vector of punctuation to use in the citation, as used in natbib. See the Details 
  section.

previous  A list of keys that have been previously cited, to be used when 
  abbreviate == TRUE and longnamesfirst == TRUE
Details

Argument names are chosen based on the documentation for the LaTeX \texttt{natbib} package. See that documentation for the interpretation of the \texttt{bibpunct} entries.

The entries in \texttt{bibpunct} are as follows:

1. The left delimiter.
2. The right delimiter.
3. The separator between references within a citation.
4. An indicator of the “mode”: "n" for numbers, "s" for superscripts, anything else for author-year.
5. Punctuation to go between the author and year.
6. Punctuation to go between years when authorship is suppressed.

Note that if \texttt{mode} is specified, it overrides the mode specification in \texttt{bibpunct}[4]. Partial matching is used for \texttt{mode}.

The defaults for \texttt{citeNatbib} have been chosen to match the JSS style, and by default these are used in \texttt{cite}. See \texttt{bibstyle} for how to set a different default style.

Value

A single element character string is returned, containing the citation.

  \texttt{organization = "R Foundation for Statistical Computing"},
  \texttt{address = "Vienna, Austria"},
  \texttt{year = 2013},
  \texttt{url = "http://www.R-project.org/"},
  \texttt{key = "R"})

## References for boot package and associated book

bref <- \texttt{c}(
  \texttt{bibentry}(
    \texttt{bibtype = "Manual"},
    \texttt{title = "boot: Bootstrap R (S-PLUS) Functions"},
    \texttt{author = c(}
      \texttt{person("Angelo", "Canty", role = "aut",}
      \texttt{comment = "S original"),}
      \texttt{person(c("Brian", "D."), "Ripley", role = c("aut", "trl", "cre"),}
      \texttt{comment = "R port, author of parallel support"},
    \texttt{)}
  \texttt{)}
)
citEntry

Bibliography Entries (Older Interface)

Description

Functionality for specifying bibliographic information in enhanced BibTeX style.

Usage

citEntry(entry, textVersion, header = NULL, footer = NULL, ...)
citHeader(...)  
citFooter(...)
close.socket

Arguments

- entry: a character string with a BibTeX entry type. See section Entry Types in bibentry for details.
- textVersion: a character string with a text representation of the reference.
- header: a character string with optional header text.
- footer: a character string with optional footer text.
- ... for citEntry, arguments of the form tag=value giving the fields of the entry, with tag and value the name and value of the field, respectively. See section Entry Fields in bibentry for details.
  For citHeader and citFooter, character strings.

Value

citEntry produces an object of class "bibentry".

See Also

citation for more information about citing R and R packages and ‘CITATION’ files; bibentry for the newer functionality for representing and manipulating bibliographic information.

---

close.socket Close a Socket

Description

Closes the socket and frees the space in the file descriptor table. The port may not be freed immediately.

Usage

close.socket(socket, ...)

Arguments

- socket: A socket object
- ... further arguments passed to or from other methods.

Value

logical indicating success or failure

Author(s)

Thomas Lumley

See Also

make.socket, read.socket
combn

Generate All Combinations of n Elements, Taken m at a Time

Description

Generate all combinations of the elements of x taken m at a time. If x is a positive integer, returns all combinations of the elements of seq(x) taken m at a time. If argument FUN is not NULL, applies a function given by the argument to each point. If simplify is FALSE, returns a list; otherwise returns an array, typically a matrix. ... are passed unchanged to the FUN function, if specified.

Usage

combn(x, m, FUN = NULL, simplify = TRUE, ...)

Arguments

x vector source for combinations, or integer n for x <- seq_len(n).
m number of elements to choose.
FUN function to be applied to each combination; default NULL means the identity, i.e., to return the combination (vector of length m).
simplify logical indicating if the result should be simplified to an array (typically a matrix); if FALSE, the function returns a list. Note that when simplify = TRUE as by default, the dimension of the result is simply determined from FUN(1st combination) (for efficiency reasons). This will badly fail if FUN(u) is not of constant length.
... optionally, further arguments to FUN.

Value

a list or array, see the simplify argument above. In the latter case, the identity dim(combn(n, m)) == c(m, choose(n, m)) holds.

Author(s)

Scott Chasalow wrote the original in 1994 for S; R package combinat and documentation by Vince Carey <stvjc@channing.harvard.edu>; small changes by the R core team, notably to return an array in all cases of simplify = TRUE, e.g., for combn(5,5).

References

See Also

choose for fast computation of the number of combinations. expand.grid for creating a data frame from all combinations of factors or vectors.
Examples

```r
combn(letters[1:4], 2)
(m <- combn(10, 5, min))  # minimum value in each combination
mm <- combn(15, 6, function(x) matrix(x, 2, 3))
stopifnot(round(choose(10, 5)) == length(m),
          c(2, 3, round(choose(15, 6))) == dim(mm))

## Different way of encoding points:
combn(c(1,1,1,1,2,2,2,3,3,4), 3, tabulate, nbins = 4)

## Compute support points and (scaled) probabilities for a
## Multivariate-Hypergeometric(n = 3, N = c(4,3,2,1)) p.f.:
# table.mat(t(combn(c(1,1,1,1,2,2,2,3,3,4), 3, tabulate, nbins = 4)))

## Assuring the identity
for(n in 1:7)
  for(m in 0:n) stopifnot(is.array(cc <- combn(n, m)),
                         dim(cc) == c(m, choose(n, m)))
```

Description

Compare two package version numbers to see which is later.

Usage

```r
compareVersion(a, b)
```

Arguments

- `a, b` Character strings representing package version numbers.

Details

R package version numbers are of the form `x.y-z` for integers `x`, `y` and `z`, with components after `x` optionally missing (in which case the version number is older than those with the components present).

Value

0 if the numbers are equal, -1 if `b` is later and 1 if `a` is later (analogous to the C function `strcmp`).

See Also

- `package_version`, `library`, `packageStatus`
Examples

```r
compareVersion("1.0", "1.0-1")
compareVersion("7.2-0","7.1-12")
```

Description

Compile given source files so that they can subsequently be collected into a shared object using `R CMD SHLIB` and be loaded into R using `dyn.load()`.

Usage

```r
R CMD Compile [options] srcfiles
```

Arguments

- **srcfiles**: A list of the names of source files to be compiled. Currently, C, C++, Objective C, Objective C++ and FORTRAN are supported; the corresponding files should have the extensions `.c`, `.cc` (or `.cpp`), `.m`, `.mm` (or `.M`), `.f` and `.f90` or `.f95`, respectively.
- **options**: A list of compile-relevant settings, such as special values for `CFLAGS` or `FFLAGS`, or for obtaining information about usage and version of the utility.

Details

Note that Ratfor is not supported. If you have Ratfor source code, you need to convert it to FORTRAN. On many Solaris systems mixing Ratfor and FORTRAN code will work.

Objective C and Objective C++ support is optional and will work only if the corresponding compilers were available at R configure time.

Note

Some binary distributions of R have `COMPILE` in a separate bundle, e.g. an `R-devel` RPM.

See Also

- `SHLIB`, `dyn.load`: the section on “Customizing compilation under Unix” in “R Administration and Installation” (see the ‘doc/manual’ subdirectory of the R source tree).
**contrib.url**

Find Appropriate Paths in CRAN-like Repositories

**Description**

*contrib.url* adds the appropriate type-specific path within a repository to each URL in *repos*.

**Usage**

```r
contrib.url(repos, type = getOption("pkgType"))
```

**Arguments**

- **repos** character vector, the base URL(s) of the repositories to use.
- **type** character string, indicating which type of packages: see *install.packages*.

**Value**

A character vector of the same length as *repos*.

**See Also**

*available.packages, download.packages, install.packages.*

The ‘R Installation and Administration’ manual for how to set up a repository.

---

**count.fields**

Count the Number of Fields per Line

**Description**

*count.fields* counts the number of fields, as separated by *sep*, in each of the lines of *file* read.

**Usage**

```r
count.fields(file, sep = "", quote = "\"", skip = 0,
        blank.lines.skip = TRUE, comment.char = ")
```
create.post

Arguments

file a character string naming an ASCII data file, or a connection, which will be opened if necessary, and if so closed at the end of the function call.

sep the field separator character. Values on each line of the file are separated by this character. By default, arbitrary amounts of whitespace can separate fields.

quote the set of quoting characters

skip the number of lines of the data file to skip before beginning to read data.

blank.lines.skip logical: if TRUE blank lines in the input are ignored.

comment.char character: a character vector of length one containing a single character or an empty string.

Details

This used to be used by read.table and can still be useful in discovering problems in reading a file by that function.

For the handling of comments, see scan.

Consistent with scan, count.fields allows quoted strings to contain newline characters. In such a case the starting line will have the field count recorded as NA, and the ending line will include the count of all fields from the beginning of the record.

Value

A vector with the numbers of fields found.

See Also

read.table

Examples

cat("NAME", "1:John", "2:Paul", file = "foo", sep = "\n")
count.fields("foo", sep = ":")
unlink("foo")

create.post Ancillary Function for Preparing Emails and Postings

Description

An ancillary function used by bug.report and help.request to prepare emails for submission to package maintainers or to R mailing lists.
create.post 1861

Usage

create.post(instructions = character(), description = "post",
subject = "", method = getOption("mailer"),
address = "the relevant mailing list",
ccaddress = getOption("ccaddress", ""),
filename = "R.post", info = character())

Arguments

instructions Character vector of instructions to put at the top of the template email.
description Character string: a description to be incorporated into messages.
subject Subject of the email. Optional except for the "mailx" method.
method Submission method, one of "none", "mailto", "gnudoit", "ess" or (Unix only) "mailx". See ‘Details’.
address Recipient’s email address, where applicable: for package bug reports sent by email this defaults to the address of the package maintainer (the first if more than one is listed).
ccaddress Optional email address for copies with the "mailx" and "mailto" methods. Use ccaddress = "" for no copy.
filename Filename to use for setting up the email (or storing it when method is "none" or sending mail fails).
info character vector of information to include in the template email below the ‘please do not edit the information below’ line.

Details

What this does depends on the method. The function first creates a template email body.

none A file editor (see file.edit) is opened with instructions and the template email. When this returns, the completed email is in file file ready to be read/pasted into an email program.

mailto This opens the default email program with a template email (including address, Cc: address and subject) for you to edit and send.

This works where default mailers are set up (usual on OS X and Windows, and where xdg-open is available and configured on other Unix-alikes: if that fails it tries the browser set by R_BROWSER).

This is the ‘factory-fresh’ default method as from R 2.13.0.

mailx (Unix-alikes only.) A file editor (see file.edit) is opened with instructions and the template email. When this returns, it is mailed using a Unix command line mail utility such as mailx, to the address (and optionally, the Cc: address) given.

gnudoit An (X)emacs mail buffer is opened for the email to be edited and sent: this requires the gnudoit program to be available. Currently subject is ignored.

ess The body of the template email is sent to stdout.
Value

Invisible NULL.

See Also

bug.report, help.request.

data

Data Sets

Description

Loads specified data sets, or list the available data sets.

Usage

data(..., list = character(), package = NULL, lib.loc = NULL,
    verbose = getOption("verbose"), envir = .GlobalEnv)

Arguments

... literal character strings or names.
list a character vector.
package a character vector giving the package(s) to look in for data sets, or NULL.
   By default, all packages in the search path are used, then the ‘data’ subdirectory
   (if present) of the current working directory.
lib.loc a character vector of directory names of R libraries, or NULL. The default value
   of NULL corresponds to all libraries currently known.
verbose a logical. If TRUE, additional diagnostics are printed.
envir the environment where the data should be loaded.

Details

Currently, four formats of data files are supported:

1. files ending ‘.R’ or ‘.r’ are source()d in, with the R working directory changed temporarily
   to the directory containing the respective file. (data ensures that the utils package is attached,
   in case it had been run via utils::data.)
2. files ending ‘.RData’ or ‘.rda’ are load()ed.
3. files ending ‘.tab’, ‘.txt’ or ‘.TXT’ are read using read.table(..., header = TRUE), and
   hence result in a data frame.
4. files ending ‘.csv’ or ‘.CSV’ are read using read.table(..., header = TRUE, sep = ";")
   and also result in a data frame.
If more than one matching file name is found, the first on this list is used. (Files with extensions ‘.txt’, ‘.tab’ or ‘.csv’ can be compressed, with or without further extension ‘.gz’, ‘.bz2’ or ‘.xz’.)

The data sets to be loaded can be specified as a set of character strings or names, or as the character vector list, or as both.

For each given data set, the first two types (‘.R’ or ‘.r’, and ‘.RData’ or ‘.rda’ files) can create several variables in the load environment, which might all be named differently from the data set. The third and fourth types will always result in the creation of a single variable with the same name (without extension) as the data set.

If no data sets are specified, data lists the available data sets. It looks for a new-style data index in the ‘Meta’ or, if this is not found, an old-style ‘00Index’ file in the ‘data’ directory of each specified package, and uses these files to prepare a listing. If there is a ‘data’ area but no index, available data files for loading are computed and included in the listing, and a warning is given: such packages are incomplete. The information about available data sets is returned in an object of class “packageIQR”. The structure of this class is experimental. Where the datasets have a different name from the argument that should be used to retrieve them the index will have an entry like beaver1 (beavers) which tells us that dataset beaver1 can be retrieved by the call data(beaver).

If lib.loc and package are both NULL (the default), the data sets are searched for in all the currently loaded packages then in the ‘data’ directory (if any) of the current working directory.

If lib.loc = NULL but package is specified as a character vector, the specified package(s) are searched for first amongst loaded packages and then in the default library/ies (see .libPaths).

If lib.loc is specified (and not NULL), packages are searched for in the specified library/ies, even if they are already loaded from another library.

To just look in the ‘data’ directory of the current working directory, set package = character(0) (and lib.loc = NULL, the default).

**Value**

A character vector of all data sets specified, or information about all available data sets in an object of class “packageIQR” if none were specified.

**Good practice**

data() was originally intended to allow users to load datasets from packages for use in their examples, and as such it loaded the datasets into the workspace .GlobalEnv. This avoided having large datasets in memory when not in use. That need has been almost entirely superseded by lazy-loading of datasets.

The ability to specify a dataset by name (without quotes) is a convenience: in programming the datasets should be specified by character strings (with quotes).

Use of data within a function without an envir argument has the almost always undesirable side-effect of putting an object in the user’s workspace (and indeed, of replacing any object of that name already there). It would almost always be better to put the object in the current evaluation environment by data(..., envir = environment()). However, two alternatives are usually preferable, both described in the ‘Writing R Extensions’ manual.

- For sets of data, set up a package to use lazy-loading of data.
• For objects which are system data, for example lookup tables used in calculations within the function, use a file ‘R/sysdata.rda’ in the package sources or create the objects by R code at package installation time.

A sometimes important distinction is that the second approach places objects in the namespace but the first does not. So if it is important that the function sees mytable as an object from the package, it is system data and the second approach should be used.

Note

One can take advantage of the search order and the fact that a ‘.R’ file will change directory. If raw data are stored in ‘mydata.txt’ then one can set up ‘mydata.R’ to read ‘mydata.txt’ and pre-process it, e.g., using transform. For instance one can convert numeric vectors to factors with the appropriate labels. Thus, the ‘.R’ file can effectively contain a metadata specification for the plaintext formats.

See Also

help for obtaining documentation on data sets, save for creating the second (‘.rda’) kind of data, typically the most efficient one.

The ‘Writing R Extensions’ for considerations in preparing the ‘data’ directory of a package.

Examples

```r
require(utils)
data() # list all available data sets
try(data(package = "rpart") ) # list the data sets in the rpart package
data(USArrests, "VADeaths") # load the data sets 'USArrests' and 'VADeaths'
## Not run: ## Alternatively
ds <- c("USArrests", "VADeaths"); data(list = ds)
## End(Not run)
help(USArrests) # give information on data set 'USArrests'
```

---

**dataentry**  
*Spreadsheet Interface for Entering Data*

**Description**  
A spreadsheet-like editor for entering or editing data.

**Usage**

```r
data.entry(..., Modes = NULL, Names = NULL)
dataentry(data, modes)
de(..., Modes = list(), Names = NULL)
```
Arguments

... A list of variables: currently these should be numeric or character vectors or list containing such vectors.

Modes The modes to be used for the variables.

Names The names to be used for the variables.

data A list of numeric and/or character vectors.

modes A list of length up to that of data giving the modes of (some of) the variables. list() is allowed.

Details

The data entry editor is only available on some platforms and GUIs. Where available it provides a means to visually edit a matrix or a collection of variables (including a data frame) as described in the Notes section.

data.entry has side effects, any changes made in the spreadsheet are reflected in the variables. The functions de, de.ncols, de.setup and de.restore are designed to help achieve these side effects. If the user passes in a matrix, X say, then the matrix is broken into columns before dataentry is called. Then on return the columns are collected and glued back together and the result assigned to the variable X. If you don’t want this behaviour use dataentry directly.

The primitive function is dataentry. It takes a list of vectors of possibly different lengths and modes (the second argument) and opens a spreadsheet with these variables being the columns. The columns of the dataentry window are returned as vectors in a list when the spreadsheet is closed.

de.ncols counts the number of columns which are supplied as arguments to data.entry. It attempts to count columns in lists, matrices and vectors. de.setup sets things up so that on return the columns can be regrouped and reassigned to the correct name. This is handled by de.restore.

Value

de and dataentry return the edited value of their arguments. data.entry invisibly returns a vector of variable names but its main value is its side effect of assigning new version of those variables in the user’s workspace.

Resources

The data entry window responds to X resources of class R_dataentry. Resources foreground, background and geometry are utilized.

Note

The details of interface to the data grid may differ by platform and GUI. The following description applies to the X11-based implementation under Unix.

You can navigate around the grid using the cursor keys or by clicking with the (left) mouse button on any cell. The active cell is highlighted by thickening the surrounding rectangle. Moving to the right or down will scroll the grid as needed: there is no constraint to the rows or columns currently in use.
There are alternative ways to navigate using the keys. Return and (keypad) Enter and LineFeed all move down. Tab moves right and Shift-Tab move left. Home moves to the top left.

PageDown or Control-F moves down a page, and PageUp or Control-B up by a page. End will show the last used column and the last few rows used (in any column).

Using any other key starts an editing process on the currently selected cell: moving away from that cell enters the edited value whereas Esc cancels the edit and restores the previous value. When the editing process starts the cell is cleared. In numerical columns (the default) only letters making up a valid number (including -.eE) are accepted, and entering an invalid edited value (such as blank) enters NA in that cell. The last entered value can be deleted using the BackSpace or Del(ete) key. Only a limited number of characters (currently 29) can be entered in a cell, and if necessary only the start or end of the string will be displayed, with the omissions indicated by > or <. (The start is shown except when editing.)

Entering a value in a cell further down a column than the last used cell extends the variable and fills the gap (if any) by NAs (not shown on screen).

The column names can only be selected by clicking in them. This gives a popup menu to select the column type (currently Real (numeric) or Character) or to change the name. Changing the type converts the current contents of the column (and converting from Character to Real may generate NAs.) If changing the name is selected the header cell becomes editable (and is cleared). As with all cells, the value is entered by moving away from the cell by clicking elsewhere or by any of the keys for moving down (only).

New columns are created by entering values in them (and not by just assigning a new name). The mode of the column is auto-detected from the first value entered: if this is a valid number it gives a numeric column. Unused columns are ignored, so adding data in var5 to a three-column grid adds one extra variable, not two.

The Copy button copies the currently selected cell: paste copies the last copied value to the current cell, and right-clicking selects a cell and copies in the value. Initially the value is blank, and attempts to paste a blank value will have no effect.

Control-L will refresh the display, recalculating field widths to fit the current entries.

In the default mode the column widths are chosen to fit the contents of each column, with a default of 10 characters for empty columns. You can specify fixed column widths by setting option `de.cellwidth` to the required fixed width (in characters). (set it to zero to return to variable widths). The displayed width of any field is limited to 600 pixels (and by the window width).

See Also

`vi`, `edit`: edit uses dataentry to edit data frames.

Examples

```r
# call data entry with variables x and y
## Not run: data.entry(x, y)
```
**Post-Mortem Debugging**

**Description**

Functions to dump the evaluation environments (frames) and to examine dumped frames.

**Usage**

```r
dump.frames(dumpto = "last.dump", to.file = FALSE)
debugger(dump = last.dump)
```

**Arguments**

- `dumpto` a character string. The name of the object or file to dump to.
- `to.file` logical. Should the dump be to an R object or to a file?
- `dump` An R dump object created by `dump.frames`.

**Details**

To use post-mortem debugging, set the option `error` to be a call to `dump.frames`. By default this dumps to an R object `last.dump` in the workspace, but it can be set to dump to a file (a dump of the object produced by a call to `save`). The dumped object contain the call stack, the active environments and the last error message as returned by `geterrmessage`.

When dumping to file, `dumpto` gives the name of the dumped object and the file name has `.rda` appended.

A dump object of class "dump.frames" can be examined by calling `debugger`. This will give the error message and a list of environments from which to select repeatedly. When an environment is selected, it is copied and the `browser` called from within the copy. Note that not all the information in the original frame will be available, e.g. promises which have not yet been evaluated and the contents of any `...` argument.

If `dump.frames` is installed as the error handler, execution will continue even in non-interactive sessions. See the examples for how to dump and then quit.

**Value**

Invisible `NULL`.

**Note**

Functions such as `sys.parent` and `environment` applied to closures will not work correctly inside `debugger`.

If the error occurred when computing the default value of a formal argument the debugger will report “recursive default argument reference” when trying to examine that environment.

Of course post-mortem debugging will not work if R is too damaged to produce and save the dump, for example if it has run out of workspace.

Available environments had calls:
1: f()
2: g()
3: stop("test dump.frames")

Enter an environment number, or 0 to exit
Selection: 0

## A possible setting for non-interactive sessions
options(error = quote({dump.frames(to.file = TRUE); q()}))

## End(Not run)
Description

demo is a user-friendly interface to running some demonstration R scripts. demo() gives the list of available topics.

Usage

demo(topic, package = NULL, lib.loc = NULL,  
character.only = FALSE, verbose = getOption("verbose"),  
echo = TRUE, ask = getOption("demo.ask"),  
encoding = getOption("encoding"))

Arguments

topic the topic which should be demonstrated, given as a name or literal character string, or a character string, depending on whether character.only is FALSE (default) or TRUE. If omitted, the list of available topics is displayed.

package a character vector giving the packages to look into for demos, or NULL. By default, all packages in the search path are used.

lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.

character.only logical; if TRUE, use topic as character string.

verbose a logical. If TRUE, additional diagnostics are printed.

echo a logical. If TRUE, show the R input when sourcing.

ask a logical (or "default") indicating if devAskNewPage(ask = TRUE) should be called before graphical output happens from the demo code. The value "default" (the factory-fresh default) means to ask if echo == TRUE and the graphics device appears to be interactive. This parameter applies both to any currently opened device and to any devices opened by the demo code. If this is evaluated to TRUE and the session is interactive, the user is asked to press RETURN to start.

encoding See source. If the package has a declared encoding, that takes preference.

Details

If no topics are given, demo lists the available demos. The corresponding information is returned in an object of class "packageIQR".

See Also

source and devAskNewPage which are called by demo.
Examples

demo() # for attached packages

## All available demos:
demo(package = .packages(all.available = TRUE))

## Display a demo, pausing between pages
demo(lm.glm, package = "stats", ask = TRUE)

## Display it without pausing
demo(lm.glm, package = "stats", ask = FALSE)

## Not run:
ch <- "scoping"
demo(ch, character = TRUE)

## End(Not run)

## Find the location of a demo
system.file("demo", "lm.glm.R", package = "stats")

---

download.file Download File from the Internet

Description

This function can be used to download a file from the Internet.

Usage

download.file(url, destfile, method, quiet = FALSE, mode = "w",
cacheOK = TRUE,
extra = getOption("download.file.extra"))

Arguments

url A character string naming the URL of a resource to be downloaded.
destfile A character string with the name where the downloaded file is saved. Tilde-
expansion is performed.
method Method to be used for downloading files. Currently download methods
"internal", "wget", "curl" and "lynx" are available, and there is a value
"auto": see ‘Details’ and ‘Note’. The method can also be set through the option "download.file.method": see
options()
quiet If TRUE, suppress status messages (if any), and the progress bar.
mode character. The mode with which to write the file. Useful values are "w", "wb" (binary), "a" (append) and "ab". Only used for the "internal" method.
cacheOK logical. Is a server-side cached value acceptable? Implemented for the "internal", "wget" and "curl" methods.
extra character vector of additional command-line arguments for the "wget", "curl" and "lynx" methods.

Details

The function `download.file` can be used to download a single file as described by `url` from the internet and store it in `destfile`. The `url` must start with a scheme such as `http://`, `ftp://` or `file://`.

If `method = "auto"` is chosen (the default), the internal method is chosen for `file://` URLs, and for the others provided `capabilities("http/ftp")` is true (which it almost always is). Otherwise methods "wget", "curl" and "lynx" are tried in turn.

`cacheOK = FALSE` is useful for `http://` URLs, and will attempt to get a copy directly from the site rather than from an intermediate cache. (Not all platforms support it.) It is used by `available.packages`.

The remaining details apply to method "internal" only.

Note that `https://` URLs are not supported.

See `url` for how `file://` URLs are interpreted, especially on Windows. This function does decode encoded URLs.

The timeout for many parts of the transfer can be set by the option `timeout` which defaults to 60 seconds.

The level of detail provided during transfer can be set by the `quiet` argument and the `internet.info` option. The details depend on the platform and scheme, but setting `internet.info = 0` gives all available details, including all server responses. Using 2 (the default) gives only serious messages, and 3 or more suppresses all messages.

A progress bar tracks the transfer. If the file length is known, an equals sign represents 2% of the transfer completed: otherwise a dot represents 10Kb.

Code written to download binary files must use `mode = "wb"`, but the problems incurred by a text transfer will only be seen on Windows.

Method "wget" can be used with proxy firewalls which require user/password authentication if proper values are stored in the configuration file for `wget`.

Value

An (invisible) integer code, 0 for success and non-zero for failure. For the "wget" and "lynx" methods this is the status code returned by the external program. The "internal" method can return 1, but will in most cases throw an error.

Setting Proxies

This applies to the internal code only.
Proxies can be specified via environment variables. Setting "no_proxy" to "*" stops any proxy being tried. Otherwise the setting of "http_proxy" or "ftp_proxy" (or failing that, the all upper-case version) is consulted and if non-empty used as a proxy site. For FTP transfers, the username and password on the proxy can be specified by "ftp_proxy_user" and "ftp_proxy_password". The form of "http_proxy" should be "http://proxy.dom.com/" or "http://proxy.dom.com:8080/" where the port defaults to 80 and the trailing slash may be omitted. For "ftp_proxy" use the form "ftp://proxy.dom.com:3128/" where the default port is 21. These environment variables must be set before the download code is first used: they cannot be altered later by calling Sys.setenv.

Usernames and passwords can be set for HTTP proxy transfers via environment variable http_proxy_user in the form user:passwd. Alternatively, http_proxy can be of the form "http://user:pass@proxy.dom.com:8080/" for compatibility with wget. Only the HTTP/1.0 basic authentication scheme is supported.

Note

Methods "wget" and "lynx" are mainly for historical compatibility, but they and "curl" can be used for URLs (e.g. ‘https://’ URLs or those that use cookies) which the internal method does not support. They will block all other activity on the R process.

For methods "wget", "curl" and "lynx" a system call is made to the tool given by method, and the respective program must be installed on your system and be in the search path for executables.

wget (http://www.gnu.org/software/wget/) is commonly installed on Unix-alikes (but not OS X). Windows binaries are available from Cygwin, gnuwin32 and elsewhere.

curl (http://curl.haxx.se/) is installed on OS X and commonly on Unix-alikes. Windows binaries are available at that URL.

lynx (http://lynx.browser.org/) is of historical interest.

See Also

options to set the HTTPUserAgent, timeout and internet.info options.

url for a finer-grained way to read data from URLs.

url.show, available.packages, download.packages for applications.

Contributed package RCurl provides more comprehensive facilities to download from URLs.

Description

These functions can be used to automatically compare the version numbers of installed packages with the newest available version on the repositories and update outdated packages on the fly.
download.packages

Usage

download.packages(pkgs, destdir, available = NULL,
repos = getOption("repos"),
contriburl = contrib.url(repos, type),
method, type = getOption("pkgType"), ...)  

Arguments

pkgs character vector of the names of packages whose latest available versions should be downloaded from the repositories.
destdir directory where downloaded packages are to be stored.
available an object as returned by available.packages listing packages available at the repositories, or NULL which makes an internal call to available.packages.
repos character vector, the base URL(s) of the repositories to use, i.e., the URL of the CRAN master such as "http://cran.r-project.org" or its Statlib mirror, "http://lib.stat.cmu.edu/R/CRAN".
contriburl URL(s) of the contrib sections of the repositories. Use this argument only if your repository mirror is incomplete, e.g., because you burned only the `contrib` section on a CD. Overrides argument repos.
method Download method, see download.file.
type character string, indicate which type of packages: see install.packages.
... additional arguments to be passed to download.file.

Details

download.packages takes a list of package names and a destination directory, downloads the newest versions and saves them in destdir. If the list of available packages is not given as argument, it is obtained from repositories. If a repository is local, i.e. the URL starts with "file: ", then the packages are not downloaded but used directly. Both "file:" and "file:////" are allowed as prefixes to a file path. Use the latter only for URLs: see url for their interpretation. (Other forms of 'file:///' URLs are not supported.)

Value

A two-column matrix of names and destination file names of those packages successfully downloaded. If packages are not available or there is a problem with the download, suitable warnings are given.

See Also

available.packages, contrib.url.
The main use is by install.packages.
See download.file for how to handle proxies and other options to monitor file transfers.
The ‘R Installation and Administration’ manual for how to set up a repository.

edit

edit

Invoke a Text Editor

Description
Invoke a text editor on an R object.
Usage
## Default S3 method:
edit(name = NULL, file = "", title = NULL,
editor = getOption("editor"), ...)
vi(name = NULL, file = "")
emacs(name = NULL, file = "")
pico(name = NULL, file = "")
xemacs(name = NULL, file = "")
xedit(name = NULL, file = "")
Arguments
name

a named object that you want to edit. If name is missing then the file specified
by file is opened for editing.

file

a string naming the file to write the edited version to.

title

a display name for the object being edited.

editor

a string naming the text editor you want to use. On Unix the default is set from
the environment variables EDITOR or VISUAL if either is set, otherwise vi is used.
On Windows it defaults to "internal", the script editor. On the OS X GUI the
argument is ignored and the document editor is always used.

...

further arguments to be passed to or from methods.

Details
edit invokes the text editor specified by editor with the object name to be edited. It is a generic
function, currently with a default method and one for data frames and matrices.
data.entry can be used to edit data, and is used by edit to edit matrices and data frames on
systems for which data.entry is available.
It is important to realize that edit does not change the object called name. Instead, a copy of name
is made and it is that copy which is changed. Should you want the changes to apply to the object
name you must assign the result of edit to name. (Try fix if you want to make permanent changes
to an object.)
In the form edit(name), edit deparses name into a temporary file and invokes the editor editor
on this file. Quitting from the editor causes file to be parsed and that value returned. Should an
error occur in parsing, possibly due to incorrect syntax, no value is returned. Calling edit(), with
no arguments, will result in the temporary file being reopened for further editing.


edit.data.frame

Note that deparsing is not perfect, and the object recreated after editing can differ in subtle ways from that deparsed: see `dput` and `.deparseOpts`. (The deparse options used are the same as the defaults for `dump`.) Editing a function will preserve its environment. See `edit.data.frame` for further changes that can occur when editing a data frame or matrix.

Currently only the internal editor in Windows makes use of the `title` option; it displays the given name in the window header.

Note

The functions `vi`, `emacs`, `pico`, `xemacs`, `xedit` rely on the corresponding editor being available and being on the path. This is system-dependent.

See Also

`edit.data.frame`, `data.entry`, `fix`.

Examples

```r
## Not run:
# use xedit on the function mean and assign the changes
mean <- edit(mean, editor = "xedit")

# use vi on mean and write the result to file mean.out
vi(mean, file = "mean.out")

## End(Not run)
```

Description

Use data editor on data frame or matrix contents.

Usage

```r
## S3 method for class 'data.frame'
edit(name, factor.mode = c("character", "numeric"),
    edit.row.names = any(row.names(name) != 1:nrow(name)), ...)  

## S3 method for class 'matrix'
edit(name, edit.row.names = !is.null(dn[[1]]), ...)  
```
Arguments

name | A data frame or (numeric, logical or character) matrix.
factor.mode | How to handle factors (as integers or using character levels) in a data frame.
edit.row.names | logical. Show the row names (if they exist) be displayed as a separate editable column? It is an error to ask for this on a matrix with NULL row names.
... | further arguments passed to or from other methods.

Details

At present, this only works on simple data frames containing numeric, logical or character vectors and factors, and numeric, logical or character matrices. Any other mode of matrix will give an error, and a warning is given when the matrix has a class (which will be discarded).

Data frame columns are coerced on input to character unless numeric (in the sense of is.numeric), logical or factor. A warning is given when classes are discarded. Special characters (tabs, non-printing ASCII, etc.) will be displayed as escape sequences.

Factors columns are represented in the spreadsheet as either numeric vectors (which are more suitable for data entry) or character vectors (better for browsing). After editing, vectors are padded with NA to have the same length and factor attributes are restored. The set of factor levels can not be changed by editing in numeric mode; invalid levels are changed to NA and a warning is issued. If new factor levels are introduced in character mode, they are added at the end of the list of levels in the order in which they encountered.

It is possible to use the data-editor’s facilities to select the mode of columns to swap between numerical and factor columns in a data frame. Changing any column in a numerical matrix to character will cause the result to be coerced to a character matrix. Changing the mode of logical columns is not supported.

For a data frame, the row names will be taken from the original object if edit.row.names = FALSE and the number of rows is unchanged, and from the edited output if edit.row.names = TRUE and there are no duplicates. (If the row.names column is incomplete, it is extended by entries like row223.) In all other cases the row names are replaced by seq(length = nrows).

For a matrix, colnames will be added (of the form col7) if needed. The rrownames will be taken from the original object if edit.row.names = FALSE and the number of rows is unchanged (otherwise NULL), and from the edited output if edit.row.names = TRUE. (If the row.names column is incomplete, it is extended by entries like row223.)

Editing a matrix or data frame will lose all attributes apart from the row and column names.

Value

The edited data frame or matrix.

Note

fix(dataframe) works for in-place editing by calling this function.

If the data editor is not available, a dump of the object is presented for editing using the default method of edit.

At present the data editor is limited to 65535 rows.

edit(InsectSprays)
edit(InsectSprays, factor.mode = "numeric")

## End(Not run)

---

Run an Examples Section from the Online Help

Description

Run all the R code from the Examples part of R’s online help topic topic with two possible exceptions, dontrun and dontshow, see ‘Details’ below.

Usage

example(topic, package = NULL, lib.loc = NULL, character.only = FALSE, give.lines = FALSE, local = FALSE, echo = TRUE, verbose = getOption("verbose"), setRNG = FALSE, ask = getOption("example.ask"), prompt.prefix = abbreviate(topic, 6))

Arguments

topic name or literal character string: the online help topic the examples of which should be run.
package a character vector giving the package names to look into for the topic, or NULL (the default), when all packages on the search path are used.
lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.
character.only a logical indicating whether topic can be assumed to be a character string.
give.lines logical: if true, the lines of the example source code are returned as a character vector.
local logical: if TRUE evaluate locally, if FALSE evaluate in the workspace.
echo logical; if TRUE, show the R input when sourcing.
verbose logical; if TRUE, show even more when running example code.

setRNG logical or expression; if not FALSE, the random number generator state is saved, then initialized to a specified state, the example is run and the (saved) state is restored. setRNG = TRUE sets the same state as R CMD check does for running a package's examples. This is currently equivalent to setRNG = (RNGkind("default", "default"); set.seed(1)).

ask logical (or "default") indicating if devAskNewPage(ask = TRUE) should be called before graphical output happens from the example code. The value "default" (the factory-fresh default) means to ask if echo == TRUE and the graphics device appears to be interactive. This parameter applies both to any currently opened device and to any devices opened by the example code.

prompt.prefix character; prefixes the prompt to be used if echo = TRUE.

Details

If lib.loc is not specified, the packages are searched for amongst those already loaded, then in the libraries given by .libPaths(). If lib.loc is specified, packages are searched for only in the specified libraries, even if they are already loaded from another library. The search stops at the first package found that has help on the topic.

An attempt is made to load the package before running the examples, but this will not replace a package loaded from another location.

If local = TRUE objects are not created in the workspace and so not available for examination after example completes; on the other hand they cannot overwrite objects of the same name in the workspace.

As detailed in the manual Writing R Extensions, the author of the help page can markup parts of the examples for two exception rules

dontrun encloses code that should not be run.

dontshow encloses code that is invisible on help pages, but will be run both by the package checking tools, and the example() function. This was previously testonly, and that form is still accepted.

Value

The value of the last evaluated expression, unless give.lines is true, where a character vector is returned.

                example, character.only = TRUE, give.lines = TRUE)
sapply(lmex, length)

file.edit

Edit One or More Files

Description

Edit one or more files in a text editor.

Usage

file.edit(..., title = file, editor = getOption("editor"),
            fileEncoding = "")

Arguments

... one or more character vectors containing the names of the files to be displayed. These will be tilde-expanded: see path.expand.
title the title to use in the editor; defaults to the filename.
eteditor the text editor to be used. See ‘Details’.
fileEncoding the encoding to assume for the file: the default is to assume the native encoding. See the ‘Encoding’ section of the help for file.
Details

The behaviour of this function is very system dependent. Currently files can be opened only one at a time on Unix; on Windows, the internal editor allows multiple files to be opened, but has a limit of 50 simultaneous edit windows.

The title argument is used for the window caption in Windows, and is currently ignored on other platforms.

The fileEncoding argument was added in R 2.13.0: any error in re-encoding the files to the native encoding will cause the function to fail.

The default for editor is system-dependent. On Windows it defaults to "internal", the script editor, and in the OS X GUI the document editor is used whatever the value of editor. On Unix the default is set from the environment variables EDITOR or VISUAL if either is set, otherwise vi is used.

---

**file_test**  
*Shell-style Tests on Files*

Description

Utility for shell-style file tests.

Usage

`file_test(op, x, y)`

Arguments

- `op` a character string specifying the test to be performed. Unary tests (only `x` is used) are 
  "-f" (existence and not being a directory), "-d" (existence and directory) and 
  "-x" (executable as a file or searchable as a directory). Binary tests are 
  "-nt" (strictly newer than, using the modification dates) and "-ot" (strictly 
  older than): in both cases the test is false unless both files exist.
- `x, y` character vectors giving file paths.
Details

‘Existence’ here means being on the file system and accessible by the stat system call (or a 64-bit extension) – on a Unix-alike this requires execute permission on all of the directories in the path that leads to the file, but no permissions on the file itself.

For the meaning of "-x" on Windows see file.access.

See Also

file.exists which only tests for existence (test -e on some systems) but not for not being a directory.

file.path, file.info

Examples

dir <- file.path(R.home(), "library", "stats")
file_test("-d", dir)
file_test("-nt", file.path(dir, "R"), file.path(dir, "demo"))

findLineNum

Find the Location of a Line of Source Code, or Set a Breakpoint There.

Description

These functions locate objects containing particular lines of source code, using the information saved when the code was parsed with keep.source = TRUE.

Usage

findLineNum(srcfile, line, nameonly = TRUE, 
envir = parent.frame(), lastenv)

setBreakpoint(srcfile, line, nameonly = TRUE, 
envir = parent.frame(), lastenv, verbose = TRUE, 
tracer, print = FALSE, clear = FALSE, ...)

Arguments

srcfile The name of the file containing the source code.
line The line number within the file. See Details for an alternate way to specify this.
nameonly If TRUE (the default), we require only a match to basename(srcfile), not to the full path.
envir Where do we start looking for function objects?
lastenv Where do we stop? See the Details.
verbose Should we print information on where breakpoints were set?
tracer          An optional tracer function to pass to `trace`. By default, a call to `browser` is inserted.
print           The print argument to pass to `trace`.
clear           If TRUE, call `untrace` rather than `trace`.

...             Additional arguments to pass to `trace`.

Details

The `findLineNum` function searches through all objects in environment `envir`, its parent, grandparent, etc., all the way back to `lastenv`.

`lastenv` defaults to the global environment if `envir` is not specified, and to the root environment `emptyenv()` if `envir` is specified. (The first default tends to be quite fast, and will usually find all user code other than S4 methods; the second one is quite slow, as it will typically search all attached system libraries.)

For convenience, `envir` may be specified indirectly: if it is not an environment, it will be replaced with `environment(envir)`.

`setBreakpoint` is a simple wrapper function for `trace` and `untrace`. It will set or clear breakpoints at the locations found by `findLineNum`.

The `srcfile` is normally a filename entered as a character string, but it may be a "srcfile" object, or it may include a suffix like "filename.R#nn", in which case the number `nn` will be used as a default value for `line`.

As described in the description of the `where` argument on the man page for `trace`, the R package system uses a complicated scheme that may include more than one copy of a function in a package. The user will typically see the public one on the search path, while code in the package will see a private one in the package `NAMESPACE`. If you set `envir` to the environment of a function in the package, by default `findLineNum` will find both versions, and `setBreakpoint` will set the breakpoint in both. (This can be controlled using `lastenv`; e.g. `envir = environment(foo)`, `lastenv = globalenv()` will find only the private copy, as the search is stopped before seeing the public copy.)

S version 4 methods are also somewhat tricky to find. They are stored with the generic function, which may be in the `base` or other package, so it is usually necessary to have `lastenv = emptyenv()` in order to find them. In some cases transformations are done by R when storing them and `findLineNum` may not be able to find the original code. Many special cases, e.g. methods on primitive generics, are not yet supported.

Value

`findLineNum` returns a list of objects containing location information. A `print` method is defined for them.

`setBreakpoint` has no useful return value; it is called for the side effect of calling `trace` or `untrace`.

Examples

## Not run:
# Find what function was defined in the file mysource.R at line 100:
findLineNum("mysource.R#100")

# Set a breakpoint in both copies of that function, assuming one is in the
# same namespace as myfunction and the other is on the search path
setBreakpoint("mysource.R#100", envir = myfunction)

## End(Not run)

fix

**Fix an Object**

Description
fix invokes edit on x and then assigns the new (edited) version of x in the user’s workspace.

Usage
fix(x, ...)

Arguments
x the name of an R object, as a name or a character string.
... arguments to pass to editor: see edit.

Details
The name supplied as x need not exist as an R object, in which case a function with no arguments and an empty body is supplied for editing.

Editing an R object may change it in ways other than are obvious: see the comment under edit. See edit.data.frame for changes that can occur when editing a data frame or matrix.

See Also
eedit, edit.data.frame
Examples

## Not run:
## Assume 'my.fun' is a user defined function:
fix(my.fun)
## now my.fun is changed
## Also,
fix(my.data.frame) # calls up data editor
fix(my.data.frame, factor.mode="char") # use of ...

## End(Not run)

flush.console

Flush Output to A Console

Description

This does nothing except on console-based versions of R. On the OS X and Windows GUIs, it ensures that the display of output in the console is current, even if output buffering is on.

Usage

flush.console()

format

Format Unordered and Ordered Lists

Description

Format unordered (itemize) and ordered (enumerate) lists.

Usage

formatUL(x, label = "+", offset = 0,
               width = 0.9 * getOption("width"))
formatOL(x, type = "arabic", offset = 0, start = 1,
               width = 0.9 * getOption("width"))

Arguments

x a character vector of list items.
label a character string used for labelling the items.
offset a non-negative integer giving the offset (indentation) of the list.
width a positive integer giving the target column for wrapping lines in the output.
type

A character string specifying the ‘type’ of the labels in the ordered list. If "arabic" (default), arabic numerals are used. For "Alph" or "alph", single upper or lower case letters are employed (in this case, the number of the last item must not exceed 26). Finally, for "Roman" or "roman", the labels are given as upper or lower case roman numerals (with the number of the last item maximally 3899). type can be given as a unique abbreviation of the above, or as one of the HTML style tokens "1" (arabic), "A"/"a" (alphabetic), or "I"/"i" (roman), respectively.

start

A positive integer specifying the starting number of the first item in an ordered list.

Value

A character vector with the formatted entries.

See Also

formatDL for formatting description lists.

Examples

## A simpler recipe.
x <- c("Mix dry ingredients thoroughly. ",
    "Pour in wet ingredients. ",
    "Mix for 10 minutes. ",
    "Bake for one hour at 300 degrees." )
## Format and output as an unordered list.
writeLines(formatUL(x))
## Format and output as an ordered list.
writeLines(formatOL(x))
## Ordered list using lower case roman numerals.
writeLines(formatOL(x, type = "i"))
## Ordered list using upper case letters and some offset.
writeLines(formatOL(x, type = "A", offset = 5))
Arguments

x a character string or name.

Details

These functions look at all loaded namespaces, whether or not they are associated with a package on the search list.

They do not search literally “anywhere”: for example, local evaluation frames and namespaces that are not loaded will not be searched.

Where functions are found as registered S3 methods, an attempt is made to find which namespace registered them. This may not be correct, especially if namespaces have been unloaded.

Value

For `getAnywhere()` an object of class "getAnywhere". This is a list with components

name the name searched for
objs a list of objects found
where a character vector explaining where the object(s) were found
visible logical: is the object visible
dups logical: is the object identical to one earlier in the list.

In computing whether objects are identical, their environments are ignored.

Normally the structure will be hidden by the `print` method. There is a `[]` method to extract one or more of the objects found.

For `argsAnywhere()` one or more argument lists as returned by `args`.

See Also

`getS3method` to find the method which would be used: this might not be the one of those returned by `getAnywhere` since it might have come from a namespace which was unloaded or be registered under another name.

`get, getFromNamespace, args`

Examples

`getAnywhere("format.dist")`
`getAnywhere("simpleLoess")` # not exported from stats
`argsAnywhere(format.dist)`
**getFromNamespace**  
**Utility functions for Developing Namespaces**

**Description**
Utility functions to access and replace the non-exported functions in a namespace, for use in developing packages with namespaces.

They should not be used in production code (except perhaps assignInMyNamespace, but see the ‘Note’).

**Usage**

```r
getFromNamespace(x, ns, pos = -1, envir = as.environment(pos))
assignInNamespace(x, value, ns, pos = -1, 
                  envir = as.environment(pos))
assignInMyNamespace(x, value)
fixInNamespace(x, ns, pos = -1, envir = as.environment(pos), ...)
```

**Arguments**

- `x` an object name (given as a character string).
- `value` an R object.
- `ns` a namespace, or character string giving the namespace.
- `pos` where to look for the object: see `get`.
- `envir` an alternative way to specify an environment to look in.
- `...` arguments to pass to the editor: see `edit`.

**Details**

assignInMyNamespace is intended to be called from functions within a package, and chooses the namespace as the environment of the function calling it.

The namespace can be specified in several ways. Using, for example, `ns = "stats"` is the most direct, but a loaded package can be specified via any of the methods used for `get`: `ns` can also be the environment printed as `<namespace:foo>`.

getFromNamespace is similar to (but predates) the `:::` operator: it is more flexible in how the namespace is specified.

fixInNamespace invokes `edit` on the object named `x` and assigns the revised object in place of the original object. For compatibility with `fix`, `x` can be unquoted.
getParseData

Get detailed parse information from object.

Description

If the "keep.source" option is TRUE, R's parser will attach detailed information on the object it has parsed. These functions retrieve that information.

Usage

getParseData(x, includeText = NA)
getParseText(parseData, id)
**getParseData**

**Arguments**

- `x`: an expression returned from `parse`, or a function or other object with source reference information
- `includeText`: logical; whether to include the text of parsed items in the result
- `parseData`: a dataframe returned from `getParseData`
- `id`: a vector of item identifiers whose text is to be retrieved

**Details**

In version 3.0.0, the R parser was modified to include code written by Romain Francois in his `parser` package. This constructs a detailed table of information about every token and higher level construct in parsed code. This table is stored in the `srcfile` record associated with source references in the parsed code, and retrieved by the `getParseData` function.

**Value**

For `getParseData`:

If parse data is not present, `NULL`. Otherwise a dataframe is returned, containing the following columns:

- `line1`: integer. The line number where the item starts. This is the parsed line number called "parse" in `getSrcLocation`, which ignores #line directives.
- `col1`: integer. The column number where the item starts. The first character is column 1. This corresponds to "column" in `getSrcLocation`.
- `line2`: integer. The line number where the item ends.
- `col2`: integer. The column number where the item ends.
- `id`: integer. An identifier associated with this item.
- `parent`: integer. The id of the parent of this item.
- `token`: character. The type of the token.
- `terminal`: logical. Whether the token is “terminal”, i.e. a leaf in the parse tree.
- `text`: character. If `includeText` is TRUE, the text of all tokens; if it is NA (the default), the text of terminal tokens. If `includeText` == FALSE, this column is not included.

The rownames of the dataframe will be equal to the id values, and the dataframe will have a "srcfile" attribute containing the `srcfile` record which was used. The rows will be ordered by starting position within the source file, with parent items occurring before their children.

For `getParseText`:

A character vector of the same length as `id` containing the associated text items. If they are not included in `parseData`, they will be retrieved from the original file.
Note

There are a number of differences in the results returned by `getParseData` relative to those in the original `parser` code:

- Fewer columns are kept.
- The internal token number is not returned.
- `col1` starts counting at 1, not 0.
- The `id` values are not attached to the elements of the parse tree, they are only retained in the table returned by `getParseData`.
- `#` line directives are identified, but other comment markup (e.g., `roxygen` comments) are not.

`parse`, `srcref`

Examples

```r
fn <- function(x) {
  x + 1 # A comment, kept as part of the source
}

d <- getParseData(fn)
if (!is.null(d)) {
  plus <- which(d$token == "+'")
  sum <- d$parent[plus]
  print(d[as.character(sum),])
  print(getParseText(d, sum))
}
```

---

**getS3method**

Get An S3 Method

Description

Get a method for an S3 generic, possibly from a namespace or the generic’s registry.

Usage

```r
gets3method(f, class, optional = FALSE)
```
Arguments

f character: name of the generic.
class character: name of the class.
optional logical: should failure to find the generic or a method be allowed?

Details

S3 methods may be hidden in namespaces, and will not then be found by get: this function can retrieve such functions, primarily for debugging purposes.

Further, S3 methods can be registered on the generic when a namespace is loaded, and the registered method will be used if none is visible (using namespace scoping rules).

It is possible that which S3 method will be used may depend on where the generic $f$ is called from:

getS3method returns the method found if $f$ were called from the same environment.

Value

The function found, or NULL if no function is found and optional = TRUE.

See Also

methods, get, getAnywhere

Examples

```r
require(stats)
exists("predict.ppr") # false
getS3method("predict", "ppr")
```

Description

Change wildcard aka globbing patterns into the corresponding regular expressions (regexp).

Usage

glob2rx(pattern, trim.head = FALSE, trim.tail = TRUE)

Arguments

pattern character vector
trim.head logical specifying if leading "^.*" should be trimmed from the result.
trim.tail logical specifying if trailing ".*$" should be trimmed from the result.
Details

This takes a wildcard as used by most shells and returns an equivalent regular expression. \? is mapped to . (match a single character), * to .* (match any string, including an empty one), and the pattern is anchored (it must start at the beginning and end at the end). Optionally, the resulting regexp is simplified.

Note that now even (, [ and { can be used in pattern, but glob2rx() may not work correctly with arbitrary characters in pattern.

Value

A character vector of the same length as the input pattern where each wildcard is translated to the corresponding regular expression.

Author(s)

Martin Maechler, Unix/sed based version, 1991; current: 2004

See Also

regexp about regular expression, sub, etc about substitutions using regexps.

Examples

stopifnot(glob2rx("abc.*") == "^abc\..",
glob2rx("a?b.*") == "^a.b\..",
glob2rx("a?b.*", trim.tail = FALSE) == "^a.b\..*$",
glob2rx("*.doc") == "^.*\.doc$",
glob2rx("*.doc", trim.head = TRUE) == "\\..doc$",
glob2rx("*.t\.*") == "^.*\.t",
glob2rx("*.t??") == "^.*\.t..$",
glob2rx("*[\]") == "^.*\["")

---

globalVariables

Declare Variables to be Treated as Global in Checking a Package

Description

The names supplied are of functions or other objects that should be regarded as defined globally when the check tool is applied to this package. The call to globalVariables will be included in the package’s source. Repeated calls in the same package accumulate the names of the global variables.

Typical examples are the fields and methods in reference classes, which appear to be global objects to codetools. (This case is handled automatically by setRefClass() and friends, using the supplied field and method names.)
Usage

globalVariables(names, package, add = TRUE)

Arguments

names    The character vector of object names. If omitted, the current list of global variables declared in the package will be returned, unchanged.
package   The relevant package, usually the character string name of the package but optionally its corresponding namespace environment.
   When the call to globalVariables comes in the package's source file, the argument is normally omitted, as in the example below.
add       Should the contents of names be added to the current global variables or replace it?

Details

The list of declared global variables is stored in a metadata object in the package's namespace, assuming the globalVariables call(s) occur as top-level calls in the package's source code.

The check command, as implemented in package utils, queries the global variables list before checking the R source code in the package for possible problems.

This was introduced in R 2.15.1 so should be used conditionally: see the example.

Value

The current list of declared global variables, possibly modified by this call.

Note

The global variables list really belongs to a restricted scope (a function or a group of method definitions, for example) rather than the package as a whole. However, implementing finer control would require changes in check and/or in codetools, so in this version the information is stored at the package level.

Author(s)

John Chambers

Examples

## Not run:
## assume your package has some code that assigns ".obj1" and ".obj2"
## but not in a way that codetools can find.
## In the same source file (to remind you that you did it) add:
if(getRversion() >= "2.15.1") utils::globalVariables(c(".obj1", "obj2"))

## End(Not run)
head

Return the First or Last Part of an Object

Description

Returns the first or last parts of a vector, matrix, table, data frame or function. Since head() and tail() are generic functions, they may also have been extended to other classes.

Usage

head(x, ...)
## Default S3 method:
head(x, n = 6L, ...)
## S3 method for class 'data.frame'
head(x, n = 6L, ...)
## S3 method for class 'matrix'
head(x, n = 6L, ...)
## S3 method for class 'ftable'
head(x, n = 6L, ...)
## S3 method for class 'table'
head(x, n = 6L, ...)
## S3 method for class 'function'
head(x, n = 6L, ...)

tail(x, ...)
## Default S3 method:
tail(x, n = 6L, ...)
## S3 method for class 'data.frame'
tail(x, n = 6L, ...)
## S3 method for class 'matrix'
tail(x, n = 6L, addrownums = TRUE, ...)
## S3 method for class 'ftable'
tail(x, n = 6L, addrownums = FALSE, ...)
## S3 method for class 'table'
tail(x, n = 6L, addrownums = TRUE, ...)
## S3 method for class 'function'
tail(x, n = 6L, ...)

Arguments

x an object
n a single integer. If positive, size for the resulting object: number of elements for a vector (including lists), rows for a matrix or data frame or lines for a function. If negative, all but the n last/first number of elements of x.
addrownums if there are no row names, create them from the row numbers.
... arguments to be passed to or from other methods.
Details

For matrices, 2-dim tables and data frames, head() (tail()) returns the first (last) \( n \) rows when \( n > 0 \) or all but the last (first) \( n \) rows when \( n < 0 \). head.matrix() and tail.matrix() are exported. For functions, the lines of the deparsed function are returned as character strings.

If a matrix has no row names, then tail() will add row names of the form "[n,]" to the result, so that it looks similar to the last lines of \( x \) when printed. Setting addrownums = FALSE suppresses this behaviour.

Value

An object (usually) like \( x \) but generally smaller. For \texttt{ftable} objects \( x \), a transformed \texttt{format(x)}.

Author(s)

Patrick Burns, improved and corrected by R-Core. Negative argument added by Vincent Goulet.

Examples

```r
head(letters)
head(letters, n = -6L)
head(freeny.x, n = 10L)
head(freeny.y)
tail(letters)
tail(letters, n = -6L)
tail(freeny.x)
tail(freeny.y)
tail(library)
head(stats::ftable(Titanic))
```

Description

help is the primary interface to the help systems.

Usage

```r
help(topic, package = NULL, lib.loc = NULL,
     verbose = getOption("verbose"),
     try.all.packages = getOption("help.try.all.packages"),
     help_type = getOption("help_type"))
```
Arguments

- **topic**: usually, a name or character string specifying the topic for which help is sought. A character string (enclosed in explicit single or double quotes) is always taken as naming a topic. If the value of `topic` is a length-one character vector the topic is taken to be the value of the only element. Otherwise `topic` must be a name or a reserved word (if syntactically valid) or character string. See ‘Details’ for what happens if this is omitted.

- **package**: a name or character vector giving the packages to look into for documentation, or NULL. By default, all packages in the search path are used. To avoid a name being deparsed use e.g. `(pkg_ref)` (see the examples).

- **lib.loc**: a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries. This is not used for HTML help (see ‘Details’).

- **verbose**: logical; if TRUE, the file name is reported.

- **try.all.packages**: logical; see Note.

- **help_type**: character string: the type of help required. Possible values are "text", "html" and "pdf". Case is ignored, and partial matching is allowed.

Details

The following types of help are available:

- Plain text help
- HTML help pages with hyperlinks to other topics, shown in a browser by `browseURL`. (Where possible an existing browser window is re-used: the OS X GUI uses its own browser window.) If for some reason HTML help is unavailable (see `startDynamicHelp`), plain text help will be used instead.
- For `help` only, typeset as PDF – see the section on ‘Offline help’.

The ‘factory-fresh’ default is text help except from the Mac OS GUI, which uses HTML help displayed in its own browser window.

The rendering of text help will use directional quotes in suitable locales (UTF-8 and single-byte Windows locales): sometimes the fonts used do not support these quotes so this can be turned off by setting `options(useFancyQuotes = FALSE)`.

**topic** is not optional: if it is omitted R will give

- If a package is specified, (text or, in interactive use only, HTML) information on the package, including hints/links to suitable help topics.
- If `lib.loc` only is specified, a (text) list of available packages.
- Help on `help` itself if none of the first three arguments is specified.
Some topics need to be quoted (by backticks) or given as a character string. These include those which cannot syntactically appear on their own such as unary and binary operators, function and control-flow reserved words (including if, else for, in, repeat, while, break and next). The other reserved words can be used as if they were names, for example TRUE, NA and Inf.

If multiple help files matching topic are found, in interactive use a menu is presented for the user to choose one: in batch use the first on the search path is used. (For HTML help the menu will be an HTML page, otherwise a graphical menu if possible if `getOption("menu.graphics")` is true, the default.)

Note that HTML help does not make use of lib.loc: it will always look first in the attached packages and then along .libPaths().

**Offline help**

Typeset documentation is produced by running the LaTeX version of the help page through `pdflatex`: this will produce a PDF file.

The appearance of the output can be customized through a file `Rhelp.cfg` somewhere in your LaTeX search path: this will be input as a LaTeX style file after `Rd.sty`. Some environment variables are consulted, notably `R_PAPERSIZE` (via `getOption("papersize")`) and `R_RD4PDF` (see ‘Making manuals’ in the ‘R Installation and Administration Manual’).

If there is a function `offline_help_helper` in the workspace or further down the search path it is used to do the typesetting, otherwise the function of that name in the `utils` namespace (to which the first paragraph applies). It should accept at least two arguments, the name of the LaTeX file to be typeset and the type (which as from R 2.15.0 is ignored). As from R 2.14.0 it should accept a third argument, `texinputs`, which will give the graphics path when the help document contains figures, and will otherwise not be supplied.

**Note**

Unless `lib.loc` is specified explicitly, the loaded packages are searched before those in the specified libraries. This ensures that if a library is loaded from a library not in the known library trees, then the help from the loaded library is used. If `lib.loc` is specified explicitly, the loaded packages are not searched.

If this search fails and argument `try.all.packages` is `TRUE` and neither packages nor `lib.loc` is specified, then all the packages in the known library trees are searched for help on topic and a list of (any) packages where help may be found is displayed (with hyperlinks for `help_type = "html"`). **NB:** searching all packages can be slow, especially the first time (caching of files by the OS can expedite subsequent searches dramatically).

**References**

**See Also**

? for shortcuts to help topics.
help.search() or ?? for finding help pages on a vague topic; help.start() which opens the HTML version of the R help pages; library() for listing available packages and the help objects they contain; data() for listing available data sets; methods().

Use prompt() to get a prototype for writing help pages of your own package.

Examples

help()
help(help) # the same

default(lapply)
help("for") # or ?"for", but quotes/backticks are needed

try({
  # requires working TeX installation:
  help(dgamma, help_type = "pdf")
  # -> nicely formatted pdf -- including math formula -- for help(dgamma):
  system2(getOption("pdfviewer"), "dgamma.pdf", wait = FALSE)
})

help(package = "splines") # get help even when package is not loaded

topi <- "women"
help(topi)

try(help("bs", try.all.packages = FALSE)) # reports not found (an error)
help("bs", try.all.packages = TRUE) # reports can be found
  # in package 'splines'

# For programmatic use:
topic <- "family": pkg_ref <- "stats"
help((topic), (pkg_ref))

help.request

Send a Post to R-help

Description

Prompts the user to check they have done all that is expected of them before sending a post to the R-help mailing list, provides a template for the post with session information included and optionally sends the email (on Unix systems).

Usage

help.request(subject = "",
               address = "r-help@R-project.org",
               file = "R.help.request", ...)

Arguments

subject  subject of the email. Please do not use single quotes (’) in the subject! Post separate help requests for multiple queries.
address  recipient’s email address.
file  filename to use (if needed) for setting up the email.
...  additional named arguments such as method and ccaddress to pass to create.post.

Details

This function is not intended to replace the posting guide. Please read the guide before posting to R-help or using this function (see http://www.r-project.org/posting-guide.html).

The help.request function:

- asks whether the user has consulted relevant resources, stopping and opening the relevant URL if a negative response if given.
- checks whether the current version of R is being used and whether the add-on packages are up-to-date, giving the option of updating where necessary.
- asks whether the user has prepared appropriate (minimal, reproducible, self-contained, commented) example code ready to paste into the post.

Once this checklist has been completed a template post is prepared including current session information, and passed to create.post.

Value

Nothing useful.

Author(s)

Heather Turner, based on the then current code and help page of bug.report().

See Also

The posting guide (http://www.r-project.org/posting-guide.html), also sessionInfo() from which you may add to the help request.

create.post.
help.search

Search the Help System

Description

 Allows for searching the help system for documentation matching a given character string in the (file) name, alias, title, concept or keyword entries (or any combination thereof), using either fuzzy matching or regular expression matching. Names and titles of the matched help entries are displayed nicely formatted.

Vignette names, titles and keywords and demo names and titles may also be searched.

Usage

 help.search(pattern, fields = c("alias", "concept", "title"),
 apropos, keyword, whatis, ignore.case = TRUE,
 package = NULL, lib.loc = NULL,
 help.db = getOption("help.db"),
 verbose = getOption("verbose"),
 rebuild = FALSE, agrep = NULL, use_UTF8 = FALSE,
 types = getOption("help.search.types"))

?pattern
 field??pattern

Arguments

pattern a character string to be matched in the specified fields. If this is given, the arguments apropos, keyword, and whatis are ignored.

fields a character vector specifying the fields of the help database to be searched. The entries must be abbreviations of "name", "title", "alias", "concept", and "keyword", corresponding to the help page's (file) name, its title, the topics and concepts it provides documentation for, and the keywords it can be classified to. See below for how vignettes and demos are searched.

apropos a character string to be matched in the help page topics and title.

keyword a character string to be matched in the help page 'keywords'. ‘Keywords’ are really categories: the standard categories are listed in file ‘R.home("doc")/KEYWORDS’ (see also the example) and some package writers have defined their own. If keyword is specified, agrep defaults to FALSE.

whatis a character string to be matched in the help page topics.

ignore.case a logical. If TRUE, case is ignored during matching; if FALSE, pattern matching is case sensitive.

package a character vector with the names of packages to search through, or NULL in which case all available packages in the library trees specified by lib.loc are searched.

lib.loc a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known.
help.db

a character string giving the file path to a previously built and saved help database, or NULL.

verbose

logical; if TRUE, the search process is traced. Integer values are also accepted, with TRUE being equivalent to 2, and 1 being less verbose. On Windows a progress bar is shown during rebuilding, and on Unix a heartbeat is shown for verbose = 1 and a package-by-package list for verbose >= 2.

rebuild

a logical indicating whether the help database should be rebuilt. This will be done automatically if lib.loc or the search path is changed, or if package is used and a value is not found.

agrep

if NULL (the default unless keyword is used) and the character string to be matched consists of alphanumeric characters, whitespace or a dash only, approximate (fuzzy) matching via agrep is used unless the string has fewer than 5 characters; otherwise, it is taken to contain a regular expression to be matched via grep. If FALSE, approximate matching is not used. Otherwise, one can give a numeric or a list specifying the maximal distance for the approximate match, see argument max.distance in the documentation for agrep.

use_UTF8

logical: should be results be given in UTF-8 encoding? Also changes the meaning of regexps in agrep to be Perl regexps.

types

a character vector listing the types of documentation to search. The entries must be abbreviations of "vignette" "help" or "demo". Results will be presented in the order specified.

field

a single value of fields to search.

Details

Upon installation of a package, a pre-built help.search index is serialized as ‘hsearch.rds’ in the ‘Meta’ directory (provided the package has any help pages). Vignettes are also indexed in the ‘Meta/vignette.rds’ file. These files are used to create the help search database.

The arguments apropos and whatis play a role similar to the Unix commands with the same names.

Searching with agrep = FALSE will be several times faster than the default (once the database is built). However, as from R 2.10.0 approximate searches should be fast enough (around a second with 2000 packages installed).

If possible, the help database is saved in memory for use by subsequent calls in the session.

Note that currently the aliases in the matching help files are not displayed.

As with ? in ?? the pattern may be prefixed with a package name followed by :: or ::: to limit the search to that package.

Vignettes are searched as follows. The "name" and "alias" are both the base of the vignette filename, and the "concept" entries are taken from the \VignetteKeywords entries. Vignettes are not classified using the help system "keyword" classifications. Demos are handled similarly to vignettes, without the "concept" search.

Value

The results are returned in a list object of class "hsearch", which has a print method for nicely formatting the results of the query. This mechanism is experimental, and may change in future versions of R.
In R.app on OS X, this will show up a browser with selectable items. On exiting this browser, the help pages for the selected items will be shown in separate help windows.

The internal format of the class is undocumented and subject to change.

See Also

`help`: `help.start` for starting the hypertext (currently HTML) version of R’s online documentation, which offers a similar search mechanism.

`RSiteSearch` to access an on-line search of R resources.

`apropos` uses regexps and has nice examples.

Examples

```r
help.search("linear models")  # In case you forgot how to fit linear
#    models
help.search("non-existent topic")

??utils::help  # All the topics matching "help" in the utils package

## Not run:
help.search("print")  # All help pages with topics or title
#    matching 'print'
help.search(apropos = "print")  # The same
help.search(keyword = "hplot")  # All help pages documenting high-level
#    plots.
file.show(file.path(R.home("doc"), "KEYWORDS"))  # show all keywords

## Help pages with documented topics starting with 'try'.
help.search("\btry", fields = "alias")

## End(Not run)
```

---

**help.start**  
*Hypertext Documentation*

### Description

Start the hypertext (currently HTML) version of R’s online documentation.

### Usage

```r
help.start(update = FALSE, gui = "irrelevant",
            browser = getOption("browser"), remote = NULL)
```
help.start

Arguments

update logical: should this attempt to update the package index to reflect the currently available packages. (Not attempted if remote is non-NULL.)

gui just for compatibility with S-PLUS.

browser the name of the program to be used as hypertext browser. It should be in the PATH, or a full path specified. Alternatively, it can be an R function which will be called with a URL as its only argument. This option is normally unset on Windows, when the file-association mechanism will be used.

remote A character string giving a valid URL for the ‘R_HOME’ directory on a remote location.

Details

Unless remote is specified this requires the HTTP server to be available (it will be started if possible: see startDynamicHelp).

One of the links on the index page is the HTML package index, ‘R.home("docs")/html/packages.html’, which can be remade by make.packages.html(). For local operation, the HTTP server will remake a temporary version of this list when the link is first clicked, and each time thereafter check if updating is needed (if .libPaths has changed or any of the directories has been changed). This can be slow, and using update = TRUE will ensure that the packages list is updated before launching the index page.

Argument remote can be used to point to HTML help published by another R installation: it will typically only show packages from the main library of that installation.

See Also

help() for on- and off-line help in other formats.
browseURL for how the help file is displayed.
RSiteSearch to access an on-line search of R resources.

Examples

help.start()

## Not run:
## the 'remote' arg can be tested by
help.start(remote = paste0("file://", R.home()))

## End(Not run)
**Install Add-on Packages**

**Description**

Utility for installing add-on packages.

**Usage**

```
R CMD INSTALL [options] [-l lib] pkgs
```

**Arguments**

- **pkgs**: a space-separated list with the path names of the packages to be installed. See 'Details'.
- **lib**: the path name of the R library tree to install to. Also accepted in the form `--library=lib`. Paths including spaces should be quoted, using the conventions for the shell in use.
- **options**: a space-separated list of options through which in particular the process for building the help files can be controlled. Use `R CMD INSTALL --help` for the full current list of options.

**Details**

This will stop at the first error, so if you want all the pkgs to be tried, call this via a shell loop.

If used as `R CMD INSTALL pkgs` without explicitly specifying `lib`, packages are installed into the library tree rooted at the first directory in the library path which would be used by R run in the current environment.

To install into the library tree `lib`, use `R CMD INSTALL -l lib pkgs`. This prepends `lib` to the library path for duration of the install, so required packages in the installation directory will be found (and used in preference to those in other libraries).

Both `lib` and the elements of `pkgs` may be absolute or relative path names of directories. `pkgs` may also contain names of package archive files: these are then extracted to a temporary directory. These are tarballs containing a single directory, optionally compressed by gzip, bzip2, xz or compress. Finally, binary package archive files (as created by `R CMD INSTALL --build`) can be supplied.

Tarballs are by default unpackaged by the internal `untar` function: if needed an external `tar` command can be specified by the environment variable `R_INSTALL_TAR`: please ensure that it can handle the type of compression used on the tarball. (This is sometimes needed for tarballs containing invalid or unsupported sections, and can be faster on very large tarballs. Setting `R_INSTALL_TAR` to `tar.exe` has been needed to overcome permissions issues on some Windows systems.)

The package sources can be cleaned up prior to installation by `--preclean` or after by `--clean`: cleaning is essential if the sources are to be used with more than one architecture or platform.

Some package sources contain a `configure` script that can be passed arguments or variables via the option `--configure-args` and `--configure-vars`, respectively, if necessary. The latter is
useful in particular if libraries or header files needed for the package are in non-system directories. In this case, one can use the configure variables LIBS and CPPFLAGS to specify these locations (and set these via `--configure-vars`), see section “Configuration variables” in “R Installation and Administration” for more information. (If these are used more than once on the command line they are concatenated.) The configure mechanism can be bypassed using the option `--no-configure`.

If the attempt to install the package fails, leftovers are removed. If the package was already installed, the old version is restored. This happens either if a command encounters an error or if the install is interrupted from the keyboard: after cleaning up the script terminates.

For details of the locking which is done, see the section ‘Locking’ in the help for `install.packages`.

Some platforms (notably OS X and Windows) support sub-architectures in which binaries for different CPUs are installed within the same library tree. For such installations, the default behaviour is to try to build packages for all installed sub-architectures unless the package has a configure script or a ‘src/Makefile’, when only the sub-architecture running R CMD INSTALL is used. To use only that sub-architecture, use `--no-multiarch`. To install just the compiled code for another sub-architecture, use `--libs-only`.

By default a package is installed with static HTML help pages if and only if R was: use options `--html` and `--no-html` to override this.

Packages are not by default installed keeping the source formatting (see the `keep.source` argument to `source`); this can be enabled by the option `--with-keep.source` or by setting environment variable R_KEEP_PKG_SOURCE to yes.

Use R CMD INSTALL --help for concise usage information, including all the available options.

**Note**

The options do not have to precede ‘pkgs’ on the command line, although it will be more legible if they do. All the options are processed before any packages, and where options have conflicting effects the last one will win.

Some parts of the operation of INSTALL depend on the R temporary directory (see `tempdir`, usually under ‘/tmp’) having both write and execution access to the account running R. This is usually the case, but if ‘/tmp’ has been mounted as noexec, environment variable TMPDIR may need to be set to a directory from which execution is allowed.

**See Also**

`REMOVE` and `library` for information on using several library trees; `update.packages` for automatic update of packages using the internet (or other R level installation of packages, such as by `install.packages`).

install.packages  Install Packages from Repositories or Local Files

Description

Download and install packages from CRAN-like repositories or from local files.

Usage

install.packages(pkgs, lib, repos = getOption("repos"),
                contriburl = contrib.url(repos, type),
                method, available = NULL, destdir = NULL,
                dependencies = NA, type = getOption("pkgType"),
                configure.args = getOption("configure.args"),
                configure.vars = getOption("configure.vars"),
                clean = FALSE, Ncpus = getOption("Ncpus", 1L),
                verbose = getOption("verbose"),
                libs_only = FALSE, INSTALL_opts, quiet = FALSE,
                keep_outputs = FALSE, ...)  

Arguments

pkgs  character vector of the names of packages whose current versions should be downloaded from the repositories.
If repos = NULL, a character vector of file paths of ".tar.gz" files.
These can be source archives or binary package archive files (as created by R CMD build --binary). On a CRAN build of R for OS X these can be ".tgz" files containing binary package archives. Tilde-expansion will be done on the file paths.
If this is missing or a zero-length character vector, a listbox of available packages is presented where possible in an interactive R session.

lib  character vector giving the library directories where to install the packages. Recycled as needed. If missing, defaults to the first element of .libPaths().

repos  character vector, the base URL(s) of the repositories to use, e.g., the URL of a CRAN mirror such as "http://cran.us.r-project.org".
Can be NULL to install from local files (with extension ".tar.gz" for source packages).

contriburl  URL(s) of the contrib sections of the repositories. Use this argument if your repository mirror is incomplete, e.g., because you burned only the ‘contrib’ section on a CD, or only have binary packages. Overrides argument repos. As with repos, can also be NULL to install from local files.

method  download method, see download.file.

available  an object as returned by available.packages listing packages available at the repositories, or NULL when the function makes an internal call to available.packages.
destdir directory where downloaded packages are stored. If it is NULL (the default) a subdirectory downloaded_packages of the session temporary directory will be used (and the files will be deleted at the end of the session).

dependencies logical indicating to also install uninstalled packages which these packages depend on/link to/import/suggest (and so on recursively). Not used if repos = NULL. Can also be a character vector, a subset of c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances"). Only supported if lib is of length one (or missing), so it is unambiguous where to install the dependent packages. If this is not the case it is ignored, with a warning.

The default, NA, means c("Depends", "Imports", "LinkingTo").

TRUE means (as from R 2.15.0) to use c("Depends", "Imports", "LinkingTo", "Suggests") for pkgs and c("Depends", "Imports", "LinkingTo") for added dependencies: this installs all the packages needed to run pkgs, their examples, tests and vignettes (if the package author specified them correctly).

type character, indicating the type of package to download and install. Possible values are "source", "mac.binary.leopard" and "win.binary": the binary types can be listed and downloaded but not installed on other platforms. The default is the appropriate binary type on Windows and on the CRAN binary OS X distribution, otherwise "source". For the platforms where binary packages are the default, an alternative is "both" which means 'try binary if available, otherwise try source'. (This will only choose the binary package if its version number is no older than the source version. In interactive use it will ask before attempting to install source packages.)

configure.args (not used on Windows) a character vector or a named list. If a character vector with no names is supplied, the elements are concatenated into a single string (separated by a space) and used as the value for the ‘--configure-args’ flag in the call to R CMD INSTALL. If the character vector has names these are assumed to identify values for ‘--configure-args’ for individual packages. This allows one to specify settings for an entire collection of packages which will be used if any of those packages are to be installed. (These settings can therefore be re-used and act as default settings.)

