#### Abstract

A generalized transformation is applied to a model Hamiltonian incorporating both local and nonlocal exciton-phonon coupling. For the application of the usual transport theory, the difference between the transformed coupling and its thermal average over the free phonon ensemble must be small. This is achieved by a temperature-dependent set of transformation coefficients defined by a transcendental equation which is soluble numerically after some approximation. Nonlocal coupling increases both the exciton binding energy and the usual band narrowing, but it also changes the band shape in a way which may introduce new minima and band broadening. The exciton velocities are then no longer related to the exciton hopping and scattering rates in the same way as in local coupling.

## I. INTRODUCTION

In a previous paper, ${ }^{1}$ we presented a theory of exciton transport ${ }^{2,3}$ in a system with local linear phonon-exciton scattering, valid in both the limit of weak coupling (where it reduces to standard band theories) ${ }^{4}$ and in the limit of strong coupling (where it reduces to the small polaron theory). ${ }^{5}$ In addition, because this theory used density matrix methods and retained the thermally averaged exciton bandwidth in the zeroth order Hamiltonian (in contrast to most treatments), the results interpolate smoothly from the weak to the strong coupling limits. Thus this theory provides an excellent first order description of exciton transport in all regimes.

The measurement of the transport of electrons and holes in aromatic hydrocarbon crystals in recent years ${ }^{6}$ has indicated that nonlocal linear phonon coupling may play a significant role in the scattering of the transporting species. Although some aspects of the theory of nonlocal scattering have been treated by Sumi, ${ }^{7}$ Metiu et al., ${ }^{8}$ Duke et al., ${ }^{9}$ Friedman, ${ }^{10}$ and Vilfan, ${ }^{11}$ there is no theory which attempts to interpolate between the two limits of band and hopping transport which includes both local and nonlocal scattering. In this paper, we begin this task by formulating zeroth order states for this problem; transport is considered in a later paper.

Local electron-phonon coupling changes the vibrations at a site where an excitation is created; for linear coupling, the equilibrium position of the vibration changes but the frequency does not. For molecular modes, this coupling corresponds to the usual vibronic coupling leading to molecular distortion in the excited state or molecular ion. For lattice modes involving the relative displacement of molecules (optic modes or the shorter-wavelength acoustic modes), this coupling corresponds to fluctuations in the exciton site shift or in the charge-carrier polarization energy. The importance of polarization energy fluctuations has been stressed several times. ${ }^{12-14}$

Nonlocal electron-phonon coupling changes the vibrations when an excitation is transferred between sites. It is usually considered conversely as a vibrational variation of the excitation transfer integral between molecules, which gives rise to the "phonon-assisted current. ${ }^{11,12,15}$ This coupling should arise mainly from lattice modes, both translational and librational.

Since lattice modes may produce simultaneous local and nonlocal coupling, in this paper we treat both types together. Our methods of deducing transport properties are outlined elsewhere. ${ }^{15}$ They require the Hamiltonian to be transformed to yield a weak residual coupling. For local coupling, the conventional polaron transformation is local in excitation operators, ${ }^{16}$ but on including nonlocal coupling we have to use a more general nonlocal transformation. ${ }^{17}$ This transformation is not only new, so far as we are aware, but it is also more complicated. The coupling term can be eliminated only in the thermal average, which means that the transformation parameters are determined only implicitly and are temperature dependent. The present paper is therefore confined to an analysis of the nonlocal polaron transformation and the polaron states it produces.

In Sec. II we describe the Hamiltonian and the transformation, evaluating certain thermal averages which determine the transformation parameters and the polaron energies. In Sec. III and the appendices we evaluate the transformation parameters algebraically by assuming that they are scalar multiples of the corresponding coupling parameters. This yields a nonlinear equation which is solved numerically in Sec. IV for a simple model distribution of nonlocal coupling parameters. The solutions are then used to calculate the polaron band structure for a simple model.