A named list can be used also to the same effect, and that allows multi-element character strings for each package which are concatenated to a single string to be used as the value for ‘--configure-args’.

configure.vars (not used on Windows) analogous to configure.args for flag ‘--configure-vars’, which is used to set environment variables for the configure run.

clean a logical value indicating whether to specify to add the ‘--clean’ flag to the call to R CMD INSTALL. This is sometimes used to perform additional operations at the end of the package installation in addition to removing intermediate files.

Ncpus the number of parallel processes to use for a parallel install of more than one source package. Values greater than one are supported if the make command specified by Sys.getenv("MAKE", "make") accepts argument -k -j Ncpus.
install.packages

   verbose  a logical indicating if some “progress report” should happen.
   libs_only a logical value: should the ‘--libs-only’ option be used to install only additional sub-architectures? (See also INSTALL_opts.) This can also be used on Windows to install just the DLL(s) from a binary package, e.g. to add 64-bit DLLs to a 32-bit install.
   INSTALL_opts an optional character vector of additional option(s) to be passed to R CMD INSTALL for a source package install. E.g., c("--html", "--no-multiarch"). Can also be a named list of character vectors of to be used as additional options, with names the respective package names.
   quiet logical: if true, reduce the amount of output.
   keep_outputs a logical: if true, keep the outputs from installing source packages in the current working directory, with the names of the output files the package names with ‘.out’ appended. Alternatively, a character string giving the directory where to save the outputs. Ignored when installing from local files.

Arguments to be passed to download.file or to the functions for binary installs on OS X and Windows (which accept an argument "lock": see the section on ‘Locking’).

Details

R packages are primarily distributed as source packages, but binary packages (a packaging up of the installed package) are also supported, and the type most commonly used on Windows and from the CRAN distribution for OS X. This function can install either type where supported, either by downloading a file from a repository or from a local file. The default type is given by getOption("pkgType"): this defaults to "source" apart from under Windows or a CRAN binary distribution for OS X.

This is the main function to install packages. It takes a vector of names and a destination library, downloads the packages from the repositories and installs them. (If the library is omitted it defaults to the first directory in .libPaths(), with a message if there is more than one.) If lib is omitted or is of length one and is not a (group) writable directory, the code offers to create a personal library tree (the first element of Sys.getenv("R_LIBS_USER")) and install there.

For source packages from a repository an attempt is made to install the packages in an order that respects their dependencies. This does assume that all the entries in lib are on the default library path for installs (set by R_LIBS).

You are advised to run update.packages before install.packages to ensure that any already installed dependencies have their latest versions.

Argument libs_only = TRUE is supported for source installs and for Windows binary installs.

For binary installs, the function also checks for the availability of a source package on the same repository, and reports if the source package has a later version, or is available but no binary version is. This check can be suppressed by

options(install.packages.check.source = "no")

and should be if there is a partial repository containing only binary files.
Value

Invisible NULL.

Locking

There are various options for locking: these differ between source and binary installs.

By default for a source install, the library directory is ‘locked’ by creating a directory ‘00LOCK’ within it. This has two purposes: it prevents any other process installing into that library concurrently, and is used to store any previous version of the package to restore on error. A finer-grained locking is provided by the option ‘--pkglock’ which creates a separate lock for each package: this allows enough freedom for parallel installation. Per-package locking is the default when installing a single package, and for multiple packages when Ncpus > 1L. Finally locking (and restoration on error) can be suppressed by ‘--no-lock’.

For an OS X or Windows binary install, no locking is done by default. Setting argument lock to TRUE (it defaults to the value of `getOption("install.lock", FALSE)`) will use per-directory locking as described for source installs: if the value is "pkglock" per-package locking will be used.

If package locking is used on Windows with `libs_only = TRUE` and the installation fails, the package will be restored to its previous state.

Note that it is possible for the package installation to fail so badly that the lock directory is not removed: this inhibits any further installs to the library directory (or for --pkglock, of the package) until the lock directory is removed manually.

Parallel installs

Parallel installs are attempted if pkgs has length greater than one and Ncpus > 1. It makes use of a parallel make, so the make specified (default make) when R was built must be capable of supporting make -j n: GNU make and dmake do, but FreeBSD and Solaris make do not: if necessary environment variable MAKE can be set for the current session to select a suitable make.

install.packages needs to be able to compute all the dependencies of pkgs from available, including if one element of pkgs depends indirectly on another. This means that if for example you are installing CRAN packages which depend on Bioconductor packages which in turn depend on CRAN packages, available needs to cover both CRAN and Bioconductor packages.

Note

Some binary distributions of R have INSTALL in a separate bundle, e.g. an R-devel RPM. install.packages will give an error if called with type = "source" on such a system.

Some binary distributions of R can be installed on a machine without the tools needed to install packages: the remedy is to do a complete install of R which should bring in all those tools as dependencies.

See Also

update.packages, available.packages, download.packages, installed.packages, contrib.url.

See download.file for how to handle proxies and other options to monitor file transfers.
The ‘R Installation and Administration’ manual for how to set up a repository.

Examples

```r
## Not run:
## A Linux example for Fedora's layout
install.packages(c("ncdf4", "RNetCDF"),
    configure.args = c(RNetCDF = "--with-netcdf-include=/usr/include/udunits2"))
## End(Not run)
```

### Description

Find (or retrieve) details of all packages installed in the specified libraries.

### Usage

```r
installed.packages(lib.loc = NULL, priority = NULL,
    noCache = FALSE, fields = NULL,
    subarch = .Platform$r_arch)
```

### Arguments

- **lib.loc**: character vector describing the location of R library trees to search through, or NULL for all known trees (see `.libPaths`).
- **priority**: character vector or NULL (default). If non-null, used to select packages; "high" is equivalent to c("base", "recommended"). To select all packages without an assigned priority use priority = "NA".
- **noCache**: Do not use cached information, nor cache it.
- **fields**: a character vector giving the fields to extract from each package’s DESCRIPTION file in addition to the default ones, or NULL (default). Unavailable fields result in NA values.
- **subarch**: character string or NULL. If non-null and non-empty, used to select packages which are installed for that sub-architecture.

### Details

`installed.packages` scans the ‘DESCRIPTION’ files of each package found along `lib.loc` and returns a matrix of package names, library paths and version numbers.

The information found is cached (by library) for the R session and specified `fields` argument, and updated only if the top-level library directory has been altered, for example by installing or removing a package. If the cached information becomes confused, it can be refreshed by running `installed.packages(noCache = TRUE)`. 
Value

A matrix with one row per package, row names the package names and column names (currently) "Package", "LibPath", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "Enhances", "OS_type", "License" and "Built" (the R version the package was built under). Additional columns can be specified using the fields argument.

Note

This can be slow when thousands of packages are installed, so do not use this to find out if a named package is installed (use system.file or find.package) nor to find out if a package is usable (call require and check the return value) nor to find details of a small number of packages (use packageDescription). It needs to read several files per installed package, which will be slow on Windows and on some network-mounted file systems.

See Also

update.packages, install.packages, INSTALL, REMOVE.

Examples

## confine search to .Library for speed
str(ip <- installed.packages(.Library, priority = "high"))
ip[, c(1,3:5)]
pllic <- installed.packages(.Library, priority = "high", fields = "License")
## what licenses are there:
table( pllic[, "License"] )

---

**LINK**  
*Create Executable Programs*

Description

Front-end for creating executable programs.

Usage

R CMD LINK [options] linkcmd

Arguments

- **linkcmd**: a list of commands to link together suitable object files (include library objects) to create the executable program.
- **options**: further options to control the linking, or for obtaining information about usage and version.
Details

The linker front-end is useful in particular when linking against the R shared library, in which case linkcmd must contain \-lR but need not specify its library path.

Currently only works if the C compiler is used for linking, and no C++ code is used.
Use R CMD LINK --help for more usage information.

Note

Some binary distributions of R have LINK in a separate bundle, e.g. an R-devel RPM.

localeToCharset

Select a Suitable Encoding Name from a Locale Name

Description

This functions aims to find a suitable coding for the locale named, by default the current locale, and if it is a UTF-8 locale a suitable single-byte encoding.

Usage

localeToCharset(locale = Sys.getlocale("LC_CTYPE"))

Arguments

locale character string naming a locale.

Details

The operation differs by OS. Locale names are normally like es_MX.iso88591. If final component indicates an encoding and it is not utf8 we just need to look up the equivalent encoding name. Otherwise, the language (here es) is used to choose a primary or fallback encoding.

In the C locale the answer will be "ASCII".

Value

A character vector naming an encoding and possibly a fallback single-encoding, NA if unknown.

Note

The encoding names are those used by libiconv, and ought also to work with glibc but maybe not with commercial Unixen.

See Also

Sys.getlocale, iconv.
Examples
localeToCharset()

**ls.str**  
*List Objects and their Structure*

**Description**

`ls.str` and `lsf.str` are variations of `ls` applying `str()` to each matched name: see section Value.

**Usage**

```r
ls.str(pos = -1, name, envir, all.names = FALSE, pattern, mode = "any")
lsf.str(pos = -1, envir, ...)
```

```r
## S3 method for class 'ls_str'
print(x, max.level = 1, give.attr = FALSE, ..., digits = max(1, getOption("str")$digits.d))
```

**Arguments**

- `pos`  
  integer indicating search path position, or -1 for the current environment.
- `name`  
  optional name indicating search path position, see `ls`.
- `envir`  
  environment to use, see `ls`.
- `all.names`  
  logical indicating if names which begin with a . are omitted; see `ls`.
- `pattern`  
  a regular expression passed to `ls`. Only names matching pattern are considered.
- `max.level`  
  maximal level of nesting which is applied for displaying nested structures, e.g., a list containing sub lists. Default 1: Display only the first nested level.
- `give.attr`  
  logical; if TRUE (default), show attributes as sub structures.
- `mode`  
  character specifying the mode of objects to consider. Passed to `exists` and `get`.
- `x`  
  an object of class "ls_str".
- `...`  
  further arguments to pass. `lsf.str` passes them to `ls.str` which passes them on to `ls`. The (non-exported) print method `print.ls_str` passes them to `str`.
- `digits`  
  the number of significant digits to use for printing.

**Value**

`ls.str` and `lsf.str` return an object of class "ls_str", basically the character vector of matching names (functions only for `lsf.str`), similarly to `ls`, with a print() method that calls `str()` on each object.

Martin Maechler

See Also

str, summary, args.

Examples

require(stats)

lssf.str()  # how do the functions look like which I am using?
lstr(mode = "list")  # what are the structured objects I have defined?

## create a few objects
example(glm, echo = FALSE)
l1 <- as.list(LETTERS)
print(ls.str(), max.level = 0)# don't show details

## which base functions have "file" in their name ?
lstr(pos = length(search())), pattern = "file")

## demonstrating that ls.str() works inside functions
## ["browser/debug mode"]:
lt <- function(x, y = 1) { aa <- 7; r <- x + y; lstr() }
(nms <- sapply(strsplit(capture.output(tt(2))," *: *"), '[', 1))
stopifnot(nms == c("aa", "r","x","y"))

Description

Show the name and email address of the maintainer of a package.

Usage

maintainer(pkg)

Arguments

pkg Character string. The name of a single package.

Details

Accesses the package description to return the name and email address of the maintainer.

Questions about contributed packages should often be addressed to the package maintainer; questions about base packages should usually be addressed to the R-help or R-devel mailing lists. Bug reports should be submitted using the bug.report function.
Value

A character string giving the name and email address of the maintainer of the package, or NA if no such package is installed.

Author(s)

David Scott <d.scott@auckland.ac.nz> from code on R-help originally due to Charlie Sharpsteen <source@sharpsteen.net>; multiple corrections by R-core.

---

**Description**

Re-create the HTML list of packages.

**Usage**

make.packages.html(lib.loc = .libPaths(), temp = FALSE, verbose = TRUE, docdir = R.home("doc"))

**Arguments**

- **lib.loc**: character vector. List of libraries to be included.
- **temp**: logical: should the package indices be created in a temporary location for use by the HTTP server?
- **verbose**: logical. If true, print out a message.
- **docdir**: If temp is false, directory in whose ‘html’ directory the ‘packages.html’ file is to be created/updated.
make.socket

Create a Socket Connection

Description

With server = FALSE attempts to open a client socket to the specified port and host. With server = TRUE the R process listens on the specified port for a connection and then returns a server socket. It is a good idea to use on.exit to ensure that a socket is closed, as you only get 64 of them.

Usage

make.socket(host = "localhost", port, fail = TRUE, server = FALSE)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>name of remote host</td>
</tr>
<tr>
<td>port</td>
<td>port to connect to/listen on</td>
</tr>
<tr>
<td>fail</td>
<td>failure to connect is an error?</td>
</tr>
<tr>
<td>server</td>
<td>a server socket?</td>
</tr>
</tbody>
</table>
memory.size

Value

An object of class "socket", a list with components:

- **socket**: socket number. This is for internal use. On a Unix-alike it is a file descriptor.
- **port**: port number of the connection.
- **host**: name of remote computer.

Warning

I don’t know if the connecting host name returned when `server = TRUE` can be trusted. I suspect not.

Author(s)

Thomas Lumley

References

Adapted from Luke Tierney’s code for XLISP-Stat, in turn based on code from Robbins and Robbins “Practical UNIX Programming”.

See Also

close.socket, read.socket

Examples

daytime <- function(host = "localhost"){
  a <- make.socket(host, 13)
  on.exit(close.socket(a))
  read.socket(a)
}
## Official time (UTC) from US Naval Observatory
## Not run: daytime("tick.usno.navy.mil")

Description

memory.size and memory.limit are used to manage the total memory allocation on Windows. On other platforms these are stubs which report infinity with a warning.

Usage

memory.size(max = FALSE)

memory.limit(size = NA)
Arguments

max

logical. If true the maximum amount of memory obtained from the OS is reported, otherwise the amount currently in use.

size

numeric. If NA report the memory size, otherwise request a new limit, in Mb.

Details

To restrict memory usage on a Unix-alike use the facilities of the shell used to launch R, e.g. limit or ulimit.

Value

Size in bytes: always Inf.

See Also

Memory-limits for other limits.

---

**menu**

*Menu Interaction Function*

Description

menu presents the user with a menu of choices labelled from 1 to the number of choices. To exit without choosing an item one can select '0'.

Usage

menu(choices, graphics = FALSE, title = NULL)

Arguments

choices

a character vector of choices

graphics

a logical indicating whether a graphics menu should be used if available.

title

a character string to be used as the title of the menu. NULL is also accepted.

Details

If graphics = TRUE and a windowing system is available (Windows, OS X or X11 via Tcl/Tk) a listbox widget is used, otherwise a text menu. It is an error to use menu in a non-interactive session.

Ten or fewer items will be displayed in a single column, more in multiple columns if possible within the current display width.

No title is displayed if title is NULL or "".

Value

The number corresponding to the selected item, or 0 if no choice was made.
methods

References

See Also

`select.list`, which is used to implement the graphical menu, and allows multiple selections.

Examples

```r
## Not run:
switch(menu(c("List letters", "List LETTERS")) + 1,
      cat("Nothing done\n"), letters, LETTERS)
## End(Not run)
```

---

**methods**

List Methods for S3 Generic Functions or Classes

Description

List all available methods for an S3 generic function, or all methods for a class.

Usage

```r
methods(generic.function, class)
```

Arguments

- `generic.function`:
  - a generic function, or a character string naming a generic function.
- `class`:
  - a symbol or character string naming a class: only used if `generic.function` is not supplied.

Details

Function `methods` can be used to find out about the methods for a particular generic function or class. The functions listed are those which are named like `methods` and may not actually be methods (known exceptions are discarded in the code). Note that the listed methods may not be user-visible objects, but often help will be available for them.

If `class` is used, we check that a matching generic can be found for each user-visible object named. If `generic.function` is given, there is a warning if it appears not to be a generic function. (The check for being generic used can be fooled.)
Value

An object of class "MethodsFunction", a character vector of function names with an "info" attribute. There is a print method which marks with an asterisk any methods which are not visible: such functions can be examined by `getS3method` or `getAnywhere`.

The "info" attribute is a data frame, currently with a logical column, `visible` and a factor column `from` (indicating where the methods were found).

Note

This scheme is called S3 (S version 3). For new projects, it is recommended to use the more flexible and robust S4 scheme provided in the `methods` package. Functions can have both S3 and S4 methods, and function `showMethods` will list the S4 methods (possibly none).

The original `methods` function was written by Martin Maechler.

References

See Also

`S3Methods`, `class`, `getS3method`.

For S4, `showMethods`, `Methods`.

Examples

```r
require(stats)
methods(summary)
methods(class = "aov")
methods("[" # uses C-internal dispatching
methods("$")
methods("$<-") # replacement function
methods("+") # binary operator
methods("Math") # group generic
require(graphics)
methods("axis") # looks like it has methods, but not generic
## Not run:
methods(print) # over 100
## End(Not run)
## --> help(showMethods) for related examples
```
mirrorAdmin  

Managing Repository Mirrors

Description

Functions helping to maintain CRAN, some of them may also be useful for administrators of other repository networks.

Usage

```r
mirror2html(mirrors = NULL, file = "mirrors.html",
    head = "mirrors-head.html", foot = "mirrors-foot.html")
checkCRAN(method)
```

Arguments

- `mirrors` A data frame, by default the CRAN list of mirrors is used.
- `file` A connection or a character string.
- `head` Name of optional header file.
- `foot` Name of optional footer file.
- `method` Download method, see `download.file`.

Details

- `mirror2html` creates the HTML file for the CRAN list of mirrors and invisibly returns the HTML text.
- `checkCRAN` performs a sanity checks on all CRAN mirrors.

modifyList  

Recursively Modify Elements of a List

Description

Modifies a possibly nested list recursively by changing a subset of elements at each level to match a second list.

Usage

```r
modifyList(x, val)
```

Arguments

- `x` a named list, possibly empty.
- `val` a named list with components to replace corresponding components in `x`.
Value

A modified version of `x`, with the modifications determined as follows (here, list elements are identified by their names). Elements in `val` which are missing from `x` are added to `x`. For elements that are common to both but are not both lists themselves, the component in `x` is replaced by the one in `val`. For common elements that are both lists, `x[[name]]` is replaced by `modifyList(x[[name]], val[[name]])`.

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

Examples

```r
foo <- list(a = 1, b = list(c = "a", d = FALSE))
bar <- modifyList(foo, list(e = 2, b = list(d = TRUE)))
str(foo)
str(bar)
```

Description

Build and query the news for R or add-on packages.

Usage

```r
news(query, package = "R", lib.loc = NULL, format = NULL,
     reader = NULL, db = NULL)
```

Arguments

- `query` an expression for selecting news entries
- `package` a character string giving the name of an installed add-on package, or "R".
- `lib.loc` a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known.
- `format` Not yet used.
- `reader` Not yet used.
- `db` a news db obtained from `news()`.
Details

If package is "R" (default), a news db is built with the news since the 2.10.0 release of R (corresponding to R's top-level 'NEWS' file). Otherwise, if the given add-on package can be found in the given libraries, it is attempted to read its news in structured form from files 'inst/NEWS.Rd', 'NEWS' or 'inst/NEWS' (in that order).

File 'inst/NEWS.Rd' should be an Rd file given the entries as Rd \itemize lists, grouped according to version using section elements with names starting with a suitable prefix (e.g., “Changes in version” followed by a space and the version number, and optionally followed by a space and a parenthesized ISO 8601 (%Y-%m-%d, see \texttt{strptime}) format date, and possibly further grouped according to categories using \texttt{\subsection} elements named as the categories.

The plain text 'NEWS' files in add-on packages use a variety of different formats; the default news reader should be capable to extract individual news entries from a majority of packages from the standard repositories, which use (slight variations of) the following format:

- Entries are grouped according to version, with version header “Changes in version” at the beginning of a line, followed by a version number, optionally followed by an ISO 8601 format date, possibly parenthesized.
- Entries may be grouped according to category, with a category header (different from a version header) starting at the beginning of a line.
- Entries are written as itemize-type lists, using one of ‘o’, ‘*’, ‘-’ or ‘+’ as item tag. Entries must be indented, and ideally use a common indentation for the item texts.

Additional formats and readers may be supported in the future.

Package tools provides an (internal) utility function \texttt{news2Rd} to convert plain text 'NEWS' files to Rd. For 'NEWS' files in a format which can successfully be handled by the default reader, package maintainers can use \texttt{tools:::news2Rd(dir, "NEWS.Rd"),} possibly with additional argument \texttt{codify = TRUE,} with \texttt{dir} a character string specifying the path to a package’s root directory. Upon success, the ‘NEWS.Rd’ file can further be improved and then be moved to the ‘inst’ subdirectory of the package source directory.

The news db built is a character data frame inheriting from "news_db" with variables Version, Category, Date and Text, where the last contains the entry texts read, and the other variables may be NA if they were missing or could not be determined.

Using \texttt{query}, one can select news entries from the db. If missing or NULL, the complete db is returned. Otherwise, \texttt{query} should be an expression involving (a subset of) the variables Version, Category, Date and Text, and when evaluated within the db returning a logical vector with length the number of entries in the db. The entries for which evaluation gave \texttt{TRUE} are selected. When evaluating, Version and Date are coerced to \texttt{numeric_version} and \texttt{Date} objects, respectively, so that the comparison operators for these classes can be employed.

Value

An data frame inheriting from class "news_db".

Examples

```r
## Build a db of all R news entries.
db <- news()
```
## Bug fixes with PR number in 2.11.0.
news(Version == "2.11.0" & grepl("BUG", Category) & grepl("PR#", Text),
   db = db)
## Which categories have been in use? % R-core maybe should standardize a bit more
sort(table(db[, "Category"]), decreasing = TRUE)

R package `nsl`

### Look up the IP Address by Hostname

**Description**

Interface to `gethostbyname`.

**Usage**

```r
nsl(hostname)
```

**Arguments**

- `hostname` the name of the host.

**Value**

The IP address, as a character string, or `NULL` if the call fails.

**Note**

This was included as a test of internet connectivity, to fail if the node running R is not connected. It will also return `NULL` if BSD networking is not supported, including the header file `arpa/inet.h`.

**Examples**

```r
## Not run: nsl("www.r-project.org")
```
Description

Provides an estimate of the memory that is being used to store an R object.

Usage

object.size(x)

## S3 method for class 'object_size'
print(x, quote = FALSE, units = "b", ...)

Arguments

x       An R object.
quote   logical, indicating whether or not the result should be printed with surrounding quotes.
units   The units to be used in printing the size. Other allowed values are "Kb", "Mb", "Gb" and "auto" (see 'Details'). As from R 2.14.0, "KB" etc are also accepted.
...     Arguments to be passed to or from other methods.

Details

Exactly which parts of the memory allocation should be attributed to which object is not clear-cut. This function merely provides a rough indication: it should be reasonably accurate for atomic vectors, but does not detect if elements of a list are shared, for example. (Sharing amongst elements of a character vector is taken into account, but not that between character vectors in a single object.) The calculation is of the size of the object, and excludes the space needed to store its name in the symbol table.

Associated space (e.g. the environment of a function and what the pointer in a EXTPTRSX points to) is not included in the calculation.

Object sizes are larger on 64-bit builds than 32-bit ones, but will very likely be the same on different platforms with the same word length and pointer size.

units = "auto" in the print method chooses the largest units in which the result is one or more (before rounding). Values in kilobytes, megabytes or gigabytes are rounded to the nearest 0.1.

Value

An object of class "object_size" with a length-one double value, an estimate of the memory allocation attributable to the object in bytes.

See Also

Memory-limits for the design limitations on object size.
package.skeleton

Create a Skeleton for a New Source Package

Description

package.skeleton automates some of the setup for a new source package. It creates directories, saves functions, data, and R code files to appropriate places, and creates skeleton help files and a ‘Read-and-delete-me’ file describing further steps in packaging.

Usage

package.skeleton(name = "anRpackage", list, environment = .GlobalEnv, path = ".", force = FALSE, namespace = TRUE, code_files = character())

Arguments

name character string: the package name and directory name for your package.
list character vector naming the R objects to put in the package. Usually, at most one of list, environment, or code_files will be supplied. See ‘Details’.
environment an environment where objects are looked for. See ‘Details’.
path path to put the package directory in.
force If FALSE will not overwrite an existing directory.
namespace a logical, no longer used, and hence deprecated. A NAMESPACE file is always created to export all objects whose names begin with a letter, plus all S4 methods and classes.
code_files a character vector with the paths to R code files to build the package around. See ‘Details’.

Details

The arguments list, environment, and code_files provide alternative ways to initialize the package. If code_files is supplied, the files so named will be sourced to form the environment, then used to generate the package skeleton. Otherwise list defaults to the non-hidden files in environment (those whose name does not start with .), but can be supplied to select a subset of the objects in that environment.
Stubs of help files are generated for functions, data objects, and S4 classes and methods, using the `prompt`, `promptClass`, and `promptMethods` functions.

The package sources are placed in subdirectory name of path. If code_files is supplied, these files are copied; otherwise, objects will be dumped into individual source files. The file names in code_files should have suffix `.R` and be in the current working directory.

The filenames created for source and documentation try to be valid for all OSes known to run R. Invalid characters are replaced by `_`, invalid names are preceded by `zz`, names are converted to lower case (to avoid case collisions on case-insensitive file systems) and finally the converted names are made unique by `make.unique(sep = "_")`. This can be done for code and help files but not data files (which are looked for by name). Also, the code and help files should have names starting with an ASCII letter or digit, and this is checked and if necessary z prepended.

When you are done, delete the ‘Read-and-delete-me’ file, as it should not be distributed.

**Value**

Used for its side-effects.

**References**

Read the ‘Writing R Extensions’ manual for more details.

Once you have created a source package you need to install it: see the ‘R Installation and Administration’ manual, `INSTALL` and `install.packages`.

**See Also**

`prompt`, `promptClass`, and `promptMethods`.

**Examples**

```r
require(stats)
## two functions and two "data sets" :
f <- function(x, y) x+y
g <- function(x, y) x-y
d <- data.frame(a = 1, b = 2)
e <- rnorm(1000)

package.skeleton(list = c("f","g","d","e"), name = "mypkg")
```

**Description**

Parses and returns the ‘DESCRIPTION’ file of a package.
Usage

```r
packageDescription(pkg, lib.loc = NULL, fields = NULL,
    drop = TRUE, encoding = "")
packageVersion(pkg, lib.loc = NULL)
```

Arguments

- **pkg**: a character string with the package name.
- **lib.loc**: a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.
- **fields**: a character vector giving the tags of fields to return (if other fields occur in the file they are ignored).
- **drop**: If TRUE and the length of fields is 1, then a single character string with the value of the respective field is returned instead of an object of class "packageDescription".
- **encoding**: If there is an Encoding field, to what encoding should re-encoding be attempted? If NA, no re-encoding. The other values are as used by `iconv`, so the default "" indicates the encoding of the current locale.

Details

A package will not be ‘found’ unless it has a ‘DESCRIPTION’ file which contains a valid Version field. Different warnings are given when no package directory is found and when there is a suitable directory but no valid ‘DESCRIPTION’ file.

An attached environment named to look like a package (e.g. `package:utils2`) will be ignored.

`packageVersion()` is a convenience shortcut, allowing things like `if (packageVersion("MASS") < "7.3") { do.things }`.

Value

If a ‘DESCRIPTION’ file for the given package is found and can successfully be read, `packageDescription` returns an object of class "packageDescription", which is a named list with the values of the (given) fields as elements and the tags as names, unless drop = TRUE.

If parsing the ‘DESCRIPTION’ file was not successful, it returns a named list of NAs with the field tags as names if fields is not null, and NA otherwise.

`packageVersion()` returns a (length-one) object of class "package_version".

See Also

- `read.dcf`
packageName

Find package associated with an environment.

Description

Many environments are associated with a package; this function attempts to determine that package.

Usage

packageName(env = parent.frame())

Arguments

env The environment whose name we seek.

Details

Environment env would be associated with a package if \texttt{topenv}(env) is the namespace environment for that package. Thus when env is the environment associated with functions inside a package, or local functions defined within them, \texttt{packageName} will normally return the package name.

Not all environments are associated with a package: for example, the global environment, or the evaluation frames of functions defined there. \texttt{packageName} will return \texttt{NULL} in these cases.

Value

A length one character vector containing the name of the package, or \texttt{NULL} if there is no name.

See Also

\texttt{getPackageName} is a more elaborate function that can construct a name if none is found.

Examples

packageName()
packageName(environment(mean))
**packageStatus**

*Package Management Tools*

**Description**

Summarize information about installed packages and packages available at various repositories, and automatically upgrade outdated packages.

**Usage**

```r
packageStatus(lib.loc = NULL, repositories = NULL, method,
              type = getOption("pkgType"))
```

```r
## S3 method for class 'packageStatus'
summary(object, ...)
```

```r
## S3 method for class 'packageStatus'
update(object, lib.loc = levels(object$inst$LibPath),
        repositories = levels(object$avail$Repository), ...)
```

```r
## S3 method for class 'packageStatus'
upgrade(object, ask = TRUE, ...)
```

**Arguments**

- `lib.loc` a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known.
- `repositories` a character vector of URLs describing the location of R package repositories on the Internet or on the local machine.
- `method` Download method, see `download.file`.
- `type` type of package distribution: see `install.packages`.
- `object` an object of class "packageStatus" as returned by `packageStatus`.
- `ask` if TRUE, the user is prompted which packages should be upgraded and which not.
- `...` currently not used.

**Details**

The URLs in repositories should be full paths to the appropriate contrib sections of the repositories. The default is `contrib.url(getOption("repos"))`.

There are print and summary methods for the "packageStatus" objects: the print method gives a brief tabular summary and the summary method prints the results.

The update method updates the "packageStatus" object. The upgrade method is similar to `update.packages`: it offers to install the current versions of those packages which are not currently up-to-date.
Value

An object of class "packageStatus". This is a list with two components

inst a data frame with columns as the matrix returned by \texttt{installed.packages} plus "Status", a factor with levels c("ok", "upgrade"). Only the newest version of each package is reported, in the first repository in which it appears.

avail a data frame with columns as the matrix returned by \texttt{available.packages} plus "Status", a factor with levels c("installed", "not installed", "unavailable").

For the \texttt{summary} method the result is also of class "summary.packageStatus" with additional components

Libs a list with one element for each library
Repos a list with one element for each repository

with the elements being lists of character vectors of package name for each status.

See Also

\texttt{installed.packages}, \texttt{available.packages}

Examples

## Not run:
x <- packageStatus()
print(x)
summary(x)
upgrade(x)
x <- update(x)
print(x)

## End(Not run)

---

\textit{page} \hspace{1cm} \textit{Invoke a Pager on an R Object}

Description

Displays a representation of the object named by \texttt{x} in a pager via \texttt{file.show}.

Usage

\texttt{page(x, method = c("dput", "print"), \ldots)}
Arguments

x           An R object, or a character string naming an object.
method      The default method is to dump the object via dput. An alternative is to use
            print and capture the output to be shown in the pager.
...         additional arguments for dput, print or file.show (such as title).

Details

If x is a length-one character vector, it is used as the name of an object to look up in the environment
from which page is called. All other objects are displayed directly.

A default value of title is passed to file.show if one is not supplied in ....

See Also

file.show, edit, fix.

To go to a new page when graphing, see frame.

Examples

## Not run: ## four ways to look at the code of 'page'
page(page) # as an object
page("page") # a character string
v <- "page"; page(v) # a length-one character vector
page(utils::page) # a call

## End(Not run)

person     Persons

Description

A class and utility methods for holding information about persons like name and email address.

Usage

person(given = NULL, family = NULL, middle = NULL,
       email = NULL, role = NULL, comment = NULL,
       first = NULL, last = NULL)
## Default S3 method:
as.person(x)
## S3 method for class 'person'
format(x,
       include = c("given", "family", "email", "role", "comment"),
       braces = list(given = "", family = "", email = c("<", ">"),
       role = c("[", "]"), comment = c("", ")"),
       ...
collapse = list(given = " ", family = " ", email = ", "
  role = ", ", comment = ", "),
...)

Arguments

given a character vector with the given names, or a list thereof.
family a character string with the family name, or a list thereof.
middle a character string with the collapsed middle name(s). Deprecated, see Details.
email a character string giving the email address, or a list thereof.
role a character string specifying the role of the person (see Details), or a list thereof.
comment a character string providing a comment, or a list thereof.
first a character string giving the first name. Deprecated, see Details.
last a character string giving the last name. Deprecated, see Details.
x a character string for the as.person default method; an object of class "person" otherwise.
include a character vector giving the fields to be included when formatting.
braces a list of characters (see Details).
collapse a list of characters (see Details).
... currently not used.

Details

Objects of class "person" can hold information about an arbitrary positive number of persons. These can be obtained by one call to person() with list arguments, or by first creating objects representing single persons and combining these via c().

The format() method collapses information about persons into character vectors (one string for each person): the fields in include are selected, each collapsed to a string using the respective element of collapse and subsequently "embraced" using the respective element of braces, and finally collapsed into one string separated by white space. If braces and/or collapse do not specify characters for all fields, the defaults shown in the usage are imputed. The print() method calls the format() method and prints the result, the toBibtex() method creates a suitable BibTeX representation.

Person objects can be subscripted by fields (using $) or by position (using []).
as.person() is a generic function. Its default method tries to reverse the default person formatting, and can also handle formatted person entries collapsed by comma or "and" (with appropriate white space).

Personal names are rather tricky, e.g., http://en.wikipedia.org/wiki/Personal_name.
The current implementation (starting from R 2.12.0) of the "person" class uses the notions of given (including middle names) and family names, as specified by given and family respectively. Earlier versions used a scheme based on first, middle and last names, as appropriate for most of Western culture where the given name precedes the family name, but not universal, as some other cultures place it after the family name, or use no family name. To smooth the transition to the new scheme,
arguments first, middle and last are still supported, but their use is deprecated and they must not be given in combination with the corresponding new style arguments.

The new scheme also adds the possibility of specifying roles based on a subset of the MARC Value List for Relators and Roles (http://www.loc.gov/standards/sourcelist/relator-role.html). When giving the roles of persons in the context of authoring R packages, the following usage is suggested.

"aut" (Author) Use for full authors who have made substantial contributions to the package and should show up in the package citation.
"com" (Compiler) Use for persons who collected code (potentially in other languages) but did not make further substantial contributions to the package.
"ctb" (Contributor) Use for authors who have made smaller contributions (such as code patches etc.) but should not show up in the package citation.
"cph" (Copyright holder) Use for all copyright holders.
"cre" (Creator) Use for the package maintainer.
"ths" (Thesis advisor) If the package is part of a thesis, use for the thesis advisor.
"tr1" (Translator) If the R code is a translation from another language (typically S), use for the translator to R.

In the old scheme, person objects were used for single persons, and a separate "personList" class with corresponding creator personList() for collections of these. The new scheme employs a single class for information about an arbitrary positive number of persons, eliminating the need for the personList mechanism.

Value

person() and as.person() return objects of class "person".

See Also

citation

Examples

## Create a person object directly ...
p1 <- person("Karl", "Pearson", email = "pearson@stats.heaven")

## ... or convert a string.
p2 <- as.person("Ronald Aylmer Fisher")

## Combining and subsetting.
p <- c(p1, p2)
p[1]
p[-1]

## Extracting fields.
p$family
p$email
p[1]$email
## Specifying package authors, example from "boot":
## AC is the first author [aut] who wrote the S original.
## BR is the second author [aut], who translated the code to R [trl],
## and maintains the package [cre].
b <- c(person("Angelo", "Canty", role = "aut", comment =
    "S original, http://statwww.epfl.ch/davison/BMA/library.html"),
    person(c("Brian", "D."), "Ripley", role = c("aut", "trl", "cre"),
        comment = "R port", email = "ripley@stats.ox.ac.uk")
)
b

## Formatting.
format(b)
format(b, include = c("family", "given", "role"),
    braces = list(family = c("", ","), role = c("(Role(s): ", ")")))

## Conversion to BibTeX author field.
paste(format(b, include = c("given", "family")), collapse = " and ")
toBibtex(b)

---

**PkgUtils**

*Utilities for Building and Checking Add-on Packages*

**Description**

Utilities for checking whether the sources of an `R` add-on package work correctly, and for building a source package from them.

**Usage**

```
R CMD check [options] pkgdirs
R CMD build [options] pkgdirs
```

**Arguments**

- **pkgdirs**
  - a list of names of directories with sources of `R` add-on packages. For check these can also be the filenames of compressed tar archives with extension `.tar.gz`, `.tgz`, `.tar.bz2` or `.tar.xz`.
- **options**
  - further options to control the processing, or for obtaining information about usage and version of the utility.

**Details**

`R CMD check` checks `R` add-on packages from their sources, performing a wide variety of diagnostic checks.

`R CMD build` builds `R` source tarballs. The name(s) of the packages are taken from the `DESCRIPTION` files and not from the directory names. As from `R` 2.13.0 this works entirely on a copy of the supplied source directories.
Use `R CMD foo --help` to obtain usage information on utility `foo`.

The defaults for some of the options to `R CMD build` can be set by environment variables `_R_BUILD_RESAVE_DATA_` and `_R_BUILD_COMPACT_VIGNETTES_`: see “Writing R Extensions”.

Many of the checks in `R CMD check` can be turned off or on by environment variables; see Chapter 6 of the ‘R Internals’ manual.

By default `R CMD build` uses the "internal" option to `tar` to prepare the tarball. An external `tar` program can be specified by the `R_BUILD_TAR` environment variable. This may be substantially faster for very large packages, and can be needed for packages with long path names (over 100 bytes) or very large files (over 8GB): however, the resulting tarball may not be portable.

`R CMD check` by default unpacks tarballs by the internal `untar` function: if needed an external `tar` command can be specified by the environment variable `R_INSTALL_TAR`: please ensure that it can handle the type of compression used on the tarball. (This is sometimes needed for tarballs containing invalid or unsupported sections, and can be faster on very large tarballs. Setting `R_INSTALL_TAR` to ‘`tar.exe`’ has been needed to overcome permissions issues on some Windows systems.)

The sections on “Checking and building packages” and “Processing Rd format” in “Writing R Extensions” (see the ‘doc/manual’ subdirectory of the R source tree).

---

**process.events**

Trigger event handling

**Description**

R front ends like the Windows GUI handle key presses and mouse clicks through “events” generated by the OS. These are processed automatically by R at intervals during computations, but in some cases it may be desirable to trigger immediate event handling. The `process.events` function does that.

**Usage**

`process.events()`

**Details**

This is a simple wrapper for the C API function `R_ProcessEvents`. As such, it is possible that it will not return if the user has signalled to interrupt the calculation.

**Value**

`NULL` is returned invisibly.

**Author(s)**

Duncan Murdoch
prompt

**See Also**

---

**prompt**

*Produce Prototype of an R Documentation File*

**Description**

Facilitate the constructing of files documenting R objects.

**Usage**

```r
prompt(object, filename = NULL, name = NULL, ...)  
## Default S3 method:  
prompt(object, filename = NULL, name = NULL,  
force.function = FALSE, ...)  
## S3 method for class 'data.frame'  
prompt(object, filename = NULL, name = NULL, ...)
```

**Arguments**

- `object` an R object, typically a function for the default method. Can be `missing` when name is specified.
- `filename` usually, a `connection` or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is name followed by ".Rd". Can also be `NA` (see below).
- `name` a character string specifying the name of the object.
- `force.function` a logical. If TRUE, treat object as function in any case.
- `...` further arguments passed to or from other methods.

**Details**

Unless `filename` is `NA`, a documentation shell for `object` is written to the file specified by `filename`, and a message about this is given. For function objects, this shell contains the proper function and argument names. R documentation files thus created still need to be edited and moved into the 'man' subdirectory of the package containing the object to be documented.

If `filename` is `NA`, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n"), where x is the list-style representation.

When `prompt` is used in `for` loops or scripts, the explicit name specification will be useful.
Value

If filename is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

Warning

The default filename may not be a valid filename under limited file systems (e.g. those on Windows). Currently, calling prompt on a non-function object assumes that the object is in fact a data set and hence documents it as such. This may change in future versions of R. Use promptData to create documentation skeletons for data sets.

Note

The documentation file produced by prompt.data.frame does not have the same format as many of the data frame documentation files in the base package. We are trying to settle on a preferred format for the documentation.

Author(s)

Douglas Bates for prompt.data.frame

References

See Also

promptData, help and the chapter on “Writing R documentation” in “Writing R Extensions” (see the ‘doc/manual’ subdirectory of the R source tree).

For creation of many help pages (for a package), see package.skeleton.

To prompt the user for input, see readline.

Examples

```r
require(graphics)
prompt(plot.default)
prompt(interactive, force.function = TRUE)
unlink("plot.default.Rd")
unlink("interactive.Rd")
prompt(women) # data.frame
unlink("women.Rd")
prompt(sunspots) # non-data.frame data
unlink("sunspots.Rd")

## Not run:
## Create a help file for each function in the .GlobalEnv:
for(f in ls()) if(is.function(get(f))) prompt(name = f)
```
promptData

Generate Outline Documentation for a Data Set

Description

Generates a shell of documentation for a data set.

Usage

promptData(object, filename = NULL, name = NULL)

Arguments

- object: an R object to be documented as a data set.
- filename: usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is name followed by ".Rd". Can also be NA (see below).
- name: a character string specifying the name of the object.

Details

Unless filename is NA, a documentation shell for object is written to the file specified by filename, and a message about this is given.

If filename is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n"`, where x is the list-style representation.

Currently, only data frames are handled explicitly by the code.

Value

If filename is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

See Also

prompt

Examples

```r
promptData(sunspots)
unlink("sunspots.Rd")
```
promptPackage  Generate a Shell for Documentation of a Package

Description

Generates a shell of documentation for an installed or source package.

Usage

promptPackage(package, lib.loc = NULL, filename = NULL, name = NULL, final = FALSE)

Arguments

package  a character string with the name of an installed or source package to be documented.

lib.loc  a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known. For a source package this should specify the parent directory of the package’s sources.

filename  usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is name followed by ".Rd". Can also be NA (see below).

name  a character string specifying the name of the help topic, typically of the form ‘<pkg>-package’.

final  a logical value indicating whether to attempt to create a usable version of the help topic, rather than just a shell.

Details

Unless filename is NA, a documentation shell for package is written to the file specified by filename, and a message about this is given.

If filename is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to cat(unlist(x), file = filename, sep = "\n"), where x is the list-style representation.

If final is TRUE, the generated documentation will not include the place-holder slots for manual editing, it will be usable as-is. In most cases a manually edited file is preferable (but final = TRUE is certainly less work).

Value

If filename is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.
Question

See Also

prompt

Examples

```r
filename <- tempfile()
promptPackage("utils", filename = filename)
file.show(filename)
unlink(filename)
```

Description

These functions provide access to documentation. Documentation on a topic with name `name` (typically, an `R` object or a data set) can be displayed by either `help("name")` or `?name`.

Usage

```r
?topic

?topic
```

Arguments

- **topic**
  
  Usually, a `name` or character string specifying the topic for which help is sought. Alternatively, a function call to ask for documentation on a corresponding S4 method: see the section on S4 method documentation. The calls `pkg::topic` and `pkg:::topic` are treated specially, and look for help on `topic` in package `pkg`.

- **type**
  
  the special type of documentation to use for this topic; for example, if the type is `class`, documentation is provided for the class with name `topic`. See the Section ‘S4 Method Documentation’ for the uses of `type` to get help on formal methods, including `methods?function` and `method?call`.

Details

This is a shortcut to `help` and uses its default type of help.

Some topics need to be quoted (by `backticks`) or given as a character string. There include those which cannot syntactically appear on their own such as unary and binary operators, function and control-flow `reserved` words (including `if`, `else for`, `in`, `repeat`, `while`, `break` and `next`. The other `reserved` words can be used as if they were names, for example `TRUE`, `NA` and `Inf`. 
S4 Method Documentation

Authors of formal (‘S4’) methods can provide documentation on specific methods, as well as overall documentation on the methods of a particular function. The "?" operator allows access to this documentation in three ways.

The expression methods?f will look for the overall documentation methods for the function f. Currently, this means the documentation file containing the alias f-methods.

There are two different ways to look for documentation on a particular method. The first is to supply the topic argument in the form of a function call, omitting the type argument. The effect is to look for documentation on the method that would be used if this function call were actually evaluated. See the examples below. If the function is not a generic (no S4 methods are defined for it), the help reverts to documentation on the function name.

The "?" operator can also be called with doc_type supplied as method; in this case also, the topic argument is a function call, but the arguments are now interpreted as specifying the class of the argument, not the actual expression that will appear in a real call to the function. See the examples below.

The first approach will be tedious if the actual call involves complicated expressions, and may be slow if the arguments take a long time to evaluate. The second approach avoids these issues, but you do have to know what the classes of the actual arguments will be when they are evaluated.

Both approaches make use of any inherited methods; the signature of the method to be looked up is found by using selectMethod (see the documentation for getMethod).

# the arguments (one integer, the other numeric)

?combo(1:10, letters)  # documentation for the default method

## End(Not run)

---

**Description**

This page documents a mechanism to generate relevant completions from a partially completed command line. It is not intended to be useful by itself, but rather in conjunction with other mechanisms that use it as a backend. The functions listed in the usage section provide a simple control and query mechanism. The actual interface consists of a few unexported functions described further down.

**Usage**

rc.settings(ops, ns, args, func, ipck, S3, data, help, argdb, quotes, files)

rc.status()
rc.getOption(name)
rc.options(...)

.DollarNames(x, pattern)

## Default S3 method:
.DollarNames(x, pattern = "")
## S3 method for class 'list'
.DollarNames(x, pattern = "")
## S3 method for class 'environment'
.DollarNames(x, pattern = "")

**Arguments**

ops, ns, args, func, ipck, S3, data, help, argdb, quotes, files
    logical, turning some optional completion features on and off.
ops: Activates completion after the $ and @ operators.

ns: Controls namespace related completions.

args: Enables completion of function arguments.

func: Enables detection of functions. If enabled, a customizable extension (“(“ by default) is appended to function names. The process of determining whether a potential completion is a function requires evaluation, including for lazy loaded symbols. This is undesirable for large objects, because of potentially wasteful use of memory in addition to the time overhead associated with loading. For this reason, this feature is disabled by default.

S3: When args = TRUE, activates completion on arguments of all S3 methods (otherwise just the generic, which usually has very few arguments).

ipck: Enables completion of installed package names inside library and require.

data: Enables completion of data sets (including those already visible) inside data.

help: Enables completion of help requests starting with a question mark, by looking inside help index files.

argdb: When args = TRUE, completion is attempted on function arguments. Generally, the list of valid arguments is determined by dynamic calls to args. While this gives results that are technically correct, the use of the ... argument often hides some useful arguments. To give more flexibility in this regard, an optional table of valid arguments names for specific functions is retained internally. Setting argdb = TRUE enables preferential lookup in this internal data base for functions with an entry in it. Of course, this is useful only when the data base contains information about the function of interest. Some functions are already included, and more can be added by the user through the unexported function .addFunctionInfo (see below).

quotes: Enables completion in R code when inside quotes. This normally leads to filename completion, but can be otherwise depending on context (for example, when the open quote is preceded by ?, help completion is invoked. Setting this to FALSE relegates completion to the underlying completion front-end, which may do its own processing (for example, readline on Unix-alikes will do filename completion).

files: Deprecated. Use quotes instead.

All settings are turned on by default except ipck and func. Turn more off if your CPU cycles are valuable; you will still retain basic completion on names of objects in the search list. See below for additional details.

name, ... user-settable options. Currently valid names are

function.suffix: default "("
funarg.suffix: default " = "
package.suffix default "::"

Usage is similar to that of options.

x An R object for which valid names after "$" are computed and returned.

pattern A regular expression. Only matching names are returned.
Details

There are several types of completion, some of which can be disabled using rc.settings. The most basic level, which can not be turned off once the completion functionality is activated, provides completion on names visible on the search path, along with a few special keywords (e.g. TRUE). This type of completion is not attempted if the partial 'word' (a.k.a. token) being completed is empty (since there would be too many completions). The more advanced types of completion are described below.

Completion after extractors $ and @: When the ops setting is turned on, completion after $ and @ is attempted. This requires the prefix to be evaluated, which is attempted unless it involves an explicit function call (implicit function calls involving the use of [, $, etc do not inhibit evaluation).

Valid completions after the $ extractor are determined by the generic function .DollarNames. Some basic methods are provided, and more can be written for custom classes.

Completion inside namespaces: When the ns setting is turned on, completion inside namespaces is attempted when a token is preceded by the :: or ::: operators. Additionally, the basic completion mechanism is extended to include attached namespaces, or more precisely, foopkg:: becomes a valid completion of foo if the return value of search() includes the string "package:foopkg".

The completion of package namespaces applies only to attached packages, i.e. if MASS is not attached (whether or not it is loaded), MAS will not complete to MASS::. However, attempted completion inside an apparent namespace will attempt to load the namespace if it is not already loaded, e.g. trying to complete on MASS::fr will load MASS (but not necessarily attach it) even if it is not already loaded.

Completion for help items: When the help setting is turned on, completion on help topics is attempted when a token is preceded by ?. Prefixes (such as class, method) are supported, as well as quoted help topics containing special characters.

Completion of function arguments: When the args setting is turned on, completion on function arguments is attempted whenever deemed appropriate. The mechanism used will currently fail if the relevant function (at the point where completion is requested) was entered on a previous prompt (which implies in particular that the current line is being typed in response to a continuation prompt, usually +). Note that separation by newlines is fine.

The list of possible argument completions that is generated can be misleading. There is no problem for non-generic functions (except that ... is listed as a completion; this is intentional as it signals the fact that the function can accept further arguments). However, for generic functions, it is practically impossible to give a reliable argument list without evaluating arguments (and not even then, in some cases), which is risky (in addition to being difficult to code, which is the real reason it hasn’t even been tried), especially when that argument is itself an inline function call. Our compromise is to consider arguments of all currently available methods of that generic. This has two drawbacks. First, not all listed completions may be appropriate in the call currently being constructed. Second, for generics with many methods (like print and plot), many matches will need to be considered, which may take a noticeable amount of time. Despite these drawbacks, we believe this behaviour to be more useful than the only other practical alternative, which is to list arguments of the generic only.

Only S3 methods are currently supported in this fashion, and that can be turned off using the S3 setting.
Since arguments can be unnamed in \texttt{R} function calls, other types of completion are also appropriate whenever argument completion is. Since there are usually many many more visible objects than formal arguments of any particular function, possible argument completions are often buried in a bunch of other possibilities. However, recall that basic completion is suppressed for blank tokens. This can be useful to list possible arguments of a function. For example, trying to complete seq([\texttt{\textbackslash{}tab}] and seq(from = 1, [\texttt{\textbackslash{}tab}]) will both list only the arguments of seq (or any of its methods), whereas trying to complete seq(length[\texttt{\textbackslash{}tab}]) will list both the length.out argument and the length() function as possible completions. Note that no attempt is made to remove arguments already supplied, as that would incur a further speed penalty.

\textbf{Special functions:} For a few special functions (\texttt{library}, \texttt{data}, etc), the first argument is treated specially, in the sense that normal completion is suppressed, and some function specific completions are enabled if so requested by the settings. The \texttt{ipck} setting, which controls whether \texttt{library} and \texttt{require} will complete on \texttt{installed.packages}, is disabled by default because the first call to \texttt{installed.packages} is potentially time consuming (e.g. when packages are installed on a remote network file server). Note, however, that the results of a call to \texttt{installed.packages} is cached, so subsequent calls are usually fast, so turning this option on is not particularly onerous even in such situations.

\textbf{Value}

If \texttt{rc.settings} is called without any arguments, it returns the current settings as a named logical vector. Otherwise, it returns \texttt{NULL} invisibly.

\texttt{rc.status} returns, as a list, the contents of an internal (unexported) environment that is used to record the results of the last completion attempt. This can be useful for debugging. For such use, one must resist the temptation to use completion when typing the call to \texttt{rc.status} itself, as that then becomes the last attempt by the time the call is executed.

The items of primary interest in the returned list are:

- \texttt{comps} \quad The possible completions generated by the last call to \texttt{.completeToken}, as a character vector.
- \texttt{token} \quad The token that was (or, is to be) completed, as set by the last call to \texttt{.assignToken} (possibly inside a call to \texttt{.guessTokenFromLine}).
- \texttt{linebuffer} \quad The full line, as set by the last call to \texttt{.assignLinebuffer}.
- \texttt{start} \quad The start position of the token in the line buffer, as set by the last call to \texttt{.assignStart}.
- \texttt{end} \quad The end position of the token in the line buffer, as set by the last call to \texttt{.assignEnd}.
- \texttt{fileName} \quad Logical, indicating whether the cursor is currently inside quotes.
- \texttt{fguess} \quad The name of the function the cursor is currently inside.
- \texttt{isFirstArg} \quad Logical. If cursor is inside a function, is it the first argument?

In addition, the components \texttt{settings} and \texttt{options} give the current values of settings and options respectively.

\texttt{rc.getOption} and \texttt{rc.options} behave much like \texttt{getOption} and \texttt{options} respectively.
Unexported API

There are several unexported functions in the package. Of these, a few are special because they provide the API through which other mechanisms can make use of the facilities provided by this package (they are unexported because they are not meant to be called directly by users). The usage of these functions are:

- assignToken(text)
- assignLinebuffer(line)
- assignStart(start)
- assignEnd(end)
- completeToken()
- retrieveCompletions()
- getFileComp()
- guessTokenFromLine()
- win32consoleCompletion(linebuffer, cursorPosition, check.repeat = TRUE, minLength = -1)
- addFunctionInfo(...)

The first four functions set up a completion attempt by specifying the token to be completed (text), and indicating where (start and end, which should be integers) the token is placed within the complete line typed so far (line).

Potential completions of the token are generated by .completeToken, and the completions can be retrieved as an R character vector using .retrieveCompletions.

If the cursor is inside quotes, completion may be suppressed. The function .getFileComp can be used after a call to .completeToken to determine if this is the case (returns TRUE), and alternative completions generated as deemed useful. In most cases, filename completion is a reasonable fallback.

The .guessTokenFromLine function is provided for use with backends that do not already break a line into tokens. It requires the linebuffer and endpoint (cursor position) to be already set, and itself sets the token and the start position. It returns the token as a character string.

The .win32consoleCompletion is similar in spirit, but is more geared towards the Windows GUI (or rather, any front-end that has no completion facilities of its own). It requires the linebuffer and cursor position as arguments, and returns a list with three components, addition, possible and comps. If there is an unambiguous extension at the current position, addition contains the additional text that should be inserted at the cursor. If there is more than one possibility, these are available either as a character vector of preformatted strings in possible, or as a single string in comps. possible consists of lines formatted using the current width option, so that printing them on the console one line at a time will be a reasonable way to list them. comps is a space separated (collapsed) list of the same completions, in case the front-end wishes to display it in some other fashion.

The minlength argument can be used to suppress completion when the token is too short (which can be useful if the front-end is set up to try completion on every keypress). If check.repeat is TRUE,
it is detected if the same completion is being requested more than once in a row, and ambiguous completions are returned only in that case. This is an attempt to emulate GNU Readline behaviour, where a single TAB completes up to any unambiguous part, and multiple possibilities are reported only on two consecutive TABs.

As the various front-end interfaces evolve, the details of these functions are likely to change as well. The function .addFunctionInfo can be used to add information about the permitted argument names for specific functions. Multiple named arguments are allowed in calls to it, where the tags are names of functions and values are character vectors representing valid arguments. When the argdb setting is TRUE, these are used as a source of valid argument names for the relevant functions.

Note

If you are uncomfortable with unsolicited evaluation of pieces of code, you should set ops = FALSE. Otherwise, trying to complete foo@ba will evaluate foo. trying to complete foo[i, 1:10]$ba will evaluate foo[i, 1:10], etc. This should not be too bad, as explicit function calls (involving parentheses) are not evaluated in this manner. However, this will affect promises and lazy loaded symbols.

---

read.DIF  

**Data Input from Spreadsheet**

**Description**

Reads a file in Data Interchange Format (DIF) and creates a data frame from it. DIF is a format for data matrices such as single spreadsheets.

**Usage**

```r
read.DIF(file, header = FALSE,
          dec = ".", row.names, col.names,
          as.is = !stringsAsFactors,
          na.strings = "NA", colClasses = NA, nrows = -1,
          skip = 0, check.names = TRUE,
          blank.lines.skip = TRUE,
          stringsAsFactors = default.stringsAsFactors(),
          transpose = FALSE)
```

**Arguments**

- `file`  
  the name of the file which the data are to be read from, or a connection, or a complete URL.
  The name "clipboard" may also be used on Windows, in which case `read.DIF("clipboard")` will look for a DIF format entry in the Windows clipboard.
header: a logical value indicating whether the spreadsheet contains the names of the variables as its first line. If missing, the value is determined from the file format: header is set to TRUE if and only if the first row contains only character values and the top left cell is empty.

dec: the character used in the file for decimal points.

row.names: a vector of row names. This can be a vector giving the actual row names, or a single number giving the column of the table which contains the row names, or character string giving the name of the table column containing the row names. If there is a header and the first row contains one fewer field than the number of columns, the first column in the input is used for the row names. Otherwise if row.names is missing, the rows are numbered.

Using row.names = NULL forces row numbering.

col.names: a vector of optional names for the variables. The default is to use "V" followed by the column number.

as.is: the default behavior of read.DIF is to convert character variables to factors. The variable as.is controls the conversion of columns not otherwise specified by colClasses. Its value is either a vector of logicals (values are recycled if necessary), or a vector of numeric or character indices which specify which columns should not be converted to factors.

Note: In releases prior to R 2.12.1, cells marked as being of character type were converted to logical, numeric or complex using type.convert as in read.table.

Note: to suppress all conversions including those of numeric columns, set colClasses = "character".

Note that as.is is specified per column (not per variable) and so includes the column of row names (if any) and any columns to be skipped.

na.strings: a character vector of strings which are to be interpreted as NA values. Blank fields are also considered to be missing values in logical, integer, numeric and complex fields.

colClasses: character. A vector of classes to be assumed for the columns. Recycled as necessary, or if the character vector is named, unspecified values are taken to be NA.

Possible values are NA (when type.convert is used), "NULL" (when the column is skipped), one of the atomic vector classes (logical, integer, numeric, complex, character, raw), or “factor”, "Date" or "POSIXct". Otherwise there needs to be an as method (from package methods) for conversion from "character" to the specified formal class.

Note that colClasses is specified per column (not per variable) and so includes the column of row names (if any).

nrows: the maximum number of rows to read in. Negative values are ignored.

skip: the number of lines of the data file to skip before beginning to read data.

check.names: logical. If TRUE then the names of the variables in the data frame are checked to ensure that they are syntactically valid variable names. If necessary they are adjusted (by make.names) so that they are, and also to ensure that there are no duplicates.
blank.lines.skip
   logical: if TRUE blank lines in the input are ignored.
stringsAsFactors
   logical: should character vectors be converted to factors?
transpose
   logical, indicating if the row and column interpretation should be transposed.
   Microsoft’s Excel has been known to produce (non-standard conforming) DIF files which would need transpose = TRUE to be read correctly.

Value

A data frame (data.frame) containing a representation of the data in the file. Empty input is an error unless col.names is specified, when a 0-row data frame is returned: similarly giving just a header line if header = TRUE results in a 0-row data frame.

Note

The columns referred to in as.is and colClasses include the column of row names (if any).
Less memory will be used if colClasses is specified as one of the six atomic vector classes.

Author(s)

R Core; transpose option by Christoph Buser, ETH Zurich

References

The DIF format specification can be found by searching on http://www.wotsit.org/; the optional header fields are ignored. See also http://en.wikipedia.org/wiki/Data_Interchange_Format.

The term is likely to lead to confusion: Windows will have a ‘Windows Data Interchange Format (DIF) data format’ as part of its WinFX system, which may or may not be compatible.

scan, type.convert, read.fwf for reading fixed width formatted input; read.table; data.frame.

Examples

## read.DIF() needs transpose = TRUE for file exported from Excel
udir <- system.file("misc", package = "utils")
dd <- read.DIF(file.path(udir, "exDIF.dif"), header = TRUE, transpose = TRUE)
dc <- read.csv(file.path(udir, "exDIF.csv"), header = TRUE)
stopifnot(identical(dd, dc), dim(dd) == c(4,2))
read.fortran

Read Fixed-Format Data

Description

Read fixed-format data files using Fortran-style format specifications.

Usage

read.fortran(file, format, ..., as.is = TRUE, colClasses = NA)

Arguments

- **file**: File or connection to read from.
- **format**: Character vector or list of vectors. See ‘Details’ below.
- **...**: Other arguments for `read.fwf`
- **as.is**: Keep characters as characters?
- **colClasses**: Variable classes to override defaults. See `read.table` for details.

Details

The format for a field is of one of the following forms: rFl.d, rDl.d, rXl, rAl, rIl, where l is the number of columns, d is the number of decimal places, and r is the number of repeats. F and D are numeric formats, A is character, I is integer, and X indicates columns to be skipped. The repeat code r and decimal place code d are always optional. The length code l is required except for X formats when r is present.

For a single-line record, format should be a character vector. For a multiline record it should be a list with a character vector for each line.

Skipped (X) columns are not passed to `read.fwf`, so colClasses, col.names, and similar arguments passed to `read.fwf` should not reference these columns.

Value

A data frame

Note

`read.fortran` does not use actual Fortran input routines, so the formats are at best rough approximations to the Fortran ones. In particular, specifying d > 0 in the F or D format will shift the decimal d places to the left, even if it is explicitly specified in the input file.

See Also

`read.fwf, read.table, read.csv`
Examples

```r
ff <- tempfile()
cat(file = ff, "123456", "987654", sep = "\n")
read.fortran(ff, c("F2.1","F2.0","I2"))
read.fortran(ff, c("2F1.0","2X","2A1"))
unlink(ff)
cat(file = ff, "123456AB", "987654CD", sep = "\n")
read.fortran(ff, list(c("2F3.1","A2"), c("3I2","2X")))
unlink(ff)
# Note that the first number is read differently than Fortran would
# read it:
cat(file = ff, "12.3456", "1234567", sep = "\n")
read.fortran(ff, "F7.4")
unlink(ff)
```

---

**read.fwf**

*Read Fixed Width Format Files*

**Description**

Read a table of fixed width formatted data into a `data.frame`.

**Usage**

```r
read.fwf(file, widths, header = FALSE, sep = "\t",
         skip = 0, row.names, col.names, n = -1,
         buffersize = 2000, ...)
```

**Arguments**

- `file` the name of the file which the data are to be read from. Alternatively, `file` can be a `connection`, which will be opened if necessary, and if so closed at the end of the function call.
- `widths` integer vector, giving the widths of the fixed-width fields (of one line), or list of integer vectors giving widths for multiline records.
- `header` a logical value indicating whether the file contains the names of the variables as its first line. If present, the names must be delimited by `sep`.
- `sep` character; the separator used internally; should be a character that does not occur in the file (except in the header).
- `skip` number of initial lines to skip; see `read.table`.
- `row.names` see `read.table`.
- `col.names` see `read.table`.
- `n` the maximum number of records (lines) to be read, defaulting to no limit.
- `buffersize` Maximum number of lines to read at one time
- `...` further arguments to be passed to `read.table`. Useful further arguments include `as.is`, `na.strings`, `colClasses` and `strip.white`. 
Details

Multiline records are concatenated to a single line before processing. Fields that are of zero-width or are wholly beyond the end of the line in file are replaced by NA.

Negative-width fields are used to indicate columns to be skipped, e.g., -5 to skip 5 columns. These fields are not seen by read.table and so should not be included in a col.names or colClasses argument (nor in the header line, if present).

Reducing the buffersize argument may reduce memory use when reading large files with long lines. Increasing buffersize may result in faster processing when enough memory is available.

Value

A data.frame as produced by read.table which is called internally.

scan and read.table.

Examples

ff <- tempfile()
cat(file = ff, "123456", "987654", sep = "\n")
read.fwf(ff, widths = c(1,2,3)) #> 1 23 456 \ 9 87 654
read.fwf(ff, widths = c(1,-2,3)) #> 1 456 \ 9 654
unlink(ff)
cat(file = ff, "123", "987654", sep = "\n")
read.fwf(ff, widths = c(1,0, 2,3)) #> 1 NA 23 \ NA 9 NA 87 654
unlink(ff)
cat(file = ff, "123456", "987654", sep = "\n")
read.fwf(ff, widths = list(c(1,0, 2,3), c(2,2,2))) #> 1 NA 23 456 98 76 54
unlink(ff)

---

read.socket  
Read from or Write to a Socket

Description

read.socket reads a string from the specified socket, write.socket writes to the specified socket. There is very little error checking done by either.

Usage

read.socket(socket, maxlen = 256L, loop = FALSE)
write.socket(socket, string)
Arguments

socket    a socket object.
maxlen    maximum length (in bytes) of string to read.
loop      wait for ever if there is nothing to read?
string    string to write to socket.

Value

read.socket returns the string read as a length-one character vector.
write.socket returns the number of bytes written.

Author(s)

Thomas Lumley

Examples

finger <- function(user, host = "localhost", port = 79, print = TRUE)
{
  if (!is.character(user))
    stop("user name must be a string")
  user <- paste(user, "\r\n")
  socket <- make.socket(host, port)
  on.exit(close.socket(socket))
  write.socket(socket, user)
  output <- character(0)
  repeat{
    ss <- read.socket(socket)
    if (ss == "") break
    output <- paste(output, ss)
  }
  close.socket(socket)
  if (print) cat(output)
  invisible(output)
}
## Not run:
finger("root")  ## only works if your site provides a finger daemon
## End(Not run)
read.table

Description

Reads a file in table format and creates a data frame from it, with cases corresponding to lines and variables to fields in the file.

Usage

read.table(file, header = FALSE, sep = "", quote = "\"", dec = ".", row.names, col.names,
          as.is = !stringsAsFactors,
          na.strings = "NA", colClasses = NA, nrows = -1,
          skip = 0, check.names = TRUE, fill = !blank.lines.skip,
          strip.white = FALSE, blank.lines.skip = TRUE,
          comment.char = "#",
          allowEscapes = FALSE, flush = FALSE,
          stringsAsFactors = default.stringsAsFactors(),
          fileEncoding = "", encoding = "unknown", text)

read.csv(file, header = TRUE, sep = ",", quote = "\"",
          dec = ".", fill = TRUE, comment.char = "", ...)  

read.csv2(file, header = TRUE, sep = ";", quote = "\"",
           dec = ",", fill = TRUE, comment.char = "", ...)

read.delim(file, header = TRUE, sep = "\t", quote = "\"",
           dec = ".", fill = TRUE, comment.char = "", ...)

read.delim2(file, header = TRUE, sep = "\t", quote = "\"",
             dec = ",", fill = TRUE, comment.char = "", ...)

Arguments

file

the name of the file which the data are to be read from. Each row of the table appears as one line of the file. If it does not contain an absolute path, the file name is relative to the current working directory, getwd(). Tilde-expansion is performed where supported. As from R 2.10.0 this can be a compressed file (see file).

Alternatively, file can be a readable text-mode connection (which will be opened for reading if necessary, and if so closed (and hence destroyed) at the end of the function call). (If stdin() is used, the prompts for lines may be somewhat confusing. Terminate input with a blank line or an EOF signal, Ctrl-D on Unix and Ctrl-Z on Windows. Any pushback on stdin() will be cleared before return.)
read.table

file can also be a complete URL. (For the supported URL schemes, see the ‘URLs’ section of the help for url.)

header

a logical value indicating whether the file contains the names of the variables as its first line. If missing, the value is determined from the file format: header is set to TRUE if and only if the first row contains one fewer field than the number of columns.

sep

the field separator character. Values on each line of the file are separated by this character. If sep = "" (the default for read.table) the separator is ‘white space’, that is one or more spaces, tabs, newlines or carriage returns.

quote

the set of quoting characters. To disable quoting altogether, use quote = "". See scan for the behaviour on quotes embedded in quotes. Quoting is only considered for columns read as character, which is all of them unless colClasses is specified.

dec

the character used in the file for decimal points.

row.names

a vector of row names. This can be a vector giving the actual row names, or a single number giving the column of the table which contains the row names, or character string giving the name of the table column containing the row names. If there is a header and the first row contains one fewer field than the number of columns, the first column in the input is used for the row names. Otherwise if row.names is missing, the rows are numbered. Using row.names = NULL forces row numbering. Missing or NULL row.names generate row names that are considered to be ‘automatic’ (and not preserved by as.matrix).

col.names

a vector of optional names for the variables. The default is to use "V" followed by the column number.

as.is

the default behavior of read.table is to convert character variables (which are not converted to logical, numeric or complex) to factors. The variable as.is controls the conversion of columns not otherwise specified by colClasses. Its value is either a vector of logics (values are recycled if necessary), or a vector of numeric or character indices which specify which columns should not be converted to factors.

Note: to suppress all conversions including those of numeric columns, set colClasses = "character".

Note that as.is is specified per column (not per variable) and so includes the column of row names (if any) and any columns to be skipped.

na.strings

a character vector of strings which are to be interpreted as NA values. Blank fields are also considered to be missing values in logical, integer, numeric and complex fields.

colClasses

character. A vector of classes to be assumed for the columns. Recycled as necessary, or if the character vector is named, unspecified values are taken to be NA.

Possible values are NA (the default, when type.convert is used), "NULL" (when the column is skipped), one of the atomic vector classes (logical, integer, numeric, complex, character, raw), or "factor", "Date" or "POSIXct". Otherwise there needs to be an as method (from package methods) for conversion from "character" to the specified formal class.
Note that colClasses is specified per column (not per variable) and so includes the column of row names (if any).

**nrows**  
integer: the maximum number of rows to read in. Negative and other invalid values are ignored.

**skip**  
integer: the number of lines of the data file to skip before beginning to read data.

**check.names**  
logical. If TRUE then the names of the variables in the data frame are checked to ensure that they are syntactically valid variable names. If necessary they are adjusted (by `make.names`) so that they are, and also to ensure that there are no duplicates.

**fill**  
logical. If TRUE then in case the rows have unequal length, blank fields are implicitly added. See ‘Details’.

**strip.white**  
logical. Used only when sep has been specified, and allows the stripping of leading and trailing white space from unquoted character fields (numeric fields are always stripped). See `scan` for further details (including the exact meaning of ‘white space’), remembering that the columns may include the row names.

**blank.lines.skip**  
logical: if TRUE blank lines in the input are ignored.

**comment.char**  
character: a character vector of length one containing a single character or an empty string. Use "" to turn off the interpretation of comments altogether.

**allowEscapes**  
logical. Should C-style escapes such as '\n' be processed or read verbatim (the default)? Note that if not within quotes these could be interpreted as a delimiter (but not as a comment character). For more details see `scan`.

**flush**  
logical: if TRUE, `scan` will flush to the end of the line after reading the last of the fields requested. This allows putting comments after the last field.

**stringsAsFactors**  
logical: should character vectors be converted to factors? Note that this is over-ridden by `as.is` and `colClasses`, both of which allow finer control.

**fileEncoding**  
character string: if non-empty declares the encoding used on a file (not a connection) so the character data can be re-encoded. See the ‘Encoding’ section of the help for `file`, the ‘R Data Import/Export Manual’ and ‘Note’.

**encoding**  
encoding to be assumed for input strings. It is used to mark character strings as known to be in Latin-1 or UTF-8 (see `Encoding`): it is not used to re-encode the input, but allows R to handle encoded strings in their native encoding (if one of those two). See ‘Value’.

**text**  
character string: if file is not supplied and this is, then data are read from the value of text via a text connection. Notice that a literal string can be used to include (small) data sets within R code.

...  
Further arguments to be passed to `read.table`.

**Details**

This function is the principal means of reading tabular data into R.

Unless `colClasses` is specified, all columns are read as character columns and then converted using `type.convert` to logical, integer, numeric, complex or (depending on `as.is`) factor as appropriate.
Quotes are (by default) interpreted in all fields, so a column of values like "42" will result in an integer column.

A field or line is 'blank' if it contains nothing (except whitespace if no separator is specified) before a comment character or the end of the field or line.

If row.names is not specified and the header line has one less entry than the number of columns, the first column is taken to be the row names. This allows data frames to be read in from the format in which they are printed. If row.names is specified and does not refer to the first column, that column is discarded from such files.

The number of data columns is determined by looking at the first five lines of input (or the whole file if it has less than five lines), or from the length of col.names if it is specified and is longer. This could conceivably be wrong if fill or blank.lines.skip are true, so specify col.names if necessary (as in the ‘Examples’).

read.csv and read.csv2 are identical to read.table except for the defaults. They are intended for reading ‘comma separated value’ files (‘.csv’) or (read.csv2) the variant used in countries that use a comma as decimal point and a semicolon as field separator. Similarly, read.delim and read.delim2 are for reading delimited files, defaulting to the TAB character for the delimiter. Notice that header = TRUE and fill = TRUE in these variants, and that the comment character is disabled.

The rest of the line after a comment character is skipped; quotes are not processed in comments. Complete comment lines are allowed provided blank.lines.skip = TRUE; however, comment lines prior to the header must have the comment character in the first non-blank column.

Quoted fields with embedded newlines are supported except after a comment character.

Value

A data frame (data.frame) containing a representation of the data in the file.

Empty input is an error unless col.names is specified, when a 0-row data frame is returned: similarly giving just a header line if header = TRUE results in a 0-row data frame. Note that in either case the columns will be logical unless colClasses was supplied.

Character strings in the result (including factor levels) will have a declared encoding if encoding is "latin1" or "UTF-8".

Memory usage

These functions can use a surprising amount of memory when reading large files. There is extensive discussion in the ‘R Data Import/Export’ manual, supplementing the notes here.

Less memory will be used if colClasses is specified as one of the six atomic vector classes. This can be particularly so when reading a column that takes many distinct numeric values, as storing each distinct value as a character string can take up to 14 times as much memory as storing it as an integer.

Using nrows, even as a mild over-estimate, will help memory usage.

Using comment.char = "" will be appreciably faster than the read.table default.

read.table is not the right tool for reading large matrices, especially those with many columns: it is designed to read data frames which may have columns of very different classes. Use scan instead for matrices.
Note

The columns referred to in `as.is` and `colClasses` include the column of row names (if any).

Because this function uses `pushBack` it can only handle character strings which can be represented in the current locale. So although `fileEncoding` can be used to specify the encoding of the input file (or a connection can be specified which re-encodes), the implied re-encoding must be possible. This is not a problem in UTF-8 locales, but it can be on Windows — `readLines` or `scan` can be used to avoid this limitation since they have special provisions to convert input to UTF-8.

References

See Also

The ‘R Data Import/Export’ manual.

`scan`, `type.convert`, `read.fwf` for reading fixed width formatted input; `write.table`; `data.frame`.

`count.fields` can be useful to determine problems with reading files which result in reports of incorrect record lengths (see the ‘Examples’ below).

http://tools.ietf.org/html/rfc4180 for the IANA definition of CSV files (which requires comma as separator and CRLF line endings).

Examples

```r
## using count.fields to handle unknown maximum number of fields
## when fill = TRUE

test1 <- c(1:5, "6,7", "8,9,10")
tf <- tempfile()
writeLines(test1, tf)

read.csv(tf, fill = TRUE) # 1 column
ncol <- max(count.fields(tf, sep = ","))
read.csv(tf, fill = TRUE, header = FALSE,
    col.names = paste0("V", seq_len(ncol)))
unlink(tf)

## "Inline" data set, using text=
## Notice that leading and trailing empty lines are auto-trimmed

read.table(header = TRUE, text = "
a b
1 2
3 4
")
```
recover  Browsing after an Error

Description

This function allows the user to browse directly on any of the currently active function calls, and is suitable as an error option. The expression options(error = recover) will make this the error option.

Usage

recover()

Details

When called, recover prints the list of current calls, and prompts the user to select one of them. The standard R browser is then invoked from the corresponding environment; the user can type ordinary R language expressions to be evaluated in that environment.

When finished browsing in this call, type c to return to recover from the browser. Type another frame number to browse some more, or type 0 to exit recover.

The use of recover largely supersedes dump.frames as an error option, unless you really want to wait to look at the error. If recover is called in non-interactive mode, it behaves like dump.frames.

For computations involving large amounts of data, recover has the advantage that it does not need to copy out all the environments in order to browse in them. If you do decide to quit interactive debugging, call dump.frames directly while browsing in any frame (see the examples).

Value

Nothing useful is returned. However, you can invoke recover directly from a function, rather than through the error option shown in the examples. In this case, execution continues after you type 0 to exit recover.

Compatibility Note

The R recover function can be used in the same way as the S function of the same name; therefore, the error option shown is a compatible way to specify the error action. However, the actual functions are essentially unrelated and interact quite differently with the user. The navigating commands up and down do not exist in the R version; instead, exit the browser and select another frame.

References

See the compatibility note above, however.

See Also

browser for details about the interactive computations; options for setting the error option; dump.frames to save the current environments for later debugging.
Examples

```r
## Not run:

options(error = recover) # setting the error option

### Example of interaction

> myFit <- lm(y ~ x, data = xy, weights = w)
Error in lm.wfit(x, y, w, offset = offset, ...) :
  missing or negative weights not allowed

Enter a frame number, or 0 to exit
1:lm(y ~ x, data = xy, weights = w)
2:lm.wfit(x, y, w, offset = offset, ...)
Selection: 2
Called from: eval(expr, envir, enclos)
Browse[1]> objects() # all the objects in this frame
[1] "method" "n"    "ny"  "offset" "tol"  "w"
[7] "x"    "y"
Browse[1]> w

Enter a frame number, or 0 to exit
1:lm(y ~ x, data = xy, weights = w)
2:lm.wfit(x, y, w, offset = offset, ...)
Selection: 0 # exit recover
>

## End(Not run)
```

relist

Allow Re-Listing an unlist()ed Object

Description
relist() is an S3 generic function with a few methods in order to allow easy inversion of
unlist(obj) when that is used with an object obj of (S3) class "relistable".

Usage
relist(flesh, skeleton)
## Default S3 method:
relist(flesh, skeleton = attr(flesh, "skeleton"))
## S3 method for class 'factor'
relist(flesh, skeleton = attr(flesh, "skeleton"))
## S3 method for class 'list'
relist(flesh, skeleton = attr(flesh, "skeleton"))
## S3 method for class 'matrix'
relist(flesh, skeleton = attr(flesh, "skeleton"))

as.relistable(x)
is.relistable(x)

## S3 method for class 'relistable'
unlist(x, recursive = TRUE, use.names = TRUE)

### Arguments
- **flesh**: a vector to be relisted
- **skeleton**: a list, the structure of which determines the structure of the result
- **x**: an R object, typically a list (or vector).
- **recursive**: logical. Should unlisting be applied to list components of x?
- **use.names**: logical. Should names be preserved?

### Details
Some functions need many parameters, which are most easily represented in complex structures, e.g., nested lists. Unfortunately, many mathematical functions in R, including `optim` and `nlm` can only operate on functions whose domain is a vector. R has `unlist()` to convert nested list objects into a vector representation. `relist()`, its methods and the functionality mentioned here provide the inverse operation to convert vectors back to the convenient structural representation. This allows structured functions (such as `optim()`) to have simple mathematical interfaces.

For example, a likelihood function for a multivariate normal model needs a variance-covariance matrix and a mean vector. It would be most convenient to represent it as a list containing a vector and a matrix. A typical parameter might look like

```
list(mean = c(0, 1), vcov = cbind(c(1, 1), c(1, 0))).
```

However, `optim` cannot operate on functions that take lists as input; it only likes numeric vectors. The solution is conversion. Given a function `mvdnorm(x, mean, vcov, log = FALSE)` which computes the required probability density, then

```
ipar <- list(mean = c(0, 1), vcov = cbind(c(1, 1), c(1, 0)))
initial.param <- as.relistable(ipar)

ll <- function(param.vector)
{
  param <- relist(param.vector, skeleton = ipar)
  -sum(mvdnorm(x, mean = param$mean, vcov = param$vcov, log = TRUE))
}

optim(unlist(initial.param), ll)
relist takes two parameters: skeleton and flesh. Skeleton is a sample object that has the right shape but the wrong content. flesh is a vector with the right content but the wrong shape. Invoking

\[
\text{relist(flesh, skeleton)}
\]

will put the content of flesh on the skeleton. You don’t need to specify skeleton explicitly if the skeleton is stored as an attribute inside flesh. In particular, if flesh was created from some object obj with \text{unlist(as.relistable(obj))} then the skeleton attribute is automatically set. (Note that this does not apply to the example here, as \text{optim} is creating a new vector to pass to \text{ll} and not its \text{par} argument.)

As long as skeleton has the right shape, it should be a precise inverse of \text{unlist}. These equalities hold:

\[
\begin{align*}
\text{relist(unlist(x), x)} &= x \\
\text{unlist(relist(y, skeleton))} &= y \\
\end{align*}
\]

\[
\begin{align*}
x &\leftarrow \text{as.relistable(x)} \\
\text{relist(unlist(x))} &= x \\
\end{align*}
\]

Value

an object of (S3) class "relistable" (and "list").

Author(s)

R Core, based on a code proposal by Andrew Clausen.

See Also

\text{unlist}

Examples

\[
\begin{align*}
\text{ipar} &\leftarrow \text{list(mean = c(0, 1), vcov = \text{cbind(c(1, 1), c(1, 0))}} \\
\text{initial.param} &\leftarrow \text{as.relistable(ipar)} \\
\text{ul} &\leftarrow \text{unlist(initial.param)} \\
\text{relist(ul)} \\
\text{stopifnot(identical(relist(ul), initial.param))} \\
\end{align*}
\]

## REMOVE

Remove Add-on Packages

Description

Utility for removing add-on packages.

Usage

\[
\text{R CMD REMOVE [options] [-l lib] pkgs}
\]
Arguments

pkgs    a space-separated list with the names of the packages to be removed.
lib     the path name of the R library tree to remove from. May be absolute or relative. Also accepted in the form ‘--library=lib’.
options further options for help or version.

Details

If used as R CMD REMOVE pkgs without explicitly specifying lib, packages are removed from the library tree rooted at the first directory in the library path which would be used by R run in the current environment.

To remove from the library tree lib instead of the default one, use R CMD REMOVE -l lib pkgs.

Use R CMD REMOVE --help for more usage information.

Note

Some binary distributions of R have REMOVE in a separate bundle, e.g. an R-devel RPM.

See Also

INSTALL, remove.packages

remove.packages   Remove Installed Packages

Description

Removes installed packages/bundles and updates index information as necessary.

Usage

  remove.packages(pkgs, lib)

Arguments

pkgs    a character vector with the names of the packages to be removed.
lib     a character vector giving the library directories to remove the packages from. If missing, defaults to the first element in .libPaths().

See Also

REMOVE for a command line version; install.packages for installing packages.
removeSource

Remove Stored Source from a Function.

Description
When options("keep.source") is TRUE, a copy of the original source code to a function is stored with it. This function removes that copy.

Usage
removeSource(fn)

Arguments
fn A single function from which to remove the source.

Details
This removes both the "source" attribute (from R version 2.13.x or earlier) and the "srcref" and related attributes.

Value
A copy of the function with the source removed.

See Also
srcref for a description of source reference records, deparse for a description of how functions are deparsed.

Examples
fn <- function(x) {
  x + 1 # A comment, kept as part of the source
}
fn
fn <- removeSource(fn)
fn

RHOME

R Home Directory

Description
Returns the location of the R home directory, which is the root of the installed R tree.

Usage
R RHOME
Description

Manipulate integers as roman numerals.

Usage

as.roman(x)

Arguments

x  a numeric vector, or a character vector of arabic or roman numerals.

Details

as.roman creates objects of class "roman" which are internally represented as integers, and have suitable methods for printing, formatting, subsetting, and coercion to character.

Only numbers between 1 and 3899 have a unique representation as roman numbers.

References

Examples

## First five roman 'numbers'.
(y <- as.roman(1 : 5))
## Middle one.
y[3]
## Current year as a roman number.
(y <- as.roman(format(Sys.Date(), "%Y")))
## 10 years ago ...
y - 10
Rprof

Enable Profiling of R's Execution

**Description**

Enable or disable profiling of the execution of R expressions.

**Usage**

```r
def Rprof(filename = "Rprof.out", append = FALSE, interval = 0.02,
memory.profiling = FALSE, gc.profiling = FALSE,
line.profiling = FALSE, numfiles = 100L, bufsize = 10000L)
```

**Arguments**

- `filename`: The file to be used for recording the profiling results. Set to `NULL` or `""` to disable profiling.
- `append`: logical: should the file be over-written or appended to?
- `interval`: real: time interval between samples.
- `memory.profiling`: logical: write memory use information to the file?
- `gc.profiling`: logical: record whether GC is running?
- `line.profiling`: logical: write line locations to the file?
- `numfiles`, `bufsize`: integers: line profiling memory allocation

**Details**

Enabling profiling automatically disables any existing profiling to another or the same file.

Profiling works by writing out the call stack every `interval` seconds, to the file specified. Either the `summaryRprof` function or the wrapper script R CMD Rprof can be used to process the output file to produce a summary of the usage; use R CMD Rprof --help for usage information.

How time is measured varies by platform: on a Unix-alike it is the CPU time of the R process, so for example excludes time when R is waiting for input or for processes run by system to return.

Note that the timing interval cannot usefully be too small: once the timer goes off, the information is not recorded until the next timing click (probably in the range 1–10msecs).

Functions will only be recorded in the profile log if they put a context on the call stack (see `sys.calls`). Some primitive functions do not do so: specifically those which are of type "special" (see the 'R Internals' manual for more details).

Individual statements will be recorded in the profile log if `line.profiling` is TRUE, and if the code being executed was parsed with source references. See `parse` for a discussion of source references. By default the statement locations are not shown in `summaryRprof`, but see that help page for options to enable the display.
Note

Profiling is not available on all platforms. By default, support for profiling is compiled in if possible. Configure R with ‘--disable-R-profiling’ to change this.

As R profiling uses the same mechanisms as C profiling, the two cannot be used together, so do not use Rprof in an executable built for C-level profiling.

Note

The profiler interrupts R asynchronously, and it cannot allocate memory to store results as it runs. This affects line profiling, which needs to store an unknown number of file pathnames. The numfiles and bufsize arguments control the size of pre-allocated buffers to hold these results: the former counts the maximum number of paths, the latter counts the numbers of bytes in them. If the profiler runs out of space it will skip recording the line information for new files, and issue a warning when Rprof(NULL) is called to finish profiling.

See Also

The chapter on “Tidying and profiling R code” in “Writing R Extensions” (see the ‘doc/manual’ subdirectory of the R source tree).

summaryRprof to analyse the output file.

tracemem, Rprofmem for other ways to track memory use.

Examples

```r
## Not run: Rprof()
## some code to be profiled
Rprof(NULL)
## some code NOT to be profiled
Rprof(append = TRUE)
## some code to be profiled
Rprof(NULL)
...
## Now post-process the output as described in Details

## End(Not run)
```

Rprofmem

Enable Profiling of R’s Memory Use

Description

Enable or disable reporting of memory allocation in R.

Usage

Rprofmem(filename = "Rprofmem.out", append = FALSE, threshold = 0)
Rprofmem

Arguments

filename The file to be used for recording the memory allocations. Set to NULL or "" to disable reporting.
append logical: should the file be over-written or appended to?
threshold numeric: allocations on R’s "large vector" heap larger than this number of bytes will be reported.

Details

Enabling profiling automatically disables any existing profiling to another or the same file.

Profiling writes the call stack to the specified file every time malloc is called to allocate a large vector object or to allocate a page of memory for small objects. The size of a page of memory and the size above which malloc is used for vectors are compile-time constants, by default 2000 and 128 bytes respectively.

The profiler tracks allocations, some of which will be to previously used memory and will not increase the total memory use of R.

Value

None

Note

The memory profiler slows down R even when not in use, and so is a compile-time option. The memory profiler can be used at the same time as other R and C profilers.

See Also

The R sampling profiler, Rprof also collects memory information.

tracemem traces duplications of specific objects.

The "Writing R Extensions" manual section on "Tidying and profiling R code"

Examples

## Not run:
## not supported unless R is compiled to support it.
Rprofmem("Rprofmem.out", threshold = 1000)
extample(glm)
Rprofmem(NULL)
noquote(readLines("Rprofmem.out", n = 5))

## End(Not run)
Description

This is an alternative front end for use in ‘#!’ scripts and other scripting applications.

Usage

Rscript [options] [-e expression] file [args]

Arguments

options A list of options beginning with ‘--’. These can be any of the options of the standard R front-end, and also those described in the details.

expression a R expression.

file The name of a file containing R commands. ‘-’ indicates ‘stdin’.

args Arguments to be passed to the script in file.

Details

Rscript --help gives details of usage, and Rscript --version gives the version of Rscript.

Other invocations invoke the R front-end with selected options. This front-end is convenient for writing ‘#!’ scripts since it is an executable and takes file directly as an argument. Options ‘--slave --no-restore’ are always supplied: these imply ‘--no-save’. (The standard Windows command line has no concept of ‘#!’ scripts, but Cygwin shells do.)

Either one or more ‘-e’ options or file should be supplied. When using ‘-e’ options be aware of the quoting rules in the shell used: see the examples.

Additional options accepted (before file or args) are

‘--verbose’ gives details of what Rscript is doing. Also passed on to R.

‘--default-packages=list’ where list is a comma-separated list of package names or NULL.

Sets the environment variable R_DEFAULT_PACKAGES which determines the packages loaded on startup. The default for Rscript omits methods as it takes about 60% of the startup time.

Spaces are allowed in expression and file (but will need to be protected from the shell in use, if any, for example by enclosing the argument in quotes).

Normally the version of R is determined at installation, but this can be overridden by setting the environment variable RHOME.

stdin() refers to the input file, and file("stdin") to the stdin file stream of the process.

Note

Rscript is only supported on systems with the execv system call.
Examples

```r
## Not run:
Rscript -e 'date()' -e 'format(Sys.time(), "%a %b %d %X %Y")'

## example #! script for a Unix-alike
#! /path/to/Rscript --vanilla --default-packages=utils
args <- commandArgs(TRUE)
res <- try(install.packages(args))
if(inherits(res, "try-error")) q(status=1) else q()

## End(Not run)
```

RShowDoc

Show R Manuals and Other Documentation

Description

Utility function to find and display R documentation.

Usage

```r
RShowDoc(what, type = c("pdf", "html", "txt"), package)
```

Arguments

- `what` a character string: see ‘Details’.
- `type` an optional character string giving the preferred format.
- `package` an optional character string specifying the name of a package within which to look for documentation.

Details

`what` can specify one of several different sources of documentation, including the R manuals (`R-admin`, `R-data`, `R-exts`, `R-intro`, `R-ints`, `R-lang`), NEWS, COPYING (the GPL licence), any of the licenses in `share/licenses`, FAQ (also available as `R-FAQ`), and the files in `R_HOME/doc`.

Only on Windows, the R for Windows FAQ is specified by `rw-FAQ`.

If `package` is supplied, documentation is looked for in the ‘doc’ and top-level directories of an installed package of that name.

If `what` is missing a brief usage message is printed.

The documentation types are tried in turn starting with the first specified in `type` (or "pdf" if none is specified).

Value

A invisible character string given the path to the file found.
Examples

```r
## Not run:
RShowDoc("R-lang")
RShowDoc("FAQ", type = "html")
RShowDoc("frame", package = "grid")
RShowDoc("changes.txt", package = "grid")
RShowDoc("NEWS", package = "MASS")

## End(Not run)
```

RSiteSearch

Search for Key Words or Phrases in Documentation

Description

Search for key words or phrases in help pages, vignettes or task views, using the search engine at http://search.r-project.org and view them in a web browser.

Usage

```r
RSiteSearch(string, restrict = c("functions", "vignettes", "views"), format = c("normal", "short"), sortby = c("score", "date:late", "date:early", "subject", "subject:descending", "from", "from:descending", "size", "size:descending"), matchesPerPage = 20)
```

Arguments

- **string**: A character string specifying word(s) or a phrase to search. If the words are to be searched as one entity, enclose all words in braces (see the first example).
- **restrict**: a character vector, typically of length greater than one. Possible areas to search in: functions for help pages, views for task views and vignettes for package vignettes.
- **format**: normal or short (no excerpts); can be abbreviated.
- **sortby**: character string (can be abbreviated) indicating how to sort the search results: (score, date:late for sorting by date with latest results first, date:early for earliest first, subject for subject in alphabetical order, subject:descending for reverse alphabetical order, from or from:descending for sender (when applicable), size or size:descending for size.)
- **matchesPerPage**: How many items to show per page.
Details

This function is designed to work with the search site at http://search.r-project.org, and depends on that site continuing to be made available (thanks to Jonathan Baron and the School of Arts and Sciences of the University of Pennsylvania).

Unique partial matches will work for all arguments. Each new browser window will stay open unless you close it.

Value

(Invisibly) the complete URL passed to the browser, including the query string.

Author(s)

Andy Liaw and Jonathan Baron

See Also

help.search, help.start for local searches.
browseURL for how the help file is displayed.

Examples

# need Internet connection
RSiteSearch("{logistic regression}") # matches exact phrase
Sys.sleep(5) # allow browser to open, take a quick look
## Search in vignettes and store the query-string:
fullquery <- RSiteSearch("lattice", restrict = "vignettes")
fullquery # a string of ~ 11/zero.noslash characters

rtags
An Etags-like Tagging Utility for R

Description

rtags provides etags-like indexing capabilities for R code, using R's own parser.

Usage

rtags(path = ".", pattern = "\.\.[RrSs]$",
recursive = FALSE,
src = list.files(path = path, pattern = pattern,
full.names = TRUE,
recursive = recursive),
keep.re = NULL,
ofile = "", append = FALSE,
verbose = getOption("verbose"))
Arguments

- **path, pattern, recursive**
  Arguments passed on to `list.files` to determine the files to be tagged. By default, these are all files with extension `.R`, `.r`, `.S`, and `.s` in the current directory. These arguments are ignored if `src` is specified.

- **src**
  A vector of file names to be indexed.

- **keep.re**
  A regular expression further restricting `src` (the files to be indexed). For example, specifying `keep.re = "/R/[^/]*\.R$"` will only retain files with extension `.R` inside a directory named R.

- **ofile**
  Passed on to `cat` as the file argument; typically the output file where the tags will be written ("TAGS" by convention). By default, the output is written to the R console (unless redirected).

- **append**
  Logical, indicating whether the output should overwrite an existing file, or append to it.

- **verbose**
  Logical. If TRUE, file names are echoed to the R console as they are processed.

Details

Many text editors allow definitions of functions and other language objects to be quickly and easily located in source files through a tagging utility. This functionality requires the relevant source files to be preprocessed, producing an index (or tag) file containing the names and their corresponding locations. There are multiple tag file formats, the most popular being the vi-style ctags format and the and emacs-style etags format. Tag files in these formats are usually generated by the ctags and etags utilities respectively. Unfortunately, these programs do not recognize R code syntax. They do allow tagging of arbitrary language files through regular expressions, but this too is insufficient.

The `rtags` function is intended to be a tagging utility for R code. It parses R code files (using R's parser) and produces tags in Emacs' etags format. Support for vi-style tags is currently absent, but should not be difficult to add.

      pattern = ".[^/]*\.[RrSs]$",
      keep.re = "/R/",
```
Rtangle

R Driver for Stangle

Description

A driver for Stangle that extracts R code chunks.

Usage

Rtangle()
RtangleSetup(file, syntax, output = NULL, annotate = TRUE,
               split = FALSE, quiet = FALSE, ...)

Arguments

file            Name of Sweave source file. See the description of the corresponding argument of Sweave.
syntax          An object of class SweaveSyntax.
output          Name of output file used unless split = TRUE: see ‘Details’.
annotate        By default, code chunks are separated by comment lines specifying the names and numbers of the code chunks. If FALSE the decorating comments are omitted.
split           Split output into a file for each code chunk?
quiet           If TRUE all progress messages are suppressed.
...             Additional named arguments setting defaults for further options.

Details

Unless split = TRUE, the default name of the output file is basename(file) with an extension corresponding to the Sweave syntax (e.g. ‘Rnw’, ‘Stex’) replaced by ‘R’. File names "stdout" and "stderr" are interpreted as the output and message connection respectively.

If splitting is selected (including by the options in the file), each chunk is written to a separate file with extension the name of the ‘engine’ (default ‘.R’).

The annotation is of one of the forms
using either the chunk label or the file name and line numbers.
Note that this driver does not simple extract the code chunks verbatim because code chunks can re-use earlier chunks.

**Supported Options**

Rtangle supports the following options for code chunks (the values in parentheses show the default values):

- **engine**: character string ("R"). Only chunks with engine equal to "R" or "S" are processed.
- **keep.source**: logical (TRUE). If keep.source == TRUE the original source is copied to the file. Otherwise, deparsed source is output.
- **eval**: logical (TRUE). If FALSE, the code chunk is copied across but commented out.
- **prefix**: Used if split = TRUE. See prefix.string.
- **prefix.string**: a character string, default is the name of the source file (without extension). Used if split = TRUE as the prefix for the filename if the chunk has no label, or if it has a label and prefix = TRUE. Note that this is used as part of filenames, so needs to be portable.
- **show.line.nos** logical (FALSE). Should the output be annotated with comments showing the line number of the first code line of the chunk?

Sweave, RweaveLatex
Description

A driver for Sweave that translates R code chunks in LaTeX files.

Usage

RweaveLatex()

RweaveLatexSetup(file, syntax, output = NULL, quiet = FALSE,
                debug = FALSE, stylepath, ...)

Arguments

- **file**: Name of Sweave source file. See the description of the corresponding argument of Sweave.
- **syntax**: An object of class SweaveSyntax.
- **output**: Name of output file. The default is to remove extension ‘.nw’, ‘.Rnw’ or ‘.Snw’ and to add extension ‘.tex’. Any directory paths in file are also removed such that the output is created in the current working directory.
- **quiet**: If TRUE all progress messages are suppressed.
- **debug**: If TRUE, input and output of all code chunks is copied to the console.
- **stylepath**: See ‘Details’.
- **...**: named values for the options listed in ‘Supported Options’.

Details

The LaTeX file generated needs to contain the line ‘\usepackage{Sweave}', and if this is not present in the Sweave source file (possibly in a comment), it is inserted by the RweaveLatex driver. If stylepath = TRUE, a hard-coded path to the file ‘Sweave.sty’ in the R installation is set in place of Sweave. The hard-coded path makes the LaTeX file less portable, but avoids the problem of installing the current version of ‘Sweave.sty’ to some place in your TeX input path. However, TeX may not be able to process the hard-coded path if it contains spaces (as it often will under Windows) or TeX special characters.

The default for stylepath is now taken from the environment variable SWEAVE_STYLEPATH_DEFAULT, or is FALSE if it is unset or empty. If set, it should be exactly TRUE or FALSE: any other values are taken as FALSE.

As from R 2.12.0, the simplest way for frequent Sweave users to ensure that ‘Sweave.sty’ is in the TeX input path is to add ‘\_HOME/share/texmf’ as a ‘\textwidth’ tree (‘root directory’ in the parlance of the ‘MiKTeX settings’ utility).

By default, ‘Sweave.sty’ sets the width of all included graphics to: ‘\setkeys{Gin}{width=0.8\textwidth}'.

This setting affects the width size option passed to the \texttt{\includegraphics{}} directive for each plot file and in turn impacts the scaling of your plot files as they will appear in your final document. Thus, for example, you may set width=3 in your figure chunk and the generated graphics files will be set to 3 inches in width. However, the width of your graphic in your final document will be set to 0.8\textwidth and the height dimension will be scaled accordingly. Fonts and symbols will be similarly scaled in the final document.

You can adjust the default value by including the \texttt{\setkeys{Gin}{width=...}} directive in your \texttt{.Rnw} file after the \texttt{\begin{document}} directive and changing the width option value as you prefer, using standard LaTeX measurement values.

If you wish to override this default behavior entirely, you can add a \texttt{\usepackage[nogin]{Sweave}} directive in your preamble. In this case, no size/scaling options will be passed to the \texttt{\includegraphics{}} directive and the height and width options will determine both the runtime generated graphic file sizes and the size of the graphics in your final document.

\texttt{\textit{Sweave}} also supports the \texttt{[noae]} option, which suppresses the use of the \texttt{ae} package, the use of which may interfere with certain encoding and typeface selections. If you have problems in the rendering of certain character sets, try this option.

The use of fancy quotes (see \texttt{sQuote}) can cause problems when setting R output. Either set \texttt{\texttt{options(useFancyQuotes = FALSE)}} or arrange that LaTeX is aware of the encoding used (by a \texttt{\usepackage[utf8]{inputenc}} declaration: Windows users of \texttt{Sweave} from \texttt{Rgui.exe} will need to replace \texttt{utf8} by \texttt{cp1252} or similar) and ensure that typewriter fonts containing directional quotes are used.

Some LaTeX graphics drivers do not include \texttt{.png} or \texttt{.jpg} in the list of known extensions. To enable them, add something like \texttt{\DeclareGraphicsExtensions{.png,.pdf,.jpg}} to the preamble of your document or check the behavior of your graphics driver. When both pdf and png are \texttt{TRUE} both files will be produced by \texttt{Sweave}, and their order in the \texttt{\DeclareGraphicsExtensions} list determines which will be used by \texttt{pdflatex}.

\textbf{Supported Options}

\texttt{\textit{Rweave}} supports the following options for code chunks (the values in parentheses show the default values). Character string values should be quoted when passed from \texttt{Sweave} through \ldots but not when use in the header of a code chunk.

\begin{itemize}
  \item \textbf{engine:} character string ("R"). Only chunks with engine equal to "R" or "S" are processed.
  \item \textbf{echo:} logical (TRUE). Include R code in the output file?
  \item \textbf{keep.source:} logical (TRUE). When echoing, if keep.source \texttt{== TRUE} the original source is copied to the file. Otherwise, deparsed source is echoed.
  \item \textbf{eval:} logical (TRUE). If FALSE, the code chunk is not evaluated, and hence no text nor graphical output produced.
  \item \textbf{results:} character string ("verbatim"). If "verbatim", the output of R commands is included in the verbatim-like \texttt{\textbackslash Soutput} environment. If "tex", the output is taken to be already proper \LaTeX\ markup and included as is. If "hide" then all output is completely suppressed (but the code executed during the weave).
  \item \textbf{print:} logical (FALSE). If TRUE, this forces auto-printing of all expressions.
\end{itemize}
term: logical (TRUE). If TRUE, visibility of values emulates an interactive \texttt{R} session: values of assignments are not printed, values of single objects are printed. If FALSE, output comes only from explicit \texttt{print} or similar statements.

split: logical (FALSE). If TRUE, text output is written to separate files for each code chunk.

strip.white: character string ("true"). If "true", blank lines at the beginning and end of output are removed. If "all", then all blank lines are removed from the output. If "false" then blank lines are retained.

A 'blank line' is one that is empty or includes only whitespace (spaces and tabs).

Note that blank lines in a code chunk will usually produce a prompt string rather than a blank line on output.

prefix: logical (TRUE). If TRUE generated filenames of figures and output all have the common prefix given by the \texttt{prefix.string} option: otherwise only unlabelled chunks use the prefix.

prefix.string: a character string. default is the name of the source file (without extension). Note that this is used as part of filenames, so needs to be portable.

include: logical (TRUE), indicating whether input statements for text output (if split = TRUE) and \texttt{\includegraphics} statements for figures should be auto-generated. Use include = FALSE if the output should appear in a different place than the code chunk (by placing the input line manually).

fig: logical (FALSE), indicating whether the code chunk produces graphical output. Note that only one figure per code chunk can be processed this way. The labels for figure chunks are used as part of the file names, so should preferably be alphanumeric.

eps: logical (FALSE), indicating whether EPS figures should be generated. Ignored if fig = FALSE.

df: logical (TRUE), indicating whether PDF figures should be generated. Ignored if fig = FALSE.

df.version, df.encoding, df.compress: passed to \texttt{pdf} to set the version, encoding and compression (or not). Defaults taken from \texttt{pdf.options()}.

png: logical (FALSE), indicating whether PNG figures should be generated. Ignored if fig = FALSE. Only available in \texttt{R} \texttt{>=} 2.13.0.

jpeg: logical (FALSE), indicating whether JPEG figures should be generated. Ignored if fig = FALSE. Only available in \texttt{R} \texttt{>=} 2.13.0.

grdevice: character (NULL): see section 'Custom Graphics Devices'. Ignored if fig = FALSE. Only available in \texttt{R} \texttt{>=} 2.13.0.

width: numeric (6), width of figures in inches. See 'Details'.

height: numeric (6), height of figures in inches. See 'Details'.

resolution: numeric (300), resolution in pixels per inch: used for PNG and JPEG graphics. Note that the default is a fairly high value, appropriate for high-quality plots. Something like 100 is a better choice for package vignettes.

concordance: logical (FALSE). Write a concordance file to link the input line numbers to the output line numbers. This is an experimental feature; see the source code for the output format, which is subject to change in future releases.

figs.only: logical (FALSE). By default each figure chunk is run once, then re-run for each selected type of graphics. That will open a default graphics device for the first figure chunk and use that device for the first evaluation of all subsequent chunks. If this option is true, the figure chunk is run only for each selected type of graphics, for which a new graphics device is opened and then closed.
In addition, users can specify further options, either in the header of an individual code section or in a \texttt{\textbackslash{SweaveOpts}} line in the document. Prior to R 2.14.0 unknown options were taken as logical: now their type is set at first use.

**Custom Graphics Devices**

If option \texttt{grdevice} is supplied for a code chunk with both \texttt{fig} and \texttt{eval} true, the following call is made

\begin{verbatim}
get(options$grdevice, envir = .GlobalEnv)(name=, width=,
   height=, options)
\end{verbatim}

which should open a graphics device. The chunk's code is then evaluated and \texttt{dev.off} is called. Normally a function of the name given will have been defined earlier in the Sweave document, e.g.

\begin{example}
<<results=hide>>=
my.Swd <- function(name, width, height, ...)
grDevices::png(filename = paste(name, "png", sep = "."),
   width = width, height = height, res = 100,
   units = "in", type = "quartz", bg = "transparent")
@
\end{example}

Currently only one custom device can be used for each chunk, but different devices can be used for different chunks.

A replacement for \texttt{dev.off} can be provided as a function with suffix \texttt{.off}, e.g. \texttt{my.Swd.off(\)}.  

**Hook Functions**

Before each code chunk is evaluated, zero or more hook functions can be executed. If \texttt{getOption("SweaveHooks")} is set, it is taken to be a named list of hook functions. For each \textit{logical} option of a code chunk (\texttt{echo}, \texttt{print}, ...) a hook can be specified, which is executed if and only if the respective option is \texttt{TRUE}. Hooks must be named elements of the list returned by \texttt{getOption("SweaveHooks")} and be functions taking no arguments. E.g., if option \texttt{"SweaveHooks"} is defined as \texttt{list(fig = foo)}, and \texttt{foo} is a function, then it would be executed before the code in each figure chunk. This is especially useful to set defaults for the graphical parameters in a series of figure chunks.

Note that the user is free to define new Sweave logical options and associate arbitrary hooks with them. E.g., one could define a hook function for a new option called \texttt{clean} that removes all objects in the workspace. Then all code chunks specified with \texttt{clean = TRUE} would start operating on an empty workspace.

**See Also**

`Sweave User Manual`, a vignette in the \texttt{utils} package.

\texttt{Sweave}, \texttt{Rtangle}
savehistory

Load or Save or Display the Commands History

Description

Load or save or display the commands history.

Usage

loadhistory(file = ".Rhistory")
savehistory(file = ".Rhistory")

history(max.show = 25, reverse = FALSE, pattern, ...)

timestamp(stamp = date(),
  prefix = "##------ ", suffix = " ------##",
  quiet = FALSE)

Arguments

file The name of the file in which to save the history, or from which to load it. The path is relative to the current working directory.

max.show The maximum number of lines to show. Inf will give all of the currently available history.

reverse logical. If true, the lines are shown in reverse order. Note: this is not useful when there are continuation lines.

pattern A character string to be matched against the lines of the history

... Arguments to be passed to grep when doing the matching.

stamp A value or vector of values to be written into the history.

prefix A prefix to apply to each line.

suffix A suffix to apply to each line.

quiet If TRUE, suppress printing timestamp to the console.

Details

There are several history mechanisms available for the different R consoles, which work in similar but not identical ways. Other uses of R, in particular embedded uses, may have no history. The functions described here work under the readline command-line interface but may not otherwise (for example, in batch use or in an embedded application).

The readline history mechanism is controlled by two environment variables: R_HISTSIZE controls the number of lines that are saved (default 512), and R_HISTFILE sets the filename used for the loading/saving of history if requested at the beginning/end of a session (but not the default for these functions). There is no limit on the number of lines of history retained during a session, so setting R_HISTSIZE to a large value has no penalty unless a large file is actually generated.
These variables are read at the time of saving, so can be altered within a session by the use of \texttt{Sys.setenv}.

Note that \texttt{readline} history library saves files with permission 0600, that is with read/write permission for the user and not even read permission for any other account. \texttt{history} shows only unique matching lines if pattern is supplied.

The \texttt{timestamp} function writes a timestamp (or other message) into the history and echos it to the console. On platforms that do not support a history mechanism (where the mechanism does not support timestamps) only the console message is printed.

Note

If you want to save the history at the end of (almost) every interactive session (even those in which you do not save the workspace), you can put a call to \texttt{savehistory()} in \texttt{.Last}. See the examples.

Examples

```r
## Not run:
## save the history in the home directory: note that it is not
## (by default) read from there.
.Last <- function()
  if(interactive()) try(savehistory("~/\.Rhistory"))

## End(Not run)
```

---

select.list \hspace{1cm} \textit{Select Items from a List}

Description

Select item(s) from a character vector.

Usage

```r
select.list(choices, preselect = NULL, multiple = FALSE,
            title = NULL, graphics = getOption("menu.graphics"))
```

Arguments

- \texttt{choices}: a character vector of items.
- \texttt{preselect}: a character vector, or NULL. If non-null and if the string(s) appear in the list, the item(s) are selected initially.
- \texttt{multiple}: logical: can more than one item be selected?
- \texttt{title}: optional character string for window title, or NULL for no title.
- \texttt{graphics}: logical: should a graphical widget be used?
Details

The normal default is `graphics = TRUE`. Under the OS X GUI this brings up a modal dialog box with a (scrollable) list of items, which can be selected by the mouse. On other Unix-like platforms it will use a Tcl/Tk listbox widget if possible.

If `graphics` is `FALSE` or no graphical widget is available it displays a text list from which the user can choose by number(s). The `multiple = FALSE` case uses `menu`. Preselection is only supported for `multiple = TRUE`, where it is indicated by a "+" preceding the item.

It is an error to use `select.list` in a non-interactive session.

Value

A character vector of selected items. If `multiple` is `false` and no item was selected (or Cancel was used), "" is returned. If `multiple` is `true` and no item was selected (or Cancel was used) then a character vector of length 0 is returned.

See Also

`menu`, `tk_select.list` for a graphical version using Tcl/Tk.

Examples

```r
## Not run:
select.list(sort(.packages(all.available = TRUE)))

## End(Not run)
```

---

### sessionInfo

#### Collect Information About the Current R Session

**Description**

Print version information about R and attached or loaded packages.

**Usage**

```r
sessionInfo(package = NULL)
## S3 method for class 'sessionInfo'
print(x, locale = TRUE, ...)
## S3 method for class 'sessionInfo'
toLatex(object, locale = TRUE, ...)
```
sessionInfo

Arguments

package: a character vector naming installed packages, or NULL (the default) meaning all attached packages.

x: an object of class "sessionInfo".

object: an object of class "sessionInfo".

locale: show locale information?

...: currently not used.

Value

An object of class "sessionInfo", which has a print method. This is a list with components

R.version: a list, the result of calling R.Version().

platform: a character string describing the platform. For recent versions where sub-architectures are in use this is of the form "platform/sub-arch (nn-bit)".

locale: a character string, the result of calling Sys.getlocale().

basePkgs: a character vector of base packages which are attached.

otherPkgs: (not always present): a character vector of other attached packages.

loadedOnly: (not always present): a named list of the results of calling packageDescription on packages whose namespaces are loaded but are not attached.

Note

The information on 'loaded' packages and namespaces is the current version installed at the location the package was loaded from: it can be wrong if another process has been changing packages during the session.

See Also

R.version

Examples

sessionInfo()

toLatex(sessionInfo(), locale = FALSE)
setRepositories

Select Package Repositories

Description

Interact with the user to choose the package repositories to be used.

Usage

```r
setRepositories(graphics = getOption("menu.graphics"),
    ind = NULL, addURLs = character())
```

Arguments

- `graphics` Logical. If true, use a graphical list: on Windows or OS X GUI use a list box, and on a Unix-alike if `tcltk` and an X server are available, use Tk widget. Otherwise use a text menu.
- `ind` NULL or a vector of integer indices, which have the same effect as if they were entered at the prompt for `graphics = FALSE`.
- `addURLs` A character vector of additional URLs: it is often helpful to use a named vector.

Details

The default list of known repositories is stored in the file `R_HOME/etc/repositories`. That file can be edited for a site, or a user can have a personal copy in `HOME/.R/repositories` which will take precedence.

A Bioconductor mirror can be selected by setting `options("BioC_mirror")`: the default value is "http://www.bioconductor.org". The items that are preselected are those that are currently in `options("repos")` plus those marked as default in the list of known repositories.

The list of repositories offered depends on the setting of option "pkgType" as some repositories only offer a subset of types (e.g. only source packages or not OS X binary packages). Further, for binary packages some repositories (notably R-Forge) only offer packages for the current or recent versions of R.

Repository 'CRAN' is treated specially: the value is taken from the current setting of `getOption("repos")` if this has an element "CRAN": this ensures mirror selection is sticky.

This function requires the R session to be interactive unless `ind` is supplied.

Value

This function is invoked mainly for its side effect of updating `options("repos")`. It returns (invisibly) the previous repos options setting (as a list with component repos) or NULL if no changes were applied.
SHLIB

Build Shared Object/DLL for Dynamic Loading

Description

Compile the given source files and then link all specified object files into a shared object aka DLL which can be loaded into R using dyn.load or library.dynam.

Usage

R CMD SHLIB [options] [-o dllname] files

Arguments

files

da list specifying the object files to be included in the shared object/DLL. You can also include the name of source files (for which the object files are automagically made from their sources) and library linking commands.

dllname

the full name of the shared object/DLL to be built, including the extension (typically ‘.so’ on Unix systems, and ‘.dll’ on Windows). If not given, the basename of the object is taken from the basename of the first file.

options

Further options to control the processing. Use R CMD SHLIB --help for a current list.

Details

R CMD SHLIB is the mechanism used by INSTALL to compile source code in packages. It will generate suitable compilation commands for C, C++, ObjC(++) and Fortran sources: Fortran 90/95 sources can also be used but it may not be possible to mix these with other languages (on most platforms it is possible to mix with C, but mixing with C++ rarely works).
Please consult section ‘Creating shared objects’ in the manual ‘Writing R Extensions’ for how to customize it (for example to add cpp flags and to add libraries to the link step) and for details of some of its quirks.

Items in files with extensions ‘.c’, ‘.cpp’, ‘.cc’, ‘.C’, ‘.f’, ‘.f90’, ‘.f95’, ‘.m’ (ObjC), ‘.M’ and ‘.mm’ (ObjC++) are regarded as source files, and those with extension ‘.o’ as object files. All other items are passed to the linker.

Option ‘-n’ (also known as ‘--dry-run’) will show the commands that would be run without actually executing them.

### Note

Some binary distributions of R have SHLIB in a separate bundle, e.g., an R-devel RPM.

### See Also

COMPILE, dyn.load, library.dynam.

The section on “Customizing compilation” in the “R Administration and Installation” manual (see the ‘doc/manual’ subdirectory of the R source tree).

The ‘R Installation and Administration’ and ‘Writing R Extensions’ manuals.

### Examples

```r
## Not run:
R CMD SHLIB -o mylib.so a.f b.f -L/opt/acml3.5./gnu64/lib -lacml

## End(Not run)
```

---

sourceutils  

**Source Reference Utilities**

---

**Description**

These functions extract information from source references.

**Usage**

```r
getSrcFilename(x, full.names = FALSE, unique = TRUE)  
getSrcDirectory(x, unique = TRUE)  
getSrcref(x)  
getSrcLocation(x, which = c("line", "column", "byte", "parse"),  
                 first = TRUE)
```
Arguments

- **x**: An object (typically a function) containing source references.
- **full.names**: Whether to include the full path in the filename result.
- **unique**: Whether to list only unique filenames/directories.
- **which**: Which part of a source reference to extract.
- **first**: Whether to show the first (or last) location of the object.

Details

Each statement of a function will have its own source reference if the "keep.source" option is TRUE. These functions retrieve all of them.

The components are as follows:

- **line**: The line number where the object starts or ends.
- **column**: The column number where the object starts or ends.
- **byte**: As for "column", but counting bytes, which may differ in case of multibyte characters.
- **parse**: As for "line", but this ignores #line directives.

Value

**getSrcFilename** and **getSrcDirectory** return character vectors holding the filename/directory.

**getSrcref** returns a list of "srcref" objects or NULL if there are none.

**getSrcLocation** returns an integer vector of the requested type of locations.

See Also

- `srcref`, `getParseData`

Examples

```r
fn <- function(x) {
  x + 1 # A comment, kept as part of the source
}

# Show the temporary file directory
# where the example was saved
getSrcDirectory(fn)
getSrcLocation(fn, "line")
```
**Description**

Stacking vectors concatenates multiple vectors into a single vector along with a factor indicating where each observation originated. Unstacking reverses this operation.

**Usage**

```r
stack(x, ...)  # Default S3 method:
stack(x, ...)  # S3 method for class 'data.frame'

unstack(x, ...)  # Default S3 method:
unstack(x, form, ...)  # S3 method for class 'data.frame'
```

**Arguments**

- `x` a list or data frame to be stacked or unstacked.
- `select` an expression, indicating which variable(s) to select from a data frame.
- `form` a two-sided formula whose left side evaluates to the vector to be unstacked and whose right side evaluates to the indicator of the groups to create. Defaults to `formula(x)` in the data frame method for `unstack`.
- `...` further arguments passed to or from other methods.

**Details**

The `stack` function is used to transform data available as separate columns in a data frame or list into a single column that can be used in an analysis of variance model or other linear model. The `unstack` function reverses this operation.

Note that `stack` applies to vectors (as determined by `is.vector`): non-vector columns (e.g., factors) will be ignored (with a warning as from R 2.15.0). Where vectors of different types are selected they are concatenated by `unlist` whose help page explains how the type of the result is chosen.

These functions are generic: the supplied methods handle data frames and objects coercible to lists by `as.list`. 
Value

unstack produces a list of columns according to the formula form. If all the columns have the same length, the resulting list is coerced to a data frame.

stack produces a data frame with two columns:

values the result of concatenating the selected vectors in x.
ind a factor indicating from which vector in x the observation originated.

Examples

require(stats)
formula(PlantGrowth) # check the default formula
pg <- unstack(PlantGrowth) # unstack according to this formula
pg
stack(pg) # now it back together
stack(pg, select = -ctrl) # omitting one vector

---

str

Compactly Display the Structure of an Arbitrary R Object

Description

Compactly display the internal structure of an R object, a diagnostic function and an alternative to summary (and to some extent, dput). Ideally, only one line for each ‘basic’ structure is displayed. It is especially well suited to compactly display the (abbreviated) contents of (possibly nested) lists. The idea is to give reasonable output for any R object. It calls args for (non-primitive) function objects.

strOptions() is a convenience function for setting options(str = .), see the examples.

Usage

str(object, ...)

## S3 method for class 'data.frame'
str(object, ...)

## Default S3 method:
str(object, max.level = NA,
    vec.len = strO$vec.len, digits.d = strO$digits.d,
nchar.max = 128, give.attr = TRUE,
give.head = TRUE, give.length = give.head,
width = getOption("width"), nest.lev = 0,
indent.str = paste(rep.int(" ", max(0, nest.lev + 1)),
collapse = "."),
comp.str = "$ ", no.list = FALSE, envir = baseenv(),
strict.width = strO$strict.width,
formatNum = strO$formatNum, list.len = 99, ...)

strOptions(strict.width = "no", digits.d = 3, vec.len = 4,
formatNum = function(x, ...)
  format(x, trim = TRUE, drop0trailing = TRUE, ...))

Arguments

object any R object about which you want to have some information.
max.level maximal level of nesting which is applied for displaying nested structures, e.g.,
a list containing sub lists. Default NA: Display all nesting levels.
vec.len numeric (>= 0) indicating how many ‘first few’ elements are displayed of each
vector. The number is multiplied by different factors (from .5 to 3) depending
on the kind of vector. Defaults to the vec.len component of option "str" (see
options) which defaults to 4.
digits.d number of digits for numerical components (as for print). Defaults to the
digits.d component of option "str" which defaults to 3.
nchar.max maximal number of characters to show for character strings. Longer strings
are truncated, see longch example below.
give.attr logical; if TRUE (default), show attributes as sub structures.
give.length logical; if TRUE (default), indicate length (as [1:...]).
give.head logical; if TRUE (default), give (possibly abbreviated) mode/class and length (as
<type>[1:...]).
width the page width to be used. The default is the currently active
options("width"); note that this has only a weak effect, unless strict.width
is not "no".
nest.lev current nesting level in the recursive calls to str.
indent.str the indentation string to use.
comp.str string to be used for separating list components.
no.list logical; if true, no ‘list of...’ nor the class are printed.
envir the environment to be used for promise (see delayedAssign) objects only.
strict.width string indicating if the width argument’s specification should be followed
strictly, one of the values c("no", "cut", "wrap"). Defaults to the
strict.width component of option "str" (see options) which defaults to
"no" for back compatibility reasons; "wrap" uses strwrap(*, width = width)
whereas "cut" cuts directly to width. Note that a small vec.length may be
better than setting strict.width = "wrap".
formatNum  a function such as \texttt{format} for formatting numeric vectors. It defaults to the formatNum component of option "str", see “Usage” of \texttt{strOptions()} above, which is almost back compatible to \texttt{R} \(\leq 2.7.x\), however, using \texttt{formatC} may be slightly better.

list.len numeric; maximum number of list elements to display within a level.

... potential further arguments (required for Method/Generic reasons).

Value 

\texttt{str} does not return anything, for efficiency reasons. The obvious side effect is output to the terminal.

Author(s) 

Martin Maechler \texttt{<maechler@stat.math.ethz.ch>} since 1990.

See Also 

\texttt{ls.str} for listing objects with their structure; \texttt{summary}, \texttt{args}.

Examples 

\begin{verbatim}
require(stats); require(grDevices); require(graphics)
## The following examples show some of 'str' capabilities
str(1:12)
str(ls)
str(args) # more useful than args(args) !
str(freeny)
str(str)
str(.Machine, digits.d = 20) # extra digits for identification of binary numbers
str(lsfit(1:9, 1:9))

str(lsfit(1:9, 1:9), width = 60, strict.width = "cut")
str(lsfit(1:9, 1:9), width = 60, strict.width = "wrap")
op <- options(); str(op) # save first;
    # otherwise internal options() is used.
need.dev <-
    !exists(".Device") || is.null(.Device) || .Device == "null device"
{ if(need.dev) postscript()
    str(par())
    if(need.dev) graphics.off()
}
ch <- letters[1:12]; is.na(ch) <- 3:5
str(ch) # character NA’s

str(list(a = "A", L = as.list(1:100)), list.len = 9)
nchar(longch <- paste(rep(letters,100), collapse = ""))
str(longch)
str(longch, nchar.max = 52)

str(longch, strict.width = "wrap")
\end{verbatim}
## Settings for narrow transcript:
`op <- options(width = 60, str = strOptions(strict.width = "wrap"))`

str(lsfit(1:9,1:9))
str(options())
`## reset to previous:
options(op)`

str(quote( { A+B; list(C, D) } ))

## S4 classes:
require(stats4)
x <- 1:10; y <- c(26, 17, 13, 12, 5, 9, 8, 5, 4, 8)
ll <- function(ymax = 15, xh = 6)
    -sum(dpois(y, lambda=ymax/(1+x/xh), log=TRUE))
fit <- mle(ll)
str(fit)

---

**summaryRprof**

**Summarise Output of R Sampling Profiler**

### Description
Summarise the output of the `Rprof` function to show the amount of time used by different R functions.

### Usage

```r
summaryRprof(filename = "Rprof.out", chunksize = 5000,
    memory = c("none", "both", "tseries", "stats"),
    lines = c("hide", "show", "both"),
    index = 2, diff = TRUE, exclude = NULL,
    basenames = 1)
```

### Arguments
- **filename**: Name of a file produced by `Rprof()`.
- **chunksize**: Number of lines to read at a time.
- **memory**: Summaries for memory information. See ‘Memory profiling’ below.
- **lines**: Summaries for line information. See ‘Line profiling’ below.
- **index**: How to summarize the stack trace for memory information. See ‘Details’ below.
- **diff**: If TRUE memory summaries use change in memory rather than current memory.
summaryRprof

exclude
basenames

Functions to exclude when summarizing the stack trace for memory summaries.
Number of components of the path to filenames to display.

Details
This function provides the analysis code for Rprof files used by R CMD Rprof.
As the profiling output file could be larger than available memory, it is read in blocks of chunksize
lines. Increasing chunksize will make the function run faster if sufficient memory is available.

Value
If memory = "none" and lines = "hide", a list with components
by.self A data frame of timings sorted by ‘self’ time.
by.total A data frame of timings sorted by ‘total’ time.
sample.interval The sampling interval.
sampling.time Total time of profiling run.

The first two components have columns ‘self.time’, ‘self.pct’, ‘total.time’ and ‘total.pct’,
the times in seconds and percentages of the total time spent executing code in that function and code
in that function or called from that function, respectively.
If lines = "show", an additional component is added to the list:
by.line A data frame of timings sorted by source location.
If memory = "both" the same list but with memory consumption in Mb in addition to the timings.
If memory = "tseries" a data frame giving memory statistics over time.
If memory = "stats" a by object giving memory statistics by function.
Prior to R 2.15.3 an error was thrown if no events were recorded: now zero-row data frames are
returned.

Memory profiling
Options other than memory = "none" apply only to files produced by
Rprof(memory.profiling = TRUE).
When called with memory.profiling = TRUE, the profiler writes information on three aspects of
memory use: vector memory in small blocks on the R heap, vector memory in large blocks (from
malloc), memory in nodes on the R heap. It also records the number of calls to the internal function
duplicate in the time interval. duplicate is called by C code when arguments need to be copied.
Note that the profiler does not track which function actually allocated the memory.
With memory = "both" the change in total memory (truncated at zero) is reported in addition to
timing data.
With memory = "tseries" or memory = "stats" the index argument specifies how to summarize
the stack trace. A positive number specifies that many calls from the bottom of the stack; a nega-
tive number specifies the number of calls from the top of the stack. With memory = "tseries"
the index is used to construct labels and may be a vector to give multiple sets of labels. With
memory = "stats" the index must be a single number and specifies how to aggregate the data to the maximum and average of the memory statistics. With both memory = "tseries" and memory = "stats" the argument diff = TRUE asks for summaries of the increase in memory use over the sampling interval and diff = FALSE asks for the memory use at the end of the interval.

**Line profiling**

If the code being run has source reference information retained (via keep.source = TRUE in source or KeepSource = TRUE in a package ‘DESCRIPTION’ file or some other way), then information about the origin of lines is recorded during profiling. By default this is not displayed, but the lines parameter can enable the display.

If lines = "show", line locations will be used in preference to the usual function name information, and the results will be displayed ordered by location in addition to the other orderings.

If lines = "both", line locations will be mixed with function names in a combined display.

**See Also**

The chapter on “Tidying and profiling R code” in “Writing R Extensions” (see the ‘doc/manual’ subdirectory of the R source tree).

Rprof

tracemem traces copying of an object via the C function duplicate.

Rprofmem is a non-sampling memory-use profiler.

http://developer.r-project.org/memory-profiling.html

**Examples**

```r
## Not run:
## Rprof() is not available on all platforms
Rprof(tmp <- tempfile())
example(glm)
Rprof()
summaryRprof(tmp)
unlink(tmp)
## End(Not run)
```

---

**Sweave**

**Automatic Generation of Reports**

**Description**

Sweave provides a flexible framework for mixing text and R/S code for automatic report generation. The basic idea is to replace the code with its output, such that the final document only contains the text and the output of the statistical analysis: however, the source code can also be included.
Usage

Sweave(file, driver = RweaveLatex(),
    syntax = getOption("SweaveSyntax"), encoding = ",", ...)

Stangle(file, driver = Rtangle(),
    syntax = getOption("SweaveSyntax"), encoding = ",", ...)

Arguments

file Path to Sweave source file. Note that this can be supplied without the extension, but the function will only proceed if there is exactly one Sweave file in the directory whose basename matches file.
driver The actual workhorse, see ‘Details’.
syntax NULL or an object of class SweaveSyntax or a character string with its name. See the section ‘Syntax Definition’.
encoding The default encoding to assume for file.
... Further arguments passed to the driver’s setup function: see section ‘Drivers’, RweaveLatex and Rtangle.

Details

Automatic generation of reports by mixing word processing markup (like latex) and S code. The S code gets replaced by its output (text or graphs) in the final markup file. This allows a report to be re-generated if the input data change and documents the code to reproduce the analysis in the same file that also produces the report.

Sweave combines the documentation and code chunks together (or their output) into a single document. Stangle extracts only the code from the Sweave file creating an S source file that can be run using source. (Code inside \Sexpr{} statements is ignored by Stangle.)

Stangle is just a wrapper to Sweave specifying a different default driver. Alternative drivers can be used: the CRAN package cacheSweave and the Bioconductor package weaver both provide drivers based on the default driver RweaveLatex which incorporate ideas of caching the results of computations on code chunks.

Environment variable SWEAVE_OPTIONS can be used to override the initial options set by the driver: it should be a comma-separated set of key=value items, as would be used in a ‘\SweaveOpts’ statement in a document.

Non-ASCII source files must contain a line of the form

\usepackage[foo]{inputenc}

(where ‘foo’ is typically ‘latin1’, ‘latin2’, ‘utf8’ or ‘cp1252’ or ‘cp1250’) or they will give an error. Re-encoding can be turned off completely with argument encoding = "bytes".
Syntax Definition

Sweave allows a flexible syntax framework for marking documentation and text chunks. The default is a noweb-style syntax, as alternative a latex-style syntax can be used. (See the user manual for further details.)

If `syntax = NULL` (the default) then the available syntax objects are consulted in turn, and selected if their extension component matches (as a regexp) the file name. Objects `SweaveSyntaxNoweb` (with extension = "\.[rsRS]nw$") and `SweaveSyntaxLatex` (with extension = "\.[rsRS]tex$") are supplied, but users or packages can supply others with names matching the pattern `SweaveSyntax.*`.

Packages `cacheSweave`, `weaver` (Bioconductor) and `SweaveListingUtils`.

Further Sweave drivers are in, for example, packages `R2HTML`, `ascii`, `odfWeave` and `pgfSweave`.

Examples

```r

testfile <- system.file("Sweave", "Sweave-test-1.Rnw", package = "utils")

## enforce par(ask = FALSE)
options(device.ask.default = FALSE)

## create a LaTeX file
Sweave(testfile)

## This can be compiled to PDF by
## tools::texi2pdf("Sweave-test-1.tex")
## or outside R by
## R CMD texi2pdf Sweave-test-1.tex
## which sets the appropriate TEXINPUTS path.

## create an R source file from the code chunks
Stangle(testfile)
## which can be sourced, e.g.
source("Sweave-test-1.R")
```
SweaveSyntConv

Convert Sweave Syntax

Description

This function converts the syntax of files in Sweave format to another Sweave syntax definition.

Usage

SweaveSyntConv(file, syntax, output = NULL)

Arguments

file Name of Sweave source file.
syntax An object of class SweaveSyntax or a character string with its name giving the target syntax to which the file is converted.
output Name of output file, default is to remove the extension from the input file and to add the default extension of the target syntax. Any directory names in file are also removed such that the output is created in the current working directory.

Examples

testfile <- system.file("Sweave", "Sweave-test-1.Rnw", package = "utils")

## convert the file to latex syntax
SweaveSyntConv(testfile, SweaveSyntaxLatex)

## and run it through Sweave
Sweave("Sweave-test-1.Stex")
Create a Tar Archive

Description

Create a tar archive.

Usage

```r
tar(tarfile, files = NULL,
    compression = c("none", "gzip", "bzip2", "xz"),
    compression_level = 6, tar = Sys.getenv("tar"),
    extra_flags = "")
```

Arguments

- **tarfile**: The pathname of the tar file: tilde expansion (see `path.expand`) will be performed. Alternatively, a connection that can be used for binary writes.
- **files**: A character vector of filepaths to be archived: the default is to archive all files under the current directory.
- **compression**: character string giving the type of compression to be used (default none). Can be abbreviated.
- **compression_level**: integer: the level of compression. Only used for the internal method.
- **tar**: character string: the path to the command to be used. If the command itself contains spaces it needs to be quoted (e.g. by `shQuote`) – but argument `tar` can also contain flags separated from the command by spaces.
- **extra_flags**: any extra flags for an external tar.

Details

This is either a wrapper for a `tar` command or uses an internal implementation in R. The latter is used if `tarfile` is a connection or if the argument `tar` is "internal" or "" (the ‘factory-fresh’ default). Note that whereas Unix-alike versions of R set the environment variable `TAR`, its value is not the default for this function.

Argument `extra_flags` is passed to an external tar and so is platform-dependent. Possibly useful values include ‘-h’ (follow symbolic links, also ‘-L’ on some platforms), ‘--acls’, ‘--exclude-backups’, ‘--exclude-vcs’ (and similar) and on Windows ‘--force-local’ (so drives can be included in filepaths: however, this is the default for the Rtools `tar`). For GNU tar, ‘--format=ustar’ forces a more portable format (the current default in version 1.26 is ‘--format=gnu’, but the manual says the intention is to change to ‘--format=pax’ which GNU incorrectly calls ‘POSIX’ – it was never part of the POSIX standard for tar). For libarchive tar, ‘--format=ustar’ is more portable than the default.

Value

The return code from `system` or 0 for the internal version, invisibly.
Portability

The ‘tar’ format no longer has an agreed standard! ‘Unix Standard Tar’ was part of POSIX 1003.1:1998 but has been removed in favour of pax, and in any case many common implementations diverged from the former standard. Most R platforms use a version of GNU tar (including Rtools on Windows, but the behaviour seems to be changed with each version), Mac OS >= 10.6 and FreeBSD use bsdtar from the ‘libarchive’ project, and commercial Unixes will have their own versions.

Known problems arise from

- The handling of file paths of more than 100 bytes. These were unsupported in early versions of tar, and supported in one way by POSIX tar and in another by GNU tar and yet another by the POSIX pax command which recenttar programs often support. The internal implementation warns on paths of more than 100 bytes, uses the ‘ustar’ way from the 1998 POSIX standard which supports up to 256 bytes (depending on the path: in particular the final component is limited to 100 bytes) if possible, or the GNU way (which is widely supported). Most formats do not record the encoding of file paths.
- (File) links. tar was developed on an OS that used hard links, and physical files that were referred to more than once in the list of files to be included were included only once, the remaining instances being added as links. Later a means to include symbolic links was added. The internal implementation supports symbolic links (on OSes that support them), only. Of course, the question arises as to how links should be unpacked on OSes that do not support them: for regular files, at least, file copies can be used.
  
  Names of links in the ‘ustar’ format are restricted to 100 bytes. There is an GNU extension for arbitrarily long link names, but bsdtar does not read. As from R 2.15.3 the internal method uses the GNU extension, with a warning.
- Header fields, in particular the padding to be used when fields are not full or not used. POSIX did define the correct behaviour but commonly used implementations did (and still do) not comply.
- File sizes. The ‘ustar’ format is restricted to 8GB per (uncompressed) file.

For portability, avoid file paths of more than 100 bytes and all links (especially hard links and symbolic links to directories).

The internal implementation writes only the blocks of 512 bytes required (including trailing blocks of nuls), unlike GNU tar which by default pads with ‘nu1’ to a multiple of 20 blocks (10KB). Implementations which pad differ on whether the block padding should occur before or after compression (or both): padding was designed for improved performance on physical tape drives.

2001

Converting R Objects to BibTeX or LaTeX

Description
These methods convert R objects to character vectors with BibTeX or LaTeX markup.
Usage
toBibtex(object, ...)
toLatex(object, ...)
## S3 method for class ’Bibtex’
print(x, prefix = "", ...)
## S3 method for class ’Latex’
print(x, prefix = "", ...)
Arguments
object

object of a class for which a toBibtex or toLatex method exists.

x

object of class "Bibtex" or "Latex".

prefix

a character string which is printed at the beginning of each line, mostly used to
insert whitespace for indentation.

...

in the print methods, passed to writeLines.

Details
Objects of class "Bibtex" or "Latex" are simply character vectors where each element holds one
line of the corresponding BibTeX or LaTeX file.

citEntry and sessionInfo for examples

txtProgressBar

Text Progress Bar

Description
Text progress bar in the R console.


Usage

txtProgressBar(min = 0, max = 1, initial = 0, char = "=",
              width = NA, title, label, style = 1, file = "")

getTxtProgressBar(pb)
setTxtProgressBar(pb, value, title = NULL, label = NULL)
## S3 method for class 'txtProgressBar'
close(con, ...)

Arguments

min, max (finite) numeric values for the extremes of the progress bar. Must have
min < max.

initial, value initial or new value for the progress bar. See ‘Details’ for what happens with
invalid values.

char the character (or character string) to form the progress bar.

width the width of the progress bar, as a multiple of the width of char. If NA, the
default, the number of characters is that which fits into getOption("width").

style the ‘style’ of the bar – see ‘Details’.

file an open connection object or "" which indicates the console: stderr() might
be useful here.

pb, con an object of class "txtProgressBar".

title, label ignored, for compatibility with other progress bars.

... for consistency with the generic.

Details

txtProgressBar will display a progress bar on the R console (or a connection) via a text represen-
tation.

setTxtProgressBar will update the value. Missing (NA) and out-of-range values of value will be
(silently) ignored. (Such values of initial cause the progress bar not to be displayed until a valid
value is set.)

The progress bar should be closed when finished with: this outputs the final newline character.

style = 1 and style = 2 just shows a line of char. They differ in that style = 2 redraws the
line each time, which is useful if other code might be writing to the R console. style = 3 marks
the end of the range by | and gives a percentage to the right of the bar.

Value

For txtProgressBar an object of class "txtProgressBar".

For getTxtProgressBar and setTxtProgressBar, a length-one numeric vector giving the previ-
ous value (invisibly for setTxtProgressBar).
**Note**

Using style 2 or 3 or reducing the value with `style = 1` uses `` to return to the left margin – the interpretation of carriage return is up to the terminal or console in which R is running, and this is liable to produce ugly output on a connection other than a terminal, including when `stdout()` is redirected to a file.

**See Also**

`tkProgressBar`. Windows versions of R also have `winProgressBar`.

**Examples**

```r
# slow
testit <- function(x = sort(runif(20)), ...)
{
  pb <- txtProgressBar(...)
  for(i in c(0, x, 1)) {Sys.sleep(0.5); setTxtProgressBar(pb, i)}
  Sys.sleep(1)
  close(pb)
}
testit()
testit(runif(10))
testit(style = 3)
```

---

### type.convert

**Type Conversion on Character Variables**

**Description**

Convert a character vector to logical, integer, numeric, complex or factor as appropriate.

**Usage**

```r
type.convert(x, na.strings = "NA", as.is = FALSE, dec = ".")
```

**Arguments**

- `x`: a character vector.
- `na.strings`: a vector of strings which are to be interpreted as `NA` values. Blank fields are also considered to be missing values in logical, integer, numeric or complex vectors.
- `as.is`: logical. See ‘Details’.
- `dec`: the character to be assumed for decimal points.
Details

This is principally a helper function for read.table. Given a character vector, it attempts to convert it to logical, integer, numeric or complex, and failing that converts it to factor unless as.is = TRUE. The first type that can accept all the non-missing values is chosen (numeric and complex return values will represented approximately, of course).

Vectors which are entirely missing values are converted to logical, since NA is primarily logical.

Vectors containing just F, T, FALSE, TRUE and values from na.strings are converted to logical. Vectors containing optional whitespace followed by decimal constants representable as R integers or values from na.strings are converted to integer. Other vectors containing optional whitespace followed by other decimal or hexadecimal constants (see NumericConstants), or NaN, Inf or infinity (ignoring case) or values from na.strings are converted to numeric.

Since this is a helper function, the caller should always pass an appropriate value of as.is.

Value

A vector of the selected class, or a factor.

See Also

read.table

Description

Extract files from or list a tar archive.

Usage

untar(tarfile, files = NULL, list = FALSE, exdir = ".",
       compressed = NA, extras = NULL, verbose = FALSE,
       restore_times = TRUE, tar = Sys.getenv("TAR"))

Arguments

tarfile  The pathname of the tar file: tilde expansion (see path.expand) will be performed. Alternatively, a connection that can be used for binary reads.

files    A character vector of recorded filepaths to be extracted: the default is to extract all files.

list     If TRUE, list the files (the equivalent of tar -tf). Otherwise extract the files (the equivalent of tar -xf).

exdir    The directory to extract files to (the equivalent of tar -C). It will be created if necessary.
compressed logical or character. Values "gzip", "bzip2" and "xz" select that form of compression (and may be abbreviated to the first letter). TRUE indicates gzip compression, FALSE no known compression (but an external tar command may detect compression automatically), and NA (the default) that the type is inferred from the file header.

extras NULL or a character string: further command-line flags such as ‘-p’ to be passed to an external tar program.

verbose logical: if true echo the command used.

restore_times logical. If true (default) restore file modification times. If false, the equivalent of the ‘-m’ flag. Times in tarballs are supposed to be in UTC, but tarballs are submitted to CRAN with times in the future or far past: this argument allows such times to be discarded.

tar character string: the path to the command to be used. If the command itself contains spaces it needs to be quoted – but tar can also contain flags separated from the command by spaces.

Details

This is either a wrapper for a tar command or for an internal implementation written in R. The latter is used if tarfile is a connection or if the argument tar is "internal" or "" (except on Windows, when tar.exe is tried first).

What options are supported will depend on the tar used. Modern GNU flavours of tar will support compressed archives, and since 1.15 are able to detect the type of compression automatically: version 1.20 added support for lzma and version 1.22 for xz compression using LZMA2. Mac OS 10.6 and later (and FreeBSD and some other OSES) have a tar also known as bsdtar from the 'libarchive' project used by Mac OS 10.6 and later which can also detect gzip and bzip2 compression automatically. For other flavours of tar, environment variable R_GZICMD gives the command to decompress gzip and compress files, and R_BZICMD for bzip2 files.

Arguments compressed, extras and verbose are only used when an external tar is used.

The internal implementation restores symbolic links as links on a Unix-alike, and as file copies on Windows (which works only for existing files, not for directories), and hard links as links. If the linking operation fails (as it may on a FAT file system), a file copy is tried. Since it uses gzfile to read a file it can handle files compressed by any of the methods that function can handle: at least compress, gzip, bzip2 and xz compression, and some types of lzma compression. It does not guard against restoring absolute file paths, as some tar implementations do. It will create the parent directories for directories or files in the archive if necessary. It handles the standard (USTAR/POSIX), GNU and pax ways of handling file paths of more than 100 bytes, and the GNU way of handling link targets of more than 100 bytes.

You may see warnings from the internal implementation such as

 unsupported entry type 'x'

This often indicates an invalid archive: entry types "A-Z" are allowed as extensions, but other types are reserved. The only thing you can do with such an archive is to find a tar program that handles it, and look carefully at the resulting files. There may also be the warning

 using pax extended headers
This is indicates that additional information may have been discarded, such as ACLs, encodings .... and long path and link names are only used as from R 2.15.3.

The standards only support ASCII filenames (indeed, only alphanumeric plus period, underscore and hyphen). untar makes no attempt to map filenames to those acceptable on the current system, and treats the filenames in the archive as applicable without any re-encoding in the current locale.

Value
If list = TRUE, a character vector of (relative or absolute) paths of files contained in the tar archive. Otherwise the return code from system, invisibly.

See Also
tar, unzip.

---

unzip

Extract or List Zip Archives

Description
Extract files from or list a zip archive.

Usage
unzip(zipfile, files = NULL, list = FALSE, overwrite = TRUE,
      junkpaths = FALSE, exdir = ".", unzip = "internal",
      setTimes = FALSE)

Arguments

zipfile The pathname of the zip file: tilde expansion (see path.expand) will be performed.
files A character vector of recorded filepaths to be extracted: the default is to extract all files.
list If TRUE, list the files and extract none. The equivalent of unzip -l.
overwrite If TRUE, overwrite existing files, otherwise ignore such files. The equivalent of unzip -o.
junkpaths If TRUE, use only the basename of the stored filepath when extracting. The equivalent of unzip -j.
exdir The directory to extract files to (the equivalent of unzip -d). It will be created if necessary.
unzip The method to be used. An alternative is to use getOption("unzip"), which on a Unix-alike may be set to the path to a unzip program.
setTimes logical. For the internal method only, should the file time be set based on the times in the zip file? (NB: this applies to files, not to directories.)
Value

If list = TRUE, a data frame with columns Name (character) Length (the size of the uncompressed file, numeric) and Date (of class "POSIXct").

Otherwise for the "internal" method, a character vector of the filepaths extracted to, invisibly.

Note

The default internal method is a minimal implementation, principally designed for Windows’ users to be able to unpack Windows binary packages without external software. It does not (for example) support Unicode filenames as introduced in zip 3.0: for that use unzip = "unzip" with unzip 6.00 or later. (As from R 2.14.0 it does have support for files of more than 4GB and bzip2 compression.)

If unzip specifies a program, the format of the dates listed with list = TRUE is unknown (on Windows it can even depend on the current locale) and the return values could be NA or expressed in the wrong timezone or misinterpreted (the latter being far less likely as from unzip 6.00). File times in zip files are stored in the style of MS-DOS, as local times to an accuracy of 2 seconds. This is not very useful when transferring zip files between machines (even across continents), so we chose not to restore them by default.

Source

The internal C code uses zlib and is in particular based on the contributed ‘minizip’ application in the zlib sources (from http://zlib.net) by Gilles Vollant.

update.packages  Compare Installed Packages with CRAN-like Repositories

Description

old.packages indicates packages which have a (suitable) later version on the repositories whereas update.packages offers to download and install such packages.

new.packages looks for (suitable) packages on the repositories that are not already installed, and optionally offers them for installation.
Usage

update.packages(lib.loc = NULL, repos = getOption("repos"),
               contriburl = contrib.url(repos, type),
               method, instlib = NULL,
               ask = TRUE, available = NULL,
               oldPkgs = NULL, ..., checkBuilt = FALSE,
               type = getOption("pkgType"))

old.packages(lib.loc = NULL, repos = getOption("repos"),
              contriburl = contrib.url(repos, type),
              instPkgs = installed.packages(lib.loc = lib.loc),
              method, available = NULL, checkBuilt = FALSE,
              type = getOption("pkgType"))

ew.packages(lib.loc = NULL, repos = getOption("repos"),
             contriburl = contrib.url(repos, type),
             instPkgs = installed.packages(lib.loc = lib.loc),
             method, available = NULL, ask = FALSE, ..., 
             type = getOption("pkgType"))

Arguments

lib.loc character vector describing the location of R library trees to search through (and update packages therein), or NULL for all known trees (see .libPaths).
repos character vector, the base URL(s) of the repositories to use, e.g., the URL of a CRAN mirror such as "http://cran.us.r-project.org".
contriburl URL(s) of the contrib sections of the repositories. Use this argument if your repository is incomplete. Overrides argument repos.
method Download method, see download.file.
instlib character string giving the library directory where to install the packages.
ask logical indicating whether to ask user before packages are actually downloaded and installed, or the character string "graphics", which brings up a widget to allow the user to (de-)select from the list of packages which could be updated or added. The latter value only works on systems with a GUI version of select.list, and is otherwise equivalent to ask = TRUE.
available an object as returned by available.packages listing packages available at the repositories, or NULL which makes an internal call to available.packages.
checkBuilt If TRUE, a package built under an earlier major.minor version of R (e.g. 2.14) is considered to be 'old'.
oldPkgs if specified as non-NULL, update.packages() only considers these packages for updating. This may be a character vector of package names or a matrix as returned by old.packages().
instPkgs by default all installed packages, installed.packages(lib.loc = lib.loc). A subset can be specified; currently this must be in the same (character matrix) format as returned by installed.packages().
Arguments such as destdir and dependencies to be passed to install.packages.

type character, indicating the type of package to download and install. See install.packages.

Details

old.packages compares the information from available.packages with that from instPkgs (computed by installed.packages by default) and reports installed packages that have newer versions on the repositories or, if checkBuilt = TRUE, that were built under an earlier minor version of R (for example built under 2.14.x when running R 2.15.0). (For binary package types here is no check that the version on the repository was built under the current minor version of R, but it is advertised as being suitable for this version.)

new.packages does the same comparison but reports uninstalled packages that are available at the repositories. If ask != FALSE it asks which packages should be installed in the first element of lib.loc.

The main function of the set is update.packages. First a list of all packages found in lib.loc is created and compared with those available at the repositories. If ask = TRUE (the default) packages with a newer version are reported and for each one the user can specify if it should be updated. If so the packages are downloaded from the repositories and installed in the respective library path (or instlib if specified).

For how the list of suitable available packages is determined see available.packages. available = NULL make a call to available.packages(contriburl = contriburl, method = method) and hence by default filters on R version, OS type and removes duplicates.

Value

update.packages returns NULL invisibly.

For old.packages, NULL or a matrix with one row per package, row names the package names and column names "Package", "LibPath", "Installed" (the version), "Built" (the version built under), "ReposVer" and "Repository".

For new.packages a character vector of package names, after any selected via ask have been installed.

Warning

Take care when using dependencies (passed to install.packages) with update.packages, for it is unclear where new dependencies should be installed. The current implementation will only allow it if all the packages to be updated are in a single library, when that library will be used.

See Also

install.packages, available.packages, download.packages, installed.packages, contrib.url.

See download.file for how to handle proxies and other options to monitor file transfers.

INSTALL, REMOVE, remove.packages, library, .packages, read.dcf
url.show

Display a text URL

Description

Extension of file.show to display text files from a remote server.

Usage

url.show(url, title = url, file = tempfile(),
        delete.file = TRUE, method, ...)

Arguments

  url   The URL to read from.
  title Title for the browser.
  file  File to copy to.
  delete.file Delete the file afterwards?
  method File transfer method: see download.file
  ...   Arguments to pass to file.show.

Note

Since this is for text files, it will convert to CRLF line endings on Windows.

See Also

url, file.show, download.file

Examples

## Not run: url.show("http://lib.stat.cmu.edu/datasets/csb/ch3a.txt")
**URLencode**

*Encode or Decode a (partial) URL*

**Description**

Functions to encode or decode characters in URLs.

**Usage**

```r
URLencode(URL, reserved = FALSE)
URLdecode(URL)
```

**Arguments**

- `URL`: A character string.
- `reserved`: Should reserved characters be encoded? See ‘Details’.

**Details**

Characters in a URL other than the English alphanumeric characters and `'$ - _ . + ! * ' ( ) , '`, should be encoded as `%` plus a two-digit hexadecimal representation, and any single-byte character can be so encoded. (Multi-byte characters are encoded as byte-by-byte.)

In addition, `'; / ? : @ = &` are reserved characters, and should be encoded unless used in their reserved sense, which is scheme specific. The default in `URLencode` is to leave them alone, which is appropriate for ‘file://’ URLs, but probably not for ‘http://’ ones.

**Value**

A character string.

**References**

**Examples**

```r
(y <- URLencode("a url with spaces and / and @"))
URLdecode(y)
(y <- URLencode("a url with spaces and / and @", reserved = TRUE))
URLdecode(y)
URLdecode("ab%20cd")
```
utils-deprecated  Deprecated Functions in Package utils

Description

These functions are provided for compatibility with older versions of R only, and may be defunct as soon as of the next release.