## II. HAMILTONIAN

We consider simultaneous local and nonlocal coupling to a single phonon band. The results can be extended fairly
readily to other bands which produce only local or only nonlocal coupling. With $\hbar$ taken as 1 , the Hamiltonian is

$$
\begin{align*}
H= & \sum_{n} \epsilon a_{n}^{+} a_{n}+\sum_{n, m} J_{n m} a_{n}^{+} a_{m} \\
& +\sum_{q} \omega_{q}\left(b_{q}^{+} b_{q}+1 / 2\right) \\
& +N^{-1 / 2} \sum_{n m q} \omega_{q} f_{n m}^{q} a_{n}^{+} a_{m}\left(b_{q}+b_{-q}^{+}\right) . \tag{2.1}
\end{align*}
$$

Here the operators $a_{n}^{+}$and $a_{n}$ create and destroy an excitation (exciton or charge carrier) of energy $\epsilon$ at site $n$, while the operators $b_{q}^{+}$and $b_{q}$ create and destroy a phonon of frequency $\omega_{q}$ and wave vector $q$. The quantity $J_{n m}$ is the transfer integral between sites $n$ and $m$. The last term is the elec-tron-phonon coupling, from which a factor $\omega_{q}$ has been separated for convenience. To make $H$ Hermitian, the coupling parameter must satisfy

$$
\begin{equation*}
f_{n m^{*}}^{q}=f_{m n}^{-q} \tag{2.2}
\end{equation*}
$$

and because of translational symmetry we require also

$$
\begin{equation*}
f_{n m}^{q}=e^{-i q \cdot R_{n}} f_{n-m}^{q}, \tag{2.3}
\end{equation*}
$$

where $R_{n}$ is the position vector of site $n$. Combining Eqs. (2.2) and (2.3) shows that the new coupling parameters $f_{n-m}^{q}$ in Eq. (2.3) must satisfy

$$
\begin{equation*}
f_{n-m^{*}}^{q}=e^{-i \mathbf{q} \cdot\left(\mathbf{R}_{n}-\mathbf{R}_{m}\right)} f_{m-n}^{-q} . \tag{2.4}
\end{equation*}
$$

When $n=m, f_{n m}^{q}$ and $f_{n-m}^{q}$ reduce to the usual local coupling parameters ${ }^{1} f_{n n}^{q}=g_{q}^{n}$ and $f_{0}^{q}=g_{q}$. A general expression for the nonlocal coupling parameters for translational modes has been given ${ }^{12}$ and can be extended to librational or mixed modes.

## A. Transformation

The Hamiltonian is transformed according to

$$
\begin{equation*}
H \rightarrow \widetilde{H}=e^{\mathscr{L}} H e^{-\mathscr{S}}, \tag{2.5}
\end{equation*}
$$

with

$$
\begin{equation*}
\mathscr{S}=N^{-1 / 2} \sum_{n m q} A_{n m}^{q}\left(b_{-q}^{+}-b_{q}\right) a_{n}^{+} a_{m} \tag{2.6}
\end{equation*}
$$

and the $A_{n m}^{q}$ to be determined. For a proper unitary transformation we require $\mathscr{S}^{+}=-\mathscr{S}$ which means that $A_{n m}^{q}$ must satisfy the same condition (2.2) as $f_{n m}^{q}$. Under the transformation (2.5), the phonon operators change according to

$$
\begin{align*}
& b_{q} \rightarrow b_{q}-N^{-1 / 2} \sum_{n m} A_{n m}^{-q} a_{n}^{+} a_{m},  \tag{2.7}\\
& b_{q}^{+} \rightarrow b_{q}^{+}-N^{-1 / 2} \sum_{n m} A_{n m}^{q} a_{n}^{+} a_{m},  \tag{2.8}\\
& \left(b_{q}+b_{-q}^{+}\right) \rightarrow\left(b_{q}+b_{-q}^{+}\right)-2 N^{-1 / 2} \sum_{n m} A_{n m}^{q} a_{n}^{+} a_{m}, \tag{2.9}
\end{align*}
$$

much as for local coupling. ${ }^{16}$ The excitation operators
change in a more complicated way which can, however, be deduced using techniques for handling exponential quadratic operators. ${ }^{18}$ The results are

$$
\begin{align*}
& a_{n} \rightarrow \sum_{m} \theta_{n m} a_{m},  \tag{2.10}\\
& a_{n}^{+} \rightarrow \sum_{m} \theta_{n m}^{+} a_{m}^{+}, \tag{2.11}
\end{align*}
$$

where

$$
\begin{align*}
& \theta_{n m}=\left\{\exp \left[-N^{-1 / 2} \sum_{q} \mathrm{~A}^{q}\left(b_{-q}^{+}-b_{q}\right)\right]\right\}_{n m}  \tag{2.12}\\
& \theta_{n m}^{+}=\left\{\exp \left[N^{-1 / 2} \sum_{q} \mathrm{~A}^{q}\left(b_{-q}^{+}-b_{q}\right)\right]\right\} n m \tag{2.13}
\end{align*}
$$

so that

$$
\begin{equation*}
\sum_{m} \theta_{m n}^{+} \theta_{p m}=\delta_{n p}=\sum_{m} \theta_{n m} \theta_{m p}^{+} \tag{2.14}
\end{equation*}
$$

Here $\mathrm{A}^{q}$ is the matrix of the $A_{n m}^{q}$ and the derivation of Eq. (2.13) from Eq. (2.12) uses the symmetry property (2.2) and the result $f\left(\mathrm{~A}^{T}\right)=[f(\mathrm{~A})]^{T}$, where $T$ denotes the transpose.