See Also

Deprecated, Defunct

View

Invoke a Data Viewer

Description

Invoke a spreadsheet-style data viewer on a matrix-like R object.

Usage

View(x, title)

Arguments

x  an R object which can be coerced to a data frame with non-zero numbers of rows and columns.

x  title  title for viewer window. Defaults to name of x prefixed by Data:.

Details

Object x is coerced (if possible) to a data frame, and all non-numeric columns are then coerced to character. The object is then viewed in a spreadsheet-like data viewer, a read-only version of data.entry.

If there are row names on the data frame that are not 1:nrow, they are displayed in a separate first column called row.names.

Objects with zero columns or zero rows are not accepted.

The array of cells can be navigated by the cursor keys and Home, End, Page Up and Page Down (where supported by X11) as well as Enter and Tab.

Value

Invisible NULL. The functions puts up a window and returns immediately: the window can be closed via its controls or menus.
vignette

Description

View a specified vignette, or list the available ones.

Usage

vignette(topic, package = NULL, lib.loc = NULL, all = TRUE)

## S3 method for class 'vignette'
print(x, ...)

## S3 method for class 'vignette'
edit(name, ...)

Arguments

topic a character string giving the (base) name of the vignette to view. If omitted, all vignettes from all installed packages are listed.

package a character vector with the names of packages to search through, or NULL in which "all" packages (as defined by argument all) are searched.

lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known.

all logical; if TRUE search all available packages in the library trees specified by lib.loc, and if FALSE, search only attached packages.

x, name Object of class vignette.

... Ignored by the print method, passed on to file.edit by the edit method.

Details

Function vignette returns an object of the same class, the print method opens a viewer for it. Currently, only PDF versions of vignettes can be viewed. The program specified by the pdfviewer option is used for this. If several vignettes have PDF versions with base name identical to topic, the first one found is used.

If no topics are given, all available vignettes are listed. The corresponding information is returned in an object of class "packageIQR".

The edit method extracts the R code from the vignette to a temporary file and opens the file in an editor (see edit). This makes it very easy to execute the commands line by line, modify them in any way you want to help you test variants, etc.. An alternative way of extracting the R code from the vignette is to run Stangle on the source code of the vignette, see the examples below.

See Also

edit.data.frame, data.entry.
See Also

browseVignettes for an HTML-based vignette browser.

Examples

```r
## List vignettes from all *attached* packages
vignette(all = FALSE)

## List vignettes from all *installed* packages (can take a long time!):
vignette(all = TRUE)

## Not run:
## Open the grid intro vignette
vignette("grid")

## The same
v1 <- vignette("grid")
print(v1)

## Now let us have a closer look at the code
edit(v1)

## An alternative way of extracting the code,
## R file is written to current working directory
Stangle(v1$file)

## A package can have more than one vignette (package grid has several):
vignette(package = "grid")
vignette("rotated")

## The same, but without searching for it:
vignette("rotated", package = "grid")

## End(Not run)
```

---

**write.table**

**Data Output**

**Description**

`write.table` prints its required argument `x` (after converting it to a data frame if it is not one nor a matrix) to a file or `connection`.

**Usage**

```r
write.table(x, file = "", append = FALSE, quote = TRUE, sep = " ", eol = "\n", na = "NA", dec = ".", row.names = TRUE, col.names = TRUE, qmethod = c("escape", "double"), fileEncoding = """)
```
write.table
write.csv(...)
write.csv2(....)

Arguments

x the object to be written, preferably a matrix or data frame. If not, it is attempted
to coerce x to a data frame.
file either a character string naming a file or a connection open for writing. "" indicates output to the console.
append logical. Only relevant if file is a character string. If TRUE, the output is ap-
pended to the file. If FALSE, any existing file of the name is destroyed.
quote a logical value (TRUE or FALSE) or a numeric vector. If TRUE, any character or
factor columns will be surrounded by double quotes. If a numeric vector, its
elements are taken as the indices of columns to quote. In both cases, row and
column names are quoted if they are written. If FALSE, nothing is quoted.
sep the field separator string. Values within each row of x are separated by this string.
eol the character(s) to print at the end of each line (row). For example,
eol = "\r\n" will produce Windows' line endings on a Unix-alike OS, and
eol = "\r" will produce files as expected by Excel:mac 2004.
na the string to use for missing values in the data.
dec the string to use for decimal points in numeric or complex columns: must be a
single character.
row.names either a logical value indicating whether the row names of x are to be written
along with x, or a character vector of row names to be written.
col.names either a logical value indicating whether the column names of x are to be written
along with x, or a character vector of column names to be written. See the
section on ‘CSV files’ for the meaning of col.names = NA.
qmethod a character string specifying how to deal with embedded double quote characters
when quoting strings. Must be one of "escape" (default for write.table), in
which case the quote character is escaped in C style by a backslash, or "double"
(default for write.csv and write.csv2), in which case it is doubled. You can
specify just the initial letter.
fileEncoding character string: if non-empty declares the encoding to be used on a file (not
a connection) so the character data can be re-encoded as they are written. See
file.
... arguments to write.table: append, col.names, sep, dec and qmethod cannot
be altered.

Details

If the table has no columns the rownames will be written only if row.names = TRUE, and vice versa.
Real and complex numbers are written to the maximal possible precision.
If a data frame has matrix-like columns these will be converted to multiple columns in the result (via `as.matrix`) and so a character `col.names` or a numeric quote should refer to the columns in the result, not the input. Such matrix-like columns are unquoted by default.

Any columns in a data frame which are lists or have a class (e.g. dates) will be converted by the appropriate `as.character` method: such columns are unquoted by default. On the other hand, any class information for a matrix is discarded and non-atomic (e.g. list) matrices are coerced to character.

Only columns which have been converted to character will be quoted if specified by `quote`.

The `dec` argument only applies to columns that are not subject to conversion to character because they have a class or are part of a matrix-like column (or matrix), in particular to columns protected by `I()`. Use `options("OutDec")` to control such conversions.

In almost all cases the conversion of numeric quantities is governed by the option "scipen" (see `options`), but with the internal equivalent of `digits = 15`. For finer control, use `format` to make a character matrix/data frame, and call `write.table` on that.

These functions check for a user interrupt every 1000 lines of output.

If `file` is a non-open connection, an attempt is made to open it and then close it after use.

To write a Unix-style file on Windows, use a binary connection e.g. `file = file("filename", "wb")`.

**CSV files**

By default there is no column name for a column of row names. If `col.names = NA` and `row.names = TRUE` a blank column name is added, which is the convention used for CSV files to be read by spreadsheets. Note that such CSV files can be read in R by

```r
read.csv(file = "<filename>", row.names = 1)
```

`write.csv` and `write.csv2` provide convenience wrappers for writing CSV files. They set `sep` and `dec` (see below), `qmethod = "double"`, and `col.names` to `NA` if `row.names = TRUE` (the default) and to `TRUE` otherwise.

`write.csv` uses "," for the decimal point and a comma for the separator.

`write.csv2` uses a comma for the decimal point and a semicolon for the separator, the Excel convention for CSV files in some Western European locales.

These wrappers are deliberately inflexible: they are designed to ensure that the correct conventions are used to write a valid file. Attempts to change `append`, `col.names`, `sep`, `dec` or `qmethod` are ignored, with a warning.

CSV files do not record an encoding, and this causes problems if they are not ASCII for many other applications. Windows Excel 2007/10 will open files (e.g. by the file association mechanism) correctly if they are ASCII or UTF-16 (use `fileEncoding = "UTF-16LE"`) or perhaps in the current Windows codepage (e.g. "CP1252"), but the ‘Text Import Wizard’ (from the ‘Data’ tab) allows far more choice of encodings. Excel:mac 2004/8 can import only Macintosh (which seems to mean MacRoman), Windows (perhaps Latin-1) and ‘PC-8’ files. OpenOffice 3.x asks for the character set when opening the file.

There is an IETF RFC4180 (http://tools.ietf.org/html/rfc4180) for CSV files, which mandates comma as the separator and CRLF line endings. `write.csv` writes compliant files on Windows: use `eol = "\r\n"` on other platforms.
Note

write.table can be slow for data frames with large numbers (hundreds or more) of columns: this is inevitable as each column could be of a different class and so must be handled separately. If they are all of the same class, consider using a matrix instead.

See Also

The 'R Data Import/Export' manual.

read.table, write.
write.matrix in package MASS.

Examples

## Not run:
## To write a CSV file for input to Excel one might use
x <- data.frame(a = I("a \" quote"), b = pi)
write.table(x, file = "foo.csv", sep = ",", col.names = NA,
qmethod = "double")
## and to read this file back into R one needs
read.table("foo.csv", header = TRUE, sep = ",", row.names = 1)
## NB: you do need to specify a separator if qmethod = "double".

### Alternatively
write.csv(x, file = "foo.csv")
read.csv("foo.csv", row.names = 1)
## or without row names
write.csv(x, file = "foo.csv", row.names = FALSE)
read.csv("foo.csv")

## To write a file in MacRoman for simple use in Mac Excel 2004/8
write.csv(x, file = "foo.csv", fileEncoding = "macroman")
## or for Windows Excel 2007/10
write.csv(x, file = "foo.csv", fileEncoding = "UTF-16LE")

## End(Not run)

zip

Create Zip archives

Description

A wrapper for an external zip command to create zip archives.

Usage

zip(zipfile, files, flags = "-r9X", extras = "",
zip = Sys.getenv("R_ZIPCMD", "zip"))
Arguments

zipfile The pathname of the zip file: tilde expansion (see `path.expand`) will be performed.
files A character vector of recorded filepaths to be included.
flags A character string of flags to be passed to the command: see ‘Details’.
extras An optional character vector: see ‘Details’.
zip A character string specifying the external command to be used.

Details

On a Unix-alike, the default for `zip` will by default use the value of `R_ZIPCMD`, which is set in `etc/Renviron` if an `unzip` command was found during configuration. On Windows, the default relies on a zip program (for example that from Rtools) being in the path.

The default for `flags` is that appropriate for zipping up a directory tree in a portable way: see the system-specific help for the `zip` command for other possibilities.

Argument `extras` can be used to specify `-x` or `-i` followed by a list of filepaths to exclude or include.

Value

The status value returned by the external command, invisibly.

See Also

`unzip`, `unz`. 

Part II
Chapter 15

The boot package

\[\text{abc.ci} \quad \text{Nonparametric ABC Confidence Intervals}\]

**Description**

Calculate equi-tailed two-sided nonparametric approximate bootstrap confidence intervals for a parameter, given a set of data and an estimator of the parameter, using numerical differentiation.

**Usage**

\[
\text{abc.ci}(\text{data}, \text{statistic}, \text{index}=1, \text{strata}=\text{rep}(1, n), \text{conf}=0.95, \\
\text{eps}=0.001/n, \ldots)
\]

**Arguments**

- **data**
  A data set expressed as a vector, matrix or data frame.

- **statistic**
  A function which returns the statistic of interest. The function must take at least 2 arguments; the first argument should be the data and the second a vector of weights. The weights passed to statistic will be normalized to sum to 1 within each stratum. Any other arguments should be passed to abc.ci as part of the \ldots{} argument.

- **index**
  If statistic returns a vector of length greater than 1, then this indicates the position of the variable of interest within that vector.

- **strata**
  A factor or numerical vector indicating to which sample each observation belongs in multiple sample problems. The default is the one-sample case.

- **conf**
  A scalar or vector containing the confidence level(s) of the required interval(s).

- **eps**
  The value of epsilon to be used for the numerical differentiation.

- **...**
  Any other arguments for statistic. These will be passed unchanged to statistic each time it is called within abc.ci.
Details

This function is based on the function abcnon written by R. Tibshirani. A listing of the original function is available in DiCiccio and Efron (1996). The function uses numerical differentiation for the first and second derivatives of the statistic and then uses these values to approximate the bootstrap BCa intervals. The total number of evaluations of the statistic is $2n + 2 + 2\times\text{length(conf)}$ where $n$ is the number of data points (plus calculation of the original value of the statistic). The function works for the multiple sample case without the need to rewrite the statistic in an artificial form since the stratified normalization is done internally by the function.

Value

A length(conf) by 3 matrix where each row contains the confidence level followed by the lower and upper end-points of the ABC interval at that level.

`boot.ci`

Examples

```r
# 90% and 95% confidence intervals for the correlation
# coefficient between the columns of the bigcity data
abc.ci(bigcity, corr, conf=c(0.90, 0.95))

# A 95% confidence interval for the difference between the means of
# the last two samples in gravity
mean.diff <- function(y, w)
  { gp1 <- 1:table(as.numeric(y$series))[1]
    sum(y[gp1, 1] * w[gp1]) - sum(y[-gp1, 1] * w[-gp1])
  }
grav1 <- gravity[, 2] >= 7
abc.ci(grav1, mean.diff, strata = grav1$series)
```
**acme**

*Monthly Excess Returns*

**Description**

The `acme` data frame has 60 rows and 3 columns.

The excess return for the Acme Cleveland Corporation are recorded along with those for all stocks listed on the New York and American Stock Exchanges were recorded over a five year period. These excess returns are relative to the return on a risk-less investment such a U.S. Treasury bills.

**Usage**

`acme`

**Format**

This data frame contains the following columns:

- `month` A character string representing the month of the observation.
- `market` The excess return of the market as a whole.
- `acme` The excess return for the Acme Cleveland Corporation.

**Source**

The data were obtained from

**aids**

*Delay in AIDS Reporting in England and Wales*

**Description**

The `aids` data frame has 570 rows and 6 columns.

Although all cases of AIDS in England and Wales must be reported to the Communicable Disease Surveillance Centre, there is often a considerable delay between the time of diagnosis and the time that it is reported. In estimating the prevalence of AIDS, account must be taken of the unknown number of cases which have been diagnosed but not reported. The data set here records the reported cases of AIDS diagnosed from July 1983 and until the end of 1992. The data are cross-classified by the date of diagnosis and the time delay in the reporting of the cases.
This data frame contains the following columns:

- **year**: The year of the diagnosis.
- **quarter**: The quarter of the year in which diagnosis was made.
- **delay**: The time delay (in months) between diagnosis and reporting. 0 means that the case was reported within one month. Longer delays are grouped in 3 month intervals and the value of delay is the midpoint of the interval (therefore a value of 2 indicates that reporting was delayed for between 1 and 3 months).
- **dud**: An indicator of censoring. These are categories for which full information is not yet available and the number recorded is a lower bound only.
- **time**: The time interval of the diagnosis. That is the number of quarters from July 1983 until the end of the quarter in which these cases were diagnosed.
- **y**: The number of AIDS cases reported.

**Source**

The data were obtained from

**References**

**Description**

Proschan (1963) reported on the times between failures of the air-conditioning equipment in 10 Boeing 720 aircraft. The `aircondit` data frame contains the intervals for the ninth aircraft while `aircondit7` contains those for the seventh aircraft.

Both data frames have just one column. Note that the data have been sorted into increasing order.

**Usage**

`aircondit`
Format

The data frames contain the following column:

hours  The time interval in hours between successive failures of the air-conditioning equipment

Car Speeding and Warning Signs

Description

The amis data frame has 8437 rows and 4 columns.

In a study into the effect that warning signs have on speeding patterns, Cambridgeshire County Council considered 14 pairs of locations. The locations were paired to account for factors such as traffic volume and type of road. One site in each pair had a sign erected warning of the dangers of speeding and asking drivers to slow down. No action was taken at the second site. Three sets of measurements were taken at each site. Each set of measurements was nominally of the speeds of 100 cars but not all sites have exactly 100 measurements. These speed measurements were taken before the erection of the sign, shortly after the erection of the sign, and again after the sign had been in place for some time.

Usage

amis

Format

This data frame contains the following columns:

speed  Speeds of cars (in miles per hour).
period  A numeric column indicating the time that the reading was taken. A value of 1 indicates a reading taken before the sign was erected, a 2 indicates a reading taken shortly after erection of the sign and a 3 indicates a reading taken after the sign had been in place for some time.
warning  A numeric column indicating whether the location of the reading was chosen to have a warning sign erected. A value of 1 indicates presence of a sign and a value of 2 indicates that no sign was erected.
pair A numeric column giving the pair number at which the reading was taken. Pairs were numbered from 1 to 14.

Source
The data were kindly made available by Mr. Graham Amis, Cambridgeshire County Council, U.K.

**Description**

The aml data frame has 23 rows and 3 columns.

A clinical trial to evaluate the efficacy of maintenance chemotherapy for acute myelogenous leukaemia was conducted by Embury et al. (1977) at Stanford University. After reaching a stage of remission through treatment by chemotherapy, patients were randomized into two groups. The first group received maintenance chemotherapy and the second group did not. The aim of the study was to see if maintenance chemotherapy increased the length of the remission. The data here formed a preliminary analysis which was conducted in October 1974.

**Usage**

aml

**Format**

This data frame contains the following columns:

- **time** The length of the complete remission (in weeks).
- **cens** An indicator of right censoring. 1 indicates that the patient had a relapse and so time is the length of the remission. 0 indicates that the patient left the study or was still in remission in October 1974, that is the length of remission is right-censored.
- **group** The group into which the patient was randomized. Group 1 received maintenance chemotherapy, group 2 did not.

**Note**

Package *survival* also has a dataset aml. It is the same data with different names and with group replaced by a factor x.

beaver  Beaver Body Temperature Data

Description

The beaver data frame has 100 rows and 4 columns. It is a multivariate time series of class "ts" and also inherits from class "data.frame".

This data set is part of a long study into body temperature regulation in beavers. Four adult female beavers were live-trapped and had a temperature-sensitive radio transmitter surgically implanted. Readings were taken every 10 minutes. The location of the beaver was also recorded and her activity level was dichotomized by whether she was in the retreat or outside of it since high-intensity activities only occur outside of the retreat.

The data in this data frame are those readings for one of the beavers on a day in autumn.

Usage

beaver

Format

This data frame contains the following columns:

day  The day number. The data includes only data from day 307 and early 308.
time  The time of day formatted as hour-minute.
temp  The body temperature in degrees Celsius.
activ  The dichotomized activity indicator. 1 indicates that the beaver is outside of the retreat and therefore engaged in high-intensity activity.

**bigcity**  
*Population of U.S. Cities*

---

**Description**

The `bigcity` data frame has 49 rows and 2 columns.  
The `city` data frame has 10 rows and 2 columns.  
The measurements are the population (in 1000's) of 49 U.S. cities in 1920 and 1930. The 49 cities are a random sample taken from the 196 largest cities in 1920. The `city` data frame consists of the first 10 observations in `bigcity`.

**Usage**

`bigcity`

**Format**

This data frame contains the following columns:

- u  The 1920 population.  
- x  The 1930 population.

**Source**

The data were obtained from  

**References**

Description

Generate \( R \) bootstrap replicates of a statistic applied to data. Both parametric and nonparametric resampling are possible. For the nonparametric bootstrap, possible resampling methods are the ordinary bootstrap, the balanced bootstrap, antithetic resampling, and permutation. For nonparametric multi-sample problems stratified resampling is used: this is specified by including a vector of strata in the call to `boot`. Importance resampling weights may be specified.

Usage

```r
boot(data, statistic, R, sim = "ordinary", stype = c("i", "f", "w"),
     strata = rep(1,n), L = NULL, m = 0, weights = NULL,
     ran.gen = function(d, p) d, mle = NULL, simple = FALSE, ...,
     parallel = c("no", "multicore", "snow"),
     ncpus = getOption("boot.ncpus", 1L), cl = NULL)
```

Arguments

- `data` The data as a vector, matrix or data frame. If it is a matrix or data frame then each row is considered as one multivariate observation.
- `statistic` A function which when applied to data returns a vector containing the statistic(s) of interest. When `sim = "parametric"`, the first argument to `statistic` must be the data. For each replicate a simulated dataset returned by `ran.gen` will be passed. In all other cases `statistic` must take at least two arguments. The first argument passed will always be the original data. The second will be a vector of indices, frequencies or weights which define the bootstrap sample. Further, if predictions are required, then a third argument is required which would be a vector of the random indices used to generate the bootstrap predictions. Any further arguments can be passed to `statistic` through the `...` argument.
- `R` The number of bootstrap replicates. Usually this will be a single positive integer. For importance resampling, some resamples may use one set of weights and others use a different set of weights. In this case \( R \) would be a vector of integers where each component gives the number of resamples from each of the rows of weights.
- `sim` A character string indicating the type of simulation required. Possible values are "ordinary" (the default), "parametric", "balanced", "permutation", or "antithetic". Importance resampling is specified by including importance weights; the type of importance resampling must still be specified but may only be "ordinary" or "balanced" in this case.
- `stype` A character string indicating what the second argument of `statistic` represents. Possible values of `stype` are "i" (indices - the default), "f" (frequencies), or "w" (weights). Not used for `sim = "parametric"`. 
strata   An integer vector or factor specifying the strata for multi-sample problems. This may be specified for any simulation, but is ignored when sim = "parametric". When strata is supplied for a nonparametric bootstrap, the simulations are done within the specified strata.

L      Vector of influence values evaluated at the observations. This is used only when sim is "antithetic". If not supplied, they are calculated through a call to empinf. This will use the infinitesimal jackknife provided that stype is "w", otherwise the usual jackknife is used.

m      The number of predictions which are to be made at each bootstrap replicate. This is most useful for (generalized) linear models. This can only be used when sim is "ordinary". m will usually be a single integer but, if there are strata, it may be a vector with length equal to the number of strata, specifying how many of the errors for prediction should come from each strata. The actual predictions should be returned as the final part of the output of statistic, which should also take an argument giving the vector of indices of the errors to be used for the predictions.

weights Vector or matrix of importance weights. If a vector then it should have as many elements as there are observations in data. When simulation from more than one set of weights is required, weights should be a matrix where each row of the matrix is one set of importance weights. If weights is a matrix then R must be a vector of length nrow(weights). This parameter is ignored if sim is not "ordinary" or "balanced".

ran.gen This function is used only when sim = "parametric" when it describes how random values are to be generated. It should be a function of two arguments. The first argument should be the observed data and the second argument consists of any other information needed (e.g. parameter estimates). The second argument may be a list, allowing any number of items to be passed to ran.gen. The returned value should be a simulated data set of the same form as the observed data which will be passed to statistic to get a bootstrap replicate. It is important that the returned value be of the same shape and type as the original dataset. If ran.gen is not specified, the default is a function which returns the original data in which case all simulation should be included as part of statistic. Use of sim = "parametric" with a suitable ran.gen allows the user to implement any types of nonparametric resampling which are not supported directly.

mle    The second argument to be passed to ran.gen. Typically these will be maximum likelihood estimates of the parameters. For efficiency mle is often a list containing all of the objects needed by ran.gen which can be calculated using the original data set only.

simple logical, only allowed to be TRUE for sim = "ordinary", stype = "i", n = 0 (otherwise ignored with a warning). By default a n by R index array is created: this can be large and if simple = TRUE this is avoided by sampling separately for each replication, which is slower but uses less memory.

...    Other named arguments for statistic which are passed unchanged each time it is called. Any such arguments to statistic should follow the arguments which statistic is required to have for the simulation. Beware of partial matching to arguments of boot listed above, and that arguments named X and FUN cause conflicts in some versions of boot (but not this one).
The type of parallel operation to be used (if any). If missing, the default is taken from the option "boot.parallel" (and if that is not set, "no").

ncpus
integer: number of processes to be used in parallel operation: typically one would chose this to the number of available CPUs.

c1
An optional parallel or snow cluster for use if parallel = "snow". If not supplied, a cluster on the local machine is created for the duration of the boot call.

Details
The statistic to be bootstrapped can be as simple or complicated as desired as long as its arguments correspond to the dataset and (for a nonparametric bootstrap) a vector of indices, frequencies or weights. statistic is treated as a black box by the boot function and is not checked to ensure that these conditions are met.

The first order balanced bootstrap is described in Davison, Hinkley and Schechtman (1986). The antithetic bootstrap is described by Hall (1989) and is experimental, particularly when used with strata. The other non-parametric simulation types are the ordinary bootstrap (possibly with unequal probabilities), and permutation which returns random permutations of cases. All of these methods work independently within strata if that argument is supplied.

For the parametric bootstrap it is necessary for the user to specify how the resampling is to be conducted. The best way of accomplishing this is to specify the function ran.gen which will return a simulated data set from the observed data set and a set of parameter estimates specified in mle.

Value
The returned value is an object of class "boot", containing the following components:

  t0                  The observed value of statistic applied to data.
  t                  A matrix with sum(R) rows each of which is a bootstrap replicate of the result of calling statistic.
  R                  The value of R as passed to boot.
  data               The data as passed to boot.
  seed               The value of .Random.seed when boot was called.
  statistic          The function statistic as passed to boot.
  sim                Simulation type used.
  stype              Statistic type as passed to boot.
  call               The original call to boot.
  strata             The strata used. This is the vector passed to boot, if it was supplied or a vector of ones if there were no strata. It is not returned if sim is "parametric".
  weights            The importance sampling weights as passed to boot or the empirical distribution function weights if no importance sampling weights were specified. It is omitted if sim is not one of "ordinary" or "balanced".
  pred.i             If predictions are required (m > 0) this is the matrix of indices at which predictions were calculated as they were passed to statistic. Omitted if m is 0 or sim is not "ordinary".
The influence values used when sim is "antithetic". If no such values were specified and stype is not "w" then L is returned as consecutive integers corresponding to the assumption that data is ordered by influence values. This component is omitted when sim is not "antithetic".

The random generator function used if sim is "parametric". This component is omitted for any other value of sim.

The parameter estimates passed to boot when sim is "parametric". It is omitted for all other values of sim.

There are c, plot and print methods for this class.

Parallel operation

When parallel = "multicore" is used (not available on Windows), each worker process inherits the environment of the current session, including the workspace and the loaded namespaces and attached packages (but not the random number seed: see below).

More work is needed when parallel = "snow" is used: the worker processes are newly created R processes, and statistic needs to arrange to set up the environment it needs: often a good way to do that is to make use of lexical scoping since when statistic is sent to the worker processes its enclosing environment is also sent. (E.g. see the example for jack.after.boot where ancillary functions are nested inside the statistic function.) parallel = "snow" is primarily intended to be used on multi-core Windows machine where parallel = "multicore" is not available.

For most of the boot methods the resampling is done in the master process, but not if simple = TRUE nor sim = "parametric". In those cases (or where statistic itself uses random numbers), more care is needed if the results need to be reproducible. Resampling is done in the worker processes by censboot(sim = "wierd") and by most of the schemes in tsboot (the exceptions being sim == "fixed" and sim == "geom" with the default ran.gen).

Where random-number generation is done in the worker processes, the default behaviour is that each worker chooses a separate seed, non-reproducibly. However, with parallel = "multicore" or parallel = "snow" using the default cluster, a second approach is used if RNGkind("L'Ecuyer-CMRG") has been selected. In that approach each worker gets a different subsequence of the RNG stream based on the seed at the time the worker is spawned and so the results will be reproducible if ncpus is unchanged, and for parallel = "multicore" if parallel::mc.reset.stream() is called: see the examples for mclapply.

Examples

```r
# Usual bootstrap of the ratio of means using the city data
data(city)
ratio <- function(d, w) sum(d$x * w)/sum(d$u * w)
boot(city, ratio, R = 999, stype = "w")

# Stratified resampling for the difference of means. In this
# example we will look at the difference of means between the final
# two series in the gravity data.
data(gravity)
diff.means <- function(d, f)
  { n <- nrow(d)
gp1 <- 1:table(as.numeric(d$series))[1]
m1 <- sum(d[g1,1] * f[g1])/sum(f[g1])
m2 <- sum(d[-gp1,1] * f[-gp1])/sum(f[-gp1])
ss1 <- sum(d[g1,1]^2 * f[g1]) - (m1 * m1 * sum(f[g1]))
ss2 <- sum(d[-gp1,1]^2 * f[-gp1]) - (m2 * m2 * sum(f[-gp1]))
c(m1 - m2, (ss1 + ss2)/(sum(f) - 2))
}
data(gravity)
grav1 <- gravity[as.numeric(gravity[,2]) >= 7,]
boot(grav1, diff.means, R = 999, stype = "f", strata = grav1[,2])

# In this example we show the use of boot in a prediction from
# regression based on the nuclear data. This example is taken
# from Example 6.8 of Davison and Hinkley (1997). Notice also
# that two extra arguments to 'statistic' are passed through boot.
data(nuclear)
nuke.lm <- glm(log(cost) ~ date+log(cap)+ne+ct+log(cum.n)+pt, data = nuke)
nuke.diag <- glm.diag(nuke.lm)
nuke.res <- nuke.diag$res * nuke.diag$sd
nuke.res <- nuke.res - mean(nuke.res)

# We set up a new data frame with the data, the standardized
# residuals and the fitted values for use in the bootstrap.
data.frame(nuke, resid = nuke.res, fit = fitted(nuke.lm))
```
# Now we want a prediction of plant number 32 but at date 73.00
new.data <- data.frame(cost = 1, date = 73.00, cap = 886, ne = 0, ct = 0, cum.n = 11, pt = 1)
new.fit <- predict(nuke.lm, new.data)

nuke.fun <- function(dat, inds, i.pred, fit.pred, x.pred)
{
  lm.b <- glm(fit+resid[inds] ~ date+log(cap)+ne+ct+log(cum.n)+pt,
             data = dat)
  pred.b <- predict(lm.b, x.pred)
  c(coef(lm.b), pred.b - (fit.pred + dat$resid[i.pred]))
}

nuke.boot <- boot(nuke.data, nuke.fun, R = 999, m = 1,
                   fit.pred = new.fit, x.pred = new.data)
# The bootstrap prediction squared error would then be found by
mean(nuke.boot$t[, 8]^2)
# Basic bootstrap prediction limits would be
new.fit - sort(nuke.boot$t[, 8])[c(975, 25)]

# Finally a parametric bootstrap. For this example we shall look
# at the air-conditioning data. In this example our aim is to test
# the hypothesis that the true value of the index is 1 (i.e. that
# the data come from an exponential distribution) against the
# alternative that the data come from a gamma distribution with
# index not equal to 1.
air.fun <- function(data) {
  ybar <- mean(data$hours)
  para <- c(log(ybar), mean(log(data$hours)))
  ll <- function(k) {
    if (k <= 0) 1e20 else lgamma(k)-k*(log(k)-1-para[1]+para[2])
  }
  khat <- nlm(ll, ybar^2/var(data$hours))$estimate
  c(ybar, khat)
}

air.rg <- function(data, mle) {
  # Function to generate random exponential variates.
  # mle will contain the mean of the original data
  out <- data
  out$hours <- rexp(nrow(out), 1/mle)
  out
}

air.boot <- boot(aircondit, air.fun, R = 999, sim = "parametric",
                 ran.gen = air.rg, mle = mean(aircondit$hours))
# The bootstrap p-value can then be approximated by
sum(abs(air.boot$t[,2]-1) > abs(air.boot$t[0][2]-1))/(1+air.boot$R)
**Description**

This function takes a bootstrap object calculated by one of the functions `boot`, `censboot`, or `tilt.boot` and returns the frequency (or index) array for the bootstrap resamples.

**Usage**

```r
boot.array(boot.out, indices)
```

**Arguments**

- `boot.out`: An object of class "boot" returned by one of the generation functions for such an object.
- `indices`: A logical argument which specifies whether to return the frequency array or the raw index array. The default is `indices=FALSE` unless `boot.out` was created by `tsboot` in which case the default is `indices=TRUE`.

**Details**

The process by which the original index array was generated is repeated with the same value of `.Random.seed`. If the frequency array is required then `freq.array` is called to convert the index array to a frequency array.

A resampling array can only be returned when such a concept makes sense. In particular it cannot be found for any parametric or model-based resampling schemes. Hence for objects generated by `censboot` the only resampling scheme for which such an array can be found is ordinary case resampling. Similarly if `boot.out$sim` is "parametric" in the case of `boot` or "model" in the case of `tsboot` the array cannot be found. Note also that for post-blackened bootstraps from `tsboot` the indices found will relate to those prior to any post-blackening and so will not be useful.

Frequency arrays are used in many post-bootstrap calculations such as the jackknife-after-bootstrap and finding importance sampling weights. They are also used to find empirical influence values through the regression method.

**Value**

A matrix with `boot.out$R` rows and `n` columns where `n` is the number of observations in `boot.out$data`. If `indices` is `FALSE` then this will give the frequency of each of the original observations in each bootstrap resample. If `indices` is `TRUE` it will give the indices of the bootstrap resamples in the order in which they would have been passed to the statistic.

**Side Effects**

This function temporarily resets `.Random.seed` to the value in `boot.out$seed` and then returns it to its original value at the end of the function.

- `tilt.boot`
- `tsboot`

Examples

```r
# A frequency array for a nonparametric bootstrap
city.boot <- boot(city, corr, R = 40, stype = "w")
boot.array(city.boot)

perm.cor <- function(d,i) cor(d$x,d$u[i])
city.perm <- boot(city, perm.cor, R = 40, sim = "permutation")
boot.array(city.perm, indices = TRUE)
```

### boot.ci

**Nonparametric Bootstrap Confidence Intervals**

**Description**

This function generates 5 different types of equi-tailed two-sided nonparametric confidence intervals. These are the first order normal approximation, the basic bootstrap interval, the studentized bootstrap interval, the bootstrap percentile interval, and the adjusted bootstrap percentile (BCa) interval. All or a subset of these intervals can be generated.

**Usage**

```r
boot.ci(boot.out, conf = 0.95, type = "all",
index = 1:min(2,length(boot.out$t)), var.t = NULL,
var.t = NULL, t0 = NULL, t = NULL, L = NULL,
index = 1:length(t), h = function(t) t, hdot = function(t) rep(1,length(t)),
index = NULL)
```

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>boot.out</code></td>
<td>An object of class &quot;boot&quot; containing the output of a bootstrap calculation.</td>
</tr>
<tr>
<td><code>conf</code></td>
<td>A scalar or vector containing the confidence level(s) of the required interval(s).</td>
</tr>
<tr>
<td><code>type</code></td>
<td>A vector of character strings representing the type of intervals required. The value should be any subset of the values c(&quot;norm&quot;,&quot;basic&quot;, &quot;stud&quot;, &quot;perc&quot;, &quot;bca&quot;) or simply &quot;all&quot; which will compute all five types of intervals.</td>
</tr>
<tr>
<td><code>index</code></td>
<td>This should be a vector of length 1 or 2. The first element of <code>index</code> indicates the position of the variable of interest in <code>boot.out$t0</code> and the relevant column in <code>boot.out$t</code>. The second element indicates the position of the variance of the variable of interest. If both <code>var.t0</code> and <code>var.t</code> are supplied then the second element of <code>index</code> (if present) is ignored. The default is that the variable of interest is in position 1 and its variance is in position 2 (as long as there are 2 positions in <code>boot.out$t0</code>).</td>
</tr>
</tbody>
</table>
var.t0 If supplied, a value to be used as an estimate of the variance of the statistic for
the normal approximation and studentized intervals. If it is not supplied and
length(index) is 2 then var.t0 defaults to boot.out$t0[index[2]] otherwise var.t0 is undefined. For studentized intervals var.t0 must be defined.
For the normal approximation, if var.t0 is undefined it defaults to var(t). If a
transformation is supplied through the argument h then var.t0 should be the
variance of the untransformed statistic.

var.t This is a vector (of length boot.out$R) of variances of the bootstrap replicates
of the variable of interest. It is used only for studentized intervals. If it is not sup-
plied and length(index) is 2 then var.t defaults to boot.out$t[,index[2]],
otherwise its value is undefined which will cause an error for studentized inter-
vals. If a transformation is supplied through the argument h then var.t should
be the variance of the untransformed bootstrap statistics.

t0 The observed value of the statistic of interest. The default value is
boot.out$t0[index[1]]. Specification of t0 and t allows the user to get inter-
vals for a transformed statistic which may not be in the bootstrap output object.
See the second example below. An alternative way of achieving this would be
to supply the functions h, hdot, and hinv below.

t The bootstrap replicates of the statistic of interest. It must be a vector of length
boot.out$R. It is an error to supply one of t0 or t but not the other. Also if
studentized intervals are required and t0 and t are supplied then so should be
var.t0 and var.t. The default value is boot.out$t[,index].

L The empirical influence values of the statistic of interest for the observed data.
These are used only for BCa intervals. If a transformation is supplied through
the parameter h then L should be the influence values for t; the values for h(t)
are derived from these and hdot within the function. If L is not supplied then
the values are calculated using empinf if they are needed.

h A function defining a transformation. The intervals are calculated on the scale of
h(t) and the inverse function hinv applied to the resulting intervals. It must be a
function of one variable only and for a vector argument, it must return a vector of
the same length, i.e. h(c(t1,t2,t3)) should return c(h(t1),h(t2),h(t3)).
The default is the identity function.

hdot A function of one argument returning the derivative of h. It is a required argu-
ment if h is supplied and normal, studentized or BCa intervals are required. The
function is used for approximating the variances of h(t0) and h(t) using the
delta method, and also for finding the empirical influence values for BCa inter-
vals. Like h it should be able to take a vector argument and return a vector of
the same length. The default is the constant function 1.

hinv A function, like h, which returns the inverse of h. It is used to transform the
intervals calculated on the scale of h(t) back to the original scale. The default is
the identity function. If h is supplied but hinv is not, then the intervals returned
will be on the transformed scale.

... Any extra arguments that boot.out$statistic is expecting. These arguments
are needed only if BCa intervals are required and L is not supplied since in that
case L is calculated through a call to empinf which calls boot.out$statistic.
Details

The formulae on which the calculations are based can be found in Chapter 5 of Davison and Hinkley (1997). Function boot must be run prior to running this function to create the object to be passed as boot.out.

Variance estimates are required for studentized intervals. The variance of the observed statistic is optional for normal theory intervals. If it is not supplied then the bootstrap estimate of variance is used. The normal intervals also use the bootstrap bias correction.

Interpolation on the normal quantile scale is used when a non-integer order statistic is required. If the order statistic used is the smallest or largest of the R values in boot.out a warning is generated and such intervals should not be considered reliable.

Value

An object of type "bootci" which contains the intervals. It has components

- \( R \) The number of bootstrap replicates on which the intervals were based.
- \( t_0 \) The observed value of the statistic on the same scale as the intervals.
- \( call \) The call to boot.ci which generated the object.
  It will also contain one or more of the following components depending on the value of type used in the call to bootci.
- \( normal \) A matrix of intervals calculated using the normal approximation. It will have 3 columns, the first being the level and the other two being the upper and lower endpoints of the intervals.
- \( basic \) The intervals calculated using the basic bootstrap method.
- \( student \) The intervals calculated using the studentized bootstrap method.
- \( percent \) The intervals calculated using the bootstrap percentile method.
- \( bca \) The intervals calculated using the adjusted bootstrap percentile (BCa) method.
  These latter four components will be matrices with 5 columns, the first column containing the level, the next two containing the indices of the order statistics used in the calculations and the final two the calculated endpoints themselves.

**bbrambles**

**Spatial Location of Bramble Canes**

**Description**

The `bbrambles` data frame has 823 rows and 3 columns.

The location of living bramble canes in a 9m square plot was recorded. We take 9m to be the unit of distance so that the plot can be thought of as a unit square. The bramble canes were also classified by their age.

**Usage**

`bbrambles`

**Format**

This data frame contains the following columns:

- `x`: The x coordinate of the position of the cane in the plot.
- `y`: The y coordinate of the position of the cane in the plot.
- `age`: The age classification of the canes; 0 indicates a newly emerged cane, 1 indicates a one year old cane and 2 indicates a two year old cane.

**Smoking Deaths Among Doctors**

**Description**

The `breslow` data frame has 10 rows and 5 columns.

In 1961 Doll and Hill sent out a questionnaire to all men on the British Medical Register enquiring about their smoking habits. Almost 70% of such men replied. Death certificates were obtained for medical practitioners and causes of death were assigned on the basis of these certificates. The `breslow` data set contains the person-years of observations and deaths from coronary artery disease accumulated during the first ten years of the study.

Format

This data frame contains the following columns:

n  The total number of shoots in each plot.
r  The number of diseased shoots.
x  The number of pieces of the stems, out of 50, planted in each plot.
var  A factor indicating the variety of sugar-cane in each plot.
block  A factor for the blocks.

Details

The aim of the experiment was to classify the varieties into resistant, intermediate and susceptible to a disease called "coal of sugar-cane" (carvao da cana-de-acucar). This is a disease that is common in sugar-cane plantations in certain areas of Brazil.

For each plot, fifty pieces of sugar-cane stem were put in a solution containing the disease agent and then some were planted in the plot. After a fixed period of time, the total number of shoots and the number of diseased shoots were recorded.

capability Simulated Manufacturing Process Data

Description

The capability data frame has 75 rows and 1 columns.

The data are simulated successive observations from a process in equilibrium. The process is assumed to have specification limits (5.49, 5.79).

Usage

capability

Format

This data frame contains the following column:

y The simulated measurements.

Source

The data were obtained from

References

Description

The `catsM` data frame has 97 rows and 3 columns.
144 adult (over 2kg in weight) cats used for experiments with the drug digitalis had their heart and body weight recorded. 47 of the cats were female and 97 were male. The `catsM` data frame consists of the data for the male cats. The full data are in dataset `cats` in package `MASS`.

Usage

cats

Format

This data frames contain the following columns:

- **Sex**: A factor for the sex of the cat (levels are `F` and `M`).
- **Bwt**: Body weight in kg.
- **Hwt**: Heart weight in g.

Source

The data were obtained from

### cav

**Position of Muscle Caveolae**

**Description**

The `cav` data frame has 138 rows and 2 columns.

The data gives the positions of the individual caveolae in a square region with sides of length 500 units. This grid was originally on a 2.65um square of muscle fibre. The data are those points falling in the lower left hand quarter of the region used for the dataset `caveolae.dat` in the `spatial` package by B.D. Ripley (1994).

**Usage**

`cav`

**Format**

This data frame contains the following columns:

- `x` The x coordinate of the caveola’s position in the region.
- `y` The y coordinate of the caveola’s position in the region.

### cd4

**CD4 Counts for HIV-Positive Patients**

**Description**

The `cd4` data frame has 20 rows and 2 columns.

CD4 cells are carried in the blood as part of the human immune system. One of the effects of the HIV virus is that these cells die. The count of CD4 cells is used in determining the onset of full-blown AIDS in a patient. In this study of the effectiveness of a new anti-viral drug on HIV, 20 HIV-positive patients had their CD4 counts recorded and then were put on a course of treatment with this drug. After using the drug for one year, their CD4 counts were again recorded. The aim of the experiment was to show that patients taking the drug had increased CD4 counts which is not generally seen in HIV-positive patients.
Usage

cd4

Format

This data frame contains the following columns:

- baseline  The CD4 counts (in 100's) on admission to the trial.
- onyear    The CD4 counts (in 100's) after one year of treatment with the new drug.

censboot

Bootstrap for Censored Data

Description

This function applies types of bootstrap resampling which have been suggested to deal with right-censored data. It can also do model-based resampling using a Cox regression model.

Usage

censboot(data, statistic, R, F.surv, G.surv, strata = matrix(1,n,2),
          sim = "ordinary", cox = NULL, index = c(1, 2), ...
          parallel = c("no", "multicore", "snow"),
          ncpus = getOption("boot.ncpus", 1L), cl = NULL)

Arguments

data

The data frame or matrix containing the data. It must have at least two columns, one of which contains the times and the other the censoring indicators. It is allowed to have as many other columns as desired (although efficiency is reduced for large numbers of columns) except for sim = "weird" when it should only have two columns - the times and censoring indicators. The columns of data referenced by the components of index are taken to be the times and censoring indicators.

statistic

A function which operates on the data frame and returns the required statistic. Its first argument must be the data. Any other arguments that it requires can be passed using the ... argument. In the case of sim = "weird", the data passed to statistic only contains the times and censoring indicator regardless of the actual number of columns in data. In all other cases the data passed to statistic will be of the same form as the original data. When sim = "weird", the actual number of observations in the resampled data sets may not be the same as the number in data. For this reason, if sim = "weird" and strata is supplied, statistic should also take a numeric vector indicating the strata. This allows the statistic to depend on the strata if required.

R

The number of bootstrap replicates.

F.surv

An object returned from a call to survfit giving the survivor function for the data. This is a required argument unless sim = "ordinary" or sim = "model" and cox is missing.

G.surv

Another object returned from a call to survfit but with the censoring indicators reversed to give the product-limit estimate of the censoring distribution. Note that for consistency the uncensored times should be reduced by a small amount in the call to survfit. This is a required argument whenever sim = "cond" or when sim = "model" and cox is supplied.

strata

The strata used in the calls to survfit. It can be a vector or a matrix with 2 columns. If it is a vector then it is assumed to be the strata for the survival
distribution, and the censoring distribution is assumed to be the same for all observations. If it is a matrix then the first column is the strata for the survival distribution and the second is the strata for the censoring distribution. When sim = "weird" only the strata for the survival distribution are used since the censoring times are considered fixed. When sim = "ordinary", only one set of strata is used to stratify the observations, this is taken to be the first column of strata when it is a matrix.

sim  The simulation type. Possible types are "ordinary" (case resampling), "model" (equivalent to "ordinary" if cox is missing, otherwise it is model-based resampling), "weird" (the weird bootstrap - this cannot be used if cox is supplied), and "cond" (the conditional bootstrap, in which censoring times are resampled from the conditional censoring distribution).

cox  An object returned from coxph. If it is supplied, then F.surv should have been generated by a call of the form survfit(cox).

index  A vector of length two giving the positions of the columns in data which correspond to the times and censoring indicators respectively.

...  Other named arguments which are passed unchanged to statistic each time it is called. Any such arguments to statistic must follow the arguments which statistic is required to have for the simulation. Beware of partial matching to arguments of censboot listed above, and that arguments named X and FUN cause conflicts in some versions of boot (but not this one).

parallel, ncpus, cl

See the help for boot.

Details

The various types of resampling are described in Davison and Hinkley (1997) in sections 3.5 and 7.3. The simplest is case resampling which simply resamples with replacement from the observations.

The conditional bootstrap simulates failure times from the estimate of the survival distribution. Then, for each observation its simulated censoring time is equal to the observed censoring time if the observation was censored and generated from the estimated censoring distribution conditional on being greater than the observed failure time if the observation was uncensored. If the largest value is censored then it is given a nominal failure time of Inf and conversely if it is uncensored it is given a nominal censoring time of Inf. This is necessary to allow the largest observation to be in the resamples.

If a Cox regression model is fitted to the data and supplied, then the failure times are generated from the survival distribution using that model. In this case the censoring times can either be simulated from the estimated censoring distribution (sim = "model") or from the conditional censoring distribution as in the previous paragraph (sim = "cond").

The weird bootstrap holds the censored observations as fixed and also the observed failure times. It then generates the number of events at each failure time using a binomial distribution with mean 1 and denominator the number of failures that could have occurred at that time in the original data set. In our implementation we insist that there is a least one simulated event in each stratum for every bootstrap dataset.

When there are strata involved and sim is either "model" or "cond" the situation becomes more difficult. Since the strata for the survival and censoring distributions are not the same it is possible
that for some observations both the simulated failure time and the simulated censoring time are infinite. To see this consider an observation in stratum 1F for the survival distribution and stratum 1G for the censoring distribution. Now if the largest value in stratum 1F is censored it is given a nominal failure time of $\text{Inf}$, also if the largest value in stratum 1G is uncensored it is given a nominal censoring time of $\text{Inf}$ and so both the simulated failure and censoring times could be infinite. When this happens the simulated value is considered to be a failure at the time of the largest observed failure time in the stratum for the survival distribution.

When parallel = "snow" and cl is not supplied, library(survival) is run in each of the worker processes.

Value

An object of class "boot" containing the following components:

t0          The value of statistic when applied to the original data.
t          A matrix of bootstrap replicates of the values of statistic.
R          The number of bootstrap replicates performed.
sim        The simulation type used. This will usually be the input value of sim unless that was "model" but cox was not supplied, in which case it will be "ordinary".
data       The data used for the bootstrap. This will generally be the input value of data unless sim = "weird", in which case it will just be the columns containing the times and the censoring indicators.
seed       The value of .Random.seed when censboot was called.
statistic  The input value of statistic.
strata      The strata used in the resampling. When sim = "ordinary" this will be a vector which stratifies the observations, when sim = "weird" it is the strata for the survival distribution and in all other cases it is a matrix containing the strata for the survival distribution and the censoring distribution.
call       The original call to censboot.

**channing**

**Channing House Data**

**Description**

The `channing` data frame has 462 rows and 5 columns.

Channing House is a retirement centre in Palo Alto, California. These data were collected between the opening of the house in 1964 until July 1, 1975. In that time 97 men and 365 women passed
through the centre. For each of these, their age on entry and also on leaving or death was recorded. A large number of the observations were censored mainly due to the resident being alive on July 1, 1975 when the data was collected. Over the time of the study 130 women and 46 men died at Channing House. Differences between the survival of the sexes, taking age into account, was one of the primary concerns of this study.

**Usage**

channing

**Format**

This data frame contains the following columns:

- **sex** A factor for the sex of each resident ("Male" or "Female").
- **entry** The resident's age (in months) on entry to the centre.
- **exit** The age (in months) of the resident on death, leaving the centre or July 1, 1975 whichever event occurred first.
- **time** The length of time (in months) that the resident spent at Channing House. (time=exit-entry)
- **cens** The indicator of right censoring. 1 indicates that the resident died at Channing House, 0 indicates that they left the house prior to July 1, 1975 or that they were still alive and living in the centre at that date.

**claridge**

*Genetic Links to Left-handedness*

**Description**

The claridge data frame has 37 rows and 2 columns.

The data are from an experiment which was designed to look for a relationship between a certain genetic characteristic and handedness. The 37 subjects were women who had a son with mental retardation due to inheriting a defective X-chromosome. For each such mother a genetic measurement of their DNA was made. Larger values of this measurement are known to be linked to the defective gene and it was hypothesized that larger values might also be linked to a progressive shift
away from right-handedness. Each woman also filled in a questionnaire regarding which hand they used for various tasks. From these questionnaires a measure of hand preference was found for each mother. The scale of this measure goes from 1, indicating someone who always favours their right hand, to 8, indicating someone who always favours their left hand. Between these two extremes are people who favour one hand for some tasks and the other for other tasks.

**Usage**
claridge

**Format**
This data frame contains the following columns:

- dnan  The genetic measurement on each woman's DNA.
- hand  The measure of left-handedness on an integer scale from 1 to 8.

Description
This function will find control variate estimates from a bootstrap output object. It can either find the adjusted bias estimate using post-simulation balancing or it can estimate the bias, variance, third cumulant and quantiles, using the linear approximation as a control variate.

Usage
control(boot.out, L = NULL, distn = NULL, index = 1, t0 = NULL, t = NULL, bias.adj = FALSE, alpha = NULL, ...)
Arguments

boot.out  A bootstrap output object returned from boot. The bootstrap replicates must have been generated using the usual nonparametric bootstrap.

L  The empirical influence values for the statistic of interest. If L is not supplied then empinf is called to calculate them from boot.out.

distn  If present this must be the output from smooth.spline giving the distribution function of the linear approximation. This is used only if bias.adj is FALSE. Normally this would be found using a saddlepoint approximation. If it is not supplied in that case then it is calculated by saddle.distn.

index  The index of the variable of interest in the output of boot.out$statistic.

t0  The observed value of the statistic of interest on the original data set boot.out$data. This argument is used only if bias.adj is FALSE. The input value is ignored if t is not also supplied. The default value is is boot.out$t0[index].

t  The bootstrap replicate values of the statistic of interest. This argument is used only if bias.adj is FALSE. The input is ignored if t0 is not supplied also. The default value is boot.out$t[,index].

bias.adj  A logical variable which if TRUE specifies that the adjusted bias estimate using post-simulation balance is all that is required. If bias.adj is FALSE (default) then the linear approximation to the statistic is calculated and used as a control variate in estimates of the bias, variance and third cumulant as well as quantiles.

alpha  The alpha levels for the required quantiles if bias.adj is FALSE.

...  Any additional arguments that boot.out$statistic requires. These are passed unchanged every time boot.out$statistic is called. boot.out$statistic is called once if bias.adj is TRUE, otherwise it may be called by empinf for empirical influence calculations if L is not supplied.

Details

If bias.adj is FALSE then the linear approximation to the statistic is found and evaluated at each bootstrap replicate. Then using the equation $T^* = Tl^* + (T^* - Tl^*)$, moment estimates can be found. For quantile estimation the distribution of the linear approximation to t is approximated very accurately by saddlepoint methods, this is then combined with the bootstrap replicates to approximate the bootstrap distribution of t and hence to estimate the bootstrap quantiles of t.

Value

If bias.adj is TRUE then the returned value is the adjusted bias estimate.

If bias.adj is FALSE then the returned value is a list with the following components

L  The empirical influence values used. These are the input values if supplied, and otherwise they are the values calculated by empinf.

tL  The linear approximations to the bootstrap replicates t of the statistic of interest.

bias  The control estimate of bias using the linear approximation to t as a control variate.
### Description

Calculates the weighted correlation given a data set and a set of weights.
Usage

corr(d, w = rep(1, nrow(d))/nrow(d))

Arguments

d A matrix with two columns corresponding to the two variables whose correlation we wish to calculate.
w A vector of weights to be applied to each pair of observations. The default is equal weights for each pair. Normalization takes place within the function so \( \sum(w) \) need not equal 1.

Details

This function finds the correlation coefficient in weighted form. This is often useful in bootstrap methods since it allows for numerical differentiation to get the empirical influence values. It is also necessary to have the statistic in this form to find ABC intervals.

Value

The correlation coefficient between \( d[,1] \) and \( d[,2] \).

See Also

cor

---

**cum3**

*Calculate Third Order Cumulants*

Description

Calculates an estimate of the third cumulant, or skewness, of a vector. Also, if more than one vector is specified, a product-moment of order 3 is estimated.

Usage

cum3(a, b = a, c = a, unbiased = TRUE)

Arguments

a A vector of observations.
b Another vector of observations, if not supplied it is set to the value of a. If supplied then it must be the same length as a.
c Another vector of observations, if not supplied it is set to the value of a. If supplied then it must be the same length as a.
unbiased A logical value indicating whether the unbiased estimator should be used.
Details

The unbiased estimator uses a multiplier of \( n/((n-1)*(n-2)) \) where \( n \) is the sample size, if unbiased is FALSE then a multiplier of \( 1/n \) is used. This is multiplied by \( \text{sum}((a-\text{mean}(a))*(b-\text{mean}(b))*(c-\text{mean}(c))) \) to give the required estimate.

Value

The required estimate.

cv.glm

Cross-validation for Generalized Linear Models

Description

This function calculates the estimated K-fold cross-validation prediction error for generalized linear models.

Usage

cv.glm(data, glmfit, cost, K)

Arguments

data A matrix or data frame containing the data. The rows should be cases and the columns correspond to variables, one of which is the response.

glmfit An object of class "glm" containing the results of a generalized linear model fitted to data.

cost A function of two vector arguments specifying the cost function for the cross-validation. The first argument to cost should correspond to the observed responses and the second argument should correspond to the predicted or fitted responses from the generalized linear model. cost must return a non-negative scalar value. The default is the average squared error function.

K The number of groups into which the data should be split to estimate the cross-validation prediction error. The value of K must be such that all groups are of approximately equal size. If the supplied value of K does not satisfy this criterion then it will be set to the closest integer which does and a warning is generated specifying the value of K used. The default is to set K equal to the number of observations in data which gives the usual leave-one-out cross-validation.

Details

The data is divided randomly into K groups. For each group the generalized linear model is fit to data omitting that group, then the function cost is applied to the observed responses in the group that was omitted from the fit and the prediction made by the fitted models for those observations.

When K is the number of observations leave-one-out cross-validation is used and all the possible splits of the data are used. When K is less than the number of observations the K splits to be used...
are found by randomly partitioning the data into \( K \) groups of approximately equal size. In this latter case a certain amount of bias is introduced. This can be reduced by using a simple adjustment (see equation 6.48 in Davison and Hinkley, 1997). The second value returned in \( \text{delta} \) is the estimate adjusted by this method.

Value

The returned value is a list with the following components.

- **call**: The original call to \( \text{cv.glm} \).
- **\( K \)**: The value of \( K \) used for the \( K \)-fold cross validation.
- **\( \text{delta} \)**: A vector of length two. The first component is the raw cross-validation estimate of prediction error. The second component is the adjusted cross-validation estimate. The adjustment is designed to compensate for the bias introduced by not using leave-one-out cross-validation.
- **seed**: The value of \( \text{.Random.seed} \) when \( \text{cv.glm} \) was called.

Side Effects

The value of \( \text{.Random.seed} \) is updated.

Examples

```r
# leave-one-out and 6-fold cross-validation prediction error for
# the mammals data set.
data(mammals, package="MASS")
mammals.glm <- glm(log(brain) ~ log(body), data = mammals)
(cv.err <- cv.glm(mammals, mammals.glm)$delta)
(cv.err.6 <- cv.glm(mammals, mammals.glm, K = 6)$delta)
```

# As this is a linear model we could calculate the leave-one-out
# cross-validation estimate without any extra model-fitting.
muhat <- fitted(mammals.glm)
mammals.diag <- glm.diag(mammals.glm)
(cv.err <- mean((mammals.glm$y - muhat)^2/(1 - mammals.diag$h)^2))

# leave-one-out and 11-fold cross-validation prediction error for
# the nodal data set. Since the response is a binary variable an
# appropriate cost function is

    cost <- function(r, pi = 0) mean(abs(r-pi) > 0.5)

    nodal.glm <- glm(r ~ stage+xray+acid, binomial, data = nodal)
    (cv.err <- cv.glm(nodal, nodal.glm, cost, K = nrow(nodal))$delta)
    (cv.11.err <- cv.glm(nodal, nodal.glm, cost, K = 11)$delta)

# Darwin's Plant Height Differences

darwin

## Description

The darwin data frame has 15 rows and 1 columns.

Charles Darwin conducted an experiment to examine the superiority of cross-fertilized plants over
self-fertilized plants. 15 pairs of plants were used. Each pair consisted of one cross-fertilized plant
and one self-fertilized plant which germinated at the same time and grew in the same pot. The
plants were measured at a fixed time after planting and the difference in heights between the cross-
and self-fertilized plants are recorded in eighths of an inch.

## Usage

darwin

## Format

This data frame contains the following column:

- **y**  The difference in heights for the pairs of plants (in units of 0.125 inches).

**Description**

The `downs.bc` data frame has 30 rows and 3 columns.

Down’s syndrome is a genetic disorder caused by an extra chromosome 21 or a part of chromosome 21 being translocated to another chromosome. The incidence of Down’s syndrome is highly dependent on the mother’s age and rises sharply after age 30. In the 1960’s a large scale study of the effect of maternal age on the incidence of Down’s syndrome was conducted at the British Columbia Health Surveillance Registry. These are the data which was collected in that study.

Mothers were classified by age. Most groups correspond to the age in years but the first group comprises all mothers with ages in the range 15-17 and the last is those with ages 46-49. No data for mothers over 50 or below 15 were collected.

**Usage**

downs.bc
**ducks**

**Format**

This data frame contains the following columns:

- **age**  The average age of all mothers in the age category.
- **m**    The total number of live births to mothers in the age category.
- **r**    The number of cases of Down’s syndrome.

**Source**

The data were obtained from

**ducks**  
*Behavioral and Plumage Characteristics of Hybrid Ducks*

**Description**

The ducks data frame has 11 rows and 2 columns.

Each row of the data frame represents a male duck who is a second generation cross of mallard and pintail ducks. For 11 such ducks a behavioural and plumage index were calculated. These were measured on scales devised for this experiment which was to examine whether there was any link between which species the ducks resembled physically and which they resembled in behaviour. The scale for the physical appearance ranged from 0 (identical in appearance to a mallard) to 20 (identical to a pintail). The behavioural traits of the ducks were on a scale from 0 to 15 with lower numbers indicating closer to mallard-like in behaviour.

**Usage**

ducks

**Format**

This data frame contains the following columns:

- **plumage**  The index of physical appearance based on the plumage of individual ducks.
- **behaviour** The index of behavioural characteristics of the ducks.
Source

The data were obtained from

**EEF.profile**  
*Empirical Likelihoods*

Description

Construct the empirical log likelihood or empirical exponential family log likelihood for a mean.

Usage

```r
EEF.profile(y, tmin = min(y) + 0.1, tmax = max(y) - 0.1, n.t = 25, 
u = function(y, t) y - t)
```

```r
EL.profile(y, tmin = min(y) + 0.1, tmax = max(y) - 0.1, n.t = 25, 
u = function(y, t) y - t)
```

Arguments

- **y**: A vector or matrix of data
- **tmin**: The minimum value of the range over which the likelihood should be computed. This must be larger than min(y).
- **tmax**: The maximum value of the range over which the likelihood should be computed. This must be smaller than max(y).
- **n.t**: The number of points between tmin and tmax at which the value of the log-likelihood should be computed.
- **u**: A function of the data and the parameter.

Details

These functions calculate the log likelihood for a mean using either an empirical likelihood or an empirical exponential family likelihood. They are supplied as part of the package *boot* for demonstration purposes with the practicals in chapter 10 of Davison and Hinkley (1997). The functions are not intended for general use and are not supported as part of the boot package. For more general and more robust code to calculate empirical likelihoods see Professor A. B. Owen’s empirical likelihood home page at the URL [http://www-stat.stanford.edu/~owen/empirical/](http://www-stat.stanford.edu/~owen/empirical/).
Value

A matrix with n.t rows. The first column contains the values of the parameter used. The second
column of the output of EL.profiles contains the values of the empirical log likelihood. The second
and third columns of the output of EEF.profiles contain two versions of the empirical exponential
family log-likelihood. The final column of the output matrix contains the values of the Lagrange
multiplier used in the optimization procedure.

empinf

Empirical Influence Values

Description

This function calculates the empirical influence values for a statistic applied to a data set. It allows
four types of calculation, namely the infinitesimal jackknife (using numerical differentiation), the
usual jackknife estimates, the ‘positive’ jackknife estimates and a method which estimates the em-
pirical influence values using regression of bootstrap replicates of the statistic. All methods can be
used with one or more samples.

Usage

empinf(boot.out = NULL, data = NULL, statistic = NULL,
       type = NULL, stype = NULL ,index = 1, t = NULL,
       strata = rep(1, n), eps = 0.001, ...)

Arguments

boot.out A bootstrap object created by the function boot. If type is "reg" then this
argument is required. For any of the other types it is an optional argument. If
it is included when optional then the values of data, statistic, stype, and
strata are taken from the components of boot.out and any values passed to
empinf directly are ignored.

data A vector, matrix or data frame containing the data for which empirical influence
values are required. It is a required argument if boot.out is not supplied. If
boot.out is supplied then data is set to boot.out$data and any value supplied
is ignored.
empinf

statistic  The statistic for which empirical influence values are required. It must be a function of at least two arguments, the data set and a vector of weights, frequencies or indices. The nature of the second argument is given by the value of stype. Any other arguments that it takes must be supplied to empinf and will be passed to statistic unchanged. This is a required argument if boot.out is not supplied, otherwise its value is taken from boot.out and any value supplied here will be ignored.

type  The calculation type to be used for the empirical influence values. Possible values of type are "inf" (infinitesimal jackknife), "jack" (usual jackknife), "pos" (positive jackknife), and "reg" (regression estimation). The default value depends on the other arguments. If t is supplied then the default value of type is "reg" and boot.out should be present so that its frequency array can be found. If t is not supplied then if stype is "w", the default value of type is "inf"; otherwise, if boot.out is present the default is "reg". If none of these conditions apply then the default is "jack". Note that it is an error for type to be "reg" if boot.out is missing or to be "inf" if stype is not "w".

stype  A character variable giving the nature of the second argument to statistic. It can take on three values: "w" (weights), "f" (frequencies), or "i" (indices). If boot.out is supplied the value of stype is set to boot.out$stype and any value supplied here is ignored. Otherwise it is an optional argument which defaults to "w". If type is "inf" then stype MUST be "w".

index  An integer giving the position of the variable of interest in the output of statistic.

t  A vector of length boot.out$R which gives the bootstrap replicates of the statistic of interest. t is used only when type is reg and it defaults to boot.out$t[,index].

strata  An integer vector or a factor specifying the strata for multi-sample problems. If boot.out is supplied the value of strata is set to boot.out$strata. Otherwise it is an optional argument which has default corresponding to the single sample situation.

eps  This argument is used only if type is "inf". In that case the value of epsilon to be used for numerical differentiation will be eps divided by the number of observations in data.

...  Any other arguments that statistic takes. They will be passed unchanged to statistic every time that it is called.

Details

If type is "inf" then numerical differentiation is used to approximate the empirical influence values. This makes sense only for statistics which are written in weighted form (i.e. stype is "w"). If type is "jack" then the usual leave-one-out jackknife estimates of the empirical influence are returned. If type is "pos" then the positive (include-one-twice) jackknife values are used. If type is "reg" then a bootstrap object must be supplied. The regression method then works by regressing the bootstrap replicates of statistic on the frequency array from which they were derived. The bootstrap frequency array is obtained through a call to boot.array. Further details of the methods are given in Section 2.7 of Davison and Hinkley (1997).
Empirical influence values are often used frequently in nonparametric bootstrap applications. For this reason many other functions call `empinf` when they are required. Some examples of their use are for nonparametric delta estimates of variance, BCa intervals and finding linear approximations to statistics for use as control variates. They are also used for antithetic bootstrap resampling.

**Value**

A vector of the empirical influence values of statistic applied to data. The values will be in the same order as the observations in data.

**Warning**

All arguments to `empinf` must be passed using the `name = value` convention. If this is not followed then unpredictable errors can occur.

```r
# The empirical influence values for the ratio of means in
# the city data.
ratio <- function(d, w) sum(d$x *w)/sum(d$u*w)
empinf(data = city, statistic = ratio)

city.boot <- boot(city, ratio, 499, stype="w")
empinf(boot.out = city.boot, type = "reg")

# A statistic that may be of interest in the difference of means
# problem is the t statistic for testing equality of means. In
# the bootstrap we get replicates of the difference of means and
# the variance of that statistic and then want to use this output
# to get the empirical influence values of the t statistic.
grav1 <- gravity[as.numeric(gravity[,2]) >= 7,]
grav.fun <- function(dat, w) {
    strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
    d <- dat[, 1]
    ns <- tabulate(strata)
    w <- w/tapply(w, strata, sum)[strata]
    mns <- as.vector(tapply(d * w, strata, sum)) # drop names
    mn2 <- tapply(d * d * w, strata, sum)
    s2hat <- sum((mn2 - mns^2)/ns)
}```
c(mns[2] - mns[1], s2hat)
)

grav.boot <- boot(grav1, grav.fun, R = 499, stype = "w",
                   strata = grav1[, 2])

# Since the statistic of interest is a function of the bootstrap
# statistics, we must calculate the bootstrap replicates and pass
# them to empinf using the t argument.
grav.z <- (grav.boot$t[,1]-grav.boot$t0[,1])/sqrt(grav.boot$t[,2])
empinf(boot.out = grav.boot, t = grav.z)

---

envelope

**Confidence Envelopes for Curves**

**Description**

This function calculates overall and pointwise confidence envelopes for a curve based on bootstrap replicates of the curve evaluated at a number of fixed points.

**Usage**

envelope(boot.out = NULL, mat = NULL, level = 0.95, index = 1:ncol(mat))

**Arguments**

- **boot.out**: An object of class "boot" for which boot.out$t contains the replicates of the curve at a number of fixed points.
- **mat**: A matrix of bootstrap replicates of the values of the curve at a number of fixed points. This is a required argument if boot.out is not supplied and is set to boot.out$t otherwise.
- **level**: The confidence level of the envelopes required. The default is to find 95% confidence envelopes. It can be a scalar or a vector of length 2. If it is scalar then both the pointwise and the overall envelopes are found at that level. If is a vector then the first element gives the level for the pointwise envelope and the second gives the level for the overall envelope.
- **index**: The numbers of the columns of mat which contain the bootstrap replicates. This can be used to ensure that other statistics which may have been calculated in the bootstrap are not considered as values of the function.

**Details**

The pointwise envelope is found by simply looking at the quantiles of the replicates at each point. The overall error for that envelope is then calculated using equation (4.17) of Davison and Hinkley (1997). A sequence of pointwise envelopes is then found until one of them has overall error approximately equal to the level required. If no such envelope can be found then the envelope returned will just contain the extreme values of each column of mat.
Value

A list with the following components:

- **point**: A matrix with two rows corresponding to the values of the upper and lower pointwise confidence envelope at the same points as the bootstrap replicates were calculated.
- **overall**: A matrix similar to `point` but containing the envelope which controls the overall error.
- **k.pt**: The quantiles used for the pointwise envelope.
- **err.pt**: A vector with two components, the first gives the pointwise error rate for the pointwise envelope, and the second the overall error rate for that envelope.
- **k.ov**: The quantiles used for the overall envelope.
- **err.ov**: A vector with two components, the first gives the pointwise error rate for the overall envelope, and the second the overall error rate for that envelope.
- **err.nom**: A vector of length 2 giving the nominal error rates for the pointwise and the overall envelopes.

lines(grav.qq$x, grav.env$point[2, ], lty = 4)
lines(grav.qq$x, grav.env$overall[1, ], lty = 1)
lines(grav.qq$x, grav.env$overall[2, ], lty = 1)
```
Description

This function calculates exponentially tilted multinomial distributions such that the resampling distributions of the linear approximation to a statistic have the required means.

Usage

exp.tilt(L, theta = NULL, t0 = 0, lambda = NULL, strata = rep(1, length(L)))

Arguments

- `L`: The empirical influence values for the statistic of interest based on the observed data. The length of `L` should be the same as the size of the original data set. Typically `L` will be calculated by a call to `empinf`.
- `theta`: The value at which the tilted distribution is to be centred. This is not required if `lambda` is supplied but is needed otherwise.
- `t0`: The current value of the statistic. The default is that the statistic equals 0.
- `lambda`: The Lagrange multiplier(s). For each value of `lambda` a multinomial distribution is found with probabilities proportional to \( \exp(\lambda \cdot L[j]/n) \), where \( n \) is the number of data points. `lambda` is then chosen to make the mean of the bootstrap distribution, of the linear approximation to the statistic of interest, equal to the required value `theta`. Thus `lambda` is defined as the solution of a nonlinear equation. The equation is solved by minimizing the Euclidean distance between the left and right hand sides of the equation using the function `nlmin`. If this minimum is not equal to zero then the method fails.
- `strata`: A vector or factor of the same length as `L` giving the strata for the observed data and the empirical influence values `L`.

Details

Exponential tilting involves finding a set of weights for a data set to ensure that the bootstrap distribution of the linear approximation to a statistic of interest has mean `theta`. The weights chosen to achieve this are given by \( p[j] \propto \exp(\lambda_j \cdot L[j]/n) \), where \( n \) is the number of data points. \( \lambda_j \) is then chosen to make the mean of the bootstrap distribution, of the linear approximation to the statistic of interest, equal to the required value `theta`. Thus \( \lambda_j \) is defined as the solution of a nonlinear equation. The equation is solved by minimizing the Euclidean distance between the left and right hand sides of the equation using the function `nlmin`. If this minimum is not equal to zero then the method fails.

Typically exponential tilting is used to find suitable weights for importance resampling. If a small tail probability or quantile of the distribution of the statistic of interest is required then a more efficient simulation is to centre the resampling distribution close to the point of interest and then use the functions `imp.prob` or `imp.quantile` to estimate the required quantity.

Another method of achieving a similar shifting of the distribution is through the use of `smooth.f`. The function `tilt.boot` uses `exp.tilt` or `smooth.f` to find the weights for a tilted bootstrap.
Value

A list with the following components:

- **p**: The tilted probabilities. There will be \( m \) distributions where \( m \) is the length of \( \theta \) (or \( \lambda \) if supplied). If \( m \) is 1 then \( p \) is a vector of length(\( L \)) probabilities. If \( m \) is greater than 1 then \( p \) is a matrix with \( m \) rows, each of which contain length(\( L \)) probabilities. In this case the vector \( p[i,] \) is the distribution tilted to \( \theta[i] \). \( p \) is in the form required by the argument weights of the function boot for importance resampling.

- **lambda**: The Lagrange multiplier used in the equation to determine the tilted probabilities. \( \lambda \) is a vector of the same length as \( \theta \).

- **theta**: The values of \( \theta \) to which the distributions have been tilted. In general this will be the input value of \( \theta \) but if \( \lambda \) was supplied then this is the vector of the corresponding \( \theta \) values.

Examples

```r
# Example 9.8 of Davison and Hinkley (1997) requires tilting the resampling
# distribution of the studentized statistic to be centred at the observed
# value of the test statistic 1.84. This can be achieved as follows.
grav1 <- gravity[as.numeric(gravity[,2]) >= 7, ]
grav.fun <- function(dat, w, orig) {
  strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
  d <- dat[, 1]
  ns <- tabulate(strata)
  w <- w/tapply(w, strata, sum)[strata]
  mns <- as.vector(tapply(d * w, strata, sum)) # drop names
  mn2 <- tapply(d * d * w, strata, sum)
  s2hat <- sum((mn2 - mns^2)/ns)
  c(mns[2]-mns[1], s2hat, (mns[2]-mns[1]-orig)/sqrt(s2hat))
}
grav.z0 <- grav.fun(grav1, rep(1, 26), 0)
grav.L <- empinf(data = grav1, statistic = grav.fun, stype = "w",
strata = grav1[,2], index = 3, orig = grav.z0[1])
grav.tilt <- exp.tilt(grav.L, grav.z0[3], strata = grav1[,2])
boot(grav1, grav.fun, R = 499, stype = "w", weights = grav.tilt$p,
strata = grav1[,2], orig = grav.z0[1])
```
Counts of Balsam-fir Seedlings

**Description**

The *fir* data frame has 50 rows and 3 columns.

The number of balsam-fir seedlings in each quadrant of a grid of 50 five foot square quadrants were counted. The grid consisted of 5 rows of 10 quadrants in each row.

**Usage**

```r
fir
```

**Format**

This data frame contains the following columns:

- `count` The number of seedlings in the quadrant.
- `row` The row number of the quadrant.
- `col` The quadrant number within the row.

**Source**

Bootstrap Frequency Arrays

**Description**

Take a matrix of indices for nonparametric bootstrap resamples and return the frequencies of the original observations in each resample.

**Usage**

```r
freq.array(i.array)
```

**Arguments**

- `i.array` This will be an matrix of integers between 1 and n, where n is the number of observations in a data set. The matrix will have n columns and R rows where R is the number of bootstrap resamples. Such matrices are found by boot when doing nonparametric bootstraps. They can also be found after a bootstrap has been run through the function `boot.array`.
Value

A matrix of the same dimensions as the input matrix. Each row of the matrix corresponds to a single bootstrap resample. Each column of the matrix corresponds to one of the original observations and specifies its frequency in each bootstrap resample. Thus the first column tells us how often the first observation appeared in each bootstrap resample. Such frequency arrays are often useful for diagnostic purposes such as the jackknife-after-bootstrap plot. They are also necessary for the regression estimates of empirical influence values and for finding importance sampling weights.

glm.diag  Generalized Linear Model Diagnostics

Description
Calculates jackknife deviance residuals, standardized deviance residuals, standardized Pearson residuals, approximate Cook statistic, leverage and estimated dispersion.

Usage
glm.diag(glmfit)

Arguments
glmfit glmfit is a glm.object - the result of a call to glm()

Value
Returns a list with the following components
res The vector of jackknife deviance residuals.
rd The vector of standardized deviance residuals.
rp The vector of standardized Pearson residuals.
cook The vector of approximate Cook statistics.
h The vector of leverages of the observations.
 sd The value used to standardize the residuals. This is the estimate of residual standard deviation in the Gaussian family and is the square root of the estimated shape parameter in the Gamma family. In all other cases it is 1.

Note
See the help for glm.diag.plot for an example of the use of glm.diag.

References

glm.diag.plots

Diagnostics plots for generalized linear models

**Description**

Makes plot of jackknife deviance residuals against linear predictor, normal scores plots of standardized deviance residuals, plot of approximate Cook statistics against leverage/(1-leverage), and case plot of Cook statistic.