Translational symmetry makes it natural to consider using the exciton wave vector representation instead of the site representation. For local coupling, the advantages of the wave vector representation are outweighed by the disadvantages of having to use a nonlocal transformation instead of the local transformation in the site representation. However, for nonlocal coupling the transformation is nonlocal in either representation and use of the wave vector representation becomes preferable. The untransformed Hamiltonian can be written as

$$
\begin{align*}
\mathbf{H}= & \sum_{k} \epsilon_{k} a_{k}^{+} a_{k}+\sum_{q} \omega_{q}\left(b_{q}^{+} b_{q}+1 / 2\right) \\
& +N^{-1 / 2} \sum_{k q} \omega_{q} f_{-k}^{q}\left(b_{q}+b_{-q}^{+}\right) a_{k+q}^{+} a_{k}, \tag{2.15}
\end{align*}
$$

where $\epsilon_{k}=\epsilon+J_{k}$, with

$$
\begin{equation*}
J_{k}=\sum_{m} e^{i \mathbf{k} \cdot\left(\mathbf{R}_{n}-\mathbf{R}_{m}\right)} J_{n m} \tag{2.16}
\end{equation*}
$$

and similarly,

$$
\begin{equation*}
f_{k}^{q}=\sum_{m} e^{-i \mathbf{k} \cdot\left(\mathbf{R}_{n}-\mathbf{R}_{m}\right)} f_{n-m}^{q} . \tag{2.17}
\end{equation*}
$$

The transformation exponent becomes

$$
\begin{equation*}
\mathscr{S}=N^{-1 / 2} \sum_{k q} A_{-k}^{q}\left(b_{-q}^{+}-b_{q}\right) a_{k+q}^{+} a_{k}, \tag{2.18}
\end{equation*}
$$

where

$$
\begin{equation*}
A_{k}^{q}=\sum_{m} e^{-i(\mathbf{k}-\mathbf{g}) \cdot \mathbf{R}_{n}} e^{i \mathbf{k} \cdot \mathbf{R}_{m}} A_{n m}^{q}=\left(\boldsymbol{A}_{k-q}^{-q}\right)^{*} \tag{2.19}
\end{equation*}
$$

with corresponding changes in the transformations (2.7)(2.9). If Eq. (2.18) is written in the form

$$
\begin{equation*}
\mathscr{S}=\sum_{k k^{\prime}} a_{k}^{+} S_{k k^{\prime}} a_{k^{\prime}}, \tag{2.20}
\end{equation*}
$$

where now

$$
\begin{equation*}
S_{k k^{\prime}}=N^{-1 / 2} A_{-k}^{k-k^{\prime}}\left(b_{-k+k^{\prime}}^{+}-b_{k-k^{\prime}}^{+}\right) \tag{2.21}
\end{equation*}
$$

then the transformations (2.10) and (2.11) becomes

$$
\begin{align*}
& a_{k} \rightarrow \sum_{k^{\prime}} \theta_{k k} \cdot a_{k^{\prime}},  \tag{2.22}\\
& a_{k}^{+} \rightarrow \sum_{k^{\prime}} \theta_{k k^{\prime}}^{+} \cdot a_{k^{\prime}}^{+} \tag{2.23}
\end{align*}
$$

with

$$
\begin{align*}
& \theta_{k k^{\prime}}=[\exp (-\mathrm{S})]_{k k^{\prime}},  \tag{2.24}\\
& \theta_{k k^{\prime}}^{+}=[\exp (\mathrm{S})]_{k^{\prime} k}, \tag{2.25}
\end{align*}
$$

S being the matrix $\left\{\mathrm{S}_{k k^{\prime}}\right\}$. The operator $S_{k k^{\prime}}$ creates a net phonon momentum of $k^{\prime}-k$, and it is readily shown that the same momentum is created by [ $\left.\mathrm{S}^{n}\right]_{k k}$, for any power $n>0$ and hence by all terms in the series expansion of $\theta_{k k}$, except the first, which creates zero momentum (i.e., the first term is $\delta_{k k^{\prime}}$ ).

The transformed Hamiltonian can now be written

$$
\begin{align*}
& \widetilde{H}=\sum_{k^{\prime} k^{\prime \prime}}\left(\sum_{k} \epsilon_{k} \theta_{k k^{\prime}}^{+}, \theta_{k k^{\prime \prime}}\right) a_{k^{\prime}}^{+} a_{k^{\prime \prime}}+\sum_{q} \omega_{q}\left(b_{q}^{+} b_{q}+1 / 2\right) \\
& +N^{-1 / 2} \sum_{q k^{\prime} k^{\prime \prime}} \omega_{q}\left(\sum_{k} f_{-k^{\prime}}^{q} \theta_{k^{\prime}+k^{\prime}}^{+} \theta_{k k^{\prime}}-A_{-k^{\prime \prime}}^{q} \delta_{k^{\prime}, k^{\prime \prime}+q}\right) \\
& \times\left(b_{q}+b_{-q}^{+}\right) a_{k^{\prime}}^{+} a_{k^{\prime \prime}}+N^{-1} \sum_{q k^{\prime}} \omega_{q}\left|A_{-l^{q}}^{-q}\right|^{2} a_{k}^{+} a_{k} \\
& -2 N^{-1} \sum_{q k^{\prime} k^{\prime \prime}} \omega_{q} f_{-k}^{q} A_{-k^{\prime \prime}-q}^{-q} \theta_{k}^{+}+{ }_{q, k^{\prime}} \theta_{k k^{\prime \prime}} a_{k^{\prime} \cdot}^{+} a_{k^{\prime \prime}+q}, \tag{2.26}
\end{align*}
$$

where states with more than one excitation are ignored as
usual. As in previous work, we partition $\widetilde{H}$ into a zerothorder part $H_{0}$ and a perturabtion $V$. The correct thermal equilibrium behavior is ensured by taking $H_{0}$ as the pure excitation and phonon terms plus the thermal average of the interaction terms over the free phonon ensemble. In the thermal average, nonzero contributions entail the creation and annihilation of equal numbers of phonons for each momentum, and hence entail creation of zero net momentum. It follows that

$$
\begin{equation*}
\left\langle\theta_{k, k+q}^{+} \theta_{k^{\prime}, k^{\prime}+q^{\prime}}\right\rangle=\left\langle\theta_{k, k+q}^{+} \theta_{k^{\prime}, k^{\prime}+q}\right\rangle \delta_{q q^{\prime}}, \tag{2.27}
\end{equation*}
$$

where the angle brackets denote the thermal phonon average. This and similar results ensure that $H_{0}$ is diagonal in excitation wave vector:

$$
\begin{align*}
H_{0}= & \sum_{q} \omega q\left(b_{q}^{+} b_{q}+1 / 2\right)+\sum_{k}\left\{\left(\epsilon+\widetilde{J}_{k}\right)\right. \\
& +N^{-1} \sum_{q} \omega_{q}\left|A_{-q}^{-q}\right|^{2}-2 N^{-1} \\
& \times \sum_{q k^{\prime}} \omega_{q} f_{-k^{\prime}}^{q} A_{-\frac{q}{-q}\left\langle\theta_{k^{\prime}+q, k}^{+} \theta_{k^{\prime}, k-q}\right\rangle+N^{-1 / 2}} \\
& \left.\times \sum_{q k^{\prime}} \omega_{q} f_{-k^{\prime}}^{q}\left\langle\theta_{k^{\prime}+q, k}^{+} \theta_{k^{\prime} k}\left(b_{q}+b_{-q}^{+}\right)\right\rangle\right\} a_{k}^{+} a_{k}, \tag{2.28}
\end{align*}
$$

where the renormalized transfer integral is

$$
\begin{equation*}
\widetilde{J}_{k}=\sum_{k^{\prime}} J_{k^{\prime}}\left\langle\theta_{k^{\prime} k}^{+} \theta_{k^{\prime} k}\right\rangle \tag{2.29}
\end{equation*}
$$

and Eq. (2.19) has been used to write $A_{-{ }_{k-q}}^{-q}=\left(A_{-k}^{q}\right)^{*}$. The perturbation is then