**Usage**

```r
glm.diag.plots(glmfit, glmdiag = glm.diag(glmfit), subset = NULL, iden = FALSE, labels = NULL, ret = FALSE)
```

**Arguments**

- `glmfit` 
  glm.object: the result of a call to `glm()`
- `glmdiag` 
  Diagnostics of `glmfit` obtained from a call to `glm.diag`. If it is not supplied then it is calculated.
- `subset` 
  Subset of data for which glm fitting performed: should be the same as the subset option used in the call to `glm()` which generated `glmfit`. Needed only if the subset= option was used in the call to `glm`.
- `iden` 
  A logical argument. If TRUE then, after the plots are drawn, the user will be prompted for an integer between 0 and 4. A positive integer will select a plot and invoke `identify()` on that plot. After exiting `identify()`, the user is again prompted, this loop continuing until the user responds to the prompt with 0. If `iden` is FALSE (default) the user cannot interact with the plots.
- `labels` 
  A vector of labels for use with `identify()` if `iden` is TRUE. If it is not supplied then the labels are derived from `glmfit`.
- `ret` 
  A logical argument indicating if `glmdiag` should be returned. The default is FALSE.

**Details**

The diagnostics required for the plots are calculated by `glm.diag`. These are then used to produce the four plots on the current graphics device.

The plot on the top left is a plot of the jackknife deviance residuals against the fitted values.

The plot on the top right is a normal QQ plot of the standardized deviance residuals. The dotted line is the expected line if the standardized residuals are normally distributed, i.e. it is the line with intercept 0 and slope 1.

The bottom two panels are plots of the Cook statistics. On the left is a plot of the Cook statistics against the standardized leverages. In general there will be two dotted lines on this plot. The horizontal line is at $8/(n-2p)$ where $n$ is the number of observations and $p$ is the number of parameters estimated. Points above this line may be points with high influence on the model. The vertical line is at $2p/(n-2p)$ and points to the right of this line have high leverage compared to the variance of the
raw residual at that point. If all points are below the horizontal line or to the left of the vertical line then the line is not shown.

The final plot again shows the Cook statistic this time plotted against case number enabling us to find which observations are influential.

Use of `iden=T` is encouraged for proper exploration of these four plots as a guide to how well the model fits the data and whether certain observations have an unduly large effect on parameter estimates.

**Value**

If `ret` is `TRUE` then the value of `glmdiag` is returned otherwise there is no returned value.

**Side Effects**

The current device is cleared and four plots are plotted by use of `split.screen(c(2,2))`. If `iden` is `TRUE`, interactive identification of points is enabled. All screens are closed, but not cleared, on termination of the function.

**gravity**

*Acceleration Due to Gravity*
Description

The gravity data frame has 81 rows and 2 columns.
The grav data set has 26 rows and 2 columns.
Between May 1934 and July 1935, the National Bureau of Standards in Washington D.C. conducted a series of experiments to estimate the acceleration due to gravity, g, at Washington. Each experiment produced a number of replicate estimates of g using the same methodology. Although the basic method remained the same for all experiments, that of the reversible pendulum, there were changes in configuration.
The gravity data frame contains the data from all eight experiments. The grav data frame contains the data from the experiments 7 and 8. The data are expressed as deviations from 980.000 in centimetres per second squared.

Usage

gravity

Format

This data frame contains the following columns:

- g  The deviation of the estimate from 980.000 centimetres per second squared.
- series A factor describing from which experiment the estimate was derived.

Imp.Estimates  Importance Sampling Estimates

Description

Central moment, tail probability, and quantile estimates for a statistic under importance resampling.

Usage

imp.moments(boot.out = NULL, index = 1, t = boot.out$t[, index],
            w = NULL, def = TRUE, q = NULL)
imp.prob(boot.out = NULL, index = 1, t0 = boot.out$t0[index],
         t = boot.out$t[, index], w = NULL, def = TRUE, q = NULL)
imp.quantile(boot.out = NULL, alpha = NULL, index = 1,
              t = boot.out$t[, index], w = NULL, def = TRUE, q = NULL)

Arguments

boot.out  A object of class "boot" generated by a call to boot or tilt.boot. Use of these functions makes sense only when the bootstrap resampling used unequal weights for the observations. If the importance weights w are not supplied then boot.out is a required argument. It is also required if t is not supplied.
alpha  The alpha levels for the required quantiles. The default is to calculate the 1%, 2.5%, 5%, 10%, 90%, 95%, 97.5% and 99% quantiles.
index  The index of the variable of interest in the output of boot.out$statistic. This is not used if the argument t is supplied.
The values at which tail probability estimates are required. For each value \( t_0[i] \) the function will estimate the bootstrap cdf evaluated at \( t_0[i] \). If \( \text{imp.prob} \) is called without the argument \( t_0 \) then the bootstrap cdf evaluated at the observed value of the statistic is found.

The bootstrap replicates of a statistic. By default these are taken from the bootstrap output object \( \text{boot.out} \) but they can be supplied separately if required (e.g. when the statistic of interest is a function of the calculated values in \( \text{boot.out} \)). Either \( \text{boot.out} \) or \( t \) must be supplied.

The importance resampling weights for the bootstrap replicates. If they are not supplied then \( \text{boot.out} \) must be supplied, in which case the importance weights are calculated by a call to \( \text{imp.weights} \).

A logical value indicating whether a defensive mixture is to be used for weight calculation. This is used only if \( w \) is missing and it is passed unchanged to \( \text{imp.weights} \) to calculate \( w \).

A vector of probabilities specifying the resampling distribution from which any estimates should be found. In general this would correspond to the usual bootstrap resampling distribution which gives equal weight to each of the original observations. The estimates depend on this distribution only through the importance weights \( w \) so this argument is ignored if \( w \) is supplied. If \( w \) is missing then \( q \) is passed as an argument to \( \text{imp.weights} \) and used to find \( w \).

A list with the following components:

- **alpha**: The alpha levels used for the quantiles, if \( \text{imp.quantile} \) is used.
- **t0**: The values at which the tail probabilities are estimated, if \( \text{imp.prob} \) is used.
- **raw**: The raw importance resampling estimates. For \( \text{imp.moments} \) this has length 2, the first component being the estimate of the mean and the second being the variance estimate. For \( \text{imp.prob}, \text{raw} \) is of the same length as \( t_0 \), and for \( \text{imp.quantile} \) it is of the same length as \( \alpha \).
- **rat**: The ratio importance resampling estimates. In this method the weights \( w \) are rescaled to have average value one before they are used. The format of this vector is the same as \( \text{raw} \).
- **reg**: The regression importance resampling estimates. In this method the weights which are used are derived from a regression of \( t*w \) on \( w \). This choice of weights can be shown to minimize the variance of the weights and also the Euclidean distance of the weights from the uniform weights. The format of this vector is the same as \( \text{raw} \).

  ns <- tabulate(strata)
  w <- w/tapply(w, strata, sum)[strata]
  mns <- as.vector(tapply(d * w, strata, sum)) # drop names
  mn2 <- tapply(d * d * w, strata, sum)
  s2hat <- sum((mn2 - mns^2)/ns)
}
grav.z/zero.noslash <- grav.fun(grav1, rep(1, 26), /zero.noslash)
grav.L <- empinf(data = grav1, statistic = grav.fun, stype = "w",
      strata = grav1[,2], index = 3, orig = grav.z/zero.noslash[1])
grav.tilt <- exp.tilt(grav.L, grav.z/zero.noslash[3], strata = grav1[, 2])
grav.tilt.boot <- boot(grav1, grav.fun, R = 199, stype = "w",
      strata = grav1[, 2], weights = grav.tilt$p,
      orig = grav.z/zero.noslash[1])
# Since the weights are needed for all calculations, we shall calculate
# them once only.
grav.w <- imp.weights(grav.tilt.boot)
grav.mom <- imp.moments(grav.tilt.boot, w = grav.w, index = 3)
grav.p <- imp.prob(grav.tilt.boot, w = grav.w, index = 3, t0 = grav.z/zero.noslash[3])
unlist(grav.p)
grav.q <- imp.quantile(grav.tilt.boot, w = grav.w, index = 3,
      alpha = c(0.9, 0.95, 0.975, 0.99))
as.data.frame(grav.q)
```
Usage

imp.weights(boot.out, def = TRUE, q = NULL)

Arguments

boot.out  A object of class "boot" generated by boot or tilt.boot. Typically the bootstrap simulations would have been done using importance resampling and we wish to do our calculations under the assumption of sampling with equal probabilities.

def  A logical variable indicating whether the defensive mixture distribution weights should be calculated. This makes sense only in the case where the replicates in boot.out were simulated under a number of different distributions. If this is the case then the defensive mixture weights use a mixture of the distributions used in the bootstrap. The alternative is to calculate the weights for each replicate using knowledge of the distribution from which the bootstrap resample was generated.

q  A vector of probabilities specifying the resampling distribution from which we require inferences to be made. In general this would correspond to the usual bootstrap resampling distribution which gives equal weight to each of the original observations and this is the default. q must have length equal to the number of observations in the boot.out$data and all elements of q must be positive.

Details

The importance sampling weight for a bootstrap replicate with frequency vector \( f \) is given by \( \prod ((q/p)^f) \). This reweights the replicates so that estimates can be found as if the bootstrap resamples were generated according to the probabilities \( q \) even though, in fact, they came from the distribution \( p \).

Value

A vector of importance weights of the same length as boot.out$t. These weights can then be used to reweight boot.out$t so that estimates can be found as if the simulations were from a distribution with probabilities \( q \).

Note

See the example in the help for imp.moments for an example of using imp.weights.

References

inv.logit  Inverse Logit Function

Description
Given a numeric object return the inverse logit of the values.

Usage
inv.logit(x)

Arguments
x  A numeric object. Missing values (NAs) are allowed.

Details
The inverse logit is defined by \( \frac{\exp(x)}{1+\exp(x)} \). Values in \( x \) of \(-\infty\) or \( \infty \) return logits of 0 or 1 respectively. Any NAs in the input will also be NAs in the output.

Value
An object of the same type as \( x \) containing the inverse logits of the input values.

See Also
logit, plogis for which this is a wrapper.

islay  Jura Quartzite Azimuths on Islay

Description
The islay data frame has 18 rows and 1 columns.
Measurements were taken of paleocurrent azimuths from the Jura Quartzite on the Scottish island of Islay.

Usage
islay
jack.after.boot

2083

Format
This data frame contains the following column:
theta The angle of the azimuth in degrees East of North.
Source
The data were obtained from
Hand, D.J., Daly, F., Lunn, A.D., McConway, K.J. and Ostrowski, E. (1994) A Handbook of Small
Data Sets, Chapman and Hall.
References
University Press.

jack.after.boot

Jackknife-after-Bootstrap Plots

Description
This function calculates the jackknife influence values from a bootstrap output object and plots the
corresponding jackknife-after-bootstrap plot.
Usage
jack.after.boot(boot.out, index = 1, t = NULL, L = NULL,
useJ = TRUE, stinf = TRUE, alpha = NULL,
main = "", ylab = NULL, ...)
Arguments
boot.out

An object of class "boot" which would normally be created by a call to boot.
It should represent a nonparametric bootstrap. For reliable results boot.out$R
should be reasonably large.

index

The index of the statistic of interest in the output of boot.out$statistic.

t

A vector of length boot.out$R giving the bootstrap replicates of the statistic of
interest. This is useful if the statistic of interest is a function of the calculated
bootstrap output. If it is not supplied then the default is boot.out$t[,index].

L

The empirical influence values for the statistic of interest. These are used only if
useJ is FALSE. If they are not supplied and are needed, they are calculated by a
call to empinf. If L is supplied then it is assumed that they are the infinitesimal
jackknife values.


useJ   A logical variable indicating if the jackknife influence values calculated from
        the bootstrap replicates should be used. If FALSE the empirical influence values
        are used. The default is TRUE.

stinf  A logical variable indicating whether to standardize the jackknife values before
        plotting them. If TRUE then the jackknife values used are divided by their stan-
        dard error.

alpha  The quantiles at which the plots are required. The default is
        c(0.05, 0.1, 0.16, 0.5, 0.84, 0.9, 0.95).

main   A character string giving the main title for the plot.

ylab   The label for the Y axis. If the default values of alpha are used and ylab is not
        supplied then a label indicating which percentiles are plotted is used. If alpha
        is supplied then the default label will not say which percentiles were used.

...    Any extra arguments required by boot.out$statistic. These are required
        only if useJ is FALSE and L is not supplied, in which case they are passed to
        empinf for use in calculation of the empirical influence values.

Details

The centred jackknife quantiles for each observation are estimated from those bootstrap samples in
which the particular observation did not appear. These are then plotted against the influence values.
If useJ is TRUE then the influence values are found in the same way as the difference between the
mean of the statistic in the samples excluding the observations and the mean in all samples. If useJ
is FALSE then empirical influence values are calculated by calling empinf.

The resulting plots are useful diagnostic tools for looking at the way individual observations affect
the bootstrap output.

The plot will consist of a number of horizontal dotted lines which correspond to the quantiles of
the centred bootstrap distribution. For each data point the quantiles of the bootstrap distribution
calculated by omitting that point are plotted against the (possibly standardized) jackknife values.
The observation number is printed below the plots. To make it easier to see the effect of omitting
points on quantiles, the plotted quantiles are joined by line segments. These plots provide a useful
diagnostic tool in establishing the effect of individual observations on the bootstrap distribution.
See the references below for some guidelines on the interpretation of the plots.

Value

There is no returned value but a plot is generated on the current graphics display.

Side Effects

A plot is created on the current graphics device.

  v <- pcorr(d)
  c(v[1,], v[2,], v[3,], v[4,])
}
frets.boot <- boot(log(as.matrix(frets)), frets.fun, R = 999)
# we will concentrate on the partial correlation between head breadth
# for the first son and head length for the second. This is the 7th
# element in the output of frets.fun so we set index = 7
jack.after.boot(frets.boot, useJ = FALSE, stinf = FALSE, index = 7)

k3.linear

Linear Skewness Estimate

DESCRIPTION

Estimates the skewness of a statistic from its empirical influence values.

USAGE

`k3.linear(L, strata = NULL)`

ARGUMENTS

L Vector of the empirical influence values of a statistic. These will usually be calculated by a call to `empinf`. 
strata  A numeric vector or factor specifying which observations (and hence which components of L) come from which strata.

Value

The skewness estimate calculated from L.

References

See Also

empinf, linear.approx, var.linear

Examples

# To estimate the skewness of the ratio of means for the city data.
ratio <- function(d, w) sum(d$x * w)/sum(d$u * w)
k3.linear(empinf(data = city, statistic = ratio))
linear.approx

The observed value of the statistic of interest. The input value is used only if one of \( t \) or \( L \) is also supplied. The default value is \( \text{boot.out}[index] \). If \( t0 \) is supplied but neither \( t \) nor \( L \) are supplied then \( t0 \) is set to \( \text{boot.out}[index] \) and a warning is generated.

\( t \)

A vector of bootstrap replicates of the statistic of interest. If \( t0 \) is missing then \( t \) is not used, otherwise it is used to calculate the empirical influence values (if they are not supplied in \( L \)).

Any extra arguments required by \( \text{boot.out}[\text{statistic}] \). These are needed if \( L \) is not supplied as they are used by \( \text{empinf} \) to calculate empirical influence values.

Details

The linear approximation to a bootstrap replicate with frequency vector \( f \) is given by \( t0 + \text{sum}(L * f)/n \) in the one sample with an easy extension to the stratified case. The frequencies are found by calling \( \text{boot.array} \).

Value

A vector of length \( \text{boot.out}[R] \) with the linear approximations to the statistic of interest for each of the bootstrap samples.

Examples

# Using the city data let us look at the linear approximation to the # ratio statistic and its logarithm. We compare these with the # corresponding plots for the bigcity data

```r
ratio <- function(d, w) sum(d$x * w)/sum(d$u * w)
city.boot <- boot(city, ratio, R = 499, stype = "w")
bigcity.boot <- boot(bigcity, ratio, R = 499, stype = "w")
```

op <- par(pty = "s", mfrow = c(2, 2))

# The first plot is for the city data ratio statistic.
city.lin1 <- linear.approx(city.boot)
lim <- range(c(city.boot$t, city.lin1))
plot(city.boot$t, city.lin1, xlim = lim, ylim = lim,
     main = "Ratio; n=1/zero.noslash", xlab = "t*", ylab = "tL*")
abline(0, 1)

# Now for the log of the ratio statistic for the city data.
city.lin2 <- linear.approx(city.boot,t0 = log(city.boot$t0),
    t = log(city.boot$t))
lim <- range(c(log(city.boot$t),city.lin2))
plot(log(city.boot$t), city.lin2, xlim = lim, ylim = lim,
    main = "Log(Ratio); n=10", xlab = "t\star", ylab = "tL\star")
abline(0, 1)

# The ratio statistic for the bigcity data.
bigcity.lin1 <- linear.approx(bigcity.boot)
lim <- range(c(bigcity.boot$t,bigcity.lin1))
plot(bigcity.lin1, bigcity.boot$t, xlim = lim, ylim = lim,
    main = "Ratio; n=49", xlab = "t\star", ylab = "tL\star")
abline(0, 1)

# Finally the log of the ratio statistic for the bigcity data.
bigcity.lin2 <- linear.approx(bigcity.boot,t0 = log(bigcity.boot$t0),
    t = log(bigcity.boot$t))
lim <- range(c(log(bigcity.boot$t),bigcity.lin2))
plot(bigcity.lin2, log(bigcity.boot$t), xlim = lim, ylim = lim,
    main = "Log(Ratio); n=49", xlab = "t\star", ylab = "tL\star")
abline(0, 1)

par(op)

---

**lines.saddle.distn**  
*Add a Saddlepoint Approximation to a Plot*

**Description**

This function adds a line corresponding to a saddlepoint density or distribution function approximation to the current plot.

**Usage**

```r
## S3 method for class 'saddle.distn'
lines(x, dens = TRUE, h = function(u) u, J = function(u) 1,
    npts = 50, lty = 1, ...)
```

**Arguments**

- `x`  
  An object of class "saddle.distn" (see `saddle.distn.object` representing a saddlepoint approximation to a distribution.

- `dens`  
  A logical variable indicating whether the saddlepoint density (TRUE; the default) or the saddlepoint distribution function (FALSE) should be plotted.

- `h`  
  Any transformation of the variable that is required. Its first argument must be the value at which the approximation is being performed and the function must be vectorized.
When \( \text{dens} = \text{TRUE} \) this function specifies the Jacobian for any transformation that may be necessary. The first argument of \( J \) must the value at which the approximation is being performed and the function must be vectorized. If \( h \) is supplied \( J \) must also be supplied and both must have the same argument list.

\( \text{npts} \)

The number of points to be used for the plot. These points will be evenly spaced over the range of points used in finding the saddlepoint approximation.

\( \text{lty} \)

The line type to be used.

\( \ldots \)

Any additional arguments to \( h \) and \( J \).

**Details**

The function uses \texttt{smooth.spline} to produce the saddlepoint curve. When \( \text{dens} = \text{TRUE} \) the spline is on the log scale and when \( \text{dens} = \text{FALSE} \) it is on the probit scale.

**Value**

\( \text{sad.d} \) is returned invisibly.

**Side Effects**

A line is added to the current plot.

**References**

**See Also**

\texttt{saddle.distn}

**Examples**

# In this example we show how a plot such as that in Figure 9.9 of # Davison and Hinkley (1997) may be produced. Note the large number of # bootstrap replicates required in this example.
expdata <- rexp(12)
vfun <- function(d, i) {
    n <- length(d)
    (n-1)/n*var(d[i])
}
exp.boot <- boot(expdata,vfun, R = 9999)
expl <- (expdata - mean(expdata))^2 - exp.boot$t
exptl <- linear.approx(exp.boot, L = expl)
hist(exptl, nclass = 50, probability = TRUE)
expt0 <- c(0, sqrt(var(exp.boot$t)))
expsp <- saddle.distn(A = expl/12,wdist = "m", t0 = expt0)

# The saddlepoint approximation in this case is to the density of # t-t0 and so t0 must be added for the plot.
lines(exp.sp, h = function(u, t0) u+t0, J = function(u, t0) 1, t0 = exp.boot$t0)

logit

*Logit of Proportions*

**Description**

This function calculates the logit of proportions.

**Usage**

`logit(p)`

**Arguments**

- `p`: A numeric Splus object, all of whose values are in the range [0,1]. Missing values (NA's) are allowed.

**Details**

If any elements of `p` are outside the unit interval then an error message is generated. Values of `p` equal to 0 or 1 (to within machine precision) will return -Inf or Inf respectively. Any NA's in the input will also be NA's in the output.

**Value**

A numeric object of the same type as `p` containing the logits of the input values.

**See Also**

`inv.logit, qlogis` for which this is a wrapper.

**manaus**

*Average Heights of the Rio Negro river at Manaus*

**Description**

The `manaus` time series is of class "ts" and has 1080 observations on one variable. The data values are monthly averages of the daily stages (heights) of the Rio Negro at Manaus. Manaus is 18km upstream from the confluence of the Rio Negro with the Amazon but because of the tiny slope of the water surface and the lower courses of its flatland affluents, they may be regarded as a good approximation of the water level in the Amazon at the confluence. The data here cover 90 years from January 1903 until December 1992.

The Manaus gauge is tied in with an arbitrary bench mark of 100m set in the steps of the Municipal Prefecture; gauge readings are usually referred to sea level, on the basis of a mark on the steps
leading to the Parish Church (Matriz), which is assumed to lie at an altitude of 35.874 m according to observations made many years ago under the direction of Samuel Pereira, an engineer in charge of the Manaus Sanitation Committee. Whereas such an altitude cannot, by any means, be considered to be a precise datum point, observations have been provisionally referred to it. The measurements are in metres.

**Source**

The data were kindly made available by Professors H. O’Reilly Sternberg and D. R. Brillinger of the University of California at Berkeley.

**References**

---

**melanoma**

*Survival from Malignant Melanoma*

**Description**

The melanoma data frame has 205 rows and 7 columns.

The data consist of measurements made on patients with malignant melanoma. Each patient had their tumour removed by surgery at the Department of Plastic Surgery, University Hospital of Odense, Denmark during the period 1962 to 1977. The surgery consisted of complete removal of the tumour together with about 2.5 cm of the surrounding skin. Among the measurements taken were the thickness of the tumour and whether it was ulcerated or not. These are thought to be important prognostic variables in that patients with a thick and/or ulcerated tumour have an increased chance of death from melanoma. Patients were followed until the end of 1977.

**Usage**

melanoma

**Format**

This data frame contains the following columns:

- **time**: Survival time in days since the operation, possibly censored.
- **status**: The patients' status at the end of the study. 1 indicates that they had died from melanoma, 2 indicates that they were still alive and 3 indicates that they had died from causes unrelated to their melanoma.
sex  The patients sex; 1=male, 0=female.
age  Age in years at the time of the operation.
year  Year of operation.
thickness  Tumour thickness in mm.
ulcer  Indicator of ulceration; 1=present, 0=absent.

Note
This dataset is not related to the dataset in the lattice package with the same name.

Source
The data were obtained from

References

motor  Data from a Simulated Motorcycle Accident

Description
The motor data frame has 94 rows and 4 columns. The rows are obtained by removing replicate values of time from the dataset mcycle. Two extra columns are added to allow for strata with a different residual variance in each stratum.

Usage
motor

Format
This data frame contains the following columns:
times  The time in milliseconds since impact.
accel  The recorded head acceleration (in g).
strata  A numeric column indicating to which of the three strata (numbered 1, 2 and 3) the observations belong.
v  An estimate of the residual variance for the observation. v is constant within the strata but a different estimate is used for each of the three strata.
Source

**neuro**  
*Neurophysiological Point Process Data*

Description

`neuro` is a matrix containing times of observed firing of a neuron in windows of 250ms either side of the application of a stimulus to a human subject. Each row of the matrix is a replication of the experiment and there were a total of 469 replicates.

Note

There are a lot of missing values in the matrix as different numbers of firings were observed in different replicates. The number of firings observed varied from 2 to 6.

Source

The data were collected and kindly made available by Dr. S.J. Boniface of the Neurophysiology Unit at the Radcliffe Infirmary, Oxford.

References

Description

The nitrofen data frame has 50 rows and 5 columns.

Nitrofen is a herbicide that was used extensively for the control of broad-leaved and grass weeds in cereals and rice. Although it is relatively non-toxic to adult mammals, nitrofen is a significant tetragen and mutagen. It is also acutely toxic and reproductively toxic to cladoceran zooplankton. Nitrofen is no longer in commercial use in the U.S., having been the first pesticide to be withdrawn due to tetragen effects.

The data here come from an experiment to measure the reproductive toxicity of nitrofen on a species of zooplankton (Ceriodaphnia dubia). 50 animals were randomized into batches of 10 and each batch was put in a solution with a measured concentration of nitrofen. Then the number of live offspring in each of the three broods to each animal was recorded.

Usage

nitrofen

Format

This data frame contains the following columns:

conc  The nitrofen concentration in the solution (mg/litre).
brood1  The number of live offspring in the first brood.
brood2  The number of live offspring in the second brood.
brood3  The number of live offspring in the third brood.
total  The total number of live offspring in the first three broods.

Source

The data were obtained from

References

The nodal data frame has 53 rows and 7 columns. The treatment strategy for a patient diagnosed with cancer of the prostate depend highly on whether the cancer has spread to the surrounding lymph nodes. It is common to operate on the patient to get samples from the nodes which can then be analysed under a microscope but clearly it would be preferable if an accurate assessment of nodal involvement could be made without surgery.

For a sample of 53 prostate cancer patients, a number of possible predictor variables were measured before surgery. The patients then had surgery to determine nodal involvement. It was required to see if nodal involvement could be accurately predicted from the predictor variables and which ones were most important.

**Format**

This data frame contains the following columns:

- `m` A column of ones.
- `r` An indicator of nodal involvement.
- `aged` The patients age dichotomized into less than 60 (0) and 60 or over 1.
- `stage` A measurement of the size and position of the tumour observed by palpitation with the fingers via the rectum. A value of 1 indicates a more serious case of the cancer.
- `grade` Another indicator of the seriousness of the cancer, this one is determined by a pathology reading of a biopsy taken by needle before surgery. A value of 1 indicates a more serious case of the cancer.
- `xray` A third measure of the seriousness of the cancer taken from an X-ray reading. A value of 1 indicates a more serious case of the cancer.
- `acid` The level of acid phosphatase in the blood serum.

**Source**

The data were obtained from

**References**

Normal Approximation Confidence Intervals

Description

Using the normal approximation to a statistic, calculate equi-tailed two-sided confidence intervals.

Usage

```r
norm.ci(boot.out = NULL, conf = 0.95, index = 1, var.t0 = NULL,
       t0 = NULL, t = NULL, L = NULL, h = function(t) t,
       hdot = function(t) 1, hinv = function(t) t)
```

Arguments

- `boot.out`: A bootstrap output object returned from a call to `boot`. If `t0` is missing then `boot.out` is a required argument. It is also required if both `var.t0` and `t` are missing.
- `conf`: A scalar or vector containing the confidence level(s) of the required interval(s).
- `index`: The index of the statistic of interest within the output of a call to `boot.out$statistic`. It is not used if `boot.out` is missing, in which case `t0` must be supplied.
- `var.t0`: The variance of the statistic of interest. If it is not supplied then `var(t)` is used.
- `t0`: The observed value of the statistic of interest. If it is missing then it is taken from `boot.out` which is required in that case.
- `t`: Bootstrap replicates of the variable of interest. These are used to estimate the variance of the statistic of interest if `var.t0` is not supplied. The default value is `boot.out$t[,index]`.
- `L`: The empirical influence values for the statistic of interest. These are used to calculate `var.t0` if neither `var.t0` nor `boot.out` are supplied. If a transformation is supplied through `h` then the influence values must be for the untransformed statistic `t0`.
- `h`: A function defining a monotonic transformation, the intervals are calculated on the scale of `h(t)` and the inverse function `hinv` is applied to the resulting intervals. `h` must be a function of one variable only and must be vectorized. The default is the identity function.
- `hdot`: A function of one argument returning the derivative of `h`. It is a required argument if `h` is supplied and is used for approximating the variance of `h(t0)`. The default is the constant function 1.
- `hinv`: A function, like `h`, which returns the inverse of `h`. It is used to transform the intervals calculated on the scale of `h(t)` back to the original scale. The default is the identity function. If `h` is supplied but `hinv` is not, then the intervals returned will be on the transformed scale.
Details

It is assumed that the statistic of interest has an approximately normal distribution with variance \( \text{var}(t_0) \) and so a confidence interval of length \( 2 \times \text{qnorm}((1+\text{conf})/2) \times \text{sqrt}(\text{var}(t_0)) \) is found. If \( \text{boot.out} \) or \( t \) are supplied then the interval is bias-corrected using the bootstrap bias estimate, and so the interval would be centred at \( 2 \times t_0 - \text{mean}(t) \). Otherwise the interval is centred at \( t_0 \).

Value

If \( \text{length} \) \( (\text{conf}) \) is 1 then a vector containing the confidence level and the endpoints of the interval is returned. Otherwise, the returned value is a matrix where each row corresponds to a different confidence level.

Note

This function is primarily designed to be called by \( \text{boot.ci} \) to calculate the normal approximation after a bootstrap but it can also be used without doing any bootstrap calculations as long as \( t_0 \) and \( \text{var}(t_0) \) can be supplied. See the examples below.

Examples

# In Example 5.1 of Davison and Hinkley (1997), normal approximation # confidence intervals are found for the air-conditioning data.
air.mean <- mean(aircondit$hours)
air.n <- nrow(aircondit)
air.v <- air.mean^2/air.n
norm.ci(t = air.mean, var.t = air.v)
exp(norm.ci(t = log(air.mean), var.t = 1/air.n)[2:3])

# Now a more complicated example - the ratio estimate for the city data.
ratio <- function(d, w)
  sum(d$x * w)/sum(d$u *w)
city.v <- var.linear(empinf(data = city, statistic = ratio))
norm.ci(t = ratio(city, rep(0.1,10)), var.t = city.v)
nuclear Power Station Construction Data

Description

The nuclear data frame has 32 rows and 11 columns. The data relate to the construction of 32 light water reactor (LWR) plants constructed in the U.S.A in the late 1960’s and early 1970’s. The data was collected with the aim of predicting the cost of construction of further LWR plants. 6 of the power plants had partial turnkey guarantees and it is possible that, for these plants, some manufacturers’ subsidies may be hidden in the quoted capital costs.

Usage

nuclear

Format

This data frame contains the following columns:

- **cost**: The capital cost of construction in millions of dollars adjusted to 1976 base.
- **date**: The date on which the construction permit was issued. The data are measured in years since January 1 1990 to the nearest month.
- **t1**: The time between application for and issue of the construction permit.
- **t2**: The time between issue of operating license and construction permit.
- **cap**: The net capacity of the power plant (MWe).
- **pr**: A binary variable where 1 indicates the prior existence of a LWR plant at the same site.
- **ne**: A binary variable where 1 indicates that the plant was constructed in the north-east region of the U.S.A.
- **ct**: A binary variable where 1 indicates the use of a cooling tower in the plant.
- **bw**: A binary variable where 1 indicates that the nuclear steam supply system was manufactured by Babcock-Wilcox.
- **cum. n**: The cumulative number of power plants constructed by each architect-engineer.
- **pt**: A binary variable where 1 indicates those plants with partial turnkey guarantees.

Source

References

Description

The `paulsen` data frame has 346 rows and 1 columns.

Sections were prepared from the brain of adult guinea pigs. Spontaneous currents that flowed into individual brain cells were then recorded and the peak amplitude of each current measured. The aim of the experiment was to see if the current flow was quantal in nature (i.e. that it is not a single burst but instead is built up of many smaller bursts of current). If the current was indeed quantal then it would be expected that the distribution of the current amplitude would be multimodal with modes at regular intervals. The modes would be expected to decrease in magnitude for higher current amplitudes.

Usage

`paulsen`

Format

This data frame contains the following column:

`y` The current flowing into individual brain cells. The currents are measured in pico-amperes.

Source

The data were kindly made available by Dr. O. Paulsen from the Department of Pharmacology at the University of Oxford.

plot.boot  
Plots of the Output of a Bootstrap Simulation

Description
This takes a bootstrap object and produces plots for the bootstrap replicates of the variable of interest.

Usage
```r
## S3 method for class 'boot'
plot(x, index = 1, t/zero.noslash = NULL, t = NULL, jack = FALSE,
     qdist = "norm", nclass = NULL, df, ...)
```

Arguments
- `x`: An object of class "boot" returned from one of the bootstrap generation functions.
- `index`: The index of the variable of interest within the output of `boot.out`. This is ignored if `t` and `t0` are supplied.
- `t/zero.noslash`: The original value of the statistic. This defaults to `boot.out$t/zero.noslash[index]` unless `t` is supplied when it defaults to NULL. In that case no vertical line is drawn on the histogram.
- `t`: The bootstrap replicates of the statistic. Usually this will take on its default value of `boot.out$t[,index]`, however it may be useful sometimes to supply a different set of values which are a function of `boot.out$t`.
- `jack`: A logical value indicating whether a jackknife-after-bootstrap plot is required. The default is not to produce such a plot.
- `qdist`: The distribution against which the Q-Q plot should be drawn. At present "norm" (normal distribution - the default) and "chisq" (chi-squared distribution) are the only possible values.
- `nclass`: An integer giving the number of classes to be used in the bootstrap histogram. The default is the integer between 10 and 100 closest to ceiling(length(t)/25).
- `df`: If `qdist` is "chisq" then this is the degrees of freedom for the chi-squared distribution to be used. It is a required argument in that case.
- `...`: When `jack` is TRUE additional parameters to `jack.after.boot` can be supplied. See the help file for `jack.after.boot` for details of the possible parameters.

Details
This function will generally produce two side-by-side plots. The left plot will be a histogram of the bootstrap replicates. Usually the breaks of the histogram will be chosen so that `t0` is at a breakpoint and all intervals are of equal length. A vertical dotted line indicates the position of `t0`. This cannot
be done if t is supplied but t0 is not and so, in that case, the breakpoints are computed by hist using the nclass argument and no vertical line is drawn.

The second plot is a Q-Q plot of the bootstrap replicates. The order statistics of the replicates can be plotted against normal or chi-squared quantiles. In either case the expected line is also plotted. For the normal, this will have intercept mean(t) and slope sqrt(var(t)) while for the chi-squared it has intercept 0 and slope 1.

If jack is TRUE a third plot is produced beneath these two. That plot is the jackknife-after-bootstrap plot. This plot may only be requested when nonparametric simulation has been used. See jack.after.boot for further details of this plot.

Value

boot.out is returned invisibly.

Side Effects

All screens are closed and cleared and a number of plots are produced on the current graphics device. Screens are closed but not cleared at termination of this function.

boot, jack.after.boot, print.boot

Examples

# We fit an exponential model to the air-conditioning data and use # that for a parametric bootstrap. Then we look at plots of the # resampled means.
air.rg <- function(data, mle) rexp(length(data), 1/mle)

air.boot <- boot(aircondit$hours, mean, R = 999, sim = "parametric",
ran.gen = air.rg, mle = mean(aircondit$hours))
plot(air.boot)

# In the difference of means example for the last two series of the # gravity data
grav1 <- gravity[as.numeric(gravity[, 2]) >= 7, ]
grav.fun <- function(dat, w) {
  strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
  d <- dat[, 1]
  ns <- tabulate(strata)
  w <- w/tapply(w, strata, sum)[strata]
  mns <- as.vector(tapply(d * w, strata, sum)) # drop names
  mn2 <- tapply(d * d * w, strata, sum)
  s2hat <- sum((mn2 - mns^2)/ns)
  c(mns[2] - mns[1], s2hat)
}

grav.boot <- boot(grav1, grav.fun, R = 499, stype = "w", strata = grav1[, 2])
plot(grav.boot)
# now suppose we want to look at the studentized differences.
poisons

Animal Survival Times

Description

The poisons data frame has 48 rows and 3 columns.

The data form a 3x4 factorial experiment, the factors being three poisons and four treatments. Each combination of the two factors was used for four animals, the allocation to animals having been completely randomized.

Usage

poisons

Format

This data frame contains the following columns:

time The survival time of the animal in units of 10 hours.
poison A factor with levels 1, 2 and 3 giving the type of poison used.
treat A factor with levels A, B, C and D giving the treatment.

print.boot  

Print a Summary of a Bootstrap Object

Description

This is a method for the function print for objects of the class "boot".

Usage

```r
## S3 method for class 'boot'
print(x, digits = getOption("digits"),
       index = 1:ncol(boot.out$t), ...)
```

Arguments

- `x`: A bootstrap output object of class "boot" generated by one of the bootstrap functions.
- `digits`: The number of digits to be printed in the summary statistics.
- `index`: Indices indicating for which elements of the bootstrap output summary statistics are required.
- `...`: further arguments passed to or from other methods.

Details

For each statistic calculated in the bootstrap the original value and the bootstrap estimates of its bias and standard error are printed. If `boot.out$t0` is missing (such as when it was created by a call to `tsboot` with `orig.t=FALSE`) the bootstrap mean and standard error are printed. If resampling was done using importance resampling weights, then the bootstrap estimates are reweighted as if uniform resampling had been done. The ratio importance sampling estimates are used and if there were a number of distributions then defensive mixture distributions are used. In this case an extra column with the mean of the observed bootstrap statistics is also printed.

Value

The bootstrap object is returned invisibly.

See Also

`boot, censboot, imp.moments, plot.boot, tilt.boot, tsboot`
print.bootci

Print Bootstrap Confidence Intervals

Description

This is a method for the function print() to print objects of the class "bootci".

Usage

## S3 method for class 'bootci'
print(x, hinv = NULL, ...

Arguments

x
The output from a call to boot.ci.

hinv
A transformation to be made to the interval end-points before they are printed.

... 
Further arguments passed to or from other methods.

Details

This function prints out the results from boot.ci in a "nice" format. It also notes whether the scale of the intervals is the original scale of the input to boot.ci or a different scale and whether the calculations were done on a transformed scale. It also looks at the order statistics that were used in calculating the intervals. If the smallest or largest values were used then it prints a message

Warning : Intervals used Extreme Quantiles

Such intervals should be considered very unstable and not relied upon for inferences. Even if the extreme values are not used, it is possible that the intervals are unstable if they used quantiles close to the extreme values. The function alerts the user to intervals which use the upper or lower 10 order statistics with the message

Some intervals may be unstable

Value

The object ci.out is returned invisibly.

See Also

boot.ci
print.saddle.distn

Print Quantiles of Saddlepoint Approximations

Description
This is a method for the function print() to print objects of class "saddle.distn".

Usage
## S3 method for class 'saddle.distn'
print(x, ...)

Arguments
x An object of class "saddle.distn" created by a call to saddle.distn.
... further arguments passed to or from other methods.

Details
The quantiles of the saddlepoint approximation to the distribution are printed along with the original call and some other useful information.

Value
The input is returned invisibly.

See Also
lines.saddle.distn, saddle.distn

print.simplex

Print Solution to Linear Programming Problem

Description
This is a method for the function print() to print objects of class "simplex".

Usage
## S3 method for class 'simplex'
print(x, ...)

Arguments
x An object of class "simplex" created by calling the function simplex to solve a linear programming problem.
... further arguments passed to or from other methods.
Details

The coefficients of the objective function are printed. If a solution to the linear programming problem was found then the solution and the optimal value of the objective function are printed. If a feasible solution was found but the maximum number of iterations was exceeded then the last feasible solution and the objective function value at that point are printed. If no feasible solution could be found then a message stating that is printed.

Value

x is returned silently.

remission  
*Cancer Remission and Cell Activity*

**Description**

The `remission` data frame has 27 rows and 3 columns.

**Usage**

`remission`

**Format**

This data frame contains the following columns:

- **LI**  A measure of cell activity.
- **m**  The number of patients in each group (all values are actually 1 here).
- **r**  The number of patients (out of m) who went into remission.

**Source**

The data were obtained from

**References**

saddle

Saddlepoint Approximations for Bootstrap Statistics

Description

This function calculates a saddlepoint approximation to the distribution of a linear combination of \( W \) at a particular point \( u \), where \( W \) is a vector of random variables. The distribution of \( W \) may be multinomial (default), Poisson or binary. Other distributions are possible also if the adjusted cumulant generating function and its second derivative are given. Conditional saddlepoint approximations to the distribution of one linear combination given the values of other linear combinations of \( W \) can be calculated for \( W \) having binary or Poisson distributions.

Usage

saddle(A = NULL, u = NULL, wdist = "m", type = "simp", d = NULL, d1 = 1, init = rep(0.1, d), mu = rep(0.5, n), LR = FALSE, strata = NULL, K.adj = NULL, K2 = NULL)

Arguments

- **A**: A vector or matrix of known coefficients of the linear combinations of \( W \). It is a required argument unless \( K.\text{adj} \) and \( K2 \) are supplied, in which case it is ignored.
- **u**: The value at which it is desired to calculate the saddlepoint approximation to the distribution of the linear combination of \( W \). It is a required argument unless \( K.\text{adj} \) and \( K2 \) are supplied, in which case it is ignored.
- **wdist**: The distribution of \( W \). This can be one of "m" (multinomial), "p" (Poisson), "b" (binary) or "o" (other). If \( K.\text{adj} \) and \( K2 \) are given \( \text{wdist} \) is set to "o".
- **type**: The type of saddlepoint approximation. Possible types are "simp" for simple saddlepoint and "cond" for the conditional saddlepoint. When \( \text{wdist} \) is "o" or "m", \( \text{type} \) is automatically set to "simp", which is the only type of saddlepoint currently implemented for those distributions.
- **d**: This specifies the dimension of the whole statistic. This argument is required only when \( \text{wdist} = "o" \) and defaults to 1 if not supplied in that case. For other distributions it is set to \( \text{nrow}(A) \).
- **d1**: When \( \text{type} \) is "cond" this is the dimension of the statistic of interest which must be less than \( \text{length}(u) \). Then the saddlepoint approximation to the conditional distribution of the first \( d1 \) linear combinations given the values of the remaining combinations is found. Conditional distribution function approximations can only be found if the value of \( d1 \) is 1.
- **init**: Used if \( \text{wdist} \) is either "m" or "o", this gives initial values to \( \text{n1min} \) which is used to solve the saddlepoint equation.
- **mu**: The values of the parameters of the distribution of \( W \) when \( \text{wdist} \) is "m", "p" "b". \( \mu \) must be of the same length as \( W \) (i.e. \( \text{ncol}(A) \)). The default is that all values of \( \mu \) are equal and so the elements of \( W \) are identically distributed.
LR
If TRUE then the Lugananni-Rice approximation to the cdf is used, otherwise the approximation used is based on Barndorff-Nielsen's r*.

strata
The strata for stratified data.

K.adj
The adjusted cumulant generating function used when wdist is "o". This is a function of a single parameter, zeta, which calculates K(zeta)-u*zeta, where K(zeta) is the cumulant generating function of W.

K2
This is a function of a single parameter zeta which returns the matrix of second derivatives of K(zeta) for use when wdist is "o". If K.adj is given then this must be given also. It is called only once with the calculated solution to the saddlepoint equation being passed as the argument. This argument is ignored if K.adj is not supplied.

Details
If wdist is "o" or "m", the saddlepoint equations are solved using nlmin to minimize K.adj with respect to its parameter zeta. For the Poisson and binary cases, a generalized linear model is fitted such that the parameter estimates solve the saddlepoint equations. The response variable 'y' for the glm must satisfy the equation t(A)%*%y = u (t() being the transpose function). Such a vector can be found as a feasible solution to a linear programming problem. This is done by a call to simplex. The covariate matrix for the glm is given by A.

Value
A list consisting of the following components

spa
The saddlepoint approximations. The first value is the density approximation and the second value is the distribution function approximation.

zeta.hat
The solution to the saddlepoint equation. For the conditional saddlepoint this is the solution to the saddlepoint equation for the numerator.

zeta2.hat
If type is "cond" this is the solution to the saddlepoint equation for the denominator. This component is not returned for any other value of type.

Examples

# To evaluate the bootstrap distribution of the mean failure time of
# air-conditioning equipment at 80 hours
saddle(A = aircondit$hours/12, u = 80)

# Alternatively this can be done using a conditional poisson
saddle(A = cbind(aircondit$hours/12, 1), u = c(80, 12),
       wdist = "p", type = "cond")

# To use the Lugananni-Rice approximation to this
saddle(A = cbind(aircondit$hours/12, 1), u = c(80, 12),
       wdist = "p", type = "cond",
       LR = TRUE)

# Example 9.16 of Davison and Hinkley (1997) calculates saddlepoint
# approximations to the distribution of the ratio statistic for the
# city data. Since the statistic is not in itself a linear combination
# of random Variables, its distribution cannot be found directly.
# Instead the statistic is expressed as the solution to a linear
# estimating equation and hence its distribution can be found. We
# get the saddlepoint approximation to the pdf and cdf evaluated at
# t = 1.25 as follows.
jacobian <- function(dat,t,zeta)
{
  p <- exp(zeta*(dat$x-t*dat$u))
  abs(sum(dat$u*p)/sum(p))
}

city.sp1 <- saddle(A = city$x-1.25*city$u, u = 0)

city.sp1$spa[1] <- jacobian(city, 1.25, city.sp1$zeta.hat) * city.sp1$spa[1]

city.sp1

saddle.distn

Saddlepoint Distribution Approximations for Bootstrap Statistics

Description

Approximate an entire distribution using saddlepoint methods. This function can calculate simple
and conditional saddlepoint distribution approximations for a univariate quantity of interest. For
the simple saddlepoint the quantity of interest is a linear combination of \( W \) where \( W \) is a vector of
random variables. For the conditional saddlepoint we require the distribution of one linear combi-
nation given the values of any number of other linear combinations. The distribution of \( W \) must
be one of multinomial, Poisson or binary. The primary use of this function is to calculate quantiles
of bootstrap distributions using saddlepoint approximations. Such quantiles are required by the
function \texttt{control} to approximate the distribution of the linear approximation to a statistic.

Usage

\texttt{saddle.distn(A, u = NULL, alpha = NULL, wdist = "m",
        type = "simp", npts = 20, t = NULL, t0 = NULL, LR = TRUE,}

init = rep(0.1, d), mu = rep(0.5, n), LR = FALSE,
strata = NULL, ...)

Arguments

A
This is a matrix of known coefficients or a function which returns such a matrix.
If a function then its first argument must be the point t at which a saddlepoint
is required. The most common reason for A being a function would be if the
statistic is not itself a linear combination of the W but is the solution to a linear
estimating equation.

u
If A is a function then u must also be a function returning a vector with length
equal to the number of columns of the matrix returned by A. Usually all compo-
nents other than the first will be constants as the other components are the values
of the conditioning variables. If A is a matrix with more than one column (such
as when wdist = "cond") then u should be a vector with length one less than
ncol(A). In this case u specifies the values of the conditioning variables. If A is
a matrix with one column or a vector then u is not used.

alpha
The alpha levels for the quantiles of the distribution which should be returned.
By default the 0.1, 0.5, 1, 2.5, 5, 10, 20, 50, 90, 95, 97.5, 99, 99.5 and 99.9
percentiles are calculated.

wdist
The distribution of W. Possible values are "m" (multinomial), "p" (Poisson), or
"b" (binary).

type
The type of saddlepoint to be used. Possible values are "simp" (simple saddle-
point) and "cond" (conditional). If wdist is "m", type is set to "simp".

npts
The number of points at which the saddlepoint approximation should be calcu-
lated and then used to fit the spline.

t
A vector of points at which the saddlepoint approximations are calculated.
These points should extend beyond the extreme quantiles required but still be
in the possible range of the bootstrap distribution. The observed value of the
statistic should not be included in t as the distribution function approximation
breaks down at that point. The points should, however cover the entire effective
range of the distribution including close to the centre. If t is supplied then npts
is set to length(t). When t is not supplied, the function attempts to find the
effective range of the distribution and then selects points to cover this range.

t0
If t is not supplied then a vector of length 2 should be passed as t0. The first
component of t0 should be the centre of the distribution and the second should
be an estimate of spread (such as a standard error). These two are then used to
find the effective range of the distribution. The range finding mechanism does
rely on an accurate estimate of location in t0[1].

init
When wdist is "m", this vector should contain the initial values to be passed to
nlmin when it is called to solve the saddlepoint equations.

mu
The vector of parameter values for the distribution. The default is that the com-
ponents of W are identically distributed.

LR
A logical flag. When LR is TRUE the Lugananni-Rice cdf approximations are
calculated and used to fit the spline. Otherwise the cdf approximations used are
based on Barndorff-Nielsen’s r*.
strata

A vector giving the strata when the rows of A relate to stratified data. This is used only when wdist is "m".

...When A and u are functions any additional arguments are passed unchanged each time one of them is called.

Details

The range at which the saddlepoint is used is such that the cdf approximation at the endpoints is more extreme than required by the extreme values of alpha. The lower endpoint is found by evaluating the saddlepoint at the points t[1]-2*t[2], t[1]-4*t[2], t[1]-8*t[2] etc. until a point is found with a cdf approximation less than min(alpha)/10, then a bisection method is used to find the endpoint which has cdf approximation in the range (min(alpha)/1000, min(alpha)/10). Then a number of, equally spaced, points are chosen between the lower endpoint and t[1] until a total of npts/2 approximations have been made. The remaining npts/2 points are chosen to the right of t[1] in a similar manner. Any points which are very close to the centre of the distribution are then omitted as the cdf approximations are not reliable at the centre. A smoothing spline is then fitted to the probit of the saddlepoint distribution function approximations at the remaining points and the required quantiles are predicted from the spline.

Sometimes the function will terminate with the message "Unable to find range". There are two main reasons why this may occur. One is that the distribution is too discrete and/or the required quantiles too extreme, this can cause the function to be unable to find a point within the allowable range which is beyond the extreme quantiles. Another possibility is that the value of t[2] is too small and so too many steps are required to find the range. The first problem cannot be solved except by asking for less extreme quantiles, although for very discrete distributions the approximations may not be very good. In the second case using a larger value of t[2] will usually solve the problem.

Value

The returned value is an object of class "saddle.distn". See the help file for saddle.distn.object for a description of such an object.

data = city)

saddle.distn.object  Saddlepoint Distribution Approximation Objects

Description

Class of objects that result from calculating saddlepoint distribution approximations by a call to saddle.distn.

Generation

This class of objects is returned from calls to the function saddle.distn.

Methods

The class "saddle.distn" has methods for the functions lines and print.

Structure

Objects of class "saddle.distn" are implemented as a list with the following components.
quantiles A matrix with 2 columns. The first column contains the probabilities \( \alpha \) and the second column contains the estimated quantiles of the distribution at those probabilities derived from the spline.

points A matrix of evaluations of the saddlepoint approximation. The first column contains the values of \( t \) which were used, the second and third contain the density and cdf approximations at those points and the rest of the columns contain the solutions to the saddlepoint equations. When type is "simp", there is only one of those. When type is "cond" there are \( 2^d - 1 \) where \( d \) is the number of columns in \( A \) or the output of \( A(t, \ldots) \). The first \( d \) of these correspond to the numerator and the remainder correspond to the denominator.

distn An object of class smooth.spline. This corresponds to the spline fitted to the saddlepoint cdf approximations in points in order to approximate the entire distribution. For the structure of the object see smooth.spline.

call The original call to saddle.distn which generated the object.

LR A logical variable indicating whether the Lugananni-Rice approximations were used.

salinity

Water Salinity and River Discharge

Description

The salinity data frame has 28 rows and 4 columns.

Biweekly averages of the water salinity and river discharge in Pamlico Sound, North Carolina were recorded between the years 1972 and 1977. The data in this set consists only of those measurements in March, April and May.

Usage

salinity

Format

This data frame contains the following columns:

sal The average salinity of the water over two weeks.

lag The average salinity of the water lagged two weeks. Since only spring is used, the value of lag is not always equal to the previous value of sal.

trend A factor indicating in which of the 6 biweekly periods between March and May, the observations were taken. The levels of the factor are from 0 to 5 with 0 being the first two weeks in March.

dis The amount of river discharge during the two weeks for which sal is the average salinity.

**simplex**

*Simplex Method for Linear Programming Problems*

**Description**
This function will optimize the linear function $a\%*\%x$ subject to the constraints $A1\%*\%x <= b1$, $A2\%*\%x >= b2$, $A3\%*\%x = b3$ and $x >= 0$. Either maximization or minimization is possible but the default is minimization.

**Usage**
```r
simplex(a, A1 = NULL, b1 = NULL, A2 = NULL, b2 = NULL, A3 = NULL, b3 = NULL, maxi = FALSE, n.iter = n + 2 * m, eps = 1e-10)
```

**Arguments**
- **a**: A vector of length $n$ which gives the coefficients of the objective function.
- **A1**: An $m1$ by $n$ matrix of coefficients for the $\leq$ type of constraints.
- **b1**: A vector of length $m1$ giving the right hand side of the $\leq$ constraints. This argument is required if $A1$ is given and ignored otherwise. All values in $b1$ must be non-negative.
- **A2**: An $m2$ by $n$ matrix of coefficients for the $\geq$ type of constraints.
- **b2**: A vector of length $m2$ giving the right hand side of the $\geq$ constraints. This argument is required if $A2$ is given and ignored otherwise. All values in $b2$ must be non-negative. Note that the constraints $x >= 0$ are included automatically and so should not be repeated here.
- **A3**: An $m3$ by $n$ matrix of coefficients for the equality constraints.
- **b3**: A vector of length $m3$ giving the right hand side of equality constraints. This argument is required if $A3$ is given and ignored otherwise. All values in $b3$ must be non-negative.
- **maxi**: A logical flag which specifies minimization if FALSE (default) and maximization otherwise. If maxi is TRUE then the maximization problem is recast as a minimization problem by changing the objective function coefficients to their negatives.
n.iter  The maximum number of iterations to be conducted in each phase of the simplex method. The default is \(n+2*(m1+m2+m3)\).

eps  The floating point tolerance to be used in tests of equality.

Details

The method employed by this function is the two phase tableau simplex method. If there are \(\geq\) or equality constraints an initial feasible solution is not easy to find. To find a feasible solution an artificial variable is introduced into each \(\geq\) or equality constraint and an auxiliary objective function is defined as the sum of these artificial variables. If a feasible solution to the set of constraints exists then the auxiliary objective will be minimized when all of the artificial variables are 0. These are then discarded and the original problem solved starting at the solution to the auxiliary problem. If the only constraints are of the \(\leq\) form, the origin is a feasible solution and so the first stage can be omitted.

Value

An object of class "simplex": see \texttt{simplex.object}.

Note

The method employed here is suitable only for relatively small systems. Also if possible the number of constraints should be reduced to a minimum in order to speed up the execution time which is approximately proportional to the cube of the number of constraints. In particular if there are any constraints of the form \(x[i] \geq b2[i]\) they should be omitted by setting \(x[i] = x[i] - b2[i]\), changing all the constraints and the objective function accordingly and then transforming back after the solution has been found.

References

Examples

# This example is taken from Exercise 7.5 of Gill, Murray and Wright (1991).

fat <- c(800, 6000, 1000, 400)
vitx <- c(50, 3, 150, 100)
vity <- c(10, 10, 75, 100)
vitz <- c(150, 35, 75, 5)
simplex(a = enj, A1 = fat, b1 = 13800, A2 = rbind(vitx, vity, vitz),
b2 = c(600, 300, 550), maxi = TRUE)
Description

Class of objects that result from solving a linear programming problem using \texttt{simplex}.

Generation

This class of objects is returned from calls to the function \texttt{simplex}.

Methods

The class "\texttt{saddle.distn}" has a method for the function \texttt{print}.

Structure

Objects of class "\texttt{simplex}" are implemented as a list with the following components.

- \texttt{soln} The values of \( x \) which optimize the objective function under the specified constraints provided those constraints are jointly feasible.
- \texttt{solved} This indicates whether the problem was solved. A value of \(-1\) indicates that no feasible solution could be found. A value of 0 that the maximum number of iterations was reached without termination of the second stage. This may indicate an unbounded function or simply that more iterations are needed. A value of 1 indicates that an optimal solution has been found.
- \texttt{value} The value of the objective function at \texttt{soln}.
- \texttt{val.aux} This is \texttt{NULL} if a feasible solution is found. Otherwise it is a positive value giving the value of the auxiliary objective function when it was minimized.
- \texttt{obj} The original coefficients of the objective function.
- \texttt{a} The objective function coefficients re-expressed such that the basic variables have coefficient zero.
- \texttt{a.aux} This is \texttt{NULL} if a feasible solution is found. Otherwise it is the re-expressed auxiliary objective function at the termination of the first phase of the simplex method.
- \texttt{A} The final constraint matrix which is expressed in terms of the non-basic variables. If a feasible solution is found then this will have dimensions \( m_1+m_2+m_3 \) by \( n+m_1+m_2 \), where the final \( m_1+m_2 \) columns correspond to slack and surplus variables. If no feasible solution is found there will be an additional \( m_1+m_2+m_3 \) columns for the artificial variables introduced to solve the first phase of the problem.
- \texttt{basic} The indices of the basic (non-zero) variables in the solution. Indices between \( n+1 \) and \( n+m_1 \) correspond to slack variables, those between \( n+m_1+1 \) and \( n+m_2 \) correspond to surplus variables and those greater than \( n+m_2 \) are artificial variables. Indices greater than \( n+m_2 \) should occur only if \texttt{solved} is \(-1\) as the artificial variables are discarded in the second stage of the simplex method.
- \texttt{slack} The final values of the \( m_1 \) slack variables which arise when the "\( \leq \)" constraints are re-expressed as the equalities \( A1\times x + \text{slack} = b1 \).
surplus The final values of the \( m_2 \) surplus variables which arise when the "\( \leq \)" constraints are re-expressed as the equalities \( A_2 \% \times x - \text{surplus} = b_2 \).

artificial This is NULL if a feasible solution can be found. If no solution can be found then this contains the values of the \( m_1 + m_2 + m_3 \) artificial variables which minimize their sum subject to the original constraints. A feasible solution exists only if all of the artificial variables can be made 0 simultaneously.

smooth.f Smooth Distributions on Data Points

Description

This function uses the method of frequency smoothing to find a distribution on a data set which has a required value, \( \theta \), of the statistic of interest. The method results in distributions which vary smoothly with \( \theta \).

Usage

\[
\text{smooth.f}(\theta, \text{boot.out}, \text{index} = 1, t = \text{boot.out}\_\text{\$statistic}[\text{index}], \\
\text{width} = 0.5)
\]

Arguments

- \( \theta \): The required value for the statistic of interest. If \( \theta \) is a vector, a separate distribution will be found for each element of \( \theta \).
- \( \text{boot.out} \): A bootstrap output object returned by a call to boot.
- \( \text{index} \): The index of the variable of interest in the output of \( \text{boot.out}\_\text{\$statistic} \). This argument is ignored if \( t \) is supplied. \( \text{index} \) must be a scalar.
- \( t \): The bootstrap values of the statistic of interest. This must be a vector of length \( \text{boot.out}\_\text{\$R} \) and the values must be in the same order as the bootstrap replicates in \( \text{boot.out} \).
- \( \text{width} \): The standardized width for the kernel smoothing. The smoothing uses a value of \( \text{width} \times \text{s} \) for epsilon, where \( \text{s} \) is the bootstrap estimate of the standard error of the statistic of interest. \( \text{width} \) should take a value in the range \( (0.2, 1) \) to produce a reasonable smoothed distribution. If \( \text{width} \) is too large then the distribution becomes closer to uniform.

Details

The new distributional weights are found by applying a normal kernel smoother to the observed values of \( t \) weighted by the observed frequencies in the bootstrap simulation. The resulting distribution may not have parameter value exactly equal to the required value \( \theta \) but it will typically have a value which is close to \( \theta \). The details of how this method works can be found in Davison, Hinkley and Worton (1995) and Section 3.9.2 of Davison and Hinkley (1997).
smooth.f

Value

If \(\text{length}(\theta)\) is 1 then a vector with the same length as the data set \(\text{boot.out}\$\text{data}\) is returned. The value in position \(i\) is the probability to be given to the data point in position \(i\) so that the distribution has parameter value approximately equal to \(\theta\). If \(\text{length}(\theta)\) is bigger than 1 then the returned value is a matrix with \(\text{length}(\theta)\) rows each of which corresponds to a distribution with the parameter value approximately equal to the corresponding value of \(\theta\).

\texttt{boot, exp.tilt, tilt.boot}

Examples

# Example 9.8 of Davison and Hinkley (1997) requires tilting the resampling distribution of the studentized statistic to be centred at the observed value of the test statistic 1.84. In the book exponential tilting was used but it is also possible to use \texttt{smooth.f}.
grav1 <- gravity[as.numeric(gravity[, 2]) >= 7, ]
grav.fun <- function(dat, w, orig) {
  strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
  d <- dat[, 1]
  ns <- table(strata)
  w <- w/tapply(w, strata, sum)[strata]
  mns <- as.vector(tapply(d * w, strata, sum)) # drop names
  mn2 <- tapply(d * d * w, strata, sum)
  s2hat <- sum((mn2 - mns^2)/ns)
  c(mns[2] - mns[1], s2hat, (mns[2]-mns[1]-orig)/sqrt(s2hat))
}
grav.z0 <- grav.fun(grav1, rep(1, 26), 0)
grav.boot <- boot(grav1, grav.fun, R = 499, stype = "w",
                   strata = grav1[, 2], orig = grav.z0[1])
grav.sm <- smooth.f(grav.z0[3], grav.boot, index = 3)

# Now we can run another bootstrap using these weights
grav.boot2 <- boot(grav1, grav.fun, R = 499, stype = "w",
                   strata = grav1[, 2], orig = grav.z0[1],
                   weights = grav.sm)

# Estimated p-values can be found from these as follows
mean(grav.boot$t[, 3] >= grav.z0[3])
imp.prob(grav.boot2, t0 = -grav.z0[3], t = -grav.boot2$t[, 3])

# Note that for the importance sampling probability we must
# multiply everything by -1 to ensure that we find the correct
# probability. Raw resampling is not reliable for probabilities
# greater than 0.5. Thus
1 - imp.prob(grav.boot2, index = 3, t0 = grav.z0[3])$raw
# can give very strange results (negative probabilities).

## sunspot

*Annual Mean Sunspot Numbers*

**Description**

sunspot is a time series and contains 289 observations.

The Zurich sunspot numbers have been analyzed in almost all books on time series analysis as well as numerous papers. The data set, usually attributed to Rudolf Wolf, consists of means of daily relative numbers of sunspot sightings. The relative number for a day is given by \( k(f+10g) \) where \( g \) is the number of sunspot groups observed, \( f \) is the total number of spots within the groups and \( k \) is a scaling factor relating the observer and telescope to a baseline. The relative numbers are then averaged to give an annual figure. See Inzenman (1983) for a discussion of the relative numbers.

The figures are for the years 1700-1988.

## survival

*Survival of Rats after Radiation Doses*

**Description**

The survival data frame has 14 rows and 2 columns.

The data measured the survival percentages of batches of rats who were given varying doses of radiation. At each of 6 doses there were two or three replications of the experiment.

**Usage**

`survival`
tau

Format

This data frame contains the following columns:

dose The dose of radiation administered (rads).
surv The survival rate of the batches expressed as a percentage.

Source

Tau Particle Decay Modes

Description

The tau data frame has 60 rows and 2 columns.

The tau particle is a heavy electron-like particle discovered in the 1970's by Martin Perl at the Stanford Linear Accelerator Center. Soon after its production the tau particle decays into various collections of more stable particles. About 86% of the time the decay involves just one charged particle. This rate has been measured independently 13 times.

The one-charged-particle event is made up of four major modes of decay as well as a collection of other events. The four main types of decay are denoted rho, pi, e and mu. These rates have been measured independently 6, 7, 14 and 19 times respectively. Due to physical constraints each experiment can only estimate the composite one-charged-particle decay rate or the rate of one of the major modes of decay.

Each experiment consists of a major research project involving many years work. One of the goals of the experiments was to estimate the rate of decay due to events other than the four main modes of decay. These are uncertain events and so cannot themselves be observed directly.

Usage

tau

Format

This data frame contains the following columns:

rate The decay rate expressed as a percentage.
decay The type of decay measured in the experiment. It is a factor with levels 1, rho, pi, e and mu.

**tilt.boot**

*Non-parametric Tilted Bootstrap*

**Description**

This function will run an initial bootstrap with equal resampling probabilities (if required) and will use the output of the initial run to find resampling probabilities which put the value of the statistic at required values. It then runs an importance resampling bootstrap using the calculated probabilities as the resampling distribution.

**Usage**

```
tilt.boot(data, statistic, R, sim = "ordinary", stype = "i",
          strata = rep(1, n), L = NULL, theta = NULL,
          alpha = c(0.025, 0.975), tilt = TRUE, width = 0.5,
          index = 1, ...)
```

**Arguments**

- `data`: The data as a vector, matrix or data frame. If it is a matrix or data frame then each row is considered as one (multivariate) observation.
- `statistic`: A function which when applied to data returns a vector containing the statistic(s) of interest. It must take at least two arguments. The first argument will always be `data` and the second should be a vector of indices, weights or frequencies describing the bootstrap sample. Any other arguments must be supplied to `tilt.boot` and will be passed unchanged to `statistic` each time it is called.
- `R`: The number of bootstrap replicates required. This will generally be a vector, the first value stating how many uniform bootstrap simulations are to be performed at the initial stage. The remaining values of `R` are the number of simulations to be performed resampling from each reweighted distribution. The first value of `R` must always be present, a value of 0 implying that no uniform resampling is to be carried out. Thus `length(R)` should always equal `1+length(theta)`. 

This is a character string indicating the type of bootstrap simulation required. There are only two possible values that this can take: "ordinary" and "balanced". If other simulation types are required for the initial un-weighted bootstrap then it will be necessary to run boot, calculate the weights appropriately, and run boot again using the calculated weights.

A character string indicating the type of second argument expected by statistic. The possible values that stype can take are "i" (indices), "w" (weights) and "f" (frequencies).

An integer vector or factor representing the strata for multi-sample problems.

The empirical influence values for the statistic of interest. They are used only for exponential tilting when tilt is TRUE. If tilt is TRUE and they are not supplied then tilt.boot uses empinf to calculate them.

The required parameter value(s) for the tilted distribution(s). There should be one value of theta for each of the non-uniform distributions. If R[1] is 0 theta is a required argument. Otherwise theta values can be estimated from the initial uniform bootstrap and the values in alpha.

The alpha level to which tilting is required. This parameter is ignored if R[1] is 0 or if theta is supplied, otherwise it is used to find the values of theta as quantiles of the initial uniform bootstrap. In this case R[1] should be large enough that min(c(alpha, 1-alpha))*R[1] > 5, if this is not the case then a warning is generated to the effect that the theta are extreme values and so the tilted output may be unreliable.

A logical variable which if TRUE (the default) indicates that exponential tilting should be used, otherwise local frequency smoothing (smooth.f) is used. If tilt is FALSE then R[1] must be positive. In fact in this case the value of R[1] should be fairly large (in the region of 500 or more).

This argument is used only if tilt is FALSE, in which case it is passed unchanged to smooth.f as the standardized bandwidth for the smoothing operation. The value should generally be in the range (0.2, 1). See smooth.f for for more details.

The index of the statistic of interest in the output from statistic. By default the first element of the output of statistic is used.

Any additional arguments required by statistic. These are passed unchanged to statistic each time it is called.

An object of class "boot" with the following components

The observed value of the statistic on the original data.

The values of the bootstrap replicates of the statistic. There will be sum(R) of these, the first R[1] corresponding to the uniform bootstrap and the remainder to the tilted bootstrap(s).

The input vector of the number of bootstrap replicates.

The original data as supplied.
statistic  The statistic function as supplied.
sim     The simulation type used in the bootstrap(s), it can either be "ordinary" or "balanced".
stype    The type of statistic supplied, it is the same as the input value stype.
call     A copy of the original call to tilt.boot.
strata   The strata as supplied.
weights  The matrix of weights used. If R[1] is greater than 0 then the first row will be the uniform weights and each subsequent row the tilted weights. If R[1] equals 0 then the uniform weights are omitted and only the tilted weights are output.
theta    The values of theta used for the tilted distributions. These are either the input values or the values derived from the uniform bootstrap and alpha.

tsboot

**Bootstrapping of Time Series**

**Description**

Generate R bootstrap replicates of a statistic applied to a time series. The replicate time series can be generated using fixed or random block lengths or can be model based replicates.

**Usage**

```r
tsboot(tseries, statistic, R, l = NULL, sim = "model",
       endcorr = TRUE, n.sim = NROW(tseries), orig.t = TRUE,
       ran.gen, ran.args = NULL, norm = TRUE, ...,
       parallel = c("no", "multicore", "snow"),
       ncpus = getOption("boot.ncpus", 1L), cl = NULL)
```

**Arguments**

- `tseries`: A univariate or multivariate time series.
- `statistic`: A function which when applied to `tseries` returns a vector containing the statistic(s) of interest. Each time statistic is called it is passed a time series of length `n.sim` which is of the same class as the original `tseries`. Any other arguments which `statistic` takes must remain constant for each bootstrap replicate and should be supplied through the `...` argument to `tsboot`.
- `R`: A positive integer giving the number of bootstrap replicates required.
- `sim`: The type of simulation required to generate the replicate time series. The possible input values are "model" (model based resampling), "fixed" (block resampling with fixed block lengths of 1), "geom" (block resampling with block lengths having a geometric distribution with mean 1) or "scramble" (phase scrambling).
1 If sim is "fixed" then 1 is the fixed block length used in generating the replicate time series. If sim is "geom" then 1 is the mean of the geometric distribution used to generate the block lengths. 1 should be a positive integer less than the length of tseries. This argument is not required when sim is "model" but it is required for all other simulation types.

endcorr A logical variable indicating whether end corrections are to be applied when sim is "fixed". When sim is "geom", endcorr is automatically set to TRUE; endcorr is not used when sim is "model" or "scramble".

n.sim The length of the simulated time series. Typically this will be equal to the length of the original time series but there are situations when it will be larger. One obvious situation is if prediction is required. Another situation in which n.sim is larger than the original length is if tseries is a residual time series from fitting some model to the original time series. In this case, n.sim would usually be the length of the original time series.

orig.t A logical variable which indicates whether statistic should be applied to tseries itself as well as the bootstrap replicate series. If statistic is expecting a longer time series than tseries or if applying statistic to tseries will not yield any useful information then orig.t should be set to FALSE.

ran.gen This is a function of three arguments. The first argument is a time series. If sim is "model" then it will always be tseries that is passed. For other simulation types it is the result of selecting n.sim observations from tseries by some scheme and converting the result back into a time series of the same form as tseries (although of length n.sim). The second argument to ran.gen is always the value n.sim, and the third argument is ran.args, which is used to supply any other objects needed by ran.gen. If sim is "model" then the generation of the replicate time series will be done in ran.gen (for example through use of arima.sim). For the other simulation types ran.gen is used for 'post-blackening'. The default is that the function simply returns the time series passed to it.

ran.args This will be supplied to ran.gen each time it is called. If ran.gen needs any extra arguments then they should be supplied as components of ran.args. Multiple arguments may be passed by making ran.args a list. If ran.args is NULL then it should not be used within ran.gen but note that ran.gen must still have its third argument.

norm A logical argument indicating whether normal margins should be used for phase scrambling. If norm is FALSE then margins corresponding to the exact empirical margins are used.

... Extra named arguments to statistic may be supplied here. Beware of partial matching to the arguments of tsboot listed above.

parallel, ncpus, cl
See the help for boot.

Details

If sim is "fixed" then each replicate time series is found by taking blocks of length 1, from the original time series and putting them end-to-end until a new series of length n.sim is created. When
sim is "geom" a similar approach is taken except that now the block lengths are generated from a geometric distribution with mean \( l \). Post-blackening can be carried out on these replicate time series by including the function \( \text{ran} \cdot \text{gen} \) in the call to \texttt{tsboot} and having \texttt{tseries} as a time series of residuals.

Model based resampling is very similar to the parametric bootstrap and all simulation must be in one of the user specified functions. This avoids the complicated problem of choosing the block length but relies on an accurate model choice being made.

Phase scrambling is described in Section 8.2.4 of Davison and Hinkley (1997). The types of statistic for which this method produces reasonable results is very limited and the other methods seem to do better in most situations. Other types of resampling in the frequency domain can be accomplished using the function \texttt{boot} with the argument \( \text{sim} = "\text{parametric}" \).

**Value**

An object of class "boot" with the following components.

- \( t_0 \): If \( \text{orig} \cdot \text{t} \) is TRUE then \( t_0 \) is the result of \( \text{statistic(tseries,...{}}) \) otherwise it is NULL.
- \( t \): The results of applying \( \text{statistic} \) to the replicate time series.
- \( R \): The value of \( R \) as supplied to \texttt{tsboot}.
- \( \text{tseries} \): The original time series.
- \( \text{statistic} \): The function \( \text{statistic} \) as supplied.
- \( \text{sim} \): The simulation type used in generating the replicates.
- \( \text{endcorr} \): The value of \( \text{endcorr} \) used. The value is meaningful only when \( \text{sim} \) is "fixed"; it is ignored for model based simulation or phase scrambling and is always set to TRUE if \( \text{sim} \) is "geom".
- \( n \cdot \text{sim} \): The value of \( n \cdot \text{sim} \) used.
- \( l \): The value of \( l \) used for block based resampling. This will be NULL if block based resampling was not used.
- \( \text{ran} \cdot \text{gen} \): The \( \text{ran} \cdot \text{gen} \) function used for generating the series or for ‘post-blackening’.
- \( \text{ran} \cdot \text{args} \): The extra arguments passed to \( \text{ran} \cdot \text{gen} \).
- \( \text{call} \): The original call to \texttt{tsboot}.

                 ran.args = list(ts = log(lynx), model = lynx.model))

lynx.2b <- tsboot(lynx.res, lynx.fun, R = 99, l = 20, sim = "geom",
                 n.sim = 114, orig.t = FALSE, ran.gen = lynx.black,
                 ran.args = list(ts = log(lynx), model = lynx.model))

# To compare the observed order of the bootstrap replicates we
# proceed as follows.
table(lynx.1$t[, 1])
table(lynx.1b$t[, 1])
table(lynx.2$t[, 1])
table(lynx.2b$t[, 1])
table(lynx.3$t[, 1])
# Notice that the post-blackened and model-based bootstraps preserve
# the true order of the model (11) in many more cases than the others.

---

### tuna

#### Tuna Sighting Data

**Description**

The tuna data frame has 64 rows and 1 columns.

The data come from an aerial line transect survey of Southern Bluefin Tuna in the Great Australian Bight. An aircraft with two spotters on board flies randomly allocated line transects. Each school of tuna sighted is counted and its perpendicular distance from the transect measured. The survey was conducted in summer when tuna tend to stay on the surface.

**Usage**

tuna

**Format**

This data frame contains the following column:

- `y` The perpendicular distance, in miles, from the transect for 64 independent sightings of tuna schools.

**Source**

The data were obtained from

**References**

The urine data frame has 79 rows and 7 columns.

79 urine specimens were analyzed in an effort to determine if certain physical characteristics of the urine might be related to the formation of calcium oxalate crystals.

This data frame contains the following columns:

- r  Indicator of the presence of calcium oxalate crystals.
- gravity  The specific gravity of the urine.
- ph  The pH reading of the urine.
- osmo  The osmolarity of the urine. Osmolarity is proportional to the concentration of molecules in solution.
- cond  The conductivity of the urine. Conductivity is proportional to the concentration of charged ions in solution.
- urea  The urea concentration in millimoles per litre.
- calc  The calcium concentration in millimoles per litre.

The data were obtained from Andrews, D.F. and Herzberg, A.M. (1985) *Data: A Collection of Problems from Many Fields for the Student and Research Worker*. Springer-Verlag.

**Description**

Estimates the variance of a statistic from its empirical influence values.

**Usage**

```r
var.linear(L, strata = NULL)
```

**Arguments**

- `L` Vector of the empirical influence values of a statistic. These will usually be calculated by a call to `empinf`.
- `strata` A numeric vector or factor specifying which observations (and hence empirical influence values) come from which strata.

**Value**

The variance estimate calculated from `L`.

**References**

**See Also**

- `empinf`, `linear.approx`, `k3.linear`

**Examples**

```r
# To estimate the variance of the ratio of means for the city data.
ratio <- function(d,w) sum(d$x * w)/sum(d$u * w)
var.linear(empinf(data = city, statistic = ratio))
```
Description

Wool is a time series of class "ts" and contains 309 observations.

Each week that the market is open the Australian Wool Corporation set a floor price which determines their policy on intervention and is therefore a reflection of the overall price of wool for the week in question. Actual prices paid can vary considerably about the floor price. The series here is the log of the ratio between the price for fine grade wool and the floor price, each market week between July 1976 and Jun 1984.

Source

The data were obtained from

The class package

batchSOM  Self-Organizing Maps: Batch Algorithm

Description

Kohonen’s Self-Organizing Maps are a crude form of multidimensional scaling.

Usage

batchSOM(data, grid = somgrid(), radii, init)

Arguments

data  a matrix or data frame of observations, scaled so that Euclidean distance is appropriate.
grid  A grid for the representatives: see somgrid.
radii  the radii of the neighbourhood to be used for each pass: one pass is run for each element of radii.
init  the initial representatives. If missing, chosen (without replacement) randomly from data.

Details

The batch SOM algorithm of Kohonen(1995, section 3.14) is used.

Value

An object of class "SOM" with components

grid  the grid, an object of class "somgrid".
codes  a matrix of representatives.
condense

Condense training set for k-NN classifier

Description

Condense training set for k-NN classifier

Usage

condense(train, class, store, trace = TRUE)

Arguments

train          matrix for training set
class          vector of classifications for test set
store          initial store set. Default one randomly chosen element of the set.
trace          logical. Trace iterations?
**Details**

The store set is used to 1-NN classify the rest, and misclassified patterns are added to the store set. The whole set is checked until no additions occur.

**Value**

Index vector of cases to be retained (the final store set).

**References**

**See Also**

`reduce.nn`, `multiedit`

**Examples**

```r
train <- rbind(iris3[1:25, ,1], iris3[1:25, ,2], iris3[1:25, ,3])
test <- rbind(iris3[26:50, ,1], iris3[26:50, ,2], iris3[26:50, ,3])
c1 <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
keep <- condense(train, c1)
knn(train[keep, , drop=FALSE], test, c1[keep])
keep2 <- reduce.nn(train, keep, c1)
knn(train[keep2, , drop=FALSE], test, c1[keep2])
```

---

**knn**

**k-Nearest Neighbour Classification**

**Description**

k-nearest neighbour classification for test set from training set. For each row of the test set, the k nearest (in Euclidean distance) training set vectors are found, and the classification is decided by majority vote, with ties broken at random. If there are ties for the kth nearest vector, all candidates are included in the vote.

**Usage**

```r
cnn(train, test, cl, k = 1, l = 0, prob = FALSE, use.all = TRUE)
```
Arguments

train  
matrix or data frame of training set cases.

test  
matrix or data frame of test set cases. A vector will be interpreted as a row vector for a single case.

cl  
factor of true classifications of training set

k  
number of neighbours considered.

l  
minimum vote for definite decision, otherwise doubt. (More precisely, less than \(k-l\) dissenting votes are allowed, even if \(k\) is increased by ties.)

prob  
If this is true, the proportion of the votes for the winning class are returned as attribute prob.

use.all  
controls handling of ties. If true, all distances equal to the \(k\)th largest are included. If false, a random selection of distances equal to the \(k\)th is chosen to use exactly \(k\) neighbours.

Value

Factor of classifications of test set. doubt will be returned as NA.

Examples

train <- rbind(iris3[1:25,,1], iris3[1:25,,2], iris3[1:25,,3])
test <- rbind(iris3[26:50,,1], iris3[26:50,,2], iris3[26:50,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
knn(train, test, cl, k = 3, prob=TRUE)
attributes(.Last.value)

---

knn.cv  
\textit{k-Nearest Neighbour Cross-Validatory Classification}

Description

\(k\)-nearest neighbour cross-validatory classification from training set.

Usage

knn.cv(train, cl, k = 1, l = 0, prob = FALSE, use.all = TRUE)
Arguments

train  matrix or data frame of training set cases.
c1    factor of true classifications of training set
k     number of neighbours considered.
l     minimum vote for definite decision, otherwise doubt. (More precisely, less than k-1 dissenting votes are allowed, even if k is increased by ties.)
prob  If this is true, the proportion of the votes for the winning class are returned as attribute prob.
use.all controls handling of ties. If true, all distances equal to the kth largest are included. If false, a random selection of distances equal to the kth is chosen to use exactly k neighbours.

Details

This uses leave-one-out cross validation. For each row of the training set train, the k nearest (in Euclidean distance) other training set vectors are found, and the classification is decided by majority vote, with ties broken at random. If there are ties for the kth nearest vector, all candidates are included in the vote.

Value

Factor of classifications of training set. doubt will be returned as NA.

knn

Examples

```r
train <- rbind(iris3[,1], iris3[,2], iris3[,3])
c1 <- factor(c(rep("s",50), rep("c",50), rep("v",50)))
knn.cv(train, c1, k = 3, prob = TRUE)
attributes(.Last.value)
```
knn1

1-nearest neighbour classification

Description

Nearest neighbour classification for test set from training set. For each row of the test set, the nearest
(by Euclidean distance) training set vector is found, and its classification used. If there is more than
one nearest, a majority vote is used with ties broken at random.

Usage

knn1(train, test, cl)

Arguments

train
matrix or data frame of training set cases.

test
matrix or data frame of test set cases. A vector will be interpreted as a row
vector for a single case.

cl
factor of true classification of training set.

Value

Factor of classifications of test set.

knn

Examples

```R
train <- rbind(iris3[1:25,,1], iris3[1:25,,2], iris3[1:25,,3])
test <- rbind(iris3[26:50,,1], iris3[26:50,,2], iris3[26:50,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
knn1(train, test, cl)
```
**Description**

Moves examples in a codebook to better represent the training set.

**Usage**

```r
lvq1(x, cl, codebk, niter = 100 * nrow(codebk$x), alpha = 0.03)
```

**Arguments**

- `x`: a matrix or data frame of examples
- `cl`: a vector or factor of classifications for the examples
- `codebk`: a codebook
- `niter`: number of iterations
- `alpha`: constant for training

**Details**

Selects `niter` examples at random with replacement, and adjusts the nearest example in the codebook for each.

**Value**

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

lvqtest(cd1, train)
```

---

**lvq2**  
*Learning Vector Quantization 2.1*

**Description**

Moves examples in a codebook to better represent the training set.

**Usage**

```r
lvq2(x, cl, codebk, niter = 100 * nrow(codebk$x), alpha = 0.03,
     win = 0.3)
```

**Arguments**

- `x`: a matrix or data frame of examples
- `cl`: a vector or factor of classifications for the examples
- `codebk`: a codebook
- `niter`: number of iterations
- `alpha`: constant for training
- `win`: a tolerance for the closeness of the two nearest vectors.

**Details**

Selects `niter` examples at random with replacement, and adjusts the nearest two examples in the codebook if one is correct and the other incorrect.

**Value**

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

cd0 <- olvq1(train, c1, cd)
lvqtest(cd0, train)
cd2 <- lvq2(train, c1, cd0)
lvqtest(cd2, train)
```

Description

Moves examples in a codebook to better represent the training set.

Usage

```r
lvq3(x, cl, codebk, niter = 100*nrow(codebk$x), alpha = 0.03,
    win = 0.3, epsilon = 0.1)
```

Arguments

- `x`: a matrix or data frame of examples
- `cl`: a vector or factor of classifications for the examples
- `codebk`: a codebook
- `niter`: number of iterations
- `alpha`: constant for training
- `win`: a tolerance for the closeness of the two nearest vectors.
- `epsilon`: proportion of move for correct vectors

Details

Selects `niter` examples at random with replacement, and adjusts the nearest two examples in the codebook for each.

Value

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

**lvqinit**

*Initialize a LVQ Codebook*

**Description**

Construct an initial codebook for LVQ methods.

**Usage**

```r
lvqinit(x, cl, size, prior, k = 5)
```

**Arguments**

- `x` : a matrix or data frame of training examples, n by p.
- `cl` : the classifications for the training examples. A vector or factor of length n.
- `size` : the size of the codebook. Defaults to \( \min(\text{round}(0.4 \times ng \times (ng-1 + p/2), 0), n) \) where ng is the number of classes.
- `prior` : Probabilities to represent classes in the codebook. Default proportions in the training set.
- `k` : k used for k-NN test of correct classification. Default is 5.
Details

Selects size examples from the training set without replacement with proportions proportional to
the prior or the original proportions.

Value

A codebook, represented as a list with components x and cl giving the examples and classes.

multiedit       Multiedit for k-NN Classifier

Description
Multiedit for k-NN classifier

Usage

```
multiedit(x, class, k = 1, V = 3, I = 5, trace = TRUE)
```

Arguments

- `x` matrix of training set.
- `class` vector of classification of training set.
- `k` number of neighbours used in k-NN.
- `V` divide training set into V parts.
- `I` number of null passes before quitting.
- `trace` logical for statistics at each pass.

Value

Index vector of cases to be retained.
olvq1

```

---

**olvq1**

*Optimized Learning Vector Quantization 1*

Description

Moves examples in a codebook to better represent the training set.

Usage

```r
olvq1(x, cl, codebk, niter = 40 * nrow(codebk$x), alpha = 0.3)
```

Arguments

- `x` a matrix or data frame of examples
- `cl` a vector or factor of classifications for the examples
- `codebk` a codebook
- `niter` number of iterations
- `alpha` constant for training
Details

Selects \texttt{niter} examples at random with replacement, and adjusts the nearest example in the codebook for each.

Value

A codebook, represented as a list with components \texttt{x} and \texttt{cl} giving the examples and classes.

\texttt{reduce.nn} \hspace{1cm} \textit{Reduce Training Set for a k-NN Classifier}

Description

Reduce training set for a k-NN classifier. Used after \texttt{condense}.

Usage

\texttt{reduce.nn(train, ind, class)}

Arguments

\begin{itemize}
  \item \texttt{train} \hspace{1cm} matrix for training set
  \item \texttt{ind} \hspace{1cm} Initial list of members of the training set (from \texttt{condense}).
  \item \texttt{class} \hspace{1cm} vector of classifications for test set
\end{itemize}
Details

All the members of the training set are tried in random order. Any which when dropped do not cause any members of the training set to be wrongly classified are dropped.

Value

Index vector of cases to be retained.

References

See Also

`condense`, `multiedit`

Examples

```r
train <- rbind(iris3[,1:25,], iris3[,1:25,], iris3[,1:25,])
test <- rbind(iris3[,26:50,], iris3[,26:50,], iris3[,26:50,])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
keep <- condense(train, cl)
keep2 <- reduce.nn(train, keep, cl)
knn(train[,], test, cl)
knn(train[,], test, cl)
```

---

**SOM**

*Self-Organizing Maps: Online Algorithm*

Description

Kohonen’s Self-Organizing Maps are a crude form of multidimensional scaling.

Usage

```r
SOM(data, grid = somgrid(), rlen = 10000, alpha, radii, init)
```

Arguments

- **data**: a matrix or data frame of observations, scaled so that Euclidean distance is appropriate.
- **grid**: A grid for the representatives: see `somgrid`.
- **rlen**: the number of updates: used only in the defaults for `alpha` and `radii`. 
alpha the amount of change: one update is done for each element of alpha. Default is to decline linearly from 0.05 to 0 over rlen updates.

radii the radii of the neighbourhood to be used for each update: must be the same length as alpha. Default is to decline linearly from 4 to 1 over rlen updates.

init the initial representatives. If missing, chosen (without replacement) randomly from data.

Details

alpha and radii can also be lists, in which case each component is used in turn, allowing two- or more phase training.

Value

An object of class "SOM" with components

grid the grid, an object of class "somgrid".

codes a matrix of representatives.

References

See Also

somgrid, batchSOM

Examples

require(graphics)
data(crabs, package = "MASS")

lcrabs <- log(crabs[, 4:8])
crabs.grp <- factor(c("B", "b", "O", "o")[rep(1:4, rep(5/zero.noslash,4))])
gr <- somgrid(topo = "hexagonal")
crabs.som <- SOM(lcrabs, gr)
plot(crabs.som)

## 2-phase training

crabs.som2 <- SOM(lcrabs, gr,
   alpha = list(seq(0.05, 0, len = 1e4), seq(0.02, 0, len = 1e5)),
   radii = list(seq(8, 1, len = 1e4), seq(4, 1, len = 1e5)))
plot(crabs.som2)
somgrid

Plot SOM Fits

Description

Plotting functions for SOM results.

Usage

```r
somgrid(xdim = 8, ydim = 6, topo = c("rectangular", "hexagonal"))
```

```r
## S3 method for class 'somgrid'
plot(x, type = "p", ...)
```

```r
## S3 method for class 'SOM'
plot(x, ...)
```

Arguments

- `xdim, ydim`: dimensions of the grid
- `topo`: the topology of the grid.
- `x`: an object inheriting from class "somgrid" or "SOM".
- `type, ...`: graphical parameters.

Details

The class "somgrid" records the coordinates of the grid to be used for (batch or on-line) SOM: this has a plot method.

The plot method for class "SOM" plots a stars plot of the representative at each grid point.

Value

For somgrid, an object of class "somgrid", a list with components

- `pts`: a two-column matrix giving locations for the grid points.
- `xdim, ydim, topo`: as in the arguments to somgrid.

References

- `SOM`
Chapter 17

The cluster package

\[\texttt{agnes}\]

\textit{Agglomerative Nesting (Hierarchical Clustering)}

**Description**

Computes agglomerative hierarchical clustering of the dataset.

**Usage**

\[\texttt{agnes}(x, \text{diss = inherits}(x, "dist"), \text{metric = "euclidean"}, \text{stand = FALSE, method = "average", par.method,}
\text{keep.diss = n < 100, keep.data = !diss})\]

**Arguments**

- **x**
  - data matrix or data frame, or dissimilarity matrix, depending on the value of the `diss` argument.
  - In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.
  - In case of a dissimilarity matrix, `x` is typically the output of \texttt{daisy} or \texttt{dist}.
  - Also a vector with length \(n\*(n-1)/2\) is allowed (where \(n\) is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.

- **diss**
  - logical flag: if TRUE (default for \texttt{dist} or dissimilarity objects), then `x` is assumed to be a dissimilarity matrix. If FALSE, then `x` is treated as a matrix of observations by variables.

- **metric**
  - character string specifying the metric to be used for calculating dissimilarities between observations. The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If `x` is already a dissimilarity matrix, then this argument will be ignored.
`agnes` logical flag: if TRUE, then the measurements in `x` are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If `x` is already a dissimilarity matrix, then this argument will be ignored.

`method` character string defining the clustering method. The six methods implemented are "average" ([unweighted pair-group average method, UPGMA), "single" (single linkage), "complete" (complete linkage), "ward" (Ward’s method), "weighted" (weighted average linkage) and its generalization "flexible" which uses (a constant version of) the Lance-Williams formula and the `par.method` argument. Default is "average".

`par.method` if `method == "flexible"`, numeric vector of length 1, 3, or 4, see in the details section.

`keep.diss`, `keep.data` logicals indicating if the dissimilarities and/or input data `x` should be kept in the result. Setting these to FALSE can give much smaller results and hence even save memory allocation time.

**Details**

`agnes` is fully described in chapter 5 of Kaufman and Rousseeuw (1990). Compared to other agglomerative clustering methods such as `hclust`, `agnes` has the following features: (a) it yields the agglomerative coefficient (see `agnes.object`) which measures the amount of clustering structure found; and (b) apart from the usual tree it also provides the banner, a novel graphical display (see `plot.agnes`).

The `agnes`-algorithm constructs a hierarchy of clusterings. At first, each observation is a small cluster by itself. Clusters are merged until only one large cluster remains which contains all the observations. At each stage the two nearest clusters are combined to form one larger cluster.

For `method="average"`, the distance between two clusters is the average of the dissimilarities between the points in one cluster and the points in the other cluster.

In `method="single"`, we use the smallest dissimilarity between a point in the first cluster and a point in the second cluster (nearest neighbor method).

When `method="complete"`, we use the largest dissimilarity between a point in the first cluster and a point in the second cluster (furthest neighbor method).

The `method = "flexible"` allows (and requires) more details: The Lance-Williams formula specifies how dissimilarities are computed when clusters are agglomerated (equation (32) in K.\& R., p.237). If clusters $C_1$ and $C_2$ are agglomerated into a new cluster, the dissimilarity between their union and another cluster $Q$ is given by

$$D(C_1 \cup C_2, Q) = \alpha_1 \ast D(C_1, Q) + \alpha_2 \ast D(C_2, Q) + \beta \ast D(C_1, C_2) + \gamma \ast |D(C_1, Q) - D(C_2, Q)|,$$

where the four coefficients $(\alpha_1, \alpha_2, \beta, \gamma)$ are specified by the vector `par.method`.

If `par.method` is of length 1, say $= \alpha$, `par.method` is extended to give the “Flexible Strategy” (K. \& R., p.236 f) with Lance-Williams coefficients $(\alpha_1 = \alpha_2 = \alpha, \beta = 1 - 2\alpha, \gamma = 0)$.

If of length 3, $\gamma = 0$ is used.
Care and expertise is probably needed when using method = "flexible" particularly for the case when par.method is specified of longer length than one. The weighted average (method="weighted") is the same as method="flexible", par.method = 0.5.

Value

an object of class "agnes" (which extends "twins") representing the clustering. See agnes.object for details, and methods applicable.

BACKGROUND

Cluster analysis divides a dataset into groups (clusters) of observations that are similar to each other.

Hierarchical methods like agnes, diana, and mona construct a hierarchy of clusterings, with the number of clusters ranging from one to the number of observations.

Partitioning methods like pam, clara, and fanny require that the number of clusters be given by the user.

## Exploring the dendrogram structure
(d2 <- as.dendrogram(agn2)) # two main branches
d2[[1]] # the first branch
agnes.object

The objects of class "agnes" represent an agglomerative hierarchical clustering of a dataset.

Value

A legitimate agnes object is a list with the following components:

- order: a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.
- order.lab: a vector similar to order, but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.
- height: a vector with the distances between merging clusters at the successive stages.
- ac: the agglomerative coefficient, measuring the clustering structure of the dataset. For each observation i, denote by m(i) its dissimilarity to the first cluster it is merged with, divided by the dissimilarity of the merger in the final step of the algorithm. The ac is the average of all 1 - m(i). It can also be seen as the average width (or the percentage filled) of the banner plot. Because ac grows with the number of observations, this measure should not be used to compare datasets of very different sizes.
- merge: an (n-1) by 2 matrix, where n is the number of observations. Row i of merge describes the merging of clusters at step i of the clustering. If a number j in the row is negative, then the single observation |j| is merged at this stage. If j is positive, then the merger is with the cluster formed at stage j of the algorithm.
- diss: an object of class "dissimilarity" (see dissimilarity.object), representing the total dissimilarity matrix of the dataset.
- data: a matrix containing the original or standardized measurements, depending on the stand option of the function agnes. If a dissimilarity matrix was given as input structure, then this component is not available.
agriculture

**GENERATION**

This class of objects is returned from `agnes`.

**METHODS**

The "agnes" class has methods for the following generic functions: `print`, `summary`, `plot`, and `as.dendrogram`.

**INHERITANCE**

The class "agnes" inherits from "twins". Therefore, the generic functions `pltree` and `as.hclust` are available for `agnes` objects. After applying `as.hclust()`, all its methods are available, of course.

**See Also**

`agnes`, `diana`, `as.hclust`, `hclust`, `plot.agnes`, `twins.object`.

---

### agriculture

**European Union Agricultural Workforces**

**Description**

Gross National Product (GNP) per capita and percentage of the population working in agriculture for each country belonging to the European Union in 1993.

**Usage**

`data(agriculture)`

**Format**

A data frame with 12 observations on 2 variables:

- `[., 1] x numeric per capita GNP
- `[., 2] y numeric percentage in agriculture

The row names of the data frame indicate the countries.

**Details**

The data seem to show two clusters, the “more agricultural” one consisting of Greece, Portugal, Spain, and Ireland.

data(animals)

## Compute the dissimilarities using Euclidean metric and without
## standardization
daisy(animals, metric = "euclidean", stand = FALSE)

## 2nd plot is similar to Figure 3 in Struyf et al (1996)
plot(pam(animals, 2))

## Plot similar to Figure 7 in Struyf et al (1996)
## Not run: plot(agnes(animals), ask = TRUE)

## Plot similar to Figure 8 in Struyf et al (1996)
## Not run: plot(diana(animals), ask = TRUE)

animals            Attributes of Animals

Description

This data set considers 6 binary attributes for 20 animals.

Usage

data(animals)

Format

A data frame with 20 observations on 6 variables:

[ , 1] war  warm-blooded
[ , 2] fly  can fly
[ , 3] ver  vertebrate
[ , 4] end  endangered
[ , 5] gro  live in groups
[ , 6] hai  have hair
All variables are encoded as 1 = ‘no’, 2 = ‘yes’.

Details

This dataset is useful for illustrating monothetic (only a single variable is used for each split) hierarchical clustering.

**bannerplot**

Plot Banner (of Hierarchical Clustering)

**Description**

Draws a “banner”, i.e. basically a horizontal barplot visualizing the (agglomerative or divisive) hierarchical clustering or an other binary dendrogram structure.

**Usage**

bannerplot(x, w = rev(x$height), fromLeft = TRUE,
           main=NULL, sub=NULL, xlab = "Height", adj = 0,
           col = c(2, 0), border = 0, axes = TRUE, frame.plot = axes,
           rev.xax = !fromLeft, xax.pretty = TRUE,
           labels = NULL, nmax.lab = 35, max.strlen = 5,
           yax.do = axes && length(x$order) <= nmax.lab,
           yaxRight = fromLeft, y.mar = 2.4 + max.strlen/2.5, ...)
Arguments

- **x**
  a list with components `order`, `order.lab` and `height` when `w` is not specified.

- **w**
  non-negative numeric vector of bar widths.

- **fromLeft**
  logical, indicating if the banner is from the left or not.

- **main, sub**
  main and sub titles, see `title`.

- **xlab**
  x axis label (with 'correct' default e.g. for `plot.agnes`).

- **adj**
  passed to `title(main, sub)` for string adjustment.

- **col**
  vector of length 2, for two horizontal segments.

- **border**
  color for bar border; now defaults to background (no border).

- **axes**
  logical indicating if axes (and labels) should be drawn at all.

- **frame.plot**
  logical indicating the banner should be framed; mainly used when `border = 0` (as per default).

- **rev.xax**
  logical indicating if the x axis should be reversed (as in `plot.diana`).

- **xax.pretty**
  logical or integer indicating if `pretty()` should be used for the x axis.

- **labels**
  labels to use on y-axis; the default is constructed from `x`.

- **nmax.lab**
  integer indicating the number of labels which is considered too large for single-name labelling the banner plot.

- **max.strlen**
  positive integer giving the length to which strings are truncated in banner plot labeling.

- **yax.do**
  logical indicating if a y axis and banner labels should be drawn.

- **yaxRight**
  logical indicating if the y axis is on the right or left.

- **y.mar**
  positive number specifying the margin width to use when banners are labeled (along a y-axis). The default adapts to the string width and optimally would also depend on the font.

- **...**
  graphical parameters (see `par`) may also be supplied as arguments to this function.

Note

This is mainly a utility called from `plot.agnes`, `plot.diana` and `plot.mona`.

Author(s)

Martin Maechler (from original code of Kaufman and Rousseeuw).

Examples

```r
data(agriculture)
bannerplot(agnes(agriculture), main = "Bannerplot")
```
**Description**

This is a small rounded subset of the C-horizon data `chorizon` from package `mvoutlier`.

**Usage**

```r
data(chorSub)
```

**Format**

A data frame with 61 observations on 10 variables. The variables contain scaled concentrations of chemical elements.

**Details**

This data set was produced from `chorizon` via these statements:

```r
data(chorizon, package = "mvoutlier")
chorSub <- round(100*scale(chorizon[,101:110]))[190:250,]
storage.mode(chorSub) <- "integer"
colnames(chorSub) <- gsub("_.*", '', colnames(chorSub))
```

**Source**

**See Also**

`chorizon` in package `mvoutlier` and other Kola data in the same package.

**Examples**

```r
data(chorSub)
summary(chorSub)
pairs(chorSub, gap= .1)# some outliers
```
Description

Computes a "clara" object, a list representing a clustering of the data into k clusters.

Usage

`clara(x, k, metric = "euclidean", stand = FALSE, samples = 5,`  
`sampsize = min(n, 40 + 2 * k), trace = 0, medoids.x = TRUE,`  
`keep.data = medoids.x, rngR = FALSE, pamLike = FALSE)`

Arguments

- `x` data matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.
- `k` integer, the number of clusters. It is required that $0 < k < n$ where $n$ is the number of observations (i.e., $n = nrow(x)$).
- `metric` character string specifying the metric to be used for calculating dissimilarities between observations. The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences.
- `stand` logical, indicating if the measurements in `x` are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation.
- `samples` integer, number of samples to be drawn from the dataset. The default, 5, is rather small for historical (and now back compatibility) reasons and we recommend to set `samples` an order of magnitude larger.
- `sampsize` integer, number of observations in each sample. `sampsize` should be higher than the number of clusters ($k$) and at most the number of observations ($n = nrow(x)$).
- `trace` integer indicating a `trace level` for diagnostic output during the algorithm.
- `medoids.x` logical indicating if the medoids should be returned, identically to some rows of the input data `x`. If `FALSE`, `keep.data` must be `false` as well, and the medoid indices, i.e., row numbers of the medoids will still be returned (i.e., `med component`), and the algorithm saves space by needing one copy less of `x`.
- `keep.data` logical indicating if the (scaled if `stand` is true) data should be kept in the result. Setting this to `FALSE` saves memory (and hence time), but disables `clusplot`ing of the result. Use `medoids.x = FALSE` to save even more memory.
clara

rngR  logical indicating if R's random number generator should be used instead of the primitive clara()-builtin one. If true, this also means that each call to clara() returns a different result – though only slightly different in good situations.

pamLike logical indicating if the “swap” phase (see pam, in C code) should use the same algorithm as pam(). Note that from Kaufman and Rousseeuw’s description this should have been true always, but as the original Fortran code and the subsequent port to C has always contained a small one-letter change (a typo according to Martin Maechler) with respect to PAM, the default, pamLike = FALSE has been chosen to remain back compatible rather than “PAM compatible”.

Details

clara is fully described in chapter 3 of Kaufman and Rousseeuw (1990). Compared to other partitioning methods such as pam, it can deal with much larger datasets. Internally, this is achieved by considering sub-datasets of fixed size (sampsize) such that the time and storage requirements become linear in n rather than quadratic.

Each sub-dataset is partitioned into k clusters using the same algorithm as in pam. Once k representative objects have been selected from the sub-dataset, each observation of the entire dataset is assigned to the nearest medoid.

The mean (equivalent to the sum) of the dissimilarities of the observations to their closest medoid is used as a measure of the quality of the clustering. The sub-dataset for which the mean (or sum) is minimal, is retained. A further analysis is carried out on the final partition.

Each sub-dataset is forced to contain the medoids obtained from the best sub-dataset until then. Randomly drawn observations are added to this set until sampsize has been reached.

Value

an object of class "clara" representing the clustering. See clara.object for details.

Note

By default, the random sampling is implemented with a very simple scheme (with period $2^{16} = 65536$) inside the Fortran code, independently of R’s random number generation, and as a matter of fact, deterministically. Alternatively, we recommend setting rngR = TRUE which uses R’s random number generators. Then, clara() results are made reproducible typically by using set.seed() before calling clara.

The storage requirement of clara computation (for small k) is about $O(n \times p) + O(j^2)$ where $j = \text{sampsize}$, and $(n, p) = \text{dim(x)}$. The CPU computing time (again assuming small k) is about $O(n \times p \times j^2 \times N)$, where $N = \text{samples}$.

For “small” datasets, the function pam can be used directly. What can be considered small, is really a function of available computing power, both memory (RAM) and speed. Originally (1990), “small” meant less than 100 observations; in 1997, the authors said “small (say with fewer than 200 observations)”; as of 2006, you can use pam with several thousand observations.

Author(s)

Kaufman and Rousseeuw (see agnes), originally. All arguments from trace on, and most R documentation and all tests by Martin Maechler.

Examples

## generate 500 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(200,0,8), rnorm(200,0,8)),
          cbind(rnorm(300,50,8), rnorm(300,50,8)))
clarax <- clara(x, 2, samples=50)
clarax
clarax$clusinfo
## using pamLike=TRUE gives the same (apart from the 'call'):
all.equal(clarax[-8],
          clara(x, 2, samples=50, pamLike = TRUE)[-8])
plot(clarax)

## 'xclara' is an artificial data set with 3 clusters of 1000 bivariate
## objects each.
data(xclara)
(clx3 <- clara(xclara, 3))
## "better" number of samples
cl.3 <- clara(xclara, 3, samples=100)
## but that did not change the result here:
stopifnot(cl.3$clustering == clx3$clustering)
## Plot similar to Figure 5 in Struyf et al (1996)
## Not run: plot(clx3, ask = TRUE)

## Try 100 times *different* random samples -- for reliability:
nSim <- 100
nCl <- 3 # = no.classes
set.seed(421)# (reproducibility)
c1 <- matrix(NA,nrow(xclara), nSim)
for(i in 1:nSim)
c1[,i] <- clara(xclara, nCl, medoids.x = FALSE, rngR = TRUE)$cluster
tcl <- apply(c1,1, tabulate, nbins = nCl)
## those that are not always in same cluster (5 out of 3000 for this seed):
(iDoubt <- which(apply(tcl,2, function(n) all(n < nSim))))
if(length(iDoubt)) { # (not for all seeds)
tab0 <- tcl[,iDoubt, drop=FALSE]
dimnames(tab0) <- list(cluster = paste(1:nCl), obs = format(iDoubt))
t(tab0) # how many times in which clusters
}
Description

The objects of class "clara" represent a partitioning of a large dataset into clusters and are typically returned from clara.

Value

A legitimate clara object is a list with the following components:

- **sample**: labels or case numbers of the observations in the best sample, that is, the sample used by the clara algorithm for the final partition.
- **medoids**: the medoids or representative objects of the clusters. It is a matrix with in each row the coordinates of one medoid. Possibly NULL, namely when the object resulted from clara(*, medoids.x=FALSE). Use the following i.med in that case.
- **i.med**: the indices of the medoids above: medoids <- x[i.med,] where x is the original data matrix in clara(x,*).
- **clustering**: the clustering vector, see partition.object.
- **objective**: the objective function for the final clustering of the entire dataset.
- **clusinfo**: matrix, each row gives numerical information for one cluster. These are the cardinality of the cluster (number of observations), the maximal and average dissimilarity between the observations in the cluster and the cluster’s medoid. The last column is the maximal dissimilarity between the observations in the cluster and the cluster’s medoid, divided by the minimal dissimilarity between the cluster’s medoid and the medoid of any other cluster. If this ratio is small, the cluster is well-separated from the other clusters.
- **diss**: dissimilarity (maybe NULL), see partition.object.
- **silinfo**: list with silhouette width information for the best sample, see partition.object.
- **call**: generating call, see partition.object.
- **data**: matrix, possibly standardized, or NULL, see partition.object.

Methods, Inheritance

The "clara" class has methods for the following generic functions: print, summary.

The class "clara" inherits from "partition". Therefore, the generic functions plot and clusplot can be used on a clara object.

See Also

clara, dissimilarity.object, partition.object, plot.partition.
Gap Statistic for Estimating the Number of Clusters

Description
clusGap() calculates a goodness of clustering measure, the “gap” statistic. For each number of clusters \( k \), it compares \( \log(W(k)) \) with \( E^* \log(W(k)) \) where the latter is defined via bootstrapping, i.e. simulating from a reference distribution.

maxSE(f, SE.f) determines the location of the maximum of \( f \), taking a “1-SE rule” into account for the *SE* methods. The default method "firstSEmax" looks for the smallest \( k \) such that its value \( f(k) \) is not more than 1 standard error away from the first local maximum. This is similar but not the same as "Tibs2001SEmax", Tibshirani et al’s recommendation of determining the number of clusters from the gap statistics and their standard deviations.

Usage
clusGap(x, FUNcluster, K.max, B = 100, verbose = interactive(), ...)

maxSE(f, SE.f, method = c("firstSEmax", "Tibs2001SEmax", "globalSEmax", "firstmax", "globalmax"), SE.factor = 1)
## S3 method for class 'clusGap'
print(x, method = "firstSEmax", SE.factor = 1, ...)

Arguments

- **x**: numeric matrix or data.frame.
- **FUNcluster**: a function which accepts as first argument a (data) matrix like \( x \), second argument, say \( k, k \geq 2 \), the number of clusters desired, and returns a list with a component named (or shortened to) cluster which is a vector of length \( n = \text{nrow}(x) \) of integers in 1:k determining the clustering or grouping of the \( n \) observations.
- **K.max**: the maximum number of clusters to consider, must be at least two.
- **B**: integer, number of Monte Carlo (“bootstrap”) samples.
- **verbose**: integer or logical, determining if “progress” output should be printed. The default prints one bit per bootstrap sample.
- **...**: optionally further arguments for FUNcluster(), see kmeans example below.
- **f**: numeric vector of ‘function values’, of length \( K \), whose (“1 SE respected”) maximum we want.
- **SE.f**: numeric vector of length \( K \) of standard errors of \( f \).
- **method**: character string indicating how the “optimal” number of clusters, \( \hat{k} \), is computed from the gap statistics (and their standard deviations), or more generally how the location \( \hat{k} \) of the maximum of \( f_k \) should be determined.
"globalmax": simply corresponds to the global maximum, i.e., is \( \text{which.max}(f) \)

"firstmax": gives the location of the first local maximum.

"Tibs2001SEmax": uses the criterion, Tibshirani et al (2001) proposed: "the smallest \( k \) such that \( f(k) \geq f(k+1) - s_{k+1} \). Note that this chooses \( k = 1 \) when all standard deviations are larger than the differences \( f(k+1) - f(k) \).

"firstSEmax": location of the first \( f() \) value which is not larger than the first local maximum minus \( \text{SE.factor} \times \text{SE.f[]} \), i.e, within an “f S.E.” range of that maximum (see also \( \text{SE.factor} \)).

"globalSEmax": (used in Dudoit and Fridlyand (2002), supposedly following Tibshirani's proposition): location of the first \( f() \) value which is not larger than the global maximum minus \( \text{SE.factor} \times \text{SE.f[]} \), i.e, within an “f S.E.” range of that maximum (see also \( \text{SE.factor} \)).

See the examples for a comparison in a simple case.

\( \text{SE.factor} \) [When method contains "SE"] Determining the optimal number of clusters, Tibshirani et al. proposed the “1 S.E.”-rule. Using an \( \text{SE.factor} \) \( f \), the “f S.E.”-rule is used, more generally.

Details

The main result \(<\text{res}>\text{Tab[, "gap"]}\) of course is from bootstrapping aka Monte Carlo simulation and hence random, or equivalently, depending on the initial random seed (see \( \text{set.seed()} \)). On the other hand, in our experience, using \( B = 500 \) gives quite precise results such that the gap plot is basically unchanged after an another run.

Value

an object of S3 class "clusGap", basically a list with components

\( \text{Tab} \) a matrix with \( \text{K.max} \) rows and 4 columns, named "logW", "E.logW", "gap", and "SE.sim", where \( gap = E.\logW - \logW \) and \( \text{SE.sim} \) corresponds to the standard error of \( gap \), \( \text{SE.sim}[k] = s_k \), where \( s_k := \sqrt{1 + 1/Bsd^2(gap_j)} \), and \( sd^2() \) is the standard deviation of the simulated ("bootstrapped") gap values.

\( n \) number of observations, i.e., \( \text{nrow(x)} \).

\( B \) input \( B \)

\( \text{FUNcluster} \) input function \( \text{FUNcluster} \)

Author(s)

This function is originally based on the functions gap of (Bioconductor) package \texttt{SAGx} by Per Broberg, gapStat() from former package \texttt{SLmisc} by Matthias Kohl and ideas from gap() and its methods of package \texttt{lga} by Justin Harrington.

The current implementation is by Martin Mächler.

Examples

### --- maxSE() methods ---------------------------------------------
(mets <- eval(formals(maxSE)$method))
fk <- c(2,3,5,4,7,8,5,4)
sk <- c(1,1,2,1,3,1,1)/2
# use plot.clusGap():
plot(structure(class="clusGap", list(Tab = cbind(gap=fk, SE.sim=sk))))
# Note that 'firstmax' and 'globalmax' are always at 3 and 6:
sapply(c(1/4, 1,2,4), function(SEf)
sapply(mets, function(M) maxSE(fk, sk, method = M, SE.factor = SEf)))

### --- clusGap() ------------------------------------------------
## ridiculously nicely separated clusters in 3 D:
x <- rbind(matrix(rnorm(15/zero.noslash, sd = /zero.noslash.1), ncol = 3),
          matrix(rnorm(15/zero.noslash, mean = 1, sd = /zero.noslash.1), ncol = 3),
          matrix(rnorm(15/zero.noslash, mean = 2, sd = /zero.noslash.1), ncol = 3),
          matrix(rnorm(15/zero.noslash, mean = 3, sd = /zero.noslash.1), ncol = 3))

## Slightly faster way to use pam (see below)
pam1 <- function(x,k) list(cluster = pam(x,k, cluster.only=TRUE))

doExtras <- cluster:::doExtras()
# or set it explicitly to TRUE for the following
if(doExtras) {
  # Note we use B = 60 in the following examples to keep them "speedy".
  # ---- rather keep the default B = 500 for your analysis!

  # note we can pass 'nstart = 20' to kmeans:
gskmm <- clusGap(x, FUN = kmeans, nstart = 20, K.max = 8, B = 60)
gskmm #-> its print() method
plot(gskmm, main = "clusGap(. , FUN = kmeans, n.start=20, B= 60")
set.seed(12); system.time(
gsPam0 <- clusGap(x, FUN = pam, K.max = 8, B = 60)
)
set.seed(12); system.time(
gsPam1 <- clusGap(x, FUN = pam1, K.max = 8, B = 60)
## and show that it gives the same:

```r
stopifnot(identical(gsPam1[-4], gsPam0[-4]))
```

```r
gsPam1
print(gsPam1, method="globalSEmax")
print(gsPam1, method="globalmax")
}
```

```r
gs.pam.RU <- clusGap(ruspini, FUN = pam1, K.max = 8, B = 60)
gs.pam.RU
plot(gs.pam.RU, main = "Gap statistic for the 'ruspini' data")
mtext("k = 4 is best .. and k = 5 pretty close")
```

## This takes a minute..

```r
## No clustering ==> k = 1 ("one cluster") should be optimal:
Z <- matrix(rnorm(256*3), 256,3)
gsP.Z <- clusGap(Z, FUN = pam1, K.max = 8, B = 200)
plot(gsP.Z)
gsP.Z
```

---

**clusplot**  
*Bivariate Cluster Plot (of a Partitioning Object)*

### Description

Draws a 2-dimensional “clusplot” (clustering plot) on the current graphics device. The generic function has a default and a partition method.

### Usage

```r
clusplot(x, ...)
## S3 method for class 'partition'
clusplot(x, main = NULL, dist = NULL, ...)
```

### Arguments

- **x**
  - an *R* object, here, specifically an object of class “partition”, e.g. created by one of the functions `pam`, `clara`, or `fanny`.
- **main**
  - title for the plot; when `NULL` (by default), a title is constructed, using `x$call`.
- **dist**
  - when `x` does not have a `diss` nor a `data` component, e.g., for `pam(dist(*), keep.diss=FALSE), dist` must specify the dissimilarity for the clusplot.
- **...**
  - optional arguments passed to methods, notably the `clusplot.default` method (except for the `diss` one) may also be supplied to this function. Many graphical parameters (see `par`) may also be supplied as arguments here.
Details

The clusplot.partition() method relies on clusplot.default.

If the clustering algorithms pam, fanny and clara are applied to a data matrix of observations-by-variables then a clusplot of the resulting clustering can always be drawn. When the data matrix contains missing values and the clustering is performed with pam or fanny, the dissimilarity matrix will be given as input to clusplot. When the clustering algorithm clara was applied to a data matrix with NAs then clusplot will replace the missing values as described in clusplot.default, because a dissimilarity matrix is not available.

Value

For the partition (and default) method: An invisible list with components Distances and Shading, as for clusplot.default, see there.

Side Effects

a 2-dimensional clusplot is created on the current graphics device.

See Also

clusplot.default for references; partition.object.pam, pam.object.clara, clara.object, fanny, fanny.object.par.

Examples

## For more, see ?clusplot.default

## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)), cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
clusplot(pam(x, 2))
## add noise, and try again:
x4 <- cbind(x, rnorm(25), rnorm(25))
clusplot(pam(x4, 2))

Description

Creates a bivariate plot visualizing a partition (clustering) of the data. All observation are represented by points in the plot, using principal components or multidimensional scaling. Around each cluster an ellipse is drawn.
Usage

```r
## Default S3 method:
clusplot(x, clus, diss = FALSE,
s.x.2d = mkCheckX(x, diss), stand = FALSE,
lines = 2, shade = FALSE, color = FALSE,
labels = 0, plotchar = TRUE,
col.p = "dark green", col.txt = col.p,
col.clus = if(color) c(2, 4, 6, 3) else 5, cex = 1, cex.txt = cex,
span = TRUE,
add = FALSE,
xlim = NULL, ylim = NULL,
main = paste("CLUSPLOT(", deparse(substitute(x)), ")"),
sub = paste("These two components explain",
  round(100 * var.dec, digits = 2), ", \% of the point variability.")
, xlab = "Component 1", ylab = "Component 2",
verbose = getOption("verbose"),
...)
```

Arguments

- **x**
  - matrix or data frame, or dissimilarity matrix, depending on the value of the `diss` argument.
  - In case of a matrix (alike), each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed. They are replaced by the median of the corresponding variable. When some variables or some observations contain only missing values, the function stops with a warning message.
  - In case of a dissimilarity matrix, `x` is the output of `daisy` or `dist` or a symmetric matrix. Also, a vector of length \( n \times (n - 1)/2 \) is allowed (where `n` is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.

- **clus**
  - a vector of length `n` representing a clustering of `x`. For each observation the vector lists the number or name of the cluster to which it has been assigned. `clus` is often the clustering component of the output of `pam`, `fanny` or `clara`.

- **diss**
  - logical indicating if `x` will be considered as a dissimilarity matrix or a matrix of observations by variables (see `x` argument above).

- **s.x.2d**
  - a `list` with components `x` (a \( n \times 2 \) matrix; typically something like principal components of original data), `labs` and `var.dec`.

- **stand**
  - logical flag: if true, then the representations of the `n` observations in the 2-dimensional plot are standardized.

- **lines**
  - integer out of `0, 1, 2`, used to obtain an idea of the distances between ellipses. The distance between two ellipses `E1` and `E2` is measured along the line connecting the centers `m1` and `m2` of the two ellipses.
  - In case `E1` and `E2` overlap on the line through `m1` and `m2`, no line is drawn. Otherwise, the result depends on the value of `lines`: If
    - `lines = 0`, no distance lines will appear on the plot;
lines = 1, the line segment between \( m_1 \) and \( m_2 \) is drawn;
lines = 2, a line segment between the boundaries of E1 and E2 is drawn (along the line connecting \( m_1 \) and \( m_2 \)).

shade logical flag: if TRUE, then the ellipses are shaded in relation to their density. The density is the number of points in the cluster divided by the area of the ellipse.

color logical flag: if TRUE, then the ellipses are colored with respect to their density. With increasing density, the colors are light blue, light green, red and purple. To see these colors on the graphics device, an appropriate color scheme should be selected (we recommend a white background).

labels integer code, currently one of 0,1,2,3,4 and 5. If
labels= 0, no labels are placed in the plot;
labels= 1, points and ellipses can be identified in the plot (see identify);
labels= 2, all points and ellipses are labelled in the plot;
labels= 3, only the points are labelled in the plot;
labels= 4, only the ellipses are labelled in the plot.
labels= 5, the ellipses are labelled in the plot, and points can be identified.

The levels of the vector clus are taken as labels for the clusters. The labels of the points are the rownames of \( x \) if \( x \) is matrix like. Otherwise (diss = TRUE), \( x \) is a vector, point labels can be attached to \( x \) as a "Labels" attribute (attr(\( x \),"Labels")), as is done for the output of daisy.
A possible names attribute of clus will not be taken into account.

plotchar logical flag: if TRUE, then the plotting symbols differ for points belonging to different clusters.

span logical flag: if TRUE, then each cluster is represented by the ellipse with smallest area containing all its points. (This is a special case of the minimum volume ellipsoid.)

If FALSE, the ellipse is based on the mean and covariance matrix of the same points. While this is faster to compute, it often yields a much larger ellipse.

There are also some special cases: When a cluster consists of only one point, a tiny circle is drawn around it. When the points of a cluster fall on a straight line, span=FALSE draws a narrow ellipse around it and span=TRUE gives the exact line segment.

add logical indicating if ellipses (and labels if labels is true) should be added to an already existing plot. If false, neither a title or sub title, see sub, is written.

col.p color code(s) used for the observation points.

col.txt color code(s) used for the labels (if labels >= 2).

col.clus color code for the ellipses (and their labels); only one if color is false (as per default).

cex, cex.txt character expansion (size), for the point symbols and point labels, respectively.

xlim, ylim numeric vectors of length 2, giving the x- and y- ranges as in plot.default.

main main title for the plot; by default, one is constructed.

sub sub title for the plot; by default, one is constructed.
clusplot.default

xlab, ylab  x- and y- axis labels for the plot, with defaults.
verbose  a logical indicating, if there should be extra diagnostic output; mainly for ‘de-bugging’.

Further graphical parameters may also be supplied, see par.

Details

clusplot uses the functions princomp and cmdscale. These functions are data reduction techniques. They will represent the data in a bivariate plot. Ellipses are then drawn to indicate the clusters. The further layout of the plot is determined by the optional arguments.

Value

An invisible list with components:

Distances  When lines is 1 or 2 we obtain a k by k matrix (k is the number of clusters). The element in [i,j] is the distance between ellipse i and ellipse j. If lines = 0, then the value of this component is NA.

Shading  A vector of length k (where k is the number of clusters), containing the amount of shading per cluster. Let y be a vector where element i is the ratio between the number of points in cluster i and the area of ellipse i. When the cluster i is a line segment, y[i] and the density of the cluster are set to NA. Let z be the sum of all the elements of y without the NAs. Then we put shading = y/z *37 + 3.

Side Effects

A visual display of the clustering is plotted on the current graphics device.

Note

When we have 4 or fewer clusters, then the color=TRUE gives every cluster a different color. When there are more than 4 clusters, clusplot uses the function pam to cluster the densities into 4 groups such that ellipses with nearly the same density get the same color. col.clus specifies the colors used.

The col.p and col.txt arguments, added for R, are recycled to have length the number of observations. If col.p has more than one value, using color = TRUE can be confusing because of a mix of point and ellipse colors.

Examples

## plotting votes.diss(dissimilarity) in a bivariate plot and ## partitioning into 2 clusters
data(votes.repub)
votes.diss <- daisy(votes.repub)
pamv <- pam(votes.diss, 2, diss = TRUE)
clusplot(pamv, shade = TRUE)
## is the same as
votes.clus <- pamv$clustering
clusplot(votes.diss, votes.clus, diss = TRUE, shade = TRUE)

clusplot(pamv, col.p = votes.clus, labels = 4)# color points and label ellipses
# "simple" cheap ellipses: larger than minimum volume:
# here they are *added* to the previous plot:
clusplot(pamv, span = FALSE, add = TRUE, col.clus = "midnightblue")

## a work-around for setting a small label size:
clusplot(votes.diss, votes.clus, diss = TRUE)
op <- par(new=TRUE, cex = .6)
clusplot(votes.diss, votes.clus, diss = TRUE,
        axes=FALSE,ann=FALSE, sub="", col.p=NA, col.txt="dark green", labels=3)
par(op)
## MM: This should now be as simple as
clusplot(votes.diss, votes.clus, diss = TRUE, labels = 3, cex.txt = .6)

if(interactive()) { # uses identify() *interactively* :
  clusplot(votes.diss, votes.clus, diss = TRUE, shade = TRUE, labels = 1)
  clusplot(votes.diss, votes.clus, diss = TRUE, labels = 5)# ident. only points
}

## plotting iris (data frame) in a 2-dimensional plot and partitioning ## into 3 clusters.
data(iris)
iris.x <- iris[, 1:4]
c13 <- pam(iris.x, 3)$clustering
op <- par(mfrow= c(2,2))
clusplot(iris.x, c13, color = TRUE)
U <- par("usr")
## zoom in :
rect(0,-1, 2,1, border = "orange", lwd=2)
clusplot(iris.x, c13, color = TRUE, xlim = c(0,2), ylim = c(-1,1))
box(col="orange",lwd=2); mtext("sub region", font = 4, cex = 2)
## or zoom out :
clusplot(iris.x, c13, color = TRUE, xlim = c(-4,4), ylim = c(-4,4))
mtext("'super’ region", font = 4, cex = 2)
rect(U[1],U[3], U[2],U[4], lwd=2, lty = 3)
# reset graphics
par(op)

---

coe.hclust  

Agglomerative / Divisive Coefficient for 'hclust' Objects

Description

Computes the “agglomerative coefficient” (aka “divisive coefficient” for diana), measuring the clustering structure of the dataset.

For each observation i, denote by \( m(i) \) its dissimilarity to the first cluster it is merged with, divided by the dissimilarity of the merger in the final step of the algorithm. The agglomerative coefficient is the average of all \( 1 - m(i) \). It can also be seen as the average width (or the percentage filled) of the banner plot.

coefHier() directly interfaces to the underlying C code, and “proves” that only object$heights is needed to compute the coefficient.

Because it grows with the number of observations, this measure should not be used to compare datasets of very different sizes.

Usage

coefHier(object)
coef.hclust(object, ...)
## S3 method for class 'hclust'
coef(object, ...)
## S3 method for class 'twins'
coef(object, ...)

Arguments

object  
an object of class "hclust" or "twins", i.e., typically the result of hclust(), agnes(), or diana().

Since coef.hclust only uses object$heights, and object$merge, object can be any list-like object with appropriate merge and heights components.

For coefHier, even only object$heights is needed.

...  
currently unused potential further arguments

Value

a number specifying the agglomerative (or divisive for diana objects) coefficient as defined by Kaufman and Rousseeuw, see agnes.object $ ac or diana.object $ dc.
Examples

data(agriculture)
aa <- agnes(agriculture)
coef(aa) # really just extracts aa$ac
coef(as.hclust(aa))# recomputes
coefHier(aa) # ditto

daisy

Dissimilarity Matrix Calculation

Description

Compute all the pairwise dissimilarities (distances) between observations in the data set. The original variables may be of mixed types. In that case, or whenever metric = "gower" is set, a generalization of Gower's formula is used, see 'Details' below.

Usage

daisy(x, metric = c("euclidean", "manhattan", "gower"),
     stand = FALSE, type = list(), weights = rep.int(1, p))

Arguments

x
numeric matrix or data frame, of dimension $n \times p$, say. Dissimilarities will be computed between the rows of x. Columns of mode numeric (i.e. all columns when x is a matrix) will be recognized as interval scaled variables, columns of class factor will be recognized as nominal variables, and columns of class ordered will be recognized as ordinal variables. Other variable types should be specified with the type argument. Missing values (NAs) are allowed.

metric
character string specifying the metric to be used. The currently available options are "euclidean" (the default), "manhattan" and "gower". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences.

"Gower's distance" is chosen by metric "gower" or automatically if some columns of x are not numeric. Also known as Gower's coefficient (1971), expressed as a dissimilarity, this implies that a particular standardisation will be applied to each variable, and the "distance" between two units is the sum of all the variable-specific distances, see the details section.

stand
logical flag: if TRUE, then the measurements in x are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation.

If not all columns of x are numeric, stand will be ignored and Gower's standardization (based on the range) will be applied in any case, see argument metric, above, and the details section.
**type**

list for specifying some (or all) of the types of the variables (columns) in x. The list may contain the following components: "ordratio" (ratio scaled variables to be treated as ordinal variables), "logratio" (ratio scaled variables that must be logarithmically transformed), "asymm" (asymmetric binary) and "symm" (symmetric binary variables). Each component’s value is a vector, containing the names or the numbers of the corresponding columns of x. Variables not mentioned in the type list are interpreted as usual (see argument x).

**weights**

an optional numeric vector of length \(p = \text{ncol}(x)\); to be used in “case 2” (mixed variables, or \text{metric} = "gower"), specifying a weight for each variable \((x[,k])\) instead of 1 in Gower’s original formula.

**Details**

The original version of daisy is fully described in chapter 1 of Kaufman and Rousseeuw (1990). Compared to dist whose input must be numeric variables, the main feature of daisy is its ability to handle other variable types as well (e.g. nominal, ordinal, (a)symmetric binary) even when different types occur in the same data set.

The handling of nominal, ordinal, and (a)symmetric binary data is achieved by using the general dissimilarity coefficient of Gower (1971). If x contains any columns of these data-types, both arguments \text{metric} and \text{stand} will be ignored and Gower’s coefficient will be used as the metric. This can also be activated for purely numeric data by \text{metric} = "gower". With that, each variable (column) is first standardized by dividing each entry by the range of the corresponding variable, after subtracting the minimum value; consequently the rescaled variable has range \([0, 1]\), exactly.

Note that setting the type to \text{symm} (symmetric binary) gives the same dissimilarities as using \text{nominal} (which is chosen for non-ordered factors) only when no missing values are present, and more efficiently.

Note that daisy now gives a warning when 2-valued numerical variables do not have an explicit type specified, because the reference authors recommend to consider using "asymm".

In the daisy algorithm, missing values in a row of x are not included in the dissimilarities involving that row. There are two main cases,

1. If all variables are interval scaled (and \text{metric} is not "gower"), the metric is "euclidean", and \(n_g\) is the number of columns in which neither row i and j have NAs, then the dissimilarity \(d(i,j)\) returned is \(\sqrt{p/n_g} (p = \text{ncol}(x))\) times the Euclidean distance between the two vectors of length \(n_g\) shortened to exclude NAs. The rule is similar for the "manhattan" metric, except that the coefficient is \(p/n_g\). If \(n_g = 0\), the dissimilarity is NA.

2. When some variables have a type other than interval scaled, or if \text{metric} = "gower" is specified, the dissimilarity between two rows is the weighted mean of the contributions of each variable. Specifically,

\[
d_{ij} = d(i,j) = \frac{\sum_{k=1}^{p} w_k \delta_{ij}^{(k)} d_{ij}^{(k)}}{\sum_{k=1}^{p} w_k \delta_{ij}^{(k)}}.
\]

In other words, \(d_{ij}\) is a weighted mean of \(d_{ij}^{(k)}\) with weights \(w_k \delta_{ij}^{(k)}\), where \(w_k = \text{weights}[k]\), \(\delta_{ij}^{(k)} = 0\) or 1, and \(d_{ij}^{(k)}\), the k-th variable contribution to the total distance, is a distance between \(x[i,k]\) and \(x[j,k]\), see below.
The 0-1 weight $\delta^{(k)}_{ij}$ becomes zero when the variable $x[,k]$ is missing in either or both rows (i and j), or when the variable is asymmetric binary and both values are zero. In all other situations it is 1.

The contribution $d^{(k)}_{ij}$ of a nominal or binary variable to the total dissimilarity is 0 if both values are equal, 1 otherwise. The contribution of other variables is the absolute difference of both values, divided by the total range of that variable. Note that “standard scoring” is applied to ordinal variables, i.e., they are replaced by their integer codes 1:K. Note that this is not the same as using their ranks (since there typically are ties).

As the individual contributions $d^{(k)}_{ij}$ are in $[0, 1]$, the dissimilarity $d_{ij}$ will remain in this range. If all weights $w_k\delta^{(k)}_{ij}$ are zero, the dissimilarity is set to NA.

Value

an object of class "dissimilarity" containing the dissimilarities among the rows of x. This is typically the input for the functions pam, fanny, agnes or diana. For more details, see dissimilarity.object.

Background

Dissimilarities are used as inputs to cluster analysis and multidimensional scaling. The choice of metric may have a large impact.

Author(s)

Anja Struyf, Mia Hubert, and Peter and Rousseeuw, for the original version.

Martin Maechler improved the NA handling and type specification checking, and extended functionality to metric = "gower" and the optional weights argument.

Examples

data(agriculture)
## Example 1 in ref:
## Dissimilarities using Euclidean metric and without standardization
d.agr <- daisy(agriculture, metric = "euclidean", stand = FALSE)
d.agr
as.matrix(d.agr)[,"DK"] # via as.matrix.dist(.)
## compare with
as.matrix(daisy(agriculture, metric = "gower"))

data(flower)
## Example 2 in ref
summary(dfl1 <- daisy(flower, type = list(asymm = 3)))
summary(dfl2 <- daisy(flower, type = list(asymm = c(1, 3), ordratio = 7)))
## this failed earlier:
summary(dfl3 <- daisy(flower,
    type = list(asymm = c("V1", "V3"), symm= 2,
    ordratio= 7, logratio= 8))))

diana

**Description**

Computes a divisive hierarchical clustering of the dataset returning an object of class **diana**.

**Usage**

diana(x, diss = inherits(x, "dist"), metric = "euclidean", stand = FALSE,
    keep.diss = n < 100, keep.data = !diss, trace.lev = 0)

**Arguments**

- **x**: data matrix or data frame, or dissimilarity matrix or object, depending on the value of the diss argument.
  - In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.
  - In case of a dissimilarity matrix, x is typically the output of daisy or dist. Also a vector of length n*(n-1)/2 is allowed (where n is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.

- **diss**: logical flag: if TRUE (default for dist or dissimilarity objects), then x will be considered as a dissimilarity matrix. If FALSE, then x will be considered as a matrix of observations by variables.

- **metric**: character string specifying the metric to be used for calculating dissimilarities between observations.
  - The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If x is already a dissimilarity matrix, then this argument will be ignored.
stand logical; if true, the measurements in x are standardized before calculating
the dissimilarities. Measurements are standardized for each variable (column), by
subtracting the variable’s mean value and dividing by the variable’s mean abso-
olute deviation. If x is already a dissimilarity matrix, then this argument will be
ignored.

keep.diss, keep.data
logicals indicating if the dissimilarities and/or input data x should be kept in the
result. Setting these to FALSE can give much smaller results and hence even save
memory allocation time.

trace.lev integer specifying a trace level for printing diagnostics during the algorithm.
Default 0 does not print anything; higher values print increasingly more.

Details
diana is fully described in chapter 6 of Kaufman and Rousseeuw (1990). It is probably unique
in computing a divisive hierarchy, whereas most other software for hierarchical clustering is ag-
gglomerative. Moreover, diana provides (a) the divisive coefficient (see diana.object) which
measures the amount of clustering structure found; and (b) the banner, a novel graphical display
(see plot.diana).
The diana-algorithm constructs a hierarchy of clusterings, starting with one large cluster contain-
ing all n observations. Clusters are divided until each cluster contains only a single observation.
At each stage, the cluster with the largest diameter is selected. (The diameter of a cluster is the
largest dissimilarity between any two of its observations.)
To divide the selected cluster, the algorithm first looks for its most disparate observation (i.e., which
has the largest average dissimilarity to the other observations of the selected cluster). This observa-
tion initiates the "splinter group". In subsequent steps, the algorithm reassigns observations that are
closer to the "splinter group" than to the "old party". The result is a division of the selected cluster
into two new clusters.

Value
an object of class "diana" representing the clustering; this class has methods for the following
generic functions: print, summary, plot.
Further, the class "diana" inherits from "twins". Therefore, the generic function pltree can be
used on a diana object, and as.hclust and as.dendrogram methods are available.
A legitimate diana object is a list with the following components:
order a vector giving a permutation of the original observations to allow for plotting,
in the sense that the branches of a clustering tree will not cross.
order.lab a vector similar to order, but containing observation labels instead of observa-
tion numbers. This component is only available if the original observations were
labelled.
height a vector with the diameters of the clusters prior to splitting.
dc the divisive coefficient, measuring the clustering structure of the dataset. For
each observation i, denote by \( d(i) \) the diameter of the last cluster to which it
belongs (before being split off as a single observation), divided by the diameter
of the whole dataset. The dc is the average of all \( 1 - d(i) \). It can also be seen as
the average width (or the percentage filled) of the banner plot. Because \( dc \) grows with the number of observations, this measure should not be used to compare datasets of very different sizes.

merge
an (n-1) by 2 matrix, where n is the number of observations. Row \( i \) of merge describes the split at step \( n-i \) of the clustering. If a number \( j \) in row \( r \) is negative, then the single observation \( |j| \) is split off at stage \( n-r \). If \( j \) is positive, then the cluster that will be splitted at stage \( n-j \) (described by row \( j \)), is split off at stage \( n-r \).

diss
an object of class "dissimilarity", representing the total dissimilarity matrix of the dataset.

data
a matrix containing the original or standardized measurements, depending on the stand option of the function \texttt{agnes}. If a dissimilarity matrix was given as input structure, then this component is not available.

See Also

\texttt{agnes} also for background and references; \texttt{cutree} (and \texttt{as.hclust}) for grouping extraction; \texttt{daisy}, \texttt{dist}, \texttt{plot.diana}, \texttt{twins.object}.

Examples

```r
data(votes.repub)
dv <- diana(votes.repub, metric = "manhattan", stand = TRUE)
print(dv)
plot(dv)

## Cut into 2 groups:
dv2 <- cutree(as.hclust(dv), k = 2)
table(dv2) # 8 and 42 group members
rownames(votes.repub)[dv2 == 1]

## For two groups, does the metric matter ?
dv0 <- diana(votes.repub, stand = TRUE) # default: Euclidean
dv.2 <- cutree(as.hclust(dv0), k = 2)
table(dv2 == dv.2)## identical group assignments

str(as.dendrogram(dv/zero.noslash)) # {via as.dendrogram.twins() method}
data(agriculture)
## Plot similar to Figure 8 in ref
## Not run: plot(diana(agriculture), ask = TRUE)
```

---

**dissimilarity.object**  
**Dissimilarity Matrix Object**

**Description**

Objects of class "dissimilarity" representing the dissimilarity matrix of a dataset.
The dissimilarity matrix is symmetric, and hence its lower triangle (column wise) is represented as a vector to save storage space. If the object, is called do, and n the number of observations, i.e., n <- attr(do, "Size"), then for i < j <= n, the dissimilarity between (row) i and j is do[n*(i-1) - i*(i-1)/2 + j-i]. The length of the vector is n * (n - 1)/2, i.e., of order n^2.

"dissimilarity" objects also inherit from class dist and can use dist methods, in particular, as.matrix, such that d_{ij} from above is just as.matrix(do)[i,j].

The object has the following attributes:

Size the number of observations in the dataset.
Metric the metric used for calculating the dissimilarities. Possible values are "euclidean", "manhattan", "mixed" (if variables of different types were present in the dataset), and "unspecified".
Labels optionally, contains the labels, if any, of the observations of the dataset.
NA.message optionally, if a dissimilarity could not be computed, because of too many missing values for some observations of the dataset.
Types when a mixed metric was used, the types for each variable as one-letter codes (as in the book, e.g. p.54):
  A Asymmetric binary
  S Symmetric binary
  N Nominal (factor)
  O Ordinal (ordered factor)
  I Interval scaled (numeric)
  T raTio to be log transformed (positive numeric)

GENERATION
daisy returns this class of objects. Also the functions pam, clara, fanny, agnes, and diana return a dissimilarity object, as one component of their return objects.

METHODS

The "dissimilarity" class has methods for the following generic functions: print, summary.

See Also
daisy, dist, pam, clara, fanny, agnes, diana.
ellipsoidhull

Compute the Ellipsoid Hull or Spanning Ellipsoid of a Point Set

Description

Compute the “ellipsoid hull” or “spanning ellipsoid”, i.e. the ellipsoid of minimal volume (‘area’ in 2D) such that all given points lie just inside or on the boundary of the ellipsoid.

Usage

ellipsoidhull(x, tol=0.01, maxit=5000,
              ret.wt = FALSE, ret.sqdist = FALSE, ret.pr = FALSE)

## S3 method for class 'ellipsoid'
print(x, digits = max(1, getOption("digits") - 2), ...)

Arguments

x
  the n p-dimensional points as numeric n × p matrix.

tol
  convergence tolerance for Titterington’s algorithm. Setting this to much smaller
  values may drastically increase the number of iterations needed, and you may
  want to increase maxit as well.

maxit
  integer giving the maximal number of iteration steps for the algorithm.

ret.wt, ret.sqdist, ret.pr
  logicals indicating if additional information should be returned, ret.wt spec-
  ifying the weights, ret.sqdist the squared distances and ret.pr the final
  probabilities in the algorithms.

digits,...
  the usual arguments to print methods.

Details

The “spanning ellipsoid” algorithm is said to stem from Titterington(1976), in Pison et al(1999) who use it for clusplot.default.
The problem can be seen as a special case of the “Min.V ol.” ellipsoid of which a more more flexible
and general implementation is cov.mve in the MASS package.

Value

an object of class "ellipsoid", basically a list with several components, comprising at least

cov    p × p covariance matrix description the ellipsoid.
loc    p-dimensional location of the ellipsoid center.
d2    average squared radius. Further, d2 = t^2, where t is "the value of a t-statistic on
      the ellipse boundary" (from ellipse in the ellipse package), and hence, more
      usefully, d2 = qchisq(alpha, df = p), where alpha is the confidence level
      for p-variate normally distributed data with location and covariance loc and cov
      to lie inside the ellipsoid.
**wt**  the vector of weights iff `ret.wt` was true.

**sqdist**  the vector of squared distances iff `ret.sqdist` was true.

**prob**  the vector of algorithm probabilities iff `ret.pr` was true.

**it**  number of iterations used.

**tol, maxit**  just the input argument, see above.

**eps**  the achieved tolerance which is the maximal squared radius minus $p$.

**ierr**  error code as from the algorithm; 0 means ok.

**conv**  logical indicating if the converged. This is defined as $it < maxit \&\& ierr == 0$.

**Author(s)**

Martin Maechler did the present class implementation; Rousseeuw et al did the underlying code.

**References**

A version of this is available as technical report from [http://www.agoras.ua.ac.be/abstract/Disclu99.htm](http://www.agoras.ua.ac.be/abstract/Disclu99.htm)

**See Also**

`predict.ellipsoid` which is also the `predict` method for ellipsoid objects.

`volume.ellipsoid` for an example of ‘manual’ ellipsoid object construction:

further `ellipse` from package `ellipse` and `ellipsePoints` from package `sfsmisc`.

`chull` for the convex hull, `clusplot` which makes use of this; `cov.mve`.

**Examples**

```r
x <- rnorm(100)
xy <- unname(cbind(x, rnorm(100) + 2*x + 10))
exy <- ellipsoidhull(xy)
exy # >> calling print.ellipsoid()

plot(xy)
lines(predict(exy))
points(rbind(exy$loc), col = "red", cex = 3, pch = 13)

exy <- ellipsoidhull(xy, tol = 1e-7, ret.wt = TRUE, ret.sq = TRUE)
str(exy) # had small 'tol', hence many iterations
(ii <- which(zapsmall(exy$wt) > 1e-6)) # only about 4 to 6 points
round(exy$wt[ii],3); sum(exy$wt[ii]) # sum to 1
```
fanny  

**Fuzzy Analysis Clustering**

### Description

Computes a fuzzy clustering of the data into $k$ clusters.

### Usage

```r
fanny(x, k, diss = inherits(x, "dist"), memb.exp = 2,
      metric = c("euclidean", "manhattan", "SqEuclidean"),
      stand = FALSE, iniMem.p = NULL, cluster.only = FALSE,
      keep.diss = !diss && !cluster.only && n < 100,
      keep.data = !diss && !cluster.only,
      maxit = 500, tol = 1e-15, trace.lev = 0)
```

### Arguments

- **x**: data matrix or data frame, or dissimilarity matrix, depending on the value of the `diss` argument.
  - In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.
  - In case of a dissimilarity matrix, `x` is typically the output of `daisy` or `dist`. Also a vector of length $n(n-1)/2$ is allowed (where $n$ is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.

- **k**: integer giving the desired number of clusters. It is required that $0 < k < n/2$ where $n$ is the number of observations.

- **diss**: logical flag: if TRUE (default for `dist` or dissimilarity objects), then `x` is assumed to be a dissimilarity matrix. If FALSE, then `x` is treated as a matrix of observations by variables.

- **memb.exp**: number $r$ strictly larger than 1 specifying the membership exponent used in the fit criterion; see the ‘Details’ below. Default: 2 which used to be hardwired inside FANNY.

- **metric**: character string specifying the metric to be used for calculating dissimilarities between observations. Options are "euclidean" (default), "manhattan", and "SqEuclidean". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences, and "SqEuclidean", the squared euclidean distances are sum-of-squares of differences. Using this last option is equivalent (but somewhat slower) to computing so called “fuzzy C-means”.
  - If `x` is already a dissimilarity matrix, then this argument will be ignored.
stand logical; if true, the measurements in \( x \) are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation. If \( x \) is already a dissimilarity matrix, then this argument will be ignored.

iniMem.p numeric \( n \times k \) matrix or NULL (by default); can be used to specify a starting membership matrix, i.e., a matrix of non-negative numbers, each row summing to one.

cluster.only logical; if true, no silhouette information will be computed and returned, see details.

keep.diss, keep.data logicals indicating if the dissimilarities and/or input data \( x \) should be kept in the result. Setting these to FALSE can give smaller results and hence also save memory allocation time.

maxit, tol maximal number of iterations and default tolerance for convergence (relative convergence of the fit criterion) for the FANNY algorithm. The defaults \( \text{maxit} = 500 \) and \( \text{tol} = 1\times 10^{-15} \) used to be hardwired inside the algorithm.

trace.lev integer specifying a trace level for printing diagnostics during the C-internal algorithm. Default 0 does not print anything; higher values print increasingly more.

Details

In a fuzzy clustering, each observation is "spread out" over the various clusters. Denote by \( u_{iv} \) the membership of observation \( i \) to cluster \( v \).

The memberships are nonnegative, and for a fixed observation \( i \) they sum to 1. The particular method \texttt{fanny} stems from chapter 4 of Kaufman and Rousseeuw (1990) (see the references in \texttt{daisy}) and has been extended by Martin Maechler to allow user specified \texttt{memb.exp}, \texttt{iniMem.p}, \texttt{maxit}, \texttt{tol}, etc.

Fanny aims to minimize the objective function

\[
\sum_{v=1}^{k} \sum_{i=1}^{n} \sum_{j=1}^{n} u_{iv}^r u_{jv}^r d(i,j) / 2 \sum_{j=1}^{n} u_{jv}^r
\]

where \( n \) is the number of observations, \( k \) is the number of clusters, \( r \) is the membership exponent \texttt{memb.exp} and \( d(i,j) \) is the dissimilarity between observations \( i \) and \( j \).

Note that \( r \to 1 \) gives increasingly crisper clusterings whereas \( r \to \infty \) leads to complete fuzzyness. K&R(1990), p.191 note that values too close to 1 can lead to slow convergence. Further note that even the default, \( r = 2 \) can lead to complete fuzzyness, i.e., memberships \( u_{iv} \equiv 1/k \). In that case a warning is signalled and the user is advised to chose a smaller \texttt{memb.exp} (= \( r \)).

Compared to other fuzzy clustering methods, \texttt{fanny} has the following features: (a) it also accepts a dissimilarity matrix; (b) it is more robust to the spherical cluster assumption; (c) it provides a novel graphical display, the silhouette plot (see \texttt{plot.partition}).

Value

an object of class "fanny" representing the clustering. See \texttt{fanny.object} for details.
See Also

agnes for background and references; fanny.object, partition.object, plot.partition, daisy, dist.

Examples

```r
## generate 10+15 objects in two clusters, plus 3 objects lying
## between those clusters.
x <- rbind(cbind(rnorm(10, 0, 0.5), rnorm(10, 0, 0.5)),
cbind(rnorm(15, 5, 0.5), rnorm(15, 5, 0.5)),
cbind(rnorm(3,3.2,0.5), rnorm(3,3.2,0.5)))
fannyx <- fanny(x, 2)
## Note that observations 26:28 are "fuzzy" (closer to # 2):
fannyx
summary(fannyx)
plot(fannyx)

(fan.x.15 <- fanny(x, 2, memb.exp = 1.5)) # 'crispier' for obs. 26:28
(fanny(x, 2, memb.exp = 3)) # more fuzzy in general

data(ruspini)
f4 <- fanny(ruspini, 4)
stopifnot(rle(f4$clustering)$lengths == c(20,23,17,15))
plot(f4, which = 1)
## Plot similar to Figure 6 in Stryuf et al (1996)
plot(fanny(ruspini, 5))
```

fanny.object

Fuzzy Analysis (FANNY) Object

Description

The objects of class "fanny" represent a fuzzy clustering of a dataset.

Value

A legitimate fanny object is a list with the following components:

- **membership** matrix containing the memberships for each pair consisting of an observation and a cluster.
- **memb.exp** the membership exponent used in the fitting criterion.
- **coeff** Dunn’s partition coefficient $F(k)$ of the clustering, where $k$ is the number of clusters. $F(k)$ is the sum of all squared membership coefficients, divided by the number of observations. Its value is between $1/k$ and 1. The normalized form of the coefficient is also given. It is defined as $(F(k) - 1/k)/(1 - 1/k)$, and ranges between 0 and 1. A low value of Dunn’s coefficient indicates a very fuzzy clustering, whereas a value close to 1 indicates a near-crisp clustering.
flower clustering the clustering vector of the nearest crisp clustering, see partition.object.
k.crisp integer (≤ k) giving the number of crisp clusters; can be less than k, where it's recommended to decrease memb.exp.
objective named vector containing the minimal value of the objective function reached by the FANNY algorithm and the relative convergence tolerance tol used.
convergence named vector with iterations, the number of iterations needed and converged indicating if the algorithm converged (in maxit iterations within convergence tolerance tol).
diss an object of class "dissimilarity", see partition.object.
call generating call, see partition.object.
silinfo list with silhouette information of the nearest crisp clustering, see partition.object.
data matrix, possibly standardized, or NULL, see partition.object.

GENERATION
These objects are returned from fanny.

METHODS
The "fanny" class has methods for the following generic functions: print, summary.

INHERITANCE
The class "fanny" inherits from "partition". Therefore, the generic functions plot and clusplot can be used on a fanny object.

See Also
fanny, print.fanny, dissimilarity.object, partition.object, plot.partition.

<table>
<thead>
<tr>
<th>flower</th>
<th>Flower Characteristics</th>
</tr>
</thead>
</table>

Description
8 characteristics for 18 popular flowers.

Usage
data(flower)

Format
A data frame with 18 observations on 8 variables:
V1 winters, is binary and indicates whether the plant may be left in the garden when it freezes.
V2 shadow, is binary and shows whether the plant needs to stand in the shadow.
V3 tubers, is asymmetric binary and distinguishes between plants with tubers and plants that grow in any other way.
V4 color, is nominal and specifies the flower’s color (1 = white, 2 = yellow, 3 = pink, 4 = red, 5 = blue).
V5 soil, is ordinal and indicates whether the plant grows in dry (1), normal (2), or wet (3) soil.
V6 preference, is ordinal and gives someone’s preference ranking going from 1 to 18.
V7 height, is interval scaled, the plant’s height in centimeters.
V8 distance, is interval scaled, the distance in centimeters that should be left between the plants.

References

Struyf, Hubert and Rousseeuw (1996), see agnes.

Examples

data(flower)
# Example 2 in ref
daisy(flower, type = list(asymm = 3))
daisy(flower, type = list(asymm = c(1, 3), ordratio = 7))
Arguments

\( n \) integer larger than 1.

Value

integer vector containing a permutation of \( 1:N \) where \( N = n(n - 1)/2 \).

Note

tese functions are mainly for internal use in the cluster package, and may not remain available (unless we see a good reason).

See Also

upper.tri, lower.tri with a related purpose.

Examples

```r
m5 <- matrix(NA, 5, 5)
m <- m5; m[lower.tri(m)] <- upper.to.lower.tri.inds(5); m
m <- m5; m[upper.tri(m)] <- lower.to.upper.tri.inds(5); m

stopifnot(lower.to.upper.tri.inds(2) == 1,
          lower.to.upper.tri.inds(3) == 1:3,
          upper.to.lower.tri.inds(3) == 1:3,
          sort(upper.to.lower.tri.inds(5)) == 1:10,
          sort(lower.to.upper.tri.inds(6)) == 1:15)
```

Description

Returns a list representing a divisive hierarchical clustering of a dataset with binary variables only.

Usage

```r
mona(x)
```

Arguments

\( x \) data matrix or data frame in which each row corresponds to an observation, and each column corresponds to a variable. All variables must be binary. A limited number of missing values (NAs) is allowed. Every observation must have at least one value different from NA. No variable should have half of its values missing. There must be at least one variable which has no missing values. A variable with all its non-missing values identical, is not allowed.
mona.object

Details

mona is fully described in chapter 7 of Kaufman and Rousseeuw (1990). It is "monothetic" in the sense that each division is based on a single (well-chosen) variable, whereas most other hierarchical methods (including agnes and diana) are "polythetic", i.e. they use all variables together.

The mona-algorithm constructs a hierarchy of clusterings, starting with one large cluster. Clusters are divided until all observations in the same cluster have identical values for all variables.

At each stage, all clusters are divided according to the values of one variable. A cluster is divided into one cluster with all observations having value 1 for that variable, and another cluster with all observations having value 0 for that variable.

The variable used for splitting a cluster is the variable with the maximal total association to the other variables, according to the observations in the cluster to be splitted. The association between variables f and g is given by a(f,g)*d(f,g) - b(f,g)*c(f,g), where a(f,g), b(f,g), c(f,g), and d(f,g) are the numbers in the contingency table of f and g. [That is, a(f,g) (resp. d(f,g)) is the number of observations for which f and g both have value 0 (resp. value 1); b(f,g) (resp. c(f,g)) is the number of observations for which f has value 0 (resp. 1) and g has value 1 (resp. 0).] The total association of a variable f is the sum of its associations to all variables.

This algorithm does not work with missing values, therefore the data are revised, e.g. all missing values are filled in. To do this, the same measure of association between variables is used as in the algorithm. When variable f has missing values, the variable g with the largest absolute association to f is looked up. When the association between f and g is positive, any missing value of f is replaced by the value of g for the same observation. If the association between f and g is negative, then any missing value of f is replaced by the value of 1-g for the same observation.

Value

an object of class "mona" representing the clustering. See mona.object for details.

See Also

agnes for background and references; mona.object, plot.mona.

Examples

data(animals)
ma <- mona(animals)
ma
## Plot similar to Figure 10 in Struyf et al (1996)
plot(ma)

mona.object

Description

The objects of class "mona" represent the divisive hierarchical clustering of a dataset with only binary variables (measurements). This class of objects is returned from mona.
Value

A legitimate mona object is a list with the following components:

- **data**: matrix with the same dimensions as the original data matrix, but with factors coded as 0 and 1, and all missing values replaced.
- **order**: a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.
- **order.lab**: a vector similar to order, but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.
- **variable**: vector of length $n-1$ where $n$ is the number of observations, specifying the variables used to separate the observations of order.
- **step**: vector of length $n-1$ where $n$ is the number of observations, specifying the separation steps at which the observations of order are separated.

METHODS

The "mona" class has methods for the following generic functions: print, summary, plot.

See Also

mona for examples etc, plot.mona.

---

**pam**

*Partitioning Around Medoids*

Description

Partitioning (clustering) of the data into $k$ clusters “around medoids”, a more robust version of K-means.

Usage

```r
pam(x, k, diss = inherits(x, "dist"), metric = "euclidean",
    medoids = NULL, stand = FALSE, cluster.only = FALSE,
    do.swap = TRUE,
    keep.diss = !diss && !cluster.only && n < 100,
    keep.data = !diss && !cluster.only,
    pamonce = FALSE, trace.lev = 0)
```
Arguments

x  
data matrix or data frame, or dissimilarity matrix or object, depending on the value of the diss argument.

In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed—as long as every pair of observations has at least one case not missing.

In case of a dissimilarity matrix, x is typically the output of daisy or dist. Also a vector of length n*(n-1)/2 is allowed (where n is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.

k  
positive integer specifying the number of clusters, less than the number of observations.

diss  
logical flag: if TRUE (default for dist or dissimilarity objects), then x will be considered as a dissimilarity matrix. If FALSE, then x will be considered as a matrix of observations by variables.

metric  
character string specifying the metric to be used for calculating dissimilarities between observations. The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If x is already a dissimilarity matrix, then this argument will be ignored.

medoids  
NULL (default) or length-k vector of integer indices (in 1:n) specifying initial medoids instead of using the 'build' algorithm.

stand  
logical; if true, the measurements in x are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation. If x is already a dissimilarity matrix, then this argument will be ignored.

cluster.only  
logical; if true, only the clustering will be computed and returned, see details.

do.swap  
logical indicating if the swap phase should happen. The default, TRUE, corresponds to the original algorithm. On the other hand, the swap phase is much more computer intensive than the build one for large n, so can be skipped by do.swap = FALSE.

keep.diss, keep.data  
logicals indicating if the dissimilarities and/or input data x should be kept in the result. Setting these to FALSE can give much smaller results and hence even save memory allocation time.

pamonce  
logical or integer in 0:2 specifying algorithmic short cuts as proposed by Reynolds et al. (2006), see below.

trace.lev  
integer specifying a trace level for printing diagnostics during the build and swap phase of the algorithm. Default 0 does not print anything; higher values print increasingly more.
Details

pam is fully described in chapter 2 of Kaufman and Rousseeuw (1990). Compared to the k-means approach in kmeans, the function pam has the following features: (a) it also accepts a dissimilarity matrix; (b) it is more robust because it minimizes a sum of dissimilarities instead of a sum of squared euclidean distances; (c) it provides a novel graphical display, the silhouette plot (see plot.partition) (d) it allows to select the number of clusters using mean(silhouette(pr)) on the result pr <- pam(...), or directly its component pr$silinfo$avg.width, see also pam.object.

When cluster.only is true, the result is simply a (possibly named) integer vector specifying the clustering, i.e.,
Pam(x,k, cluster.only=TRUE) is the same as
Pam(x,k)$clustering but computed more efficiently.

The pam-algorithm is based on the search for k representative objects or medoids among the observations of the dataset. These observations should represent the structure of the data. After finding a set of k medoids, k clusters are constructed by assigning each observation to the nearest medoid. The goal is to find k representative objects which minimize the sum of the dissimilarities of the observations to their closest representative object.

By default, when medoids are not specified, the algorithm first looks for a good initial set of medoids (this is called the build phase). Then it finds a local minimum for the objective function, that is, a solution such that there is no single switch of an observation with a medoid that will decrease the objective (this is called the swap phase).

When the medoids are specified, their order does not matter; in general, the algorithms have been designed to not depend on the order of the observations.

The pamonce option, new in cluster 1.14.2 (Jan. 2012), has been proposed by Matthias Studer, University of Geneva, based on the findings by Reynolds et al. (2006).

The default FALSE (or integer 0) corresponds to the original “swap” algorithm, whereas pamonce = 1 (or TRUE), corresponds to the first proposal .... and pamonce = 2 additionally implements the second proposal as well.

Value

an object of class "pam" representing the clustering. See ?pam.object for details.

Note

For large datasets, pam may need too much memory or too much computation time since both are \(O(n^2)\). Then, clara() is preferable, see its documentation.

Author(s)

Kaufman and Rousseeuw’s orginal Fortran code was translated to C and augmented in several ways, e.g. to allow cluster.only=TRUE or do.swap=FALSE, by Martin Maechler.

Matthias Studer, Univ.Geneva provided the pamonce implementation.

agnes for background and references; pam.object, clara, daisy, partition.object, plot.partition, dist.

Examples

## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
            cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
pamx <- pam(x, 2)
pamx
summary(pamx)
plot(pamx)
## use obs. 1 & 16 as starting medoids -- same result (typically)
(p2m <- pam(x, 2, medoids = c(1,16)))

p3m <- pam(x, 3, trace = 2)
## rather stupid initial medoids:
(p3m. <- pam(x, 3, medoids = 3:1, trace = 1))

pam(daisy(x, metric = "manhattan"), 2, diss = TRUE)
data(ruspini)
## Plot similar to Figure 4 in Stryuf et al (1996)
## Not run: plot(pam(ruspini, 4), ask = TRUE)

---

pam.object Partitioning Around Medoids (PAM) Object

Description

The objects of class "pam" represent a partitioning of a dataset into clusters.

Value

A legitimate pam object is a list with the following components:

- **medoids**
  - the medoids or representative objects of the clusters. If a dissimilarity matrix was given as input to pam, then a vector of numbers or labels of observations is given, else medoids is a matrix with in each row the coordinates of one medoid.

- **id.med**
  - integer vector of indices giving the medoid observation numbers.

- **clustering**
  - the clustering vector, see partition.object.

- **objective**
  - the objective function after the first and second step of the pam algorithm.
isolation vector with length equal to the number of clusters, specifying which clusters are isolated clusters (L- or L*-clusters) and which clusters are not isolated. A cluster is an L*-cluster iff its diameter is smaller than its separation. A cluster is an L-cluster iff for each observation i the maximal dissimilarity between i and any other observation of the cluster is smaller than the minimal dissimilarity between i and any observation of another cluster. Clearly each L*-cluster is also an L-cluster.

clusinfo matrix, each row gives numerical information for one cluster. These are the cardinality of the cluster (number of observations), the maximal and average dissimilarity between the observations in the cluster and the cluster’s medoid, the diameter of the cluster (maximal dissimilarity between two observations of the cluster), and the separation of the cluster (minimal dissimilarity between an observation of the cluster and an observation of another cluster).

silinfo list with silhouette width information, see \texttt{partition.object}.
diss dissimilarity (maybe NULL), see \texttt{partition.object}.
call generating call, see \texttt{partition.object}.
data (possibly standardized) see \texttt{partition.object}.

**GENERATION**

These objects are returned from \texttt{pam}.

**METHODS**

The "pam" class has methods for the following generic functions: \texttt{print}, \texttt{summary}.

**INHERITANCE**

The class "pam" inherits from "partition". Therefore, the generic functions \texttt{plot} and \texttt{clusplot} can be used on a \texttt{pam} object.

**See Also**

\texttt{pam}, \texttt{dissimilarity.object}, \texttt{partition.object}, \texttt{plot.partition}.

**Examples**

```r
## Use the silhouette widths for assessing the best number of clusters,
## following a one-dimensional example from Christian Hennig:
##
x <- c(rnorm(50), rnorm(50, mean=5), rnorm(30, mean=15))
asw <- numeric(2)
## Note that "k=1" won't work!
for (k in 2:2)
  asw[k] <- pam(x, k)$silinfo$avg.width
k.best <- which.max(asw)
cat("silhouette-optimal number of clusters:", k.best, "\n")

plot(1:20, asw, type= "h", main = "pam() clustering assessment",
```
**Description**

The objects of class "partition" represent a partitioning of a dataset into clusters.

**Value**

A "partition" object is a list with the following (and typically more) components:

- **clustering**: the clustering vector. An integer vector of length \( n \), the number of observations, giving for each observation the number ('id') of the cluster to which it belongs.
- **call**: the matched `call` generating the object.
- **silinfo**: a list with all silhouette information, only available when the number of clusters is non-trivial, i.e., \( 1 < k < n \) and then has the following components, see `silhouette`
  - **widths**: an (\( n \times 3 \)) matrix, as returned by `silhouette()`, with for each observation \( i \) the cluster to which \( i \) belongs, as well as the neighbor cluster of \( i \) (the cluster, not containing \( i \), for which the average dissimilarity between its observations and \( i \) is minimal), and the silhouette width \( s(i) \) of the observation.
  - **clus.avg.widths**: the average silhouette width per cluster.
  - **avg.width**: the average silhouette width for the dataset, i.e., simply the average of \( s(i) \) over all observations \( i \).

This information is also needed to construct a silhouette plot of the clustering, see `plot.partition`.

Note that `avg.width` can be maximized over different clusterings (e.g. with varying number of clusters) to choose an optimal clustering.

- **objective**: value of criterion maximized during the partitioning algorithm, may more than one entry for different stages.
- **diss**: an object of class "dissimilarity", representing the total dissimilarity matrix of the dataset (or relevant subset, e.g. for `clara`).
- **data**: a matrix containing the original or standardized data. This might be missing to save memory or when a dissimilarity matrix was given as input structure to the clustering method.

**GENERATION**

These objects are returned from `pam`, `clara` or `fanny`.
Methods

The "partition" class has a method for the following generic functions: plot, clusplot.

Inheritance

The following classes inherit from class "partition": "pam", "clara" and "fanny".
See pam.object, clara.object and fanny.object for details.

See Also

pam, clara, fanny.

plantTraits

Plant Species Traits Data

Description

This dataset constitutes a description of 136 plant species according to biological attributes (morphological or reproductive).

Usage

data(plantTraits)

Format

A data frame with 136 observations on the following 31 variables.

pdias Diaspore mass (mg)
longindex Seed bank longevity
durflow Flowering duration
height Plant height, an ordered factor with levels 1 < 2 < ... < 8.
begflow Time of first flowering, an ordered factor with levels 1 < 2 < 3 < 4 < 5 < 6 < 7 < 8 < 9
mycor Mycorrhizas, an ordered factor with levels 0never < 1 sometimes< 2always
vegaer aerial vegetative propagation, an ordered factor with levels 0never < 1 present but limited< 2important.
vegsout underground vegetative propagation, an ordered factor with 3 levels identical to vegaer above.
autopoll selfing pollination, an ordered factor with levels 0never < 1rare < 2 often< the rule3
insects insect pollination, an ordered factor with 5 levels 0 < ... < 4.
winds wind pollination, an ordered factor with 5 levels 0 < ... < 4.
lign a binary factor with levels 0:1, indicating if plant is woody.
piq a binary factor indicating if plant is thorny.
ros   a binary factor indicating if plant is rosette.
semiros semi-rosette plant, a binary factor (0: no; 1: yes).
leafy  leafy plant, a binary factor.
suman  summer annual, a binary factor.
winan  winter annual, a binary factor.
monocarp monocarpic perennial, a binary factor.
polycarp polycarpic perennial, a binary factor.
seasaes seasonal aestival leaves, a binary factor.
seashiv seasonal hibernal leaves, a binary factor.
seasver seasonal vernal leaves, a binary factor.
everalw leaves always evergreen, a binary factor.
everparti leaves partially evergreen, a binary factor.
elaio  fruits with an elaiosome (dispersed by ants), a binary factor.
endozoo endozoochorous fruits, a binary factor.
epizoo  epizoochorous fruits, a binary factor.
aquat  aquatic dispersal fruits, a binary factor.
windgl wind dispersed fruits, a binary factor.
unsp   unspecialized mechanism of seed dispersal, a binary factor.

Details

Most of factor attributes are not disjunctive. For example, a plant can be usually pollinated by insects but sometimes self-pollination can occurred.

Source

Examples

data(plantTraits)

```r
## Calculation of a dissimilarity matrix
library(cluster)
dai.b <- daisy(plantTraits,
               type = list(ordratio = 4:11, symm = 12:13, asymm = 14:31))

## Hierarchical classification
agn.trts <- agnes(dai.b, method="ward")
plot(agn.trts, which.plots = 2, cex= 0.6)
plot(agn.trts, which.plots = 1)
cutree6 <- cutree(agn.trts, k=6)
cutree6
```
## Principal Coordinate Analysis

cmdsdai.b <- cmdscale(dai.b, k=6)
plot(cmdsdai.b[, 1:2], asp = 1, col = cutree6)

---

plot.agnes

Plots of an Agglomerative Hierarchical Clustering

### Description

Creates plots for visualizing an agnes object.

### Usage

```
## S3 method for class 'agnes'
plot(x, ask = FALSE, which.plots = NULL, main = NULL,
     sub = paste("Agglomerative Coefficient = ",round(x$ac, digits = 2)),
     adj = 0, nmax.lab = 35, max.strlen = 5, xax.pretty = TRUE, ...)
```

### Arguments

- **x**: an object of class "agnes", typically created by `agnes(.)`.
- **ask**: logical; if true and `which.plots` is `NULL`, `plot.agnes` operates in interactive mode, via `menu`.
- **which.plots**: integer vector or `NULL` (default), the latter producing both plots. Otherwise, `which.plots` must contain integers of 1 for a banner plot or 2 for a dendrogram or "clustering tree".
- **main**, **sub**: main and sub title for the plot, with convenient defaults. See documentation for these arguments in `plot.default`.
- **adj**: for label adjustment in `bannerplot()`.
- **nmax.lab**: integer indicating the number of labels which is considered too large for single-name labelling the banner plot.
- **max.strlen**: positive integer giving the length to which strings are truncated in banner plot labeling.
- **xax.pretty**: logical or integer indicating if `pretty(*, n = xax.pretty)` should be used for the x axis. `xax.pretty = FALSE` is for back compatibility.
- **...**: graphical parameters (see `par`) may also be supplied and are passed to `bannerplot()` or `pltree()` (see `pltree.twins`), respectively.
Details

When ask = TRUE, rather than producing each plot sequentially, plot.agnes displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted one must set par(ask= TRUE) before invoking the plot command.

The banner displays the hierarchy of clusters, and is equivalent to a tree. See Rousseeuw (1986) or chapter 5 of Kaufman and Rousseeuw (1990). The banner plots distances at which observations and clusters are merged. The observations are listed in the order found by the agnes algorithm, and the numbers in the height vector are represented as bars between the observations.

The leaves of the clustering tree are the original observations. Two branches come together at the distance between the two clusters being merged.

For more customization of the plots, rather call bannerplot and pltree(), i.e., its method pltree.twins, respectively.

directly with corresponding arguments, e.g., xlab or ylab.

Side Effects

Appropriate plots are produced on the current graphics device. This can be one or both of the following choices:

Banner
Clustering tree

Note

In the banner plot, observation labels are only printed when the number of observations is limited less than nmax.lab (35, by default), for readability. Moreover, observation labels are truncated to maximally max.strlen (5) characters.

For the dendrogram, more flexibility than via pltree() is provided by dg <- as.dendrogram(x) and plotting dg via plot.dendrogram.

agnes and agnes.object; bannerplot, pltree.twins, and par.
Examples

```r
## Can also pass 'labels' to pltree() and bannerplot():
data(iris)
cS <- as.character(Sp <- iris$Species)
cS[Sp == "setosa"] <- "S"
cS[Sp == "versicolor"] <- "V"
cS[Sp == "virginica"] <- "g"
ai <- agnes(iris[, 1:4])
plot(ai, labels = cS, nmax = 150)# bannerplot labels are mess
```

---

plot.diana  

Plots of a Divisive Hierarchical Clustering

Description

Creates plots for visualizing a diana object.

Usage

```r
## S3 method for class 'diana'
plot(x, ask = FALSE, which.plots = NULL, main = NULL,
     sub = paste("Divisive Coefficient = ", round(x$dc, digits = 2)),
     adj = 0, nmax.lab = 35, max.strlen = 5, xax.pretty = TRUE, ...)  
```

Arguments

- `x`  
  an object of class "diana", typically created by `diana(.)`.
- `ask`  
  logical; if true and `which.plots` is NULL, `plot.diana` operates in interactive mode, via menu.
- `which.plots`  
  integer vector or NULL (default), the latter producing both plots. Otherwise, `which.plots` must contain integers of 1 for a banner plot or 2 for a dendrogram or "clustering tree".
- `main, sub`  
  main and sub title for the plot, each with a convenient default. See documentation for these arguments in `plot.default`.
- `adj`  
  for label adjustment in `bannerplot()`.
- `nmax.lab`  
  integer indicating the number of labels which is considered too large for single-name labelling the banner plot.
- `max.strlen`  
  positive integer giving the length to which strings are truncated in banner plot labeling.
- `xax.pretty`  
  logical or integer indicating if `pretty(*, n = xax.pretty)` should be used for the x axis. `xax.pretty = FALSE` is for back compatibility.
- `...`  
  graphical parameters (see `par`) may also be supplied and are passed to `bannerplot()` or `pltree()`, respectively.
plot.diana

Details

When ask = TRUE, rather than producing each plot sequentially, plot.diana displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted one must set par(ask = TRUE) before invoking the plot command.

The banner displays the hierarchy of clusters, and is equivalent to a tree. See Rousseeuw (1986) or chapter 6 of Kaufman and Rousseeuw (1990). The banner plots the diameter of each cluster being splitted. The observations are listed in the order found by the diana algorithm, and the numbers in the height vector are represented as bars between the observations.

The leaves of the clustering tree are the original observations. A branch splits up at the diameter of the cluster being splitted.

Side Effects

An appropriate plot is produced on the current graphics device. This can be one or both of the following choices:

Banner
Clustering tree

Note

In the banner plot, observation labels are only printed when the number of observations is limited less than nmax.lab (35, by default), for readability. Moreover, observation labels are truncated to maximally max.strlen (5) characters.

References

see those in plot.agnes.

See Also
diana, diana.object, twins.object, par.

Examples

example(diana)# -> dv <- diana(...)

plot(dv, which = 1, nmax.lab = 100)

## wider labels :
op <- par(mar = par("mar") + c(0, 2, 0,0))
plot(dv, which = 1, nmax.lab = 100, max.strlen = 12)
par(op)
plot.mona  

Banner of Monothetic Divisive Hierarchical Clusterings

Description

Creates the banner of a mona object.

Usage

```
## S3 method for class 'mona'
plot(x, main = paste("Banner of ", deparse(x$call)),
     sub = NULL, xlab = "Separation step",
     col = c(2,0), axes = TRUE, adj = 0,
     nmax.lab = 35, max.strlen = 5, ...)
```

Arguments

- **x**: an object of class "mona", typically created by `mona()`.
- **main, sub**: main and sub titles for the plot, with convenient defaults. See documentation in `plot.default`.
- **xlab**: x axis label, see `title`.
- **col, adj**: graphical parameters passed to `bannerplot()`.
- **axes**: logical, indicating if (labeled) axes should be drawn.
- **nmax.lab**: integer indicating the number of labels which is considered too large for labeling.
- **max.strlen**: positive integer giving the length to which strings are truncated in labeling.
- **...**: further graphical arguments are passed to `bannerplot()` and `text`.

Details

Plots the separation step at which clusters are splitted. The observations are given in the order found by the mona algorithm, the numbers in the step vector are represented as bars between the observations.

When a long bar is drawn between two observations, those observations have the same value for each variable. See chapter 7 of Kaufman and Rousseeuw (1990).

Side Effects

A banner is plotted on the current graphics device.

Note

In the banner plot, observation labels are only printed when the number of observations is limited less than `nmax.lab` (35, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.
plot.partition

References

see those in plot.agnes.

See Also

mona, mona.object.par.

---

plot.partition  
*Plot of a Partition of the Data Set*

Description

Creates plots for visualizing a partition object.

Usage

```r
## S3 method for class 'partition'
plot(x, ask = FALSE, which.plots = NULL, 
nmax.lab = 40, max.strlen = 5, data = x$data, dist = NULL, 
stand = FALSE, lines = 2, 
shade = FALSE, color = FALSE, labels = 0, plotchar = TRUE, 
span = TRUE, xlim = NULL, ylim = NULL, main = NULL, ...)
```

Arguments

- `x`: an object of class "partition", typically created by the functions `pam`, `clara`, or `fanny`.
- `ask`: logical; if true and which.plots is NULL, plot.partition operates in interactive mode, via menu.
- `which.plots`: integer vector or NULL (default), the latter producing both plots. Otherwise, which.plots must contain integers of 1 for a clusplot or 2 for silhouette.
- `nmax.lab`: integer indicating the number of labels which is considered too large for single-name labeling the silhouette plot.
- `max.strlen`: positive integer giving the length to which strings are truncated in silhouette plot labeling.
- `data`: numeric matrix with the scaled data; per default taken from the partition object x, but can be specified explicitly.
- `dist`: when x does not have a diss component as for `pam(*, keep.diss=FALSE), dist must be the dissimilarity if a clusplot is desired.
- `stand, lines, shade, color, labels, plotchar, span, xlim, ylim, main, ...`: All optional arguments available for the clusplot.default function (except for the diss one) and graphical parameters (see par) may also be supplied as arguments to this function.
Details

When ask= TRUE, rather than producing each plot sequentially, plot.partition displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted, call par(ask= TRUE) before invoking the plot command.

The clusplot of a cluster partition consists of a two-dimensional representation of the observations, in which the clusters are indicated by ellipses (see clusplot.partition for more details).

The silhouette plot of a nonhierarchical clustering is fully described in Rousseeuw (1987) and in chapter 2 of Kaufman and Rousseeuw (1990). For each observation i, a bar is drawn, representing its silhouette width s(i), see silhouette for details. Observations are grouped per cluster, starting with cluster 1 at the top. Observations with a large s(i) (almost 1) are very well clustered, a small s(i) (around 0) means that the observation lies between two clusters, and observations with a negative s(i) are probably placed in the wrong cluster.

A clustering can be performed for several values of k (the number of clusters). Finally, choose the value of k with the largest overall average silhouette width.

Side Effects

An appropriate plot is produced on the current graphics device. This can be one or both of the following choices:

Clusplot
Silhouette plot

Note

In the silhouette plot, observation labels are only printed when the number of observations is less than nmax.lab (40, by default), for readability. Moreover, observation labels are truncated to maximally max.strlen (5) characters.

For more flexibility, use plot(silhouette(x), ...), see plot.silhouette.

References

Further, the references in plot.agnes.

See Also

partition.object. clusplot.partition, clusplot.default, pam, pam.object, clara, clara.object, fanny, fanny.object.par.

Examples

## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(1/zero.noslash,/zero.noslash,/zero.noslash.5), rnorm(1/zero.noslash,/zero.noslash,/zero.noslash.5)),
    cbind(rnorm(15,5,/zero.noslash.5), rnorm(15,5,/zero.noslash.5)))
plot(pam(x, 2))

## Save space not keeping data in clus.object, and still clusplot() it:
```r
data(xclara)
cx <- clara(xclara, 3, keep.data = FALSE)
cx$data # is NULL
plot(cx, data = xclara)
```

---

**pltree**  
*Clustering Trees - Generic Function*

**Description**

Generic function drawing a clustering tree (“dendrogram”) on the current graphics device. There is a twins method, see `pltree.twins` for usage and examples.

**Usage**

```r
pltree(x, ...)
```

**Arguments**

- `x` an R object (for which a pltree method is defined).
- `...` methods may have additional arguments. Graphical parameters (see `par`) may also be supplied as arguments to this function.

**See Also**

- `pltree.twins`, `twins.object`.

---

**pltree.twins**  
*Clustering Tree of a Hierarchical Clustering*

**Description**

Draws a clustering tree (dendrogram) of a twins object, i.e., hierarchical clustering, typically resulting from `agnes()` or `diana()`.

**Usage**

```r
## S3 method for class 'twins'
pltree(x, main = paste("Dendrogram of ", deparse(x$call)),
       labels = NULL, ylab = "Height", ...)
```
Arguments

- **x**: an object of class "twins", typically created by either `agnes()` or `diana()`.
- **main**: main title with a sensible default.
- **labels**: labels to use; the default is constructed from `x`.
- **ylab**: label for y-axis.
- **...**: graphical parameters (see `par`) may also be supplied as arguments to this function.

Details

Creates a plot of a clustering tree given a `twins` object. The leaves of the tree are the original observations. In case of an agglomerative clustering, two branches come together at the distance between the two clusters being merged. For a divisive clustering, a branch splits up at the diameter of the cluster being split.

Note that currently the method function simply calls `plot(as.hclust(x), ...)`, which dispatches to `plot.hclust(...)`. If more flexible plots are needed, consider `xx <- as.dendrogram(as.hclust(x))` and plotting `xx`, see `plot.dendrogram`.

Value

a NULL value is returned.

See Also

`agnes`, `agnes.object`, `diana`, `diana.object`, `hclust`, `par`, `plot.agnes`, `plot.diana`.

Examples

```r
data(votes.repub)
agn <- agnes(votes.repub)
pltree(agn)

dagn <- as.dendrogram(as.hclust(agn))
dagn2 <- as.dendrogram(as.hclust(agn), hang = 0.2)
op <- par(mar = par("mar") + c(0,0,0, 2)) # more space to the right
plot(dagn2, horiz = TRUE)
plot(dagn, horiz = TRUE, center = TRUE,
     nodePar = list(lab.cex = 0.6, lab.col = "forest green", pch = NA),
     main = deparse(agn$call))
par(op)
```
pluton

Description

The pluton data frame has 45 rows and 4 columns, containing percentages of isotopic composition of 45 Plutonium batches.

Usage

data(pluton)

Format

This data frame contains the following columns:

- **Pu238**: the percentages of $^{238}Pu$, always less than 2 percent.
- **Pu239**: the percentages of $^{239}Pu$, typically between 60 and 80 percent (from neutron capture of Uranium, $^{238}U$).
- **Pu240**: percentage of the plutonium 240 isotope.
- **Pu241**: percentage of the plutonium 241 isotope.

Details

Note that the percentage of plutonium–242 can be computed from the other four percentages, see the examples.

In the reference below it is explained why it is very desirable to combine these plutonium patches in three groups of similar size.

Source

References

Examples

data(pluton)

```r
hist(apply(pluton,1,sum), col = "gray")  # between 94% and 100%
pu5 <- pluton
pu5$Pu242 <- 100 - apply(pluton,1,sum)  # the remaining isotope.
pairs(pu5)
```
predict.ellipsoid  

Predict Method for Ellipsoid Objects

Description

Compute points on the ellipsoid boundary, mostly for drawing.

Usage

predict.ellipsoid(object, n.out=201, ...)  
## S3 method for class 'ellipsoid'
predict(object, n.out=201, ...)
ellipsoidPoints(A, d2, loc, n.half = 201)

Arguments

object  
an object of class ellipsoid, typically from ellipsoidhull(); alternatively any list-like object with proper components, see details below.
n.out, n.half  
half the number of points to create.
A, d2, loc  
arguments of the auxiliary ellipsoidPoints, see below.
...

to and from methods.

Details

Note ellipsoidPoints is the workhorse function of predict.ellipsoid a standalone function and method for ellipsoid objects, see ellipsoidhull. The class of object is not checked; it must solely have valid components loc (length p), the p × p matrix cov (corresponding to A) and d2 for the center, the shape (“covariance”) matrix and the squared average radius (or distance) or qchisq(*, p) quantile.

Unfortunately, this is only implemented for p = 2, currently; contributions for p ≥ 3 are very welcome.

Value

a numeric matrix of dimension 2*n.out times p.

See Also

ellipsoidhull, volume.ellipsoid.

Examples

## see also example(ellipsoidhull)

## Robust vs. L.S. covariance matrix
set.seed(143)
x <- rt(200, df=3)
print.agnes

```
y <- 3*x + rt(200, df=2)
plot(x,y, main="non-normal data (N=200)"
  mtext("with classical and robust cov.matrix ellipsoids")
  X <- cbind(x,y)
  C.ls <- cov(X); m.ls <- colMeans(X)
da.99 <- qchisq(0.99, df = 2)
l lines(ellipsoidPoints(C.ls, d2=d.99, loc=m.ls), col="green")
if(require(MASS)) {
  Cxy <- cov.rob(cbind(x,y))
  lines(ellipsoidPoints(Cxy$cov, d2 = d.99, loc=Cxy$center), col="red")
}# MASS
```

print.agnes

---

**Print Method for AGNES Objects**

**Description**

Prints the call, agglomerative coefficient, ordering of objects and distances between merging clusters ('Height') of an **agnes** object.

This is a method for the generic `print()` function for objects inheriting from class **agnes**, see **agnes.object**.

**Usage**

```
## S3 method for class 'agnes'
print(x, ...)
```

**Arguments**

- `x` an **agnes** object.
- `...` potential further arguments (required by generic).

**See Also**

- `summary.agnes` producing more output; `agnes`, `agnes.object`, `print`, `print.default`.

---

print.clara

---

**Print Method for CLARA Objects**

**Description**

Prints the best sample, medoids, clustering vector and objective function of **clara** object.

This is a method for the function `print()` for objects inheriting from class **clara**.
Usage

```r
## S3 method for class 'clara'
print(x, ...)
```

Arguments

- `x`: a clara object.
- `...`: potential further arguments (require by generic).

See Also

- `summary.clara` producing more output; `clara.clara.object.print.print.default`.

---

### print.diana  
*Print Method for DIANA Objects*

Description

Prints the ordering of objects, diameters of splitted clusters, and divisive coefficient of a diana object.

This is a method for the function `print()` for objects inheriting from class `diana`.

Usage

```r
## S3 method for class 'diana'
print(x, ...)
```

Arguments

- `x`: a diana object.
- `...`: potential further arguments (require by generic).

See Also

- `diana.diana.object.print.print.default`.
print.dissimilarity  Print and Summary Methods for Dissimilarity Objects

Description

Print or summarize the distances and the attributes of a dissimilarity object.

These are methods for the functions print() and summary() for dissimilarity objects. See print, print.default, or summary for the general behavior of these.

Usage

## S3 method for class 'dissimilarity'
print(x, diag = NULL, upper = NULL,
      digits = getOption("digits"), justify = "none", right = TRUE, ...)
## S3 method for class 'dissimilarity'
summary(object,
        digits = max(3, getOption("digits") - 2), ...)
## S3 method for class 'summary.dissimilarity'
print(x, ...)  

Arguments

x, object       a dissimilarity object or a summary.dissimilarity one for print.summary.dissimilarity()
digits          the number of digits to use, see print.default.
diag, upper, justify, right
        optional arguments specifying how the triangular dissimilarity matrix is printed;
        see print.dist.
...              potential further arguments (require by generic).

See Also

daisy, dissimilarity.object, print, print.default, print.dist.

Examples

## See example(daisy)

sd <- summary(daisy(matrix(rnorm(100), 20, 5)))
sd # -> print.summary.dissimilarity(.)
str(sd)
### print.fanny

**Print and Summary Methods for FANNY Objects**

**Description**

Prints the objective function, membership coefficients and clustering vector of `fanny` object. This is a method for the function `print()` for objects inheriting from class `fanny`.

**Usage**

```r
## S3 method for class 'fanny'
print(x, digits = getOption("digits"), ...)
## S3 method for class 'fanny'
summary(object, ...)
## S3 method for class 'summary.fanny'
print(x, digits = getOption("digits"), ...)
```

**Arguments**

- `x`, `object` a `fanny` object.
- `digits` number of significant digits for printing, see `print.default`.
- `...` potential further arguments (required by generic).

**See Also**

`fanny`, `fanny.object`, `print`, `print.default`.

### print.mona

**Print Method for MONA Objects**

**Description**

Prints the ordering of objects, separation steps, and used variables of a `mona` object. This is a method for the function `print()` for objects inheriting from class `mona`.

**Usage**

```r
## S3 method for class 'mona'
print(x, ...)
```

**Arguments**

- `x` a `mona` object.
- `...` potential further arguments (require by generic).
print.pam

See Also

mona, mona.object.print, print.default.

print.pam  Print Method for PAM Objects

Description

Prints the medoids, clustering vector and objective function of pam object.
This is a method for the function print() for objects inheriting from class pam.

Usage

## S3 method for class 'pam'
print(x, ...)

Arguments

x  a pam object.
...
potential further arguments (require by generic).

See Also

pam, pam.object.print, print.default.

ruspini  Ruspini Data

Description

The Ruspini data set, consisting of 75 points in four groups that is popular for illustrating clustering

techniques.

Usage

data(ruspini)

Format

A data frame with 75 observations on 2 variables giving the x and y coordinates of the points,
respectively.

Source

References

see those in agnes.

Examples

```r
data(ruspini)

## Plot similar to Figure 4 in Stryuf et al (1996)
## Not run: plot(pam(ruspini, 4), ask = TRUE)

## Plot similar to Figure 6 in Stryuf et al (1996)
plot(fanny(ruspini, 5))
```

silhouette

Compute or Extract Silhouette Information from Clustering

Description

Compute silhouette information according to a given clustering in \( k \) clusters.

Usage

```r
silhouette(x, ...)
```

## Default S3 method:

```r
silhouette(x, dist, dmatrix, ...)
```

## S3 method for class 'partition'

```r
silhouette(x, ...)
```

## S3 method for class 'clara'

```r
silhouette(x, full = FALSE, ...)
```

```r
sortSilhouette(object, ...)
```

## S3 method for class 'silhouette'

```r
summary(object, FUN = mean, ...)
```

## S3 method for class 'silhouette'

```r
plot(x, nmax.lab = 4/zero.noslash, max.strlen = 5,
     main = NULL, sub = NULL, xlab = expression("Silhouette width "* s[i]),
     col = "gray", do.col.sort = length(col) > 1, border = 0,
     cex.names = par("cex.axis"), do.n.k = TRUE, do.clus.stat = TRUE, ...)
```

Arguments

- **x** an object of appropriate class; for the default method an integer vector with \( k \) different integer cluster codes or a list with such an \$clustering component. Note that silhouette statistics are only defined if \( 2 \leq k \leq n - 1 \).

- **dist** a dissimilarity object inheriting from class \texttt{dist} or coercible to one. If not specified, \texttt{dmatrix} must be.
a symmetric dissimilarity matrix \((n \times n)\), specified instead of \(\text{dist}\), which can be more efficient.

logical specifying if a full silhouette should be computed for \text{clara} object. Note that this requires \(O(n^2)\) memory, since the full dissimilarity (see \text{daisy}) is needed internally.

an object of class \text{silhouette}.

... further arguments passed to and from methods.

function used to summarize silhouette widths.

integer indicating the number of labels which is considered too large for single-name labeling the silhouette plot.

positive integer giving the length to which strings are truncated in silhouette plot labeling.

arguments to \text{title}; have a sensible non-NULL default here.

arguments passed \text{barplot()}; note that the default used to be \(\text{col} = \text{heat.colors}(n)\), \(\text{border} = \text{par("fg")}\) instead.

\text{col} can also be a color vector of length \(k\) for clusterwise coloring, see also \text{do.col.sort}:

logical indicating if the colors \text{col} should be sorted “along” the silhouette; this is useful for casewise or clusterwise coloring.

logical indicating if \(n\) and \(k\) “title text” should be written.

logical indicating if cluster size and averages should be written right to the silhouettes.

For each observation \(i\), the silhouette width \(s(i)\) is defined as follows:
Put \(a(i) = \text{average dissimilarity between } i \text{ and all other points of the cluster to which } i \text{ belongs (if } i \text{ is the only observation in its cluster, } s(i) := 0 \text{ without further calculations). For all other clusters } C, \text{ put } d(i, C) = \text{average dissimilarity of } i \text{ to all observations of } C. \text{ The smallest of these } d(i, C) \text{ is } b(i) := \min_C d(i, C), \text{ and can be seen as the dissimilarity between } i \text{ and its “neighbor” cluster, i.e., the nearest one to which it does not belong. Finally,}

\[
s(i) := \frac{b(i) - a(i)}{\max(a(i), b(i))}.
\]

\text{silhouette.default()} is now based on \text{C} code donated by Romain Francois (the \text{R} version being still available as \text{cluster:::silhouette.default.R}).

Observations with a large \(s(i)\) (almost 1) are very well clustered, a small \(s(i)\) (around 0) means that the observation lies between two clusters, and observations with a negative \(s(i)\) are probably placed in the wrong cluster.
Value

silhouette() returns an object, sil, of class silhouette which is an \([n \times 3]\) matrix with attributes. For each observation \(i\), \(\text{sil}[i,]\) contains the cluster to which \(i\) belongs as well as the neighbor cluster of \(i\) (the cluster, not containing \(i\), for which the average dissimilarity between its observations and \(i\) is minimal), and the silhouette width \(s(i)\) of the observation. The \text{colnames} correspondingly are c("cluster", "neighbor", "sil_width").

\text{summary(sil)} returns an object of class \text{summary.silhouette}, a list with components

- \text{si.summary}: numerical \text{summary} of the individual silhouette widths \(s(i)\).
- \text{clus.avg.widths}: numeric (rank 1) array of clusterwise \text{means} of silhouette widths where \text{mean} = \text{FUN} is used.
- \text{avg.width}: the total mean \text{FUN}(s) where \(s\) are the individual silhouette widths.
- \text{clus.sizes}: \text{table} of the \(k\) cluster sizes.
- \text{call}: if available, the call creating \text{sil}.
- \text{Ordered}: logical identical to \text{attr(sil, "Ordered")}, see below.

\text{sortSilhouette(sil)} orders the rows of \text{sil} as in the silhouette plot, by cluster (increasingly) and decreasing silhouette width \(s(i)\).

\text{attr(sil, "Ordered")} is a logical indicating if \text{sil} is ordered as by \text{sortSilhouette()}. In that case, \text{rownames(sil)} will contain case labels or numbers, and \text{attr(sil, "iOrd")} the ordering index vector.

Note

While \text{silhouette()} is intrinsic to the \text{partition} clusterings, and hence has a (trivial) method for these, it is straightforward to get silhouettes from hierarchical clusterings from \text{silhouette.default()} with \text{cutree()} and distance as input.

By default, for \text{clara()} partitions, the silhouette is just for the best random \text{subset} used. Use \text{full = TRUE} to compute (and later possibly plot) the full silhouette.

\text{partition.object, plot.partition}.

Examples

data(ruspini)
pr4 <- pam(ruspini, 4)
\text{str(sil <- silhouette(pr4))}
(\text{ssi <- summary(sil)})
plot(si) # silhouette plot
plot(si, col = c("red", "green", "blue", "purple"))# with cluster-wise coloring

si2 <- silhouette(pr4$clustering, dist(ruspini, "canberra"))
summary(si2) # has small values: "canberra"’s fault
plot(si2, nmax= 80, cex.names=0.6)

op <- par(mfrow= c(3,2), oma= c(0,0, 3, 0),
mgp= c(1.6,.8,0), mar= 1+c(4,2,2,2))
for(k in 2:6)
  plot(silhouette(pam(ruspini, k=k)), main = paste("k = ",k), do.n.k=FALSE)
mtext("PAM(Ruspini) as in Kaufman & Rousseeuw, p.101",
outer = TRUE, font = par("font.main"), cex = par("cex.main")); frame()

## the same with cluster-wise colours:
c6 <- c("tomato", "forest green", "dark blue", "purple2", "goldenrod4", "gray2")
for(k in 2:6)
  plot(silhouette(pam(ruspini, k=k)), main = paste("k = ",k), do.n.k=FALSE,
col = c6[1:k])
par(op)

## clara(): standard silhouette is just for the best random subset
data(xclara)
set.seed(7)
str(xc1k <- xclara[sample(nrow(xclara), size = 1000) ,])
c3 <- clara(xc1k, 3)
plot(silhouette(c3))# only of the "best" subset of 46

## The full silhouette: internally needs large (36 MB) dist object:
sf <- silhouette(c3, full = TRUE) ## this is the same as
s.full <- silhouette(c3$clustering, daisy(xc1k))
if(paste(R.version$major, R.version$minor, sep=".") >= "2.3.0")
  stopifnot(all.equal(sf, s.full, check.attributes = FALSE, tol = 0))
## color dependent on original "3 groups of each 1000":
plot(sf, col = 2+ as.integer(names(c3$clustering) ) %/% 1000,
main = "plot(silhouette(clara(.), full = TRUE))")

## Silhouette for a hierarchical clustering:
ar <- agnes(ruspini)
si3 <- silhouette(cutree(ar, k = 5), # k = 4 gave the same as pam() above
daisy(ruspini))
plot(si3, nmax = 80, cex.names = 0.5)
## 2 groups: Agnes() wasn’t too good:
si4 <- silhouette(cutree(ar, k = 2), daisy(ruspini))
plot(si4, nmax = 80, cex.names = 0.5)
Description

Returns the number of observations (sample size) corresponding to a dissimilarity like object, or equivalently, the number of rows or columns of a matrix when only the lower or upper triangular part (without diagonal) is given.

It is nothing else but the inverse function of \( f(n) = \frac{n(n - 1)}{2} \).

Usage

\[
\text{sizeDiss}(d)
\]

Arguments

\( d \)

any R object with length (typically) \( n(n - 1)/2 \).

Value

a number; \( n \) if length(d) == \( n(n-1)/2 \), NA otherwise.

See Also

dissimilarity.object and also as.dist for class dissimilarity and dist objects which have a Size attribute.

Examples

\[
\text{sizeDiss}(1:10) \# 5, \text{since } 10 = 5 \times (5 - 1) / 2
\]

\[
\text{sizeDiss}(1:9) \# \text{NA}
\]

\[
n <- 1:100
\]

\[
\text{stopifnot}(n == sapply( n*(n-1)/2, function(n) \text{sizeDiss(logical(n))))}
\]

summary.agnes

Summary Method for 'agnes' Objects

Description

Returns (and prints) a summary list for an agnes object. Printing gives more output than the corresponding print.agnes method.

Usage

\[
\#
\text{S3 method for class 'agnes'}
\]

\[
\text{summary(object, ...)}
\]

\[
\#
\text{S3 method for class 'summary.agnes'}
\]

\[
\text{print(x, ...)}
\]
Arguments

\texttt{x, object} \hspace{1em} \texttt{a agnes object.}

... \hspace{1em} potential further arguments (require by generic).

See Also

\texttt{agnes, agnes.object}.

Examples

\begin{verbatim}
data(photosynthesis)
summary(agnes(photosynthesis))
\end{verbatim}

## generate 2/zero.noslash/zero.noslash/zero.noslash objects, divided into 5 clusters.
set.seed(47)
x <- rbind(cbind(rnorm(4, 0, 4), rnorm(4, 0, 4)),
            cbind(rnorm(40, 10, 8), rnorm(40, 40, 6)),
            cbind(rnorm(40, 30, 4), rnorm(40, 0, 4)),
            cbind(rnorm(40, 40, 4), rnorm(40, 20, 2)),
            cbind(rnorm(40, 50, 4), rnorm(40, 50, 4)))
clx5 <- clara(x, 5)
\end{verbatim}
## Mis'classification' table:

table(rep(1:5, rep(400,5)), clx5$clust) # -> 1 "error"

## Graphically:
par(mfrow = c(3,1), mgp = c(1.5, 0.6, 0), mar = par("mar") - c(0,0,2,0))
plot(x, col = rep(2:6, rep(400,5)))
plot(clx5)

---

### summary.diana

**Summary Method for 'diana' Objects**

**Description**

Returns (and prints) a summary list for a diana object.

**Usage**

```r
## S3 method for class 'diana'
summary(object, ...)
## S3 method for class 'summary.diana'
print(x, ...)
```

**Arguments**

- `x, object` a diana object.
- `...` potential further arguments (require by generic).

**See Also**

- [diana](diana), [diana.object](diana.object).

---

### summary.mona

**Summary Method for 'mona' Objects**

**Description**

Returns (and prints) a summary list for a mona object.

**Usage**

```r
## S3 method for class 'mona'
summary(object, ...)
## S3 method for class 'summary.mona'
print(x, ...)
```
Summary Method for PAM Objects

Arguments

x, object a mona object.
...
potential further arguments (require by generic).

See Also

mona, mona.object.

twins.object

Hierarchical Clustering Object

Description

The objects of class "twins" represent an agglomerative or divisive (polythetic) hierarchical clustering of a dataset.

Value

See agnes.object and diana.object for details.
**GENERATION**

This class of objects is returned from agnes or diana.

**METHODS**

The "twins" class has a method for the following generic function: pltree.

**INHERITANCE**

The following classes inherit from class "twins": "agnes" and "diana".

**See Also**

agnes, diana.

---

**volume.ellipsoid**

*Compute the Volume of Planar Object*

**Description**

Compute the volume of a planar object. This is a generic function and a method for ellipsoid objects.

**Usage**

```r
## S3 method for class 'ellipsoid'
volume(object)
```

**Arguments**

- `object` an R object the volume of which is wanted; for the ellipsoid method, an object of that class (see ellipsoidhull or the example below).

**Value**

a number, the volume of the given object.

**See Also**

ellipsoidhull for spanning ellipsoid computation.

**Examples**

```r
## example(ellipsoidhull) # which defines 'ellipsoid' object <namefoo>
myEl <- structure(list(cov = rbind(c(3,1),1:2), loc = c(0,0), d2 = 10),
                       class = "ellipsoid")
volume(myEl)# i.e. "area" here (d = 2)
myEl # also mentions the "volume"
```
votes.repub

*Votes for Republican Candidate in Presidential Elections*

**Description**

A data frame with the percents of votes given to the republican candidate in presidential elections from 1856 to 1976. Rows represent the 50 states, and columns the 31 elections.

**Usage**

```r
data(votes.repub)
```

**Source**

---

xclara

*Bivariate Data Set with 3 Clusters*

**Description**

An artificial data set consisting of 3000 points in 3 well-separated clusters of size 1000 each.

**Usage**

```r
data(xclara)
```

**Format**

A data frame with 3000 observations on 2 numeric variables giving the $x$ and $y$ coordinates of the points, respectively.

**Source**

Sample data set accompanying the reference below.

**References**

Chapter 18

The codetools package

---

**checkUsage**  
*Check R Code for Possible Problems*

---

**Description**

Check R code for possible problems.

**Usage**

```r
checkUsage(fun, name = "<anonymous>", report = cat, all = FALSE,  
suppressLocal = FALSE, suppressParamAssigns = !all,  
suppressParamUnused = !all, suppressFundefMismatch = FALSE,  
suppressLocalUnused = FALSE, suppressNoLocalFun = !all,  
skipWith = FALSE, suppressUndefined = dfltSuppressUndefined,  
suppressPartialMatchArgs = TRUE)
```

- `checkUsageEnv(env, ...)`
- `checkUsagePackage(pack, ...)`

**Arguments**

- **fun** closure.
- **name** character; name of closure.
- **env** environment containing closures to check.
- **pack** character naming package to check.
- **...** options to be passed to checkUsage.
- **report** function to use to report possible problems.
- **all** logical; report all possible problems if TRUE.
- **suppressLocal** suppress all local variable warnings.
- **suppressParamAssigns** suppress warnings about assignments to formal parameters.
- **suppressParamUnused** suppress warnings about unused formal parameters.
- **suppressFundefMismatch** suppress warnings about function definitions that are mismatched.
- **suppressLocalUnused** suppress warnings about unused local variables.
- **suppressNoLocalFun** suppress warnings about functions that do not have local variables.
- **skipWith** suppress warnings about arguments that are defined both inside and outside the function.
- **suppressUndefined** suppress warnings about undefined variables.
- **suppressPartialMatchArgs** suppress warnings about arguments that partially match function definitions.

---

2225
suppressParamUnused
    suppress warnings about unused formal parameters.
suppressFundefMismatch
    suppress warnings about multiple local function definitions with different formal
    argument lists
suppressLocalUnused
    suppress warnings about unused local variables
suppressNoLocalFun
    suppress warnings about using local variables as functions with no apparent
    local function definition
skipWith
    logical; if true, do no examine code portion of with expressions.
suppressUndefined
    suppress warnings about undefined global functions and variables.
suppressPartialMatchArgs
    suppress warnings about partial argument matching

Details

checkUsage checks a single R closure. Options control which possible problems to report. The
default settings are moderately verbose. A first pass might use suppressLocal=TRUE to suppress
all information related to local variable usage. The suppressXYZ values can either be scalar logicals
or character vectors; then they are character vectors they only suppress problem reports for the
variables with names in the vector.

checkUsageEnv and checkUsagePackage are convenience functions that apply checkUsage to all
closures in an environment or a package. checkUsagePackage requires that the package be loaded.
If the package has a name space then the internal name space frame is checked.

Author(s)

Luke Tierney

Examples

checkUsage(checkUsage)
checkUsagePackage("codetools",all=TRUE)
## Not run: checkUsagePackage("base",suppressLocal=TRUE)

Description

These functions provide some tools for analysing R code. Mainly indented to support the other
tools in this package and byte code compilation.
Usage

collectLocals(e, collect)
collectUsage(fun, name = "<anonymous>", ...)
constantFold(e, env = NULL, fail = NULL)
findFuncLocals(formals, body)
findLocals(e, envir = .BaseEnv)
findLocalsList(elist, envir = .BaseEnv)
flattenAssignment(e)
getAssignedVar(e)
isConstantValue(v, w)
makeCodeWalker(..., handler, call, leaf)
makeLocalsCollector(..., leaf, handler, isLocal, exit, collect)
makeUsageCollector(fun, ..., name, enterLocal, enterGlobal, enterInternal,
                     startCollectLocals, finishCollectLocals, warn,
                     signal)
walkCode(e, w = makeCodeWalker())

Arguments

e R expression.
elist list of R expressions.
v R object.
fun closure.
formals formal arguments of a closure.
body body of a closure.
nname character.
env character.
envir environment.
w code walker.
... extra elements for code walker.
collect function.
fail function.
handler function.
call function.
leaf function.
isLocal function.
exit function.
enterLocal function.
enterGlobal function.
enterInternal function.
startCollectLocals function.
findGlobals

Find Global Functions and Variables Used by a Closure

Description

Finds global functions and variables used by a closure.

Usage

findGlobals(fun, merge = TRUE)

Arguments

fun closure.
merge logical

Details

The result is an approximation. R semantics only allow variables that might be local to be identified (and event that assumes no use of assign and rm).

Value

Character vector if merge is true; otherwise, a list with functions and variables components.

Author(s)

Luke Tierney

Examples

findGlobals(findGlobals)
findGlobals(findGlobals, merge = FALSE)
Description

Prints a Lisp-style representation of R expression. This can be useful for understanding how some things are parsed.

Usage

showTree(e, write = cat)

Arguments

e R expression.
write function of one argument to write the result.

Author(s)

Luke Tierney

Examples

showTree(quote(-3))
showTree(quote("x"<-1))
showTree(quote("f"(x)))
showTree
Chapter 19

The foreign package

lookup.xport

 Lookup Information on a SAS XPORT Format Library

Description
Scans a file as a SAS XPORT format library and returns a list containing information about the SAS library.

Usage
lookup.xport(file)

Arguments
file character variable with the name of the file to read. The file must be in SAS XPORT format.

Value
A list with one component for each dataset in the XPORT format library.

Author(s)
Saikat DebRoy

References

See Also
read.xport
Examples

```r
## Not run:
lookup.xport("transport")

## End(Not run)
```

---

**read.arff**  
*Read Data from ARFF Files*

**Description**

Reads data from Weka Attribute-Relation File Format (ARFF) files.

**Usage**

```r
read.arff(file)
```

**Arguments**

- `file` a character string with the name of the ARFF file to read from, or a `connection` which will be opened if necessary, and if so closed at the end of the function call.

**Value**

A data frame containing the data from the ARFF file.

**References**

**See Also**

- `write.arff`
**Description**

The function reads a DBF file into a data frame, converting character fields to factors, and trying to respect NULL fields.

**Usage**

```r
read.dbf(file, as.is = FALSE)
```

**Arguments**

- `file` : name of input file
- `as.is` : should character vectors not be converted to factors?

**Details**

DBF is the extension used for files written for the ‘XBASE’ family of database languages, ‘covering the dBase, Clipper, FoxPro, and their Windows equivalents Visual dBase, Visual Objects, and Visual FoxPro, plus some older products’ (http://www.clicketyclick.dk/databases/xbase/format/). Most of these follow the file structure used by Ashton-Tate’s dBase II, III or 4 (later owned by Borland).

`read.dbf` is based on C code from http://shapelib.maptools.org/ which implements the ‘XBASE’ specification. It can convert fields of type "L" (logical), "N" and "F" (numeric and float) and "D" (dates): all other field types are read as-is as character vectors. A numeric field is read as an R integer vector if it is encoded to have no decimals, otherwise as a numeric vector. However, if the numbers are too large to fit into an integer vector, it is changed to numeric. Note that it is possible to read integers that cannot be represented exactly even as doubles: this sometimes occurs if IDs are incorrectly coded as numeric.

**Value**

A data frame of data from the DBF file; note that the field names are adjusted to use in R using `make.names(unique=TRUE)`.

There is an attribute "data_type" giving the single-character dBase types for each field.

**Author(s)**

Nicholas Lewin-Koh and Roger Bivand; shapelib by Frank Warmerdam

**References**

http://shapelib.maptools.org/.

write.dbf

Examples

x <- read.dbf(system.file("files/sids.dbf", package="foreign")[[1]])
str(x)
summary(x)

Description

Reads a file in Stata version 5–11 binary format into a data frame.

Usage

read.dta(file, convert.dates = TRUE, convert.factors = TRUE,
missing.type = FALSE,
convert.underscore = FALSE, warn.missing.labels = TRUE)

Arguments

file
a filename or URL as a character string.

convert.dates
Convert Stata dates to Date class?

convert.factors
Use Stata value labels to create factors? (version 6.0 or later).

missing.type
For version 8 or later, store information about different types of missing data?

convert.underscore
Convert "_" in Stata variable names to "." in R names?

warn.missing.labels
Warn if a variable is specified with value labels and those value labels are not present in the file.

Details

If the filename appears to be a URL (of schemes ‘http:’, ‘ftp:’ or ‘https:’) the URL is first downloaded to a temporary file and then read. (‘https:’ is only supported on some platforms.)

The variables in the Stata data set become the columns of the data frame. Missing values are correctly handled. The data label, variable labels, and timestamp are stored as attributes of the data frame. Nothing is done with variable characteristics.

By default Stata dates (%d and %td formats) are converted to R’s Date class and variables with Stata value labels are converted to factors. Ordinarily, read.dta will not convert a variable to a factor unless a label is present for every level. Use convert.factors = NA to override this. In any case the value label and format information is stored as attributes on the returned data frame.
Stata 8.0 introduced a system of 27 different missing data values. If missing.type is TRUE a separate list is created with the same variable names as the loaded data. For string variables the list value is NULL. For other variables the value is NA where the observation is not missing and 0–26 when the observation is missing. This is attached as the "missing" attribute of the returned value.

Value

A data frame with attributes. These will include "datalabel", "time.stamp", "formats", "types", "val.labels", "var.labels" and "version" and may include "label.table". Possible versions are 5, 6, 7, -7 (Stata 7SE, ‘format-111’), 8 (Stata 8 and 9, ‘format-113’) and 10 (Stata 10 and 11, ‘format-114’). Stata 12 by default uses ‘format-115’, which is read as ‘format-114’ (the Stata documentation says its structure is identical).

The value labels in attribute "val.labels" name a table for each variable, or are an empty string. The tables are elements of the named list attribute "label.table": each is an integer vector with names.

Author(s)

Thomas Lumley and R-core members

A different approach is available in package memisc: see its help for Stata.file.

write.dta, attributes, Date, factor

Examples

data(swiss)
write.dta(swiss,swissfile <- tempfile())
read.dta(swissfile)

---

read.epiinfo

Read Epi Info Data Files

Description

Reads data files in the .REC format used by Epi Info versions 6 and earlier and by EpiData. Epi Info is a public domain database and statistics package produced by the US Centers for Disease Control and EpiData is a freely available data entry and validation system.
Usage

read.epiinfo(file, read.deleted = FALSE, guess.broken.dates = FALSE, thisyear = NULL, lower.case.names = FALSE)

Arguments

file A filename, URL, or connection.
read_deleted Deleted records are read if TRUE, omitted if FALSE or replaced with NA if NA.
guess.broken.dates Attempt to convert dates with 0 or 2 digit year information (see ‘Details’).
thisyear A 4-digit year to use for dates with no year. Defaults to the current year.
lower.case.names Convert variable names to lowercase?

Details

Epi Info allows dates to be specified with no year or with a 2 or 4 digits. Dates with four-digit years are always converted to Date class. With the guess.broken.dates option the function will attempt to convert two-digit years using the operating system’s default method (see Date) and will use the current year or the thisyear argument for dates with no year information.

If read_deleted is TRUE the “deleted” attribute of the data frame indicates the deleted records.

Value

A data frame.

Note

Epi Info 2000, the current version, uses the Microsoft Access file format to store data. This may be readable with the RODBC or RDCOM packages.

DateTimeClasses

Examples

## Not run:
data<-read.epiinfo("oswego.rec",guess.broken.dates=TRUE,thisyear="1972")
## End(Not run)
**Description**

Return a list with the data stored in a file as a Minitab Portable Worksheet.

**Usage**

```r
read.mtp(file)
```

**Arguments**

- `file` character variable with the name of the file to read. The file must be in Minitab Portable Worksheet format.

**Value**

A list with one component for each column, matrix, or constant stored in the Minitab worksheet.

**Note**

This function was written around 1990 for the format current then. Later versions of Minitab appear to have added to the format.

**Author(s)**

Douglas M. Bates

**References**

**Examples**

```r
## Not run:
read.mtp("ex1-10.mtp")
## End(Not run)
```
read.octave  Read Octave Text Data Files

Description
Read a file in Octave text data format into a list.

Usage
read.octave(file)

Arguments
file  a character string with the name of the file to read.

Details
This function is used to read in files in Octave text data format, as created by save –text in Octave. It knows about most of the common types of variables, including the standard atomic (real and complex scalars, matrices, and N-d arrays, strings, ranges, and boolean scalars and matrices) and recursive (structs, cells, and lists) ones, but has no guarantee to read all types. If a type is not recognized, a warning indicating the unknown type is issued, it is attempted to skip the unknown entry, and NULL is used as its value. Note that this will give incorrect results, and maybe even errors, in the case of unknown recursive data types.

As Octave can read MATLAB binary files, one can make the contents of such files available to R by using Octave’s load and save (as text) facilities as an intermediary step.

Value
A list with one named component for each variable in the file.

Author(s)
Stephen Eglen <stephen@gnu.org> and Kurt Hornik

References
http://www.octave.org/
read.spss  Read an SPSS Data File

Description
read.spss reads a file stored by the SPSS save or export commands.

Usage
read.spss(file, use.value.labels = TRUE, to.data.frame = FALSE,
          max.value.labels = Inf, trim.factor.names = FALSE,
          trim_values = TRUE, reencode = NA, use.missings = to.data.frame)

Arguments
  file  Character string: the name of the file or URL to read.
  use.value.labels  Convert variables with value labels into R factors with those levels?
  to.data.frame  return a data frame?
  max.value.labels  Only variables with value labels and at most this many unique values will be converted to factors if use.value.labels = TRUE.
  trim.factor.names  Logical: trim trailing spaces from factor levels?
  trim_values  logical: should values and value labels have trailing spaces ignored when matching for use.value.labels = TRUE?
  reencode  logical: should character strings be re-encoded to the current locale. The default, NA, means to do so in a UTF-8 locale, only. Alternatively a character string specifying an encoding to assume for the file.
  use.missings  logical: should information on user-defined missing values be used to set the corresponding values to NA?

Details
This uses modified code from the PSPP project (http://www.gnu.org/software/pspp/) for reading the SPSS formats.

If the filename appears to be a URL (of schemes ‘http:’, ‘ftp:’ or ‘https:’) the URL is first downloaded to a temporary file and then read. (‘https:’ is only supported on some platforms.)

Occasionally in SPSS, value labels will be added to some values of a continuous variable (e.g. to distinguish different types of missing data), and you will not want these variables converted to factors. By setting max.value.labels you can specify that variables with a large number of distinct values are not converted to factors even if they have value labels. In addition, variables will not be converted to factors if there are non-missing values that have no value label. The value labels are then returned in the "value.labels" attribute of the variable.
If SPSS variable labels are present, they are returned as the "variable.labels" attribute of the answer.

Fixed length strings (including value labels) are padded on the right with spaces by SPSS, and so are read that way by R. The default argument trim.values=TRUE causes trailing spaces to be ignored when matching to value labels, as examples have been seen where the strings and the value labels had different amounts of padding. See the examples for sub for ways to remove trailing spaces in character data.

URL http://msdn.microsoft.com/en-us/library/ms776446(VS.85).aspx provides a list of translations from Windows codepage numbers to encoding names that iconv is likely to know about and so suitable values for reencode. Automatic re-encoding is attempted for apparent codepages of 200 or more in a UTF-8 locale: some other high-numbered codepages can be re-encoded on most systems, but the encoding names are platform-dependent (see iconvlist).

Value

A list (or data frame) with one component for each variable in the saved data set.

If what looks like a Windows codepage was recorded in the SPSS file, it is attached (as a number) as attribute "codepage" to the result.

There may be attributes "label.table" and "variable.labels". Attribute "label.table" is a named list of value labels with one element per variable, either NULL or a named character vector. Attribute "variable.labels" is a named character vector with names the short variable names and elements the long names.

If there are user-defined missing values, there will be a attribute "Missings". This is a named list with one list element per variable. Each element has an element type, a length-one character vector giving the type of missingness, and may also have an element value with the values corresponding to missingness. This is a complex subject (where the R and C source code for read.spss is the main documentation), but the simplest cases are types "one", "two" and "three" with a corresponding number of (real or string) values whose labels can be found from the "label.table" attribute. Other possibilities are a finite or semi-infinite range, possibly plus a single value. See also http://www.gnu.org/software/pspp/manual/html_node/Missing-Observations.html#Missing-Observations.

Note

If SPSS value labels are converted to factors the underlying numerical codes will not in general be the same as the SPSS numerical values, since the numerical codes in R are always 1, 2, 3, . . .

You may see warnings about the file encoding for SPSS save files: it is possible such files contain non-ASCII character data which need re-encoding. The most common occurrence is Windows codepage 1252, a superset of Latin-1. The encoding is recorded (as an integer) in attribute "codepage" of the result if it looks like a Windows codepage. Automatic re-encoding is done only in UTF-8 locales: see argument reencode.

Author(s)

Saikat DebRoy and the R-core team
read.ssd

**See Also**

A different interface also based on the PSPP codebase is available in package `memisc`: see its help for `spss.system.file`.

**Examples**

```r
## Not run:
read.spss("datafile")
## don’t convert value labels to factor levels
read.spss("datafile", use.value.labels = FALSE)
## convert value labels to factors for variables with at most
## ten distinct values.
read.spss("datafile", max.value.labels = 10)
## End(Not run)
```

**read.ssd**  
*Obtain a Data Frame from a SAS Permanent Dataset, via read.xport*

**Description**

Generates a SAS program to convert the ssd contents to SAS transport format and then uses `read.xport` to obtain a data frame.

**Usage**

```r
read.ssd(libname, sectionnames, 
  tmpXport=tempfile(), tmpProgLoc=tempfile(), sascmd="sas")
```

**Arguments**

- `libname`: character string defining the SAS library (usually a directory reference).
- `sectionnames`: character vector giving member names. These are files in the `libname` directory. They will usually have a `.ssd` or `.sas7bdat` extension, which should be omitted.
- `tmpXport`: character string: location where temporary xport format archive should reside – defaults to a randomly named file in the session temporary directory, which will be removed.
- `tmpProgLoc`: character string: location where temporary conversion SAS program should reside – defaults to a randomly named file in session temporary directory, which will be removed on successful operation.
- `sascmd`: character string giving full path to SAS executable.

**Details**

Creates a SAS program and runs it.  
Error handling is primitive.
read.systat

Obtain a Data Frame from a Systat File

Value

A data frame if all goes well, or NULL with warnings and some enduring side effects (log file for auditing)

Note

This requires SAS to be available. If you have a SAS dataset without access to SAS you will need another product to convert it to a format such as .csv, for example ‘Stat/Transfer’ or ‘DBMS/Copy’ or the ‘SAS System Viewer’ (Windows only).

Author(s)

For Unix: VJ Carey <stvjc@channing.harvard.edu>

read.xport

Examples

## if there were some files on the web we could get a real
## runnable example
## Not run:
R> list.files("trialdata")
[1] "baseline.sas7bdat" "form11.sas7bdat" "form12.sas7bdat"
[4] "form13.sas7bdat" "form22.sas7bdat" "form23.sas7bdat"
[7] "form3.sas7bdat" "form4.sas7bdat" "form48.sas7bdat"
[10] "form50.sas7bdat" "form51.sas7bdat" "form71.sas7bdat"
[13] "form72.sas7bdat" "form8.sas7bdat" "form9.sas7bdat"
[16] "form90.sas7bdat" "form91.sas7bdat"
R> baseline <- read.ssd("trialdata","baseline")
R> form90 <- read.ssd("trialdata","form90")

## Or for a Windows example
sashome <- "/Program Files/SAS/SAS 9.1"
read.ssd(file.path(sashome, "core", "sashelp"), "retail",
        sascmd = file.path(sashome, "sas.exe"))

## End(Not run)
Usage

read.systat(file, to.data.frame = TRUE)

Arguments

file character variable with the name of the file to read
to.data.frame return a data frame (otherwise a list)

Details

The function only reads those Systat files that are rectangular data files (mtype = 1), and warns when files have non-standard variable name codings. The files tested were produced on MS-DOS and Windows: files for the Mac version of Systat have a completely different format.

The C code was originally written for an add-on module for Systat described in Bivand (1992 paper). Variable names retain the trailing dollar in the list returned when to.data.frame is FALSE, and in that case character variables are returned as is and filled up to 12 characters with blanks on the right. The original function was limited to reading Systat files with up to 256 variables (a Systat limitation); it will now read up to 8192 variables.

If there is a user comment in the header this is returned as attribute "comment". Such comments are always a multiple of 72 characters (with a maximum of 720 chars returned), normally padded with trailing spaces.

Value

A data frame (or list) with one component for each variable in the saved data set.

Author(s)

Roger Bivand

References

Examples

summary(iris)
iris.s <- read.systat(system.file("files/Iris.sy", package="foreign")[1])
str(iris.s)
summary(iris.s)
**Description**

Reads a file as a SAS XPORT format library and returns a list of data.frames.

**Usage**

```r
read.xport(file)
```

**Arguments**

- `file` character variable with the name of the file to read. The file must be in SAS XPORT format.

**Value**

If there is a more than one dataset in the XPORT format library, a named list of data frames, otherwise a data frame. The columns of the data frames will be either numeric (corresponding to numeric in SAS) or factor (corresponding to character in SAS). All SAS numeric missing values (including special missing values represented by ._, .A to .Z by SAS) are mapped to R NA.

Trailing blanks are removed from character columns before conversion to a factor. Some sources claim that character missing values in SAS are represented by ‘ ’ or ‘ ’: these are not treated as R missing values.

**Author(s)**

Saikat DebRoy <saikat@stat.wisc.edu>

**References**

**See Also**

- `lookup.xport`

**Examples**

```r
## Not run:
read.xport("transport")

## End(Not run)
```
**S3 read functions**

Read an S3 Binary or *data.dump* File

**Description**

Reads binary data files or *data.dump* files that were produced in S version 3.

**Usage**

```r
data.restore(file, print = FALSE, verbose = FALSE, env = .GlobalEnv)
read.S(file)
```

**Arguments**

- `file` the filename of the S-PLUS *data.dump* or binary file.
- `print` whether to print the name of each object as read from the file.
- `verbose` whether to print the name of every subitem within each object.
- `env` environment within which to create the restored object(s).

**Details**

`read.S` can read the binary files produced in some older versions of S-PLUS on either Windows (versions 3.x, 4.x, 2000) or Unix (version 3.x with 4 byte integers). It automatically detects whether the file was produced on a big- or little-endian machine and adapts itself accordingly.

`data.restore` can read a similar range of files produced by `data.dump` and for newer versions of S-PLUS, those from `data.dump(..., oldStyle=TRUE)`.

Not all S3 objects can be handled in the current version. The most frequently encountered exceptions are functions and expressions; you will also have trouble with objects that contain model formulas. In particular, comments will be lost from function bodies, and the argument lists of functions will often be changed.

**Value**

- For `read.S`, an R version of the S3 object.
- For `data.restore`, the name of the file.

**Author(s)**

Duncan Murdoch

**Examples**

```r
## Not run: read.S(file.path("_Data", "myobj"))
data.restore("dumpdata", print = TRUE)
## End(Not run)
```
write.arff  Write Data into ARFF Files

Description

Writes data into Weka Attribute-Relation File Format (ARFF) files.

Usage

write.arff(x, file, eol = "\n", relation = deparse(substitute(x)))

Arguments

x  the data to be written, preferably a matrix or data frame. If not, coercion to a
   data frame is attempted.

file  either a character string naming a file, or a connection. "" indicates output
      to the standard output connection.

eol  the character(s) to print at the end of each line (row).

relation  The name of the relation to be written in the file.

Details

relation will be passed through make.names before writing to the file, in an attempt to it
them acceptable to Weka, and column names what do not start with an alphabetic character will
have X prepended.

However, the references say that ARFF files are ASCII files, and that encoding is not enforced.

References

See Also

read.arff

Examples

write.arff(iris, file = "")
**Description**

The function tries to write a data frame to a DBF file.

**Usage**

```r
write.dbf(dataframe, file, factor2char = TRUE, max_nchar = 254)
```

**Arguments**

- `dataframe`: a data frame object.
- `file`: a file name to be written to.
- `factor2char`: logical, default TRUE, convert factor columns to character: otherwise they are written as the internal integer codes.
- `max_nchar`: The maximum number of characters allowed in a character field. Strings which exceed this will be truncated with a warning. See Details.

**Details**

Dots in column names are replaced by underlines in the DBF file, and names are truncated to 11 characters.

Only vector columns of classes "logical", "numeric", "integer", "character", "factor" and "Date" can be written. Other columns should be converted to one of these.

Maximum precision (number of digits including minus sign and decimal sign) for numeric is 19 - scale (digits after the decimal sign) which is calculated internally based on the number of digits before the decimal sign.

The original DBASE format limited character fields to 254 bytes. It is said that Clipper and FoxPro can read up to 32K, and it is possible to write a reader that could accept up to 65535 bytes. (The documentation suggests that only ASCII characters can be assumed to be supported.) Readers expecting the older standard (which includes Excel 2003, Access 2003 and OpenOffice 2.0) will truncate the field to the maximum width modulo 256, so increase `max_nchar` only if you are sure the intended reader supports wider character fields.

**Value**

Invisible NULL.

**Note**

Other applications have varying abilities to read the data types used here. Microsoft Access reads "numeric", "integer", "character" and "Date" fields, including recognizing missing values, but not "logical" (read as 0, -1). Microsoft Excel understood all possible types but did not interpret missing values in character fields correctly (showing them as character nuls).

write.dta

Write Files in Stata Binary Format

Description
Writes the data frame to file in the Stata binary format. Does not write array variables unless they can be drop-ed to a vector.

Usage
write.dta(dataframe, file, version = 7L,
convert.dates = TRUE, tz = "GMT",
convert.factors = c("labels", "string", "numeric", "codes"))

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dataframe</td>
<td>a data frame.</td>
</tr>
<tr>
<td>file</td>
<td>character string giving filename.</td>
</tr>
<tr>
<td>version</td>
<td>integer: Stata version: 6, 7, 8 and 10 are supported, and 9 is mapped to 8, 11 to 10.</td>
</tr>
<tr>
<td>convert.dates</td>
<td>Convert Date and POSIXt objects to Stata dates?</td>
</tr>
</tbody>
</table>
tz time zone for date conversion
convert.factors how to handle factors

Details

The major differences between file formats in Stata versions is that version 7.0 and later allow 32-character variable names (5 and 6 were restricted to 8-character name). The abbreviate function is used to trim long variables to the permitted length. A warning is given if this is needed and it is an error for the abbreviated names not to be unique.

The columns in the data frame become variables in the Stata data set. Missing values are handled correctly.

Unless deselected by argument convert.dates, R date and date-time objects (POSIXt classes) are converted into the Stata format. For date-time objects this may lose information – Stata dates are in days since 1960-1-1. POSIXct objects can be written without conversion but will not be understood as dates by Stata; POSIXlt objects cannot be written without conversion.

There are four options for handling factors. The default is to use Stata ‘value labels’ for the factor levels. With convert.factors="string", the factor levels are written as strings. With convert.factors="numeric" the numeric values of the levels are written, or NA if they cannot be coerced to numeric. Finally, convert.factors="codes" writes the underlying integer codes of the factors. This last used to be the only available method and is provided largely for backwards compatibility.

For Stata 8 or later use the default version=7 – the only advantage of Stata 8 format is that it can represent multiple different missing value types, and R doesn’t have them. Stata 10/11 allows longer format lists, but R does not make use of them.

Note that the Stata formats are documented to use ASCII strings – R does not enforce this, but use of non-ASCII character strings will not be portable as the encoding is not recorded. Up to 244 bytes are allowed in character data, and longer strings will be truncated with a warning.

Stata uses some large numerical values to represent missing values. This function does not currently check, and hence integers greater than 2147483620 and doubles greater than 8.988e+307 may be misinterpreted by Stata.

Value

NULL

Write Text Files and Code to Read Them

Description

This function exports simple data frames to other statistical packages by writing the data as free-format text and writing a separate file of instructions for the other package to read the data.

Usage

```r
write.foreign(df, datafile, codefile,
              package = c("SPSS", "Stata", "SAS"), ...)
```

Arguments

- `df` A data frame
- `datafile` Name of file for data output
- `codefile` Name of file for code output
- `package` Name of package
- `...` Other arguments for the individual `writeForeign` functions

Details

The work for this function is done by `foreign:::writeForeignStata`, `foreign:::writeForeignSAS` and `foreign:::writeForeignSPSS`. To add support for another package, e.g., Systat, create a function `writeForeignSystat` with the same first three arguments as `write.foreign`. This will be called from `write.foreign` when `package="Systat"`.

Numeric variables and factors are supported for all packages: dates and times (Date, dates, date, and POSIXt classes) and logical vectors are also supported for SAS and characters are supported for SPSS.

For `package="SAS"` there are optional arguments `dataname = "rdata"` taking a string that will be the SAS data set name, `validvarname` taking either "V6" or "V7", and `libpath = NULL` taking a string that will be the directory where the target SAS dataset will be written when the generated SAS code been run.

Value

Invisible NULL.

unlink(codefile)

## End(Not run)
```
Chapter 20

The KernSmooth package

bkde

Compute a Binned Kernel Density Estimate

Description

Returns x and y coordinates of the binned kernel density estimate of the probability density of the data.

Usage

bkde(x, kernel = "normal", canonical = FALSE, bandwidth, gridsize = 401L, range.x, truncate = TRUE)

Arguments

x numeric vector of observations from the distribution whose density is to be estimated. Missing values are not allowed.

bandwidth the kernel bandwidth smoothing parameter. Larger values of bandwidth make smoother estimates, smaller values of bandwidth make less smooth estimates. The default is a bandwidth computed from the variance of x, specifically the 'oversmoothed bandwidth selector' of Wand and Jones (1995, page 61).

kernel character string which determines the smoothing kernel. kernel can be: "normal" - the Gaussian density function (the default). "box" - a rectangular box. "epanech" - the centred beta(2,2) density. "biweight" - the centred beta(3,3) density. "triweight" - the centred beta(4,4) density. This can be abbreviated to any unique abbreviation.

canonical logical flag: if TRUE, canonically scaled kernels are used.

gridsize the number of equally spaced points at which to estimate the density.

range.x vector containing the minimum and maximum values of x at which to compute the estimate. The default is the minimum and maximum data values, extended by the support of the kernel.
truncate logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.

Details

This is the binned approximation to the ordinary kernel density estimate. Linear binning is used to obtain the bin counts. For each x value in the sample, the kernel is centered on that x and the heights of the kernel at each datapoint are summed. This sum, after a normalization, is the corresponding y value in the output.

Value

a list containing the following components:

x vector of sorted x values at which the estimate was computed.
y vector of density estimates at the corresponding x.

Background

Density estimation is a smoothing operation. Inevitably there is a trade-off between bias in the estimate and the estimate’s variability: large bandwidths will produce smooth estimates that may hide local features of the density; small bandwidths may introduce spurious bumps into the estimate.

References

See Also
density, dpik, hist, ksmooth.

Examples

data(geyser, package="MASS")
x <- geyser$duration
est <- bkde(x, bandwidth=0.25)
plot(est, type="l")

bkde2D Compute a 2D Binned Kernel Density Estimate

Description

Returns the set of grid points in each coordinate direction, and the matrix of density estimates over the mesh induced by the grid points. The kernel is the standard bivariate normal density.

Usage

bkde2D(x, bandwidth, gridsize = c(51L, 51L), range.x, truncate = TRUE)
Arguments

- **x**
  a two-column numeric matrix containing the observations from the distribution whose density is to be estimated. Missing values are not allowed.

- **bandwidth**
  numeric vector of length 2, containing the bandwidth to be used in each coordinate direction.

- **gridsize**
  vector containing the number of equally spaced points in each direction over which the density is to be estimated.

- **range.x**
  a list containing two vectors, where each vector contains the minimum and maximum values of x at which to compute the estimate for each direction. The default minimum in each direction is minimum data value minus 1.5 times the bandwidth for that direction. The default maximum is the maximum data value plus 1.5 times the bandwidth for that direction.

- **truncate**
  logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.

Value

a list containing the following components:

- **x1**
  vector of values of the grid points in the first coordinate direction at which the estimate was computed.

- **x2**
  vector of values of the grid points in the second coordinate direction at which the estimate was computed.

- **fhat**
  matrix of density estimates over the mesh induced by x1 and x2.

Details

This is the binned approximation to the 2D kernel density estimate. Linear binning is used to obtain the bin counts and the Fast Fourier Transform is used to perform the discrete convolutions. For each x1,x2 pair the bivariate Gaussian kernel is centered on that location and the heights of the kernel, scaled by the bandwidths, at each datapoint are summed. This sum, after a normalization, is the corresponding fhat value in the output.

persp(est$fhat)

bkfe

Compute a Binned Kernel Functional Estimate

Description

Returns an estimate of a binned approximation to the kernel estimate of the specified density functional. The kernel is the standard normal density.

Usage

bkfe(x, drv, bandwidth, gridsize = 401L, range.x, binned = FALSE, 
     truncate = TRUE)

Arguments

x numeric vector of observations from the distribution whose density is to be estimated. Missing values are not allowed.
drv order of derivative in the density functional. Must be a non-negative even integer.
bandwidth the kernel bandwidth smoothing parameter. Must be supplied.
gridsize the number of equally-spaced points over which binning is performed.
range.x vector containing the minimum and maximum values of x at which to compute the estimate. The default is the minimum and maximum data values, extended by the support of the kernel.
binned logical flag: if TRUE, then x and y are taken to be grid counts rather than raw data.
truncate logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.

Details

The density functional of order drv is the integral of the product of the density and its drvth derivative. The kernel estimates of such quantities are computed using a binned implementation, and the kernel is the standard normal density.

Value

the (scalar) estimated functional.
**Background**

Estimates of this type were proposed by Sheather and Jones (1991).

**References**

**Examples**

```r
data(geyser, package="MASS")
x <- geyser$duration
est <- bkfe(x,drv=4, bandwidth=0.3)
```

---

**dpih**

*Select a Histogram Bin Width*

**Description**

Uses direct plug-in methodology to select the bin width of a histogram.

**Usage**

```r
dpih(x, scalest = "minim", level = 2L, gridsize = 41L,
range.x = range(x), truncate = TRUE)
```

**Arguments**

- `x` numeric vector containing the sample on which the histogram is to be constructed.
- `scalest` estimate of scale.
  - "stdev" - standard deviation is used.
  - "iqr" - inter-quartile range divided by 1.349 is used.
  - "minim" - minimum of "stdev" and "iqr" is used.
- `level` number of levels of functional estimation used in the plug-in rule.
- `gridsize` number of grid points used in the binned approximations to functional estimates.
- `range.x` range over which functional estimates are obtained. The default is the minimum and maximum data values.
- `truncate` if `truncate` is TRUE then observations outside of the interval specified by `range.x` are omitted. Otherwise, they are used to weight the extreme grid points.
Details
The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bin width and bandwidths are replaced by kernel estimates, is used. The normal distribution is used to provide an initial estimate.

Value
the selected bin width.

Background
This method for selecting the bin width of a histogram is described in Wand (1995). It is an extension of the normal scale rule of Scott (1979) and uses plug-in ideas from bandwidth selection for kernel density estimation (e.g. Sheather and Jones, 1991).

```

---

**dpik**

*Select a Bandwidth for Kernel Density Estimation*

Description
Use direct plug-in methodology to select the bandwidth of a kernel density estimate.

Usage

```r
dpik(x, scalest = "minim", level = 2L, kernel = "normal",
canonical = FALSE, gridsize = 401L, range.x = range(x),
truncate = TRUE)
```
Arguments

x numeric vector containing the sample on which the kernel density estimate is to be constructed.

scalest estimate of scale.
"stdev" - standard deviation is used.
"iqr" - inter-quartile range divided by 1.349 is used.
"minim" - minimum of "stdev" and "iqr" is used.

level number of levels of functional estimation used in the plug-in rule.

kernel character string which determines the smoothing kernel. kernel can be:
"normal" - the Gaussian density function (the default).
"box" - a rectangular box.
"epanech" - the centred beta(2,2) density.
"biweight" - the centred beta(3,3) density.
"triweight" - the centred beta(4,4) density. This can be abbreviated to any unique abbreviation.

canonical logical flag: if TRUE, canonically scaled kernels are used

gridsize the number of equally-spaced points over which binning is performed to obtain kernel functional approximation.

range.x vector containing the minimum and maximum values of x at which to compute the estimate. The default is the minimum and maximum data values.

truncate logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.

Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bandwidths are replaced by kernel estimates, is used. The normal distribution is used to provide an initial estimate.

Value

the selected bandwidth.

Background

This method for selecting the bandwidth of a kernel density estimate was proposed by Sheather and Jones (1991) and is described in Section 3.6 of Wand and Jones (1995).

dpill

Select a Bandwidth for Local Linear Regression

Description

Use direct plug-in methodology to select the bandwidth of a local linear Gaussian kernel regression estimate, as described by Ruppert, Sheather and Wand (1995).

Usage

dpill(x, y, blockmax = 5, divisor = 2/zero.noslash, trim = /zero.noslash./zero.noslash1, proptrun = /zero.noslash./zero.noslash5,
gridsize = 4/zero.noslash1L, range.x, truncate = TRUE)

Arguments

x numeric vector of x data. Missing values are not accepted.
y numeric vector of y data. This must be same length as x, and missing values are not accepted.
blockmax the maximum number of blocks of the data for construction of an initial parametric estimate.
divisor the value that the sample size is divided by to determine a lower limit on the number of blocks of the data for construction of an initial parametric estimate.
trim the proportion of the sample trimmed from each end in the x direction before application of the plug-in methodology.
proptrun the proportion of the range of x at each end truncated in the functional estimates.
gridsize number of equally-spaced grid points over which the function is to be estimated.
range.x vector containing the minimum and maximum values of x at which to compute the estimate. For density estimation the default is the minimum and maximum data values with 5% of the range added to each end. For regression estimation the default is the minimum and maximum data values.
truncate logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.

Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bandwidths are replaced by kernel estimates, is used. The kernel is the standard normal density. Least squares quartic fits over blocks of data are used to obtain an initial estimate. Mallow’s $C_p$, is used to select the number of blocks.
Value

the selected bandwidth.

Warning

If there are severe irregularities (i.e. outliers, sparse regions) in the x values then the local polynomial smooths required for the bandwidth selection algorithm may become degenerate and the function will crash. Outliers in the y direction may lead to deterioration of the quality of the selected bandwidth.

lines(fit)

locpoly

Estimate Functions Using Local Polynomials

Description

Estimates a probability density function, regression function or their derivatives using local polynomials. A fast binned implementation over an equally-spaced grid is used.

Usage

locpoly(x, y, drv = 0L, degree, kernel = "normal",
    bandwidth, gridsize = 40L, bwdisc = 25,
    range.x, binned = FALSE, truncate = TRUE)
Arguments

- **x**: numeric vector of x data. Missing values are not accepted.
- **bandwidth**: the kernel bandwidth smoothing parameter. It may be a single number or an array having length `gridsize`, representing a bandwidth that varies according to the location of estimation.
- **y**: vector of y data. This must be same length as x, and missing values are not accepted.
- **drv**: order of derivative to be estimated.
- **degree**: degree of local polynomial used. Its value must be greater than or equal to the value of `drv`. The default value is of `degree` is `drv + 1`.
- **kernel**: "normal" - the Gaussian density function. Currently ignored.
- **gridsize**: number of equally-spaced grid points over which the function is to be estimated.
- **bwdisc**: number of logarithmically-equally-spaced bandwidths on which `bandwidth` is discretised, to speed up computation.
- **range.x**: vector containing the minimum and maximum values of x at which to compute the estimate.
- **binned**: logical flag: if TRUE, then x and y are taken to be grid counts rather than raw data.
- **truncate**: logical flag: if TRUE, data with x values outside the range specified by `range.x` are ignored.

Value

if y is specified, a local polynomial regression estimate of E[Y|X] (or its derivative) is computed. If y is missing, a local polynomial estimate of the density of x (or its derivative) is computed.

a list containing the following components:

- **x**: vector of sorted x values at which the estimate was computed.
- **y**: vector of smoothed estimates for either the density or the regression at the corresponding x.

Details

Local polynomial fitting with a kernel weight is used to estimate either a density, regression function or their derivatives. In the case of density estimation, the data are binned and the local fitting procedure is applied to the bin counts. In either case, binned approximations over an equally-spaced grid is used for fast computation. The bandwidth may be either scalar or a vector of length `gridsize`.

Chapter 21

The lattice package

Description

The lattice add-on package is an implementation of Trellis graphics for R. It is a powerful and elegant high-level data visualization system with an emphasis on multivariate data. It is designed to meet most typical graphics needs with minimal tuning, but can also be easily extended to handle most nonstandard requirements.

Details

Trellis Graphics, originally developed for S and S-PLUS at the Bell Labs, is a framework for data visualization developed by R. A. Becker, W. S. Cleveland, et al, extending ideas presented in Cleveland’s 1993 book Visualizing Data. The Lattice API is based on the original design in S, but extends it in many ways.

The Lattice user interface primarily consists of several ‘high-level’ generic functions (listed below in the “See Also” section), each designed to create a particular type of display by default. Although the functions produce different output, they share many common features, reflected in several common arguments that affect the resulting displays in similar ways. These arguments are extensively (sometimes only) documented in the help page for xypplot, which also includes a discussion of the important topics of conditioning and control of the Trellis layout. Features specific to other high-level functions are documented in their respective help pages.

Lattice employs an extensive system of user-controllable settings to determine the look and feel of the displays it produces. To learn how to use and customize the graphical parameters used by lattice, see trellis.par.set. For other settings, see lattice.options. The default graphical settings are (potentially) different for different graphical devices. To learn how to initialize new devices with the desired settings or change the settings of the current device, see trellis.device.

It is usually unnecessary, but sometimes important to be able to plot multiple lattice plots on a single page. Such capabilities are described in the print.trellis help page. See update.trellis to
learn about manipulating a "trellis" object. Tools to augment lattice plots after they are drawn (including locator-like functionality) are described in the trellis.focus help page.

The online documentation accompanying the package is complete, and effort has been made to present the help pages in a logical sequence, so that one can learn how to use lattice by reading the PDF reference manual available at http://cran.r-project.org/web/packages/lattice/.

However, the format in which the online documentation is written and the breadth of topics covered necessarily makes it somewhat terse and less than ideal as a first introduction. For a more gentle introduction, a book on lattice is available as part of Springer’s ‘Use R’ series; see the “References” section below.

Note

High-level lattice functions like xyplot are different from traditional R graphics functions in that they do not perform any plotting themselves. Instead, they return an object, of class "trellis", which has to be then print-ed or plot-ted to create the actual plot. Due to R’s automatic printing rule, it is usually not necessary to explicitly carry out the second step, and lattice functions appear to behave like their traditional counterparts. However, the automatic plotting is suppressed when the high-level functions are called inside another function (most often source) or in other contexts where automatic printing is suppressed (e.g., for or while loops). In such situations, an explicit call to print or plot is required.

The lattice package is based on the Grid graphics engine and requires the grid add-on package. One consequence of this is that it is not (readily) compatible with traditional R graphics tools. In particular, changing par() settings usually has no effect on Lattice plots; lattice provides its own interface for querying and modifying an extensive set of graphical and non-graphical settings.

See Also

The following is a list of high-level functions in the lattice package and their default displays. In all cases, the actual display is produced by the so-called “panel” function, which has a suitable default, but can be substituted by an user defined function to create customized displays. In many cases, the default panel function will itself have many optional arguments to customize its output. The default panel functions are named as “panel.” followed by the name of the corresponding high-level function; i.e., the default panel function for xyplot is panel.xyplot, the one for histogram
is `panel.histogram`, etc. Each default panel function has a separate help page, linked from the help pages of the corresponding high-level function. Although documented separately, arguments to these panel functions can be supplied directly to the high-level functions, which will pass on the arguments appropriately.

**Univariate:**

- **barchart**: Bar plots.
- **bwplot**: Box-and-whisker plots.
- **densityplot**: Kernel density estimates.
- **dotplot**: Cleveland dot plots.
- **histogram**: Histograms.
- **qqmath**: Theoretical quantile plots.
- **stripplot**: One-dimensional scatterplots.

**Bivariate:**

- **qq**: Quantile plots for comparing two distributions.
- **xyplot**: Scatterplots and time-series plots (and potentially a lot more).

**Trivariate:**

- **levelplot**: Level plots (similar to `image` plots).
- **contourplot**: Contour plots.
- **cloud**: Three-dimensional scatter plots.
- **wireframe**: Three-dimensional surface plots (similar to `persp` plots).

**Hypervariate:**

- **splom**: Scatterplot matrices.
- **parallel**: Parallel coordinate plots.

**Miscellaneous:**

- **rfs**: Residual and fitted value plots (also see `oneway`).
- **tmd**: Tukey Mean-Difference plots.

In addition, there are several panel functions that do little by themselves, but can be useful components of custom panel functions. These are documented in `panel.functions`. Lattice also provides a collection of convenience functions that correspond to the traditional graphics primitives `lines`, `points`, etc. These are implemented using Grid graphics, but try to be as close to the traditional versions as possible in terms of their argument list. These functions have names like `llines` or `panel.lines` and are often useful when writing (or porting from S-PLUS code) nontrivial panel functions.

Finally, many useful enhancements that extend the Lattice system are available in the `latticeExtra` package.
## Bivariate Trellis Plots

### Description

This help page documents several commonly used high-level Lattice functions. `xyplot` produces bivariate scatterplots or time-series plots, `bwplot` produces box-and-whisker plots, `dotplot` produces Cleveland dot plots, `barchart` produces bar plots, and `stripplot` produces one-dimensional scatterplots. All these functions, along with other high-level Lattice functions, respond to a common set of arguments that control conditioning, layout, aspect ratio, legends, axis annotation, and many other details in a consistent manner. These arguments are described extensively in this help page, and should be used as the reference for other high-level functions as well.

For control and customization of the actual display in each panel, the help page of the respective default panel function will often be more informative. In particular, these help pages describe many arguments commonly used when calling the corresponding high-level function but are specific to them.

### Usage

```r
xyplot(x, data, ...)  
dotplot(x, data, ...)  
barchart(x, data, ...)  
stripplot(x, data, ...)  
bwplot(x, data, ...)  
```

```r
## S3 method for class 'formula'

xyplot(x,  
       data,  
       allow.multiple = is.null(groups) || outer,  
       outer = !is.null(groups),  
       auto.key = FALSE,  
       aspect = "fill",  
       panel = lattice.getOption("panel.xyplot"),  
       prepanel = NULL,  
       scales = list(),  
       strip = TRUE,  
       groups = NULL,  
)
```

Examples

```r
## Not run:  
## Show brief history of changes to lattice, including  
## a summary of new features.  
RShowDoc("NEWS", package = "lattice")  
## End(Not run)
```
dotplot(x, data, panel = lattice.getOption("panel.dotplot"),
default.prepanel = lattice.getOption("prepanel.default.dotplot"),
...
)

## S3 method for class 'formula'
stripplot(x, data, panel = lattice.getOption("panel.stripplot"),
default.prepanel = lattice.getOption("prepanel.default.stripplot"),
...
)

## S3 method for class 'formula'
bwplot(x, data, allow.multiple = is.null(groups) || outer,
outer = FALSE, auto.key = FALSE, aspect = "fill",
panel = lattice.getOption("panel.bwplot"), prepanel = NULL,
scales = list(), strip = TRUE, groups = NULL, xlab, xlim,
ylab, ylim, drop.unused.levels = lattice.getOption("drop.unused.levels"),
..., lattice.options = NULL, default.scales,
default.prepanel = lattice.getOption("prepanel.default.xyplot"),
subscripts = !is.null(groups), subset = TRUE)

## S3 method for class 'formula'
barchart(x, data, panel = lattice.getOption("panel.barchart"),
default.prepanel = lattice.getOption("prepanel.default.barchart"),
box.ratio = 2,
...
)
Arguments

x

All high-level function in lattice are generic. x is the object on which method dispatch is carried out.

For the "formula" methods, x must be a formula describing the primary variables (used for the per-panel display) and the optional conditioning variables (which define the subsets plotted in different panels) to be used in the plot. Conditioning is described in the “Details” section below.

For the functions documented here, the formula is generally of the form

\[ y \sim x ] g1 \ast g2 \ast \ldots \] (or equivalently, \( y \sim x \mid g1 + g2 + \ldots \)),

indicating that plots of y (on the y-axis) versus x (on the x-axis) should be produced conditional on the variables g1, g2, ..... Here x and y are the primary variables, and g1, g2, ... are the conditioning variables. The conditioning variables may be omitted to give a formula of the form \( y \sim x \), in which case the plot will consist of a single panel with the full dataset. The formula can also involve expressions, e.g., \( \sqrt{} \), \( \log() \), etc. See the data argument below for rules regarding evaluation of the terms in the formula.

With the exception of xyplot, the functions documented here may also be supplied a formula of the form \( \sim x \mid g1 \ast g2 \ast \ldots \). In that case, y defaults to names(x) if x is named, and a factor with a single level otherwise.

Cases where x is not a formula is handled by appropriate methods. The numeric methods are equivalent to a call with no left hand side and no conditioning variables in the formula. For barchart and dotplot, non-trivial methods exist for tables and arrays, documented at barchart.table.

The conditioning variables g1, g2, ... must be either factors or shingles. Shingles provide a way of using numeric variables for conditioning; see the help page of shingle for details. Like factors, they have a "levels" attribute, which is used in producing the conditional plots. If necessary, numeric conditioning variables are converted to shingles using the shingle function; however, using equal.count may be more appropriate in many cases. Character variables are coerced to factors.

Extended formula interface: As a useful extension of the interface described above, the primary variable terms (both the LHS y and RHS x) may consist of multiple terms separated by a '+' sign, e.g., \( y1 + y2 \sim x \mid a \ast b \). This formula would be taken to mean that the user wants to plot both \( y1 \sim x \mid a \ast b \) and
y2 ~ x | a * b, but with the y1 ~ x and y2 ~ x superposed in each panel. The two groups will be distinguished by different graphical parameters. This is essentially what the groups argument (see below) would produce, if y1 and y2 were concatenated to produce a longer vector, with the groups argument being an indicator of which rows come from which variable. In fact, this is exactly what is done internally using the `reshape` function. This feature cannot be used in conjunction with the groups argument.

To interpret y1 + y2 as a sum, one can either set `allow.multiple=FALSE` or use `I(y1+y2)`.

A variation on this feature is when the outer argument is set to TRUE. In that case, the plots are not superposed in each panel, but instead separated into different panels (as if a new conditioning variable had been added).

**Primary variables:** The x and y variables should both be numeric in `xyplot`, and an attempt is made to coerce them if not. However, if either is a factor, the levels of that factor are used as axis labels. In the other four functions documented here, exactly one of x and y should be numeric, and the other a factor or shingle. Which of these will happen is determined by the horizontal argument — if horizontal=TRUE, then y will be coerced to be a factor or shingle, otherwise x. The default value of horizontal is FALSE if x is a factor or shingle, TRUE otherwise. (The functionality provided by horizontal=FALSE is not S-compatible.)

Note that the x argument used to be called formula in earlier versions (when the high-level functions were not generic and the formula method was essentially the only method). This is no longer allowed. It is recommended that this argument not be named in any case, but instead be the first (unnamed) argument.

**data**
For the formula methods, a data frame (or more precisely, anything that is a valid `envir` argument in `eval`, e.g., a list or an environment) containing values for any variables in the formula, as well as groups and subset if applicable. If not found in data, or if data is unspecified, the variables are looked for in the environment of the formula. For other methods (where x is not a formula), data is usually ignored, often with a warning if it is explicitly specified.

**allow.multiple** Logical flag specifying whether the extended formula interface described above should be in effect. Defaults to TRUE whenever sensible.

**outer** Logical flag controlling what happens with formulas using the extended interface described above (see the entry for x for details). Defaults to FALSE, except when groups is explicitly specified or grouping does not make sense for the default panel function.

**box.ratio** Applicable to `barchart` and `bwplot`. Specifies the ratio of the width of the rectangles to the inter-rectangle space. See also the `box.width` argument in the respective default panel functions.

**horizontal** Logical flag applicable to `bwplot`, `dotplot`, `barchart`, and `stripplot`. Determines which of x and y is to be a factor or shingle (y if TRUE, x otherwise). Defaults to FALSE if x is a factor or shingle, TRUE otherwise. This argument is used to process the arguments to these high-level functions, but more importantly, it is passed as an argument to the panel function, which is expected to use it as appropriate.
A potentially useful component of scales in this case may be abbreviate = TRUE, in which case long labels which would usually overlap will be abbreviated. scales could also contain a minlength argument in this case, which would be passed to the abbreviate function.

**Common arguments:** The following arguments are common to all the functions documented here, as well as most other high-level Trellis functions. These are not documented elsewhere, except to override the usage given here.

**panel**

Once the subset of rows defined by each unique combination of the levels of the grouping variables are obtained (see “Details”), the corresponding x and y variables (or other variables, as appropriate, in the case of other high-level functions) are passed on to be plotted in each panel. The actual plotting is done by the function specified by the panel argument. The argument may be a function object or a character string giving the name of a predefined function. Each high-level function has its own default panel function, named as “panel.” followed by the name of the corresponding high-level function (e.g., `panel.xyplot`, `panel.barchart`, etc).

Much of the power of Trellis Graphics comes from the ability to define customized panel functions. A panel function appropriate for the functions described here would usually expect arguments named x and y, which would be provided by the conditioning process. It can also have other arguments. It is useful to know in this context that all arguments passed to a high-level Lattice function (such as `xyplot`) that are not recognized by it are passed through to the panel function. It is thus generally good practice when defining panel functions to allow a ... argument. Such extra arguments typically control graphical parameters, but other uses are also common. See documentation for individual panel functions for specifics.

Note that unlike in S-PLUS, it is not guaranteed that panel functions will be supplied only numeric vectors for the x and y arguments; they can be factors as well (but not shingles). Panel functions need to handle this case, which in most cases can be done by simply coercing them to numeric.

Technically speaking, panel functions must be written using Grid graphics functions. However, knowledge of Grid is usually not necessary to construct new custom panel functions, as there are several predefined panel functions which can help; for example, `panel.grid`, `panel.loess`, etc. There are also some grid-compatible replacements of commonly used traditional graphics functions useful for this purpose. For example, lines can be replaced by `llines` (or equivalently, `panel.lines`). Note that traditional graphics functions like `lines` will not work in a lattice panel function.

One case where a bit more is required of the panel function is when the groups argument is not `NULL`. In that case, the panel function should also accept arguments named groups and subscripts (see below for details). A useful panel function predefined for use in such cases is `panel.superpose`, which can be combined with different `panel.groups` functions to determine what is plotted for each group. See the “Examples” section for an interaction plot constructed in this way. Several other panel functions can also handle the groups argument, including the default ones for `xyplot`, `barchart`, `dotplot`, and `stripplot`.

Even when groups is not present, the panel function can have subscripts as a formal argument. In either case, the subscripts argument passed to
the panel function are the indices of the x and y data for that panel in the original data, BEFORE taking into account the effect of the subset argument. Note that groups remains unaffected by any subsetting operations, so groups[subscripts] gives the values of groups that correspond to the data in that panel.

This interpretation of subscripts does not hold when the extended formula interface is in use (i.e., when allow.multiple is in effect). A comprehensive description would be too complicated (details can be found in the source code of the function latticeParseFormula), but in short, the extended interface works by creating an artificial grouping variable that is longer than the original data frame, and consequently, subscripts needs to refer to rows beyond those in the original data. To further complicate matters, the artificial grouping variable is created after any effect of subset, in which case subscripts may have no relationship with corresponding rows in the original data frame.

One can also use functions called panel.number and packet.number, representing panel order and packet order respectively, inside the panel function (as well as the strip function or while interacting with a lattice display using trellis.focus etc). Both provide a simple integer index indicating which panel is currently being drawn, but differ in how the count is calculated. The panel number is a simple incremental counter that starts with 1 and is incremented each time a panel is drawn. The packet number on the other hand indexes the combination of levels of the conditioning variables that is represented by that panel. The two indices coincide unless the order of conditioning variables is permuted and/or the plotting order of levels within one or more conditioning variables is altered (using perm.cond and index.cond respectively), in which case packet.number gives the index corresponding to the 'natural' ordering of that combination of levels of the conditioning variables.

panel.xyplot has an argument called type which is worth mentioning here because it is quite frequently used (and as mentioned above, can be passed to xyplot directly). In the event that a groups variable is used, panel.xyplot calls panel.superpose, arguments of which can also be passed directly to xyplot. Panel functions for bwplot and friends should have an argument called horizontal to account for the cases when x is the factor or shingle.

aspect

This argument controls the physical aspect ratio of the panels, which is usually the same for all the panels. It can be specified as a ratio (vertical size/horizontal size) or as a character string. In the latter case, legitimate values are "fill" (the default) which tries to make the panels as big as possible to fill the available space; "xy", which computes the aspect ratio based on the 45 degree banking rule (see banking); and "iso" for isometric scales, where the relation between physical distance on the device and distance in the data scale are forced to be the same for both axes.

If a prepanel function is specified and it returns components dx and dy, these are used for banking calculations. Otherwise, values from the default prepanel function are used. Not all default prepanel functions produce sensible banking calculations.

groups

A variable or expression to be evaluated in data, expected to act as a grouping variable within each panel, typically used to distinguish different groups by varying graphical parameters like color and line type. Formally, if groups is
specified, then groups along with subscripts is passed to the panel function, which is expected to handle these arguments. For high level functions where grouping is appropriate, the default panel functions can handle grouping.

It is very common to use a key (legend) when a grouping variable is specified. See entries for key, auto.key and simpleKey for how to draw a key.

**auto.key**

A logical, or a list containing components to be used as arguments to simpleKey. auto.key=TRUE is equivalent to auto.key=list(), in which case simpleKey is called with a set of default arguments (which may depend on the relevant high-level function). Most valid components to the key argument can be specified in this manner, as simpleKey will simply add unrecognized arguments to the list it produces.

auto.key is typically used to automatically produce a suitable legend in conjunction with a grouping variable. If auto.key=TRUE, a suitable legend will be drawn if a groups argument is also provided, and not otherwise. In list form, auto.key will modify the default legend thus produced. For example, auto.key=list(columns = 2) will create a legend split into two columns (columns is documented in the entry for key).

More precisely, if auto.key is not FALSE, groups is non-null, and there is no key or legend argument specified in the call, a key is created with simpleKey with levels(groups) as the first (text) argument. (Note: this may not work in all high-level functions, but it does work for the ones where grouping makes sense with the default panel function). If auto.key is provided as a list and includes a text component, then that is used instead as the text labels in the key, and the key is drawn even if groups is not specified.

Note that simpleKey uses the default settings (see trellis.par.get) to determine the graphical parameters in the key, so the resulting legend will be meaningful only if the same settings are used in the plot as well. The par.settings argument may be useful to temporarily modify the default settings for this purpose.

One disadvantage to using key (or even simpleKey) directly is that the graphical parameters used in the key are absolutely determined at the time when the "trellis" object is created. Consequently, if a plot once created is re-plotted with different settings, the original parameter settings will be used for the key even though the new settings are used for the actual display. However, with auto.key, the key is actually created at plotting time, so the settings will match.

**prepanel**

A function that takes the same arguments as the panel function and returns a list, possibly containing components named xlim, ylim, dx, and dy (and less frequently, xat and yat). The return value of a user-supplied prepanel function need not contain all these components; in case some are missing, they are replaced by the component-wise defaults.

The xlim and ylim components are similar to the high level xlim and ylim arguments (i.e., they are usually a numeric vector of length 2 defining a range, or a character vector representing levels of a factor). If the xlim and ylim arguments are not explicitly specified (possibly as components in scales) in the high-level call, then the actual limits of the panels are guaranteed to include the limits returned by the prepanel function. This happens globally if the relation component of scales is "same", and on a per-panel basis otherwise.
The dx and dy components are used for banking computations in case aspect is specified as "xy". See documentation of `banking` for details.

If xlim or ylim is a character vector (which is appropriate when the corresponding variable is a factor), this implicitly indicates that the scale should include the first n integers, where n is the length of xlim or ylim, as the case may be. The elements of the character vector are used as the default labels for these n integers. Thus, to make this information consistent between panels, the xlim or ylim values should represent all the levels of the corresponding factor, even if some are not used within that particular panel.

In such cases, an additional component xat or yat may be returned by the prepanel function, which should be a subset of 1:n, indicating which of the n values (levels) are actually represented in the panel. This is useful when calculating the limits with relation="free" or relation="sliced" in scales.

The prepanel function is responsible for providing a meaningful return value when the x, y (etc.) variables are zero-length vectors. When nothing else is appropriate, values of NA should be returned for the xlim and ylim components.

strip A logical flag or function. If FALSE, strips are not drawn. Otherwise, strips are drawn using the strip function, which defaults to strip.default. See documentation of `strip.default` to see the arguments that are available to the strip function. This description also applies to the strip.left argument (see . . . below), which can be used to draw strips on the left of each panel (useful for wide short panels, e.g., in time-series plots).

xlab Character or expression (or a "grob") giving label(s) for the x-axis. Generally defaults to the expression for x in the formula defining the plot. Can be specified as NULL to omit the label altogether. Finer control is possible, as described in the entry for main, with the modification that if the label component is omitted from the list, it is replaced by the default xlab.

ylab Character or expression (or "grob") giving label for the y-axis. Generally defaults to the expression for y in the formula defining the plot. Finer control is possible, see entries for main and xlab.

scales Generally a list determining how the x- and y-axes (tick marks and labels) are drawn. The list contains parameters in name=value form, and may also contain two other lists called x and y of the same form (described below). Components of x and y affect the respective axes only, while those in scales affect both. When parameters are specified in both lists, the values in x or y are used. Note that certain high-level functions have defaults that are specific to a particular axis (e.g., bwplot has alternating=FALSE for the categorical axis only); these can only be overridden by an entry in the corresponding component of scales. As a special exception, scales (or its x and y components) can also be a character string, in which case it is interpreted as the relation component.

The possible components are:

relation A character string that determines how axis limits are calculated for each panel. Possible values are "same" (default), "free" and "sliced". For relation="same", the same limits, usually large enough to encompass all the data, are used for all the panels. For relation="free", limits for each panel is determined by just the points in that panel. Behavior for
relation="sliced" is similar, except that the length (max - min) of the scales are constrained to remain the same across panels.

The determination of what axis limits are suitable for each panel can be controlled by the prepanel function, which can be overridden by xlim, ylim or scales$limits (except when relation="sliced", in which case explicitly specified limits are ignored with a warning). When relation is "free", xlim or ylim can be a list, in which case it is treated as if its components were the limit values obtained from the prepanel calculations for each panel (after being replicated if necessary).

tick.number An integer, giving the suggested number of intervals between ticks. This is ignored for a factor, shingle, or character vector, for in these cases there is no natural rule for leaving out some of the labels. But see xlim.

draw A logical flag, defaulting to TRUE, that determines whether to draw the axis (i.e., tick marks and labels) at all.

alternating Usually a logical flag specifying whether axis labels should alternate from one side of the group of panels to the other. For finer control, alternating can also be a vector (replicated to be as long as the number of rows or columns per page) consisting of the following numbers
- 0: do not draw tick labels
- 1: bottom/left
- 2: top/right
- 3: both.

alternating applies only when relation="same". The default is TRUE, or equivalently, c(1, 2)

limits Same as xlim and ylim.

at The location of tick marks along the axis (in native coordinates), or a list as long as the number of panels describing tick locations for each panel.

labels Vector of labels (characters or expressions) to go along with at. Can also be a list like at.

cex A numeric multiplier to control character sizes for axis labels. Can be a vector of length 2, to control left/bottom and right/top labels separately.

font, fontface, fontfamily Specifies the font to be used for axis labels.

lineheight Specifies the line height parameter (height of line as a multiple of the size of text); relevant for multi-line labels. (This is currently ignored for cloud.)

tck Usually a numeric scalar controlling the length of tick marks. Can also be a vector of length 2, to control the length of left/bottom and right/top tick marks separately.

col Color of tick marks and labels.

rot Angle (in degrees) by which the axis labels are to be rotated. Can be a vector of length 2, to control left/bottom and right/top axes separately.

abbreviate A logical flag, indicating whether to abbreviate the labels using the abbreviate function. Can be useful for long labels (e.g., in factors), especially on the x-axis.

minlength Argument passed to abbreviate if abbreviate=TRUE.
log Controls whether the corresponding variable (x or y) will be log transformed before being passed to the panel function. Defaults to FALSE, in which case the data are not transformed. Other possible values are any number that works as a base for taking logarithm, TRUE (which is equivalent to 10), and "e" (for the natural logarithm). As a side effect, the corresponding axis is labeled differently. Note that this is in reality a transformation of the data, not the axes. Other than the axis labeling, using this feature is no different than transforming the data in the formula; e.g., scales=list(x = list(log = 2)) is equivalent to y ~ log2(x).

See entry for equispaced.log below for details on how to control axis labeling.

equispaced.log A logical flag indicating whether tick mark locations should be equispaced when ‘log scales’ are in use. Defaults to TRUE. Tick marks are always labeled in the original (untransformed) scale, but this makes the choice of tick mark locations nontrivial. If equispaced.log is FALSE, the choice made is similar to how log scales are annotated in traditional graphics. If TRUE, tick mark locations are chosen as ‘pretty’ equispaced values in the transformed scale, and labeled in the form "base^loc", where base is the base of the logarithm transformation, and loc are the locations in the transformed scale.

See also xscale.components.logpower in the latticeExtra package.

format The format to use for POSIXct variables. See strptime for description of valid values.

axs A character string, "r" (default) or "i". In the latter case, the axis limits are calculated as the exact data range, instead of being padded on either side. (May not always work as expected.)

Note that much of the function of scales is accomplished by pscales in splom.

subscripts A logical flag specifying whether or not a vector named subscripts should be passed to the panel function. Defaults to FALSE, unless groups is specified, or if the panel function accepts an argument named subscripts. This argument is useful if one wants the subscripts to be passed on even if these conditions do not hold; a typical example is when one wishes to augment a Lattice plot after it has been drawn, e.g., using panel.identify.

subset An expression that evaluates to a logical or integer indexing vector. Like groups, it is evaluated in data. Only the resulting rows of data are used for the plot. If subscripts is TRUE, the subscripts provided to the panel function will be indices referring to the rows of data prior to the subsetting. Whether levels of factors in the data frame that are unused after the subsetting will be dropped depends on the drop.unused.levels argument.

xlim Normally a numeric vector (or a DateTime object) of length 2 giving left and right limits for the x-axis, or a character vector, expected to denote the levels of x. The latter form is interpreted as a range containing c(1, length(xlim)), with the character vector determining labels at tick positions 1:length(xlim).

xlim could also be a list, with as many components as the number of panels (recycled if necessary), with each component as described above. This is meaningful only when scales$x$relation is "free", in which case these are treated
as if they were the corresponding limit components returned by prepanel calculations.

ylim  Similar to xlim, applied to the y-axis.
drop.unused.levels  A logical flag indicating whether the unused levels of factors will be dropped,
                       usually relevant when a subsetting operation is performed or an interaction
                       is created. Unused levels are usually dropped, but it is sometimes appropriate to
                       suppress dropping to preserve a useful layout. For finer control, this argument
                       could also be list containing components cond and data, both logical, indicating
                       desired behavior for conditioning variables and primary variables respectively.
                       The default is given by lattice.getOption("drop.unused.levels"), which
                       is initially set to TRUE for both components. Note that this argument does not
                       control dropping of levels of the groups argument.
default.scales  A list giving the default values of scales for a particular high-level function.
                  This is rarely of interest to the end-user, but may be helpful when defining other
                  functions that act as a wrapper to one of the high-level Lattice functions.
default.prepanel  A function or character string giving the name of a function that serves as the
                     (component-wise) fallback prepanel function when the prepanel argument is
                     not specified, or does not return all necessary components. The main purpose
                     of this argument is to enable the defaults to be overridden through the use of
                     lattice.options.
lattice.options  A list that could be supplied to lattice.options. These options are applied
                     temporarily for the duration of the call, after which the settings revert back to
                     what they were before. The options are retained along with the object and reused
                     during plotting. This enables the user to attach options settings to the trellis
                     object itself rather than change the settings globally. See also the par.settings
                     argument described below for a similar treatment of graphical settings.

...  Further arguments, usually not directly processed by the high-level functions
      documented here, but instead passed on to other functions. Such arguments can
      be broadly categorized into two types: those that affect all high-level Lattice
      functions in a similar manner, and those that are meant for the specific panel
      function being used.

The first group of arguments are processed by a common, unexported function
called trellis.skeleton. These arguments affect all high-level functions, but
are only documented here (except to override the behaviour described here).
All other arguments specified in a high-level call, specifically those neither de-
scribed here nor in the help page of the relevant high-level function, are passed
unchanged to the panel function used. By convention, the default panel function
used for any high-level function is named as “panel.” followed by the name
of the high-level function; for example, the default panel function for bwplot is
panel.bwplot. In practical terms, this means that in addition to the help page
of the high-level function being used, the user should also consult the help page
of the corresponding panel function for arguments that may be specified in the
high-level call.

The effect of the first group of common arguments are as follows:
as.table: A logical flag that controls the order in which panels should be displayed: if FALSE (the default), panels are drawn left to right, bottom to top (as in a graph); if TRUE, left to right, top to bottom (as in a table).

between: A list with components x and y (both usually 0 by default), numeric vectors specifying the space between the panels (units are character heights). x and y are repeated to account for all panels in a page and any extra components are ignored. The result is used for all pages in a multi page display. In other words, it is not possible to use different between values for different pages.

key: A list that defines a legend to be drawn on the plot. This list is used as an argument to the draw.key function, which produces a "grob" (grid object) eventually plotted by the print method for "trellis" objects. The structure of the legend is constrained in the ways described below. Although such a list can be and often is created explicitly, it is also possible to generate such a list using the simpleKey function; the latter is more convenient but less flexible. The auto.key argument can be even more convenient for the most common situation where legends are used, namely, in conjunction with a grouping variable. To use more than one legend, or to have arbitrary legends not constrained by the structure imposed by key, use the legend argument.

The position of the key can be controlled in either of two possible ways. If a component called space is present, the key is positioned outside the plot region, in one of the four sides, determined by the value of space, which can be one of "top", "bottom", "left" and "right". Alternatively, the key can be positioned inside the plot region by specifying components x, y and corner. x and y determine the location of the corner of the key given by corner, which is usually one of c(0,0), c(1,0), c(1,1) and c(0,1), which denote the corners of the unit square. Fractional values are also allowed, in which case x and y determine the position of an arbitrary point inside (or outside for values outside the unit interval) the key. x and y should be numbers between 0 and 1, giving coordinates with respect to the “display area”. Depending on the value of the "legend.bbox" option (see lattice.getOption), this can be either the full figure region (“full”), or just the region that bounds the panels and strips (“panel”).

The key essentially consists of a number of columns, possibly divided into blocks, each containing some rows. The contents of the key are determined by (possibly repeated) components named "rectangles", "lines", "points" or "text". Each of these must be lists with relevant graphical parameters (see later) controlling their appearance. The key list itself can contain graphical parameters, these would be used if relevant graphical components are omitted from the other components.

The length (number of rows) of each such column (except "text"s) is taken to be the largest of the lengths of the graphical components, including the ones specified outside (see the entry for rep below for details on this). The "text" component must have a character or expression vector as its first component, to be used as labels. The length of this vector determines the number of rows.

The graphical components that can be included in key and also in the com-
ponents named "text", "lines", "points" and "rectangles" (as appropriate) are:

- cex=1 (text, lines, points)
- col="black" (text, rectangles, lines, points)
- alpha=1 (text, rectangles, lines, points)
- fill="transparent" (lines, points)
- lty=1 (lines)
- lwd=1 (lines, points)
- font=1 (text, points)
- fontface (text, points)
- fontfamily (text, points)
- pch=8 (lines, points)
- adj=0 (text)
- type="1" (lines)
- size=5 (rectangles, lines)
- height=1 (rectangles)
- lineheight=1 (text)
- angle=0 (rectangles, but ignored)
- density=-1 (rectangles, but ignored)

In addition, the component border can be included inside the "rect" component to control the border color of the rectangles; when specified at the top level, border controls the border of the entire key (see below). angle and density are unimplemented. size determines the width of columns of rectangles and lines in character widths. type is relevant for lines; "l" denotes a line, "p" denotes a point, and "b" and "o" both denote both together. height gives heights of rectangles as a fraction of the default.

Other possible components of key are:

- reverse.rows Logical flag, defaulting to FALSE. If TRUE, all components are reversed after being replicated (the details of which may depend on the value of rep). This is useful in certain situations, e.g., with a grouped bar chart with stack = TRUE with the categorical variable on the vertical axis, where the bars in the plot will usually be ordered from bottom to top, but the corresponding legend will have the levels from top to bottom unless reverse.rows = TRUE. Note that in this case, unless all columns have the same number or rows, they will no longer be aligned.

- between Numeric vector giving the amount of space (character widths) surrounding each column (split equally on both sides).

- title String or expression giving a title for the key.

- rep Logical flag, defaults to TRUE. By default, it is assumed that all columns in the key (except the "text"s) will have the same number of rows, and all components are replicated to be as long as the longest. This can be suppressed by specifying rep=FALSE, in which case the length of each column will be determined by components of that column alone.
**legend**: The legend argument can be useful if one wants to place more than one key. It also allows the use of arbitrary "grobs" (grid objects) as legends. If used, legend must be a list, with an arbitrary number of components. Each component must be named one of "left", "right", "top", "bottom", or "inside". The name "inside" can be repeated, but not the others. This name will be used to determine the location for that component, and is similar to the space component of key. If key (or colorkey for levelplot and wireframe) is specified, their space component must not conflict with the name of any component of legend. Each component of legend must have a component called fun. This can be a "grob", or a function (or the name of a function) that produces a "grob" when called. If this function expects any arguments, they must be supplied as a list in another component called args. For components named "inside", there can be additional components called x, y and corner, which work in the same way as for key.

**page**: A function of one argument (page number) to be called after drawing each page. The function must be 'grid-compliant', and is called with the whole display area as the default viewport.

**xlab.top, ylab.right**: Labels for the x-axis on top, and y-axis on the right. Similar to xlab and ylab, but less commonly used.

**main**: Typically a character string or expression describing the main title to be placed on top of each page. Defaults to NULL.
main (as well as xlab, ylab and sub) is usually a character string or an expression that gets used as the label, but can also be a list that controls further details. Expressions are treated as specification of LaTeX-like markup as described in \texttt{plotmath}. The label can be a vector, in which case the components will be spaced out horizontally (or vertically for ylab). This feature can be used to provide column or row labels rather than a single axis label. When main (etc.) is a list, the actual label should be specified as the label component (which may be unnamed if it is the first component). The label can be missing, in which case the default will be used (xlab and ylab usually have defaults, but main and sub do not). Further named arguments are passed on to \texttt{textGrob}; this can include arguments controlling positioning like just and rot as well as graphical parameters such as col and font (see \texttt{gpar} for a full list).

\texttt{sub}: Character string or expression (or a list or "grob") for a subtitle to be placed at the bottom of each page. See entry for \texttt{main} for finer control options.

\texttt{par.strip.text}: A list of parameters to control the appearance of strip text. Notable components are \texttt{col}, \texttt{cex}, \texttt{font}, and \texttt{lines}. The first three control graphical parameters while the last is a means of altering the height of the strips. This can be useful, for example, if the strip labels (derived from factor levels, say) are double height (i.e., contains \texttt{"n"}-s) or if the default height seems too small or too large. Additionally, the \texttt{lineheight} component can control the space between multiple lines. The labels can be abbreviated when shown by specifying \texttt{abbreviate = TRUE}, in which case the components \texttt{minlength} and \texttt{dot} (passed along to the \texttt{abbreviate} function) can be specified to control the details of how this is done.

\texttt{layout}: In general, a conditioning plot in Lattice consists of several panels arranged in a rectangular array, possibly spanning multiple pages. \texttt{layout} determines this arrangement. \texttt{layout} is a numeric vector of length 2 or 3 giving the number of columns, rows, and pages (optional) in a multipanel display. By default, the number of columns is the number of levels of the first conditioning variable and the number of rows is the number of levels of the second conditioning variable. If there is only one conditioning variable, the default layout vector is \texttt{c(0,n)}, where \texttt{n} is the number of levels of the given vector. Any time the first value in the layout vector is 0, the second value is used as the desired number of panels per page and the actual layout is computed from this, taking into account the aspect ratio of the panels and the device dimensions (via \texttt{par("din")}). If \texttt{NA} is specified for the number of rows or columns (but not both), that dimension will be filled out according to the number of panels.

The number of pages is by default set to as many as is required to plot all the panels, and so rarely needs to be specified. However, in certain situations the default calculation may be incorrect, and in that case the number of pages needs to be specified explicitly.
skip: A logical vector (default FALSE), replicated to be as long as the number of panels (spanning all pages). For elements that are TRUE, the corresponding panel position is skipped; i.e., nothing is plotted in that position. The panel that was supposed to be drawn there is now drawn in the next available panel position, and the positions of all the subsequent panels are bumped up accordingly. This may be useful for arranging plots in an informative manner.

strip.left: strip.left can be used to draw strips on the left of each panel, which can be useful for wide short panels, as in time-series (or similar) plots. See the entry for strip for detailed usage.

xlab.default, ylab.default: Fallback default for xlab and ylab when they are not specified. If NULL, the defaults are parsed from the Trellis formula. This is rarely useful for the end-user, but can be helpful when developing new Lattice functions.

xscale.components, yscale.components: Functions that determine axis annotation for the x and y axes respectively. See documentation for xscale.components.default, the default values of these arguments, to learn more.

axis: Function responsible for drawing axis annotation. See documentation for axis.default, the default value of this argument, to learn more.

perm.cond: An integer vector, a permutation of 1:n, where n is the number of conditioning variables. By default, the order in which panels are drawn depends on the order of the conditioning variables specified in the formula. perm.cond can modify this order. If the trellis display is thought of as an n-dimensional array, then during printing, its dimensions are permuted using perm.cond as the perm argument does in aperm.

index.cond: Whereas perm.cond permutes the dimensions of the multidimensional array of panels, index.cond can be used to subset (or reorder) margins of that array. index.cond can be a list or a function, with behavior in each case described below.

The panel display order within each conditioning variable depends on the order of their levels. index.cond can be used to choose a 'subset' (in the R sense) of these levels, which is then used as the display order for that variable. If index.cond is a list, it has to be as long as the number of conditioning variables, and the i-th component has to be a valid indexing vector for levels(g_i), where g_i is the i-th conditioning variable in the plot (note that these levels may not contain all levels of the original variable, depending on the effects of the subset and drop.unused.levels arguments). In particular, this indexing may repeat levels, or drop some altogether. The result of this indexing determines the order of panels within that conditioning variable. To keep the order of a particular variable unchanged, the corresponding component must be set to TRUE.

Note that the components of index.cond are interpreted in the order of the conditioning variables in the original call, and is not affected by perm.cond.

Another possibility is to specify index.cond as a function. In this case, this function is called once for each panel, potentially with all arguments that are passed to the panel function for that panel. (More specifically, if this function has a ... argument, then all panel arguments are passed,
otherwise, only named arguments that match are passed.) If there is only one conditioning variable, the levels of that variable are then sorted so that these values are in ascending order. For multiple conditioning variables, the order for each variable is determined by first taking the average over all other conditioning variables.

Although they can be supplied in high-level function calls directly, it is more typical to use perm.cond and index.cond to update an existing "trellis" object, thus allowing it to be displayed in a different arrangement without re-calculating the data subsets that go into each panel. In the update.trellis method, both can be set to NULL, which reverts these back to their defaults.

par.settings: A list that could be supplied to trellis.par.set. When the resulting object is plotted, these options are applied temporarily for the duration of the plotting, after which the settings revert back to what they were before. This enables the user to attach some display settings to the trellis object itself rather than change the settings globally. See also the lattice.options argument described above for a similar treatment of non-graphical options.

plot.args: A list containing possible arguments to plot.trellis, which will be used by the plot or print methods when drawing the object, unless overridden explicitly. This enables the user to attach such arguments to the trellis object itself. Partial matching is not performed.

Details

The high-level functions documented here, as well as other high-level Lattice functions, are generic, with the formula method usually doing the most substantial work. The structure of the plot that is produced is mostly controlled by the formula (implicitly in the case of the non-formula methods). For each unique combination of the levels of the conditioning variables \( g_1, g_2, \ldots \), a separate "packet" is produced, consisting of the points \((x, y)\) for the subset of the data defined by that combination. The display can be thought of as a three-dimensional array of panels, consisting of one two-dimensional matrix per page. The dimensions of this array are determined by the layout argument. If there are no conditioning variables, the plot produced consists of a single packet. Each packet usually corresponds to one panel, but this is not strictly necessary (see the entry for index.cond above).

The coordinate system used by lattice by default is like a graph, with the origin at the bottom left, with axes increasing to the right and top. In particular, panels are by default drawn starting from the bottom left corner, going right and then up, unless as.table = TRUE, in which case panels are drawn from the top left corner, going right and then down. It is possible to set a global preference for the table-like arrangement by changing the default to as.table=TRUE; this can be done by setting lattice.options(default.args = list(as.table = TRUE)). Default values can be set in this manner for the following arguments: as.table, aspect, between, page, main, sub, par.strip.text, layout, skip and strip. Note that these global defaults are sometimes overridden by individual functions.

The order of the panels depends on the order in which the conditioning variables are specified, with \( g_1 \) varying fastest, followed by \( g_2 \), and so on. Within a conditioning variable, the order depends on the order of the levels (which for factors is usually in alphabetical order). Both of these orders
can be modified using the \texttt{index.cond} and \texttt{perm.cond} arguments, possibly using the \texttt{update} (and other related) method(s).

\section*{Value}

The high-level functions documented here, as well as other high-level Lattice functions, return an object of class "trellis". The \texttt{update} method can be used to subsequently update components of the object, and the \texttt{print} method (usually called by default) will plot it on an appropriate plotting device.

\section*{Note}

Most of the arguments documented here are also applicable for the other high-level functions in the \texttt{lattice} package. These are not described in any detail elsewhere unless relevant, and this should be considered the canonical documentation for such arguments.

Any arguments passed to these functions and not recognized by them will be passed to the panel function. Most predefined panel functions have arguments that customize its output. These arguments are described only in the help pages for these panel functions, but can usually be supplied as arguments to the high-level plot.

  par.strip.text = list(cex = 0.75),
  aspect = "iso")

## Examples with data from 'Visualizing Data' (Cleveland, 1993) obtained
## from http://cm.bell-labs.com/cm/ms/departments/sia/wsc/
\end{verbatim}
EE <- equal.count(ethanol$E, number=9, overlap=1/4)

## Constructing panel functions on the fly; prepanel
xyplot(NOx ~ C | EE, data = ethanol,
   prepanel = function(x, y) prepanel.loess(x, y, span = 1),
   xlab = "Compression Ratio", ylab = "NOx (micrograms/J)",
   panel = function(x, y) {
     panel.grid(h = -1, v = 2)
     panel.xyplot(x, y)
     panel.loess(x, y, span=1)
   },
   aspect = "xy")

## Extended formula interface
xyplot(Sepal.Length + Sepal.Width ~ Petal.Length + Petal.Width | Species,
   data = iris, scales = "free", layout = c(2, 2),
   auto.key = list(x = .6, y = .7, corner = c(0, 0)))

## user defined panel functions
states <- data.frame(state.x77,
   state.name = dimnames(state.x77)[[1]],
   state.region = state.region)
xyplot(Murder ~ Population | state.region, data = states,
   groups = state.name,
   panel = function(x, y, subscripts, groups) {
     ltext(x = x, y = y, labels = groups[subscripts], cex=1,
       fontfamily = "HersheySans")
   })

## Stacked bar chart
barchart(yield ~ variety | site, data = barley,
   groups = year, layout = c(1,6), stack = TRUE,
   auto.key = list(space = "right"),
   ylab = "Barley Yield (bushels/acre)",
   scales = list(x = list(rot = 45)))

bwplot(voice.part ~ height, data=singer, xlab="Height (inches)"
   dotplot(variety ~ yield | year * site, data=barley)

## Grouped dot plot showing anomaly at Morris

stripplot(voice.part ~ jitter(height), data = singer, aspect = 1,
## Interaction Plot

```r
defcrease ~ treatment, OrchardSprays, groups = rowpos,
  type = "a",
  auto.key =
    list(space = "right", points = FALSE, lines = TRUE))
```

## longer version with no x-ticks

```r
bwplot(decrease ~ treatment, OrchardSprays, groups = rowpos,
  panel = "panel.superpose",
  panel.groups = "panel.linejoin",
  xlab = "treatment",
  key = list(lines = Rows(trellis.par.get("superpose.line"),
    c(1:7, 1)),
    text = list(lab = as.character(unique(OrchardSprays$rowpos))),
    columns = 4, title = "Row position"))
```

## End(Not run)

---

### Time series plotting methods

**Description**

This function handles time series plotting, including cut-and-stack plots. Examples are given of superposing, juxtaposing and styling different time series.

**Usage**

```r
# S3 method for class 'ts'
xyplot(x, data = NULL,
  screens = if (superpose) 1 else colnames(x),
  ...,
  superpose = FALSE,
  cut = FALSE,
  type = "l",
  col = NULL,
  lty = NULL,
  lwd = NULL,
  pch = NULL,
  cex = NULL,
  fill = NULL,
  auto.key = superpose,
  panel = if (superpose) "panel.superpose"
```
else "panel.superpose.plain",
par.settings = list(),
layout = NULL, as.table = TRUE,
xlab = "Time", ylab = NULL,
default.scales = list(y = list(relation =
  if (missing(cut)) "free" else "same")))

Arguments

x an object of class ts, which may be multi-variate, i.e. have a matrix structure with multiple columns.
data not used, and must be left as NULL.
... additional arguments passed to xyplot, which may pass them on to panel.xyplot.
screens factor (or coerced to factor) whose levels specify which panel each series is to be plotted in. screens = c(1, 2, 1) would plot series 1, 2 and 3 in panels 1, 2 and 1. May also be a named list, see Details below.
superpose overlays all series in one panel (via screens = 1) and uses grouped style settings (from trellis.par.get("superpose.line"), etc). Note that this is just a convenience argument: its only action is to change the default values of other arguments.
cut defines a cut-and-stack plot. cut can be a list of arguments to the function equal.count, i.e. number (number of intervals to divide into) and overlap (the fraction of overlap between cuts, default 0.5). If cut is numeric this is passed as the number argument.
cut = TRUE tries to choose an appropriate number of cuts (up to a maximum of 6), using banking, and assuming a square plot region. This should have the effect of minimising wasted space when aspect = "xy".
type, col, lty, lwd, pch, cex, fill graphical arguments, which are processed and eventually passed to panel.xyplot. These arguments can also be vectors or (named) lists, see Details for more information.
auto.key a logical, or a list describing how to draw a key. See the auto.key entry in xyplot. The default here is to draw lines, not points, and any specified style arguments should show up automatically.
panel the panel function. It is recommended to leave this alone, but one can pass a panel.groups argument which is handled by panel.superpose for each series.
par.settings style settings beyond the standard col, lty, lwd, etc; see trellis.par.set and simpleTheme.
layout numeric vector of length 2 specifying number of columns and rows in the plot. The default is to fill columns with up to 6 rows.
as.table to draw panels from top to bottom. The order is determined by the order of columns in x.
xlab, ylab X axis and Y axis labels; see xyplot. Note in particular that ylab may be a character vector, in which case the labels are spaced out equally, to correspond to
the panels; but *NOTE* in this case the vector should be reversed OR the argument
as.table set to FALSE.

default.scales scales specification. The default is set to have "free" Y axis scales un-
less cut is given. Note, users should pass the scales argument rather than
default.scales.

Details

The handling of several graphical parameters is more flexible for multivariate series. These param-
eters can be vectors of the same length as the number of series plotted or are recycled if shorter.
They can also be (partially) named list, e.g., list(A = c(1, 2), c(3, 4)) in which c(3, 4) is the
default value and c(1, 2) the value only for series A. The screens argument can be specified in a
similar way.

Some examples are given below.

Value

An object of class "trellis". The update method can be used to update components of the object
and the print method (usually called by default) will plot it on an appropriate plotting device.

Author(s)

Gabor Grothendieck, Achim Zeileis, Deepayan Sarkar and Felix Andrews <felix@nfrac.org>.
The first two authors developed xyplot.ts in their zoo package, including the screens approach.
The third author developed a different xyplot.ts for cut-and-stack plots in the latticeExtra pack-
age. The final author fused these together.

Examples

xyplot(ts(c(1:10, 10:1)))

### Figure 14.1 from Sarkar (2008)
xyplot(sunspot.year, aspect = "xy",
  strip = FALSE, strip.left = TRUE,
  cut = list(number = 4, overlap = 0.05))

### A multivariate example; first juxtaposed, then superposed
xyplot(EuStockMarkets, scales = list(y = "same"))
xyplot(EuStockMarkets, superpose = TRUE, aspect = "xy", lwd = 2,
  type = c("l","g"), ylim = c(0, max(EuStockMarkets)))
### Examples using screens (these two are identical)
```r
xyplot(EuStockMarkets, screens = c(rep("Continental", 3), "UK"))
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"))
```

### Automatic group styles
```r
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
       superpose = TRUE)
```

```r
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
       superpose = TRUE, xlim = extendrange(1996:1998),
       par.settings = standard.theme(color = FALSE))
```

### Specifying styles for series by name
```r
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
       col = list(DAX = "red", FTSE = "blue", "black"), auto.key = TRUE)
```

```r
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
       col = list(DAX = "red"), lty = list(SMI = 2), lwd = 1:2,
       auto.key = TRUE)
```

### Example with simpler data, few data points
```r
set.seed(1)
z <- ts(cbind(a = 1:5, b = 1:15, c = 21:25) + rnorm(5))
xyplot(z, screens = 1)
```

```r
xyplot(z, screens = list(a = "primary (a)", "other (b & c)")
       type = list(a = c("p", "h"), b = c("p", "s"), "o"),
       pch = list(a = 2, c = 3), auto.key = list(type = "o"))
```

---

**Description**

Contingency tables are often displayed using bar charts and dot plots. These methods operate directly on tables, bypassing the need to convert them to data frames for use with the formula interface. Matrices and arrays are also supported, by coercing them to tables.

**Usage**

```r
## S3 method for class 'table'
barchart(x, data, groups = TRUE,
       origin = 0, stack = TRUE, ..., horizontal = TRUE)
```

```r
## S3 method for class 'array'
barchart(x, data, ...)
```

```r
## S3 method for class 'matrix'
barchart(x, data, ...)
```
## S3 method for class 'table'
dotplot(x, data, groups = TRUE, ..., horizontal = TRUE)

## S3 method for class 'array'
dotplot(x, data, ...)

## S3 method for class 'matrix'
dotplot(x, data, ...)

### Arguments

- **x**: A table, array or matrix object.
- **data**: Should not be specified. If specified, will be ignored with a warning.
- **groups**: A logical flag, indicating whether to use the last dimension as a grouping variable in the display.
- **origin, stack**: Arguments to `panel.barchart`. The defaults for the table method are different.
- **horizontal**: Logical flag, indicating whether the plot should be horizontal (with the categorical variable on the y-axis) or vertical.
- **...**: Other arguments, passed to the underlying formula method.

### Details

The first dimension is used as the variable on the categorical axis. The last dimension is optionally used as a grouping variable (to produce stacked barcharts by default). All other dimensions are used as conditioning variables. The order of these variables cannot be altered (except by permuting the original argument beforehand using `t` or `aperm`). For more flexibility, use the formula method after converting the table to a data frame using the relevant `as.data.frame` method.

### Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

subscripts,
subset)

## S3 method for class 'numeric'
densityplot(x, data = NULL, xlab, ...)
do.breaks(endpoints, nint)

Arguments

x

The object on which method dispatch is carried out.

For the formula method, x can be a formula of the form ~ x | g1 * g2 * ..., indicating that histograms or kernel density estimates of the x variable should be produced conditioned on the levels of the (optional) variables g1, g2, .... x should be numeric (or possibly a factor in the case of histogram), and each of g1, g2, ... should be either factors or shingles.

As a special case, the right hand side of the formula can contain more than one term separated by '+' signs (e.g., x1 + x2 | g1 * g2). What happens in this case is described in the documentation for xyplot. Note that in either form, all the terms in the formula must have the same length after evaluation.

For the numeric and factor methods, x is the variable whose histogram or Kernel density estimate is drawn. Conditioning is not allowed in these cases.

data

For the formula method, an optional data source (usually a data frame) in which variables are to be evaluated (see xyplot for details). data should not be specified for the other methods, and is ignored with a warning if it is.

type

A character string indicating the type of histogram that is to be drawn. "percent" and "count" give relative frequency and frequency histograms respectively, and can be misleading when breakpoints are not equally spaced. "density" produces a density histogram.

type defaults to "density" when the breakpoints are unequally spaced or breaks = NULL, and to "percent" otherwise.

nint

An integer specifying the number of histogram bins, applicable only when breaks is unspecified or NULL in the call. Ignored when the variable being plotted is a factor.
endpoints  A numeric vector of length 2 indicating the range of x-values that is to be covered by the histogram. This applies only when breaks is unspecified and the variable being plotted is not a factor. In do.breaks, this specifies the interval that is to be divided up.

breaks  Usually a numeric vector of length (number of bins + 1) defining the breakpoints of the bins. Note that when breakpoints are not equally spaced, the only value of type that makes sense is density. When unspecified, the default is to use

\[
\text{breaks} = \text{seq}\_\text{len}(1 + \text{nlevels}(x)) - 0.5
\]

when x is a factor, and

\[
\text{breaks} = \text{do}\_\text{breaks}(\text{endpoints}, \text{nint})
\]

otherwise. Breakpoints calculated in such a manner are used in all panels. Other values of breaks are possible, in which case they affect the display in each panel differently. A special value of breaks is NULL, in which case the number of bins is determined by nint and then breakpoints are chosen according to the value of equal.widths. Other valid values of breaks are those of the breaks argument in hist. This allows specification of breaks as an integer giving the number of bins (similar to nint), as a character string denoting a method, or as a function.

equal.widths  A logical flag, relevant only when breaks=NULL. If TRUE, equally spaced bins will be selected, otherwise, approximately equal area bins will be selected (typically producing unequally spaced breakpoints).

n  Integer, giving the number of points at which the kernel density is to be evaluated. Passed on as an argument to density.

panel  A function, called once for each panel, that uses the packet (subset of panel variables) corresponding to the panel to create a display. The default panel functions panel.histogram and panel.densityplot are documented separately, and have arguments that can be used to customize its output in various ways. Such arguments can usually be directly supplied to the high-level function.

allow.multiple, outer  See xyplot.

auto.key  See xyplot.

aspect  See xyplot.

prepanel  See xyplot.

scales  See xyplot.

strip  See xyplot.

groups  See xyplot. Note that the default panel function for histogram does not support grouped displays, whereas the one for densityplot does.

xlab, ylab  See xyplot.

xlim, ylim  See xyplot.

drop.unused.levels  See xyplot.
lattice.options
See `xyplot`.
default.scales
See `xyplot`.
subscripts
See `xyplot`.
subset
See `xyplot`.
default.prepanel
Fallback prepanel function. See `xyplot`.
weights
numeric vector of weights for the density calculations, evaluated in the non-standard manner used for groups and terms in the formula, if any. If this is specified, it is subsetted using subscripts inside the panel function to match it to the corresponding x values.
At the time of writing, weights do not work in conjunction with an extended formula specification (this is not too hard to fix, so just bug the maintainer if you need this feature).
bw, adjust, width
Arguments controlling bandwidth. Passed on as arguments to `density`.
kernel, window
The choice of kernel. Passed on as arguments to `density`.
give.Rkern
Logical flag, passed on as argument to `density`. This argument is made available only for ease of implementation, and will produce an error if TRUE.
from, to, cut
Controls range over which density is evaluated. Passed on as arguments to `density`.
na.rm
Logical flag specifying whether NA values should be ignored. Passed on as argument to `density`, but unlike in density, the default is TRUE.
...
Further arguments. See corresponding entry in `xyplot` for non-trivial details.

Details

`histogram` draws Conditional Histograms, and `densityplot` draws Conditional Kernel Density Plots. The default panel function uses the `density` function to compute the density estimate, and all arguments accepted by `density` can be specified in the call to `densityplot` to control the output. See documentation of `density` for details. Note that the default value of the argument `n` of `density` is changed to 50.

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

do.breaks is an utility function that calculates breakpoints given an interval and the number of pieces to break it into.

Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.
Note

The form of the arguments accepted by the default panel function `panel.histogram` is different from that in S-PLUS. Whereas S-PLUS calculates the heights inside `histogram` and passes only the breakpoints and the heights to the panel function, `lattice` simply passes along the original variable `x` along with the breakpoints. This approach is more flexible; see the example below with an estimated density superimposed over the histogram.

histogram(~ height | voice.part, data = singer, nint = 17,
    endpoints = c(59.5, 76.5), layout = c(2,4), aspect = 1,
    xlab = "Height (inches)")

histogram(~ height | voice.part, data = singer,
    xlab = "Height (inches)", type = "density",
    panel = function(x, ...) {
        panel.histogram(x, ...)
        panel.mathdensity(dmath = dnorm, col = "black",
            args = list(mean=mean(x),sd=sd(x)))
    })

densityplot(~ height | voice.part, data = singer, layout = c(2, 4),
    xlab = "Height (inches)", bw = 5)
```

Description

Draw quantile-Quantile plots of a sample against a theoretical distribution, possibly conditioned on other variables.
Usage

qqmath(x, data, ...)

## S3 method for class 'formula'
qqmath(x, 
    data, 
    allow.multiple = is.null(groups) || outer, 
    outer = !is.null(groups), 
    distribution = qnorm, 
    f.value = NULL, 
    auto.key = FALSE, 
    aspect = "fill", 
    panel = lattice.getOption("panel.qqmath"), 
    prepanel = NULL, 
    scales, strip, groups, 
    xlab, xlim, ylab, ylim, 
    drop.unused.levels = lattice.getOption("drop.unused.levels"), 
    ..., 
    lattice.options = NULL, 
    default.scales = list(), 
    default.prepanel = lattice.getOption("prepanel.default.qqmath"), 
    subscripts, 
    subset)

## S3 method for class 'numeric'
qqmath(x, data = NULL, ylab, ...)

Arguments

x
The object on which method dispatch is carried out.

For the "formula" method, x should be a formula of the form
~ x | g1 * g2 * ..., where x should be a numeric variable. For the
"numeric" method, x should be a numeric vector.

data
For the formula method, an optional data source (usually a data frame) in which
variables are to be evaluated (see xyplot for details). data should not be speci-
fied for the other methods, and is ignored with a warning if it is.

distribution
A quantile function that takes a vector of probabilities as argument and produces
the corresponding quantiles from a theoretical distribution. Possible values are
qnorm, qunif, etc. Distributions with other required arguments need to be pro-
vided as user-defined functions (see example with qt).

f.value
An optional numeric vector of probabilities, quantiles corresponding to which
should be plotted. This can also be a function of a single integer (represent-
ing sample size) that returns such a numeric vector. A typical value for this
argument is the function ppoints, which is also the S-PLUS default. If speci-
fied, the probabilities generated by this function is used for the plotted quantiles,
through the quantile function for the sample, and the function specified as the
distribution argument for the theoretical distribution.
f.value defaults to NULL, which has the effect of using ppoints for the quantiles of the theoretical distribution, but the exact data values for the sample. This is similar to what happens for qqnorm, but different from the S-PLUS default of f.value=ppoints.

For large x, this argument can be used to restrict the number of points plotted. See also the tails.n argument in panel.qqmath.

panel
A function, called once for each panel, that uses the packet (subset of panel variables) corresponding to the panel to create a display. The default panel function panel.qqmath is documented separately, and has arguments that can be used to customize its output in various ways. Such arguments can usually be directly supplied to the high-level function.

allow.multiple, outer
See xyplot.

auto.key
See xyplot.

aspect
See xyplot.

prepanel
See xyplot.

scales
See xyplot.

strip
See xyplot.

groups
See xyplot.

xlab, ylab
See xyplot.

xlim, ylim
See xyplot.

drop.unused.levels
See xyplot.

lattice.options
See xyplot.

default.scales
See xyplot.

subscripts
See xyplot.

subset
See xyplot.

default.prepanel
Fallback prepanel function. See xyplot.

... Further arguments. See corresponding entry in xyplot for non-trivial details.

Details

qqmath produces Q-Q plots of the given sample against a theoretical distribution. The default behaviour of qqmath is different from the corresponding S-PLUS function, but is similar to qqnorm. See the entry for f.value for specifics.

The implementation details are also different from S-PLUS. In particular, all the important calculations are done by the panel (and prepanel function) and not qqmath itself. In fact, both the arguments distribution and f.value are passed unchanged to the panel and prepanel function. This allows, among other things, display of grouped Q-Q plots, which are often useful. See the help page for panel.qqmath for further details.

This and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for xyplot, which should be consulted to learn more detailed usage.
Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

       panel = function(x, ...) {
         panel.qqmathline(x, ...)
         panel.qqmath(x, ...)
       })
```

---

**Quantile-Quantile Plots of Two Samples**

Description

Quantile-Quantile plots for comparing two Distributions
Usage

qq(x, data, ...)

## S3 method for class 'formula'
qq(x, data, aspect = "fill",
   panel = lattice.getOption("panel.qq"),
   prepanel, scales, strip,
   groups, xlab, xlim, ylab, ylim, f.value = NULL,
   drop.unused.levels = lattice.getOption("drop.unused.levels"),
   ...
   lattice.options = NULL,
   qtype = 7,
   default.scales = list(),
   default.prepanel = lattice.getOption("prepanel.default.qq"),
   subscripts,
   subset)

Arguments

x
The object on which method dispatch is carried out.
For the "formula" method, x should be a formula of the form
y ~ x | g1 * g2 * ..., where x should be a numeric variable, and y
a factor, shingle, character, or numeric variable, with the restriction that there
must be exactly two levels of y, which divide the values of x into two groups.
Quantiles for these groups will be plotted against each other along the two axes.

data
For the formula method, an optional data source (usually a data frame) in which
variables are to be evaluated (see xyplot for details).
f.value
An optional numeric vector of probabilities, quantiles corresponding to which
should be plotted. This can also be a function of a single integer (representing
sample size) that returns such a numeric vector. A typical value for this argument
is the function ppoints, which is also the S-PLUS default. If specified, the
probabilities generated by this function is used for the plotted quantiles, through
the quantile function.

f.value defaults to NULL, which is equivalent to

f.value = function(n) ppoints(n, a = 1)

This has the effect of including the minimum and maximum data values in the
computed quantiles. This is similar to what happens for qqplot but different
from the default behaviour of qq in S-PLUS.
For large x, this argument can be used to restrict the number of quantiles plotted.

panel
A function, called once for each panel, that uses the packet (subset of panel
variables) corresponding to the panel to create a display. The default panel func-
tion panel.qq is documented separately, and has arguments that can be used to
customize its output in various ways. Such arguments can usually be directly
supplied to the high-level function.

qtype
The type argument for quantile.
qq produces Q-Q plots of two samples. The default behaviour of qq is different from the corresponding S-PLUS function. See the entry for f.value for specifics.

This and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for xyplot, which should be consulted to learn more detailed usage.

Value

An object of class "trellis". The update method can be used to update components of the object and the print method (usually called by default) will plot it on an appropriate plotting device.