$$
\begin{align*}
V= & \sum_{k k^{\prime} k^{\prime \prime}}\left\{J_{k} \mathrm{~T}_{k k^{\prime} ; k k^{\prime \prime}}-2 N^{-1} \sum_{q} \omega_{q} f_{-k^{q}}^{-q}\left(A_{-k^{\prime \prime}}^{q}\right) \mathrm{T}_{k+q, k^{\prime} ; k, k^{\prime \prime}-q}\right. \\
& \left.+N^{-1 / 2} \sum_{q} \omega_{q} f_{-k}^{q}\left[\mathrm{~T}_{k+q, k^{\prime} ; k k^{\prime \prime}}\left(b_{q}+b_{-q}^{+}\right)-\left\langle\mathrm{T}_{k+q, k^{\prime} ; k k^{\prime \prime}}\left(b_{q}+b_{-q}^{+}\right)\right\rangle\right]\right\} a_{k^{\prime}}^{+} a_{k^{\prime \prime}} \\
& +N^{-1 / 2} \sum_{q k^{\prime}} \omega_{q}\left[A_{-k}^{q}-\sum_{k^{\prime}} f_{-k^{\prime}}^{q}\left\langle\theta_{k^{\prime}+q, k+q}^{+} \theta_{k^{\prime} k}\right\rangle\right]\left(b_{q}+b_{-q}^{+}\right) a_{k+q}^{+} a_{k}, \tag{2.30}
\end{align*}
$$

where

$$
\begin{equation*}
\mathrm{T}_{k k^{\prime} ; u u^{\prime}}=\theta_{k k^{\prime}}^{+}, \theta_{u u^{\prime}}-\left\langle\theta_{k k^{\prime}}^{+}, \theta_{u u^{\prime}}\right\rangle . \tag{2.31}
\end{equation*}
$$

We now choose the transformation coefficients $A_{k}^{q}$. Strictly speaking, this should be done variationally as in previous work on local coupling, ${ }^{19,20}$ but we expect to retain most qualitative features of such a procedure by a more direct approach like that adopted for linear coupling. ${ }^{1}$ In that work, combinations of exponential operators similar to $\mathrm{T}_{k k^{\prime} ; u u^{\prime}}$ ensured that matrix elements of $V^{2}$ remained small for any electron-phonon coupling strength. For weak coupling the operators differ little from the unit operator and hence from their thermal average, while for strong coupling the exponentials of negative argument keep the terms small in magnitude. Similar considerations should apply to all the terms in Eq. (2.30) except the last, where the phonon displacement operator could give large contributions. This possibility is eliminated by the choice

$$
\begin{equation*}
A_{-k}^{q}=\sum_{k^{\prime}} f_{-k^{\prime}}^{q}\left\langle\theta_{k^{\prime}+q, k+q}^{+} \theta_{k^{\prime} k}\right\rangle, \tag{2.32}
\end{equation*}
$$

which makes the last term zero. This defines the transformation coefficients only implicitly, since the exponential operators $\theta_{k k}$. depend on $A_{k}^{q}$.

With the choice of Eq. (2.32), $H_{0}$ becomes

$$
\begin{align*}
H_{0}= & \sum_{k}\left(\epsilon+\widetilde{J}_{k}-N^{-1} \sum_{q}\left|A_{-q}^{-q}\right|^{2}\right) a_{k}^{+} a_{k}+\sum_{q} \omega_{q}\left(b_{q}^{+} b_{q}+\frac{1}{2}\right) \\
& +N^{-1 / 2} \sum_{q k k} \omega_{q} f_{-k^{\prime}}^{q}\left\langle\theta_{k^{\prime}+q, k}^{+} \theta_{k^{\prime} k}\left(b_{q}+b_{-q}^{+}\right)\right\rangle a_{k}^{+} a_{k} . \tag{2.33}
\end{align*}
$$

The form resembles that for local coupling, with a renormalized transfer integral and a polaron-like energy lowering or binding from the term in $\left|A_{-k}^{-q}\right|^{2}$. However, in contrast to the earlier case, the dependence on $\mathbf{k}$ in this latter term affects the band shape as well as its absolute energy. The last
term in Eq. (2.33) has no counterpart for local coupling, but is found below to vanish identically. The form of $V$ becomes

$$
\begin{align*}
V= & \sum_{k k^{\prime} k^{\prime \prime}}\left\{J_{k} \mathrm{~T}_{k k^{\prime} ; k k^{*}}-2 N^{-1} \sum_{q} \omega_{q} f_{-k^{\prime}}^{q} A_{-k^{\prime}{ }^{-q} \mathrm{~T}_{k+q, k^{\prime} ; k, k^{\prime \prime}-q}}\right. \\
& +N^{-1} \sum_{q} \omega_{q} f_{-k}^{q}\left[\mathrm{~T}_{k+q, k^{\prime} ; k k^{\prime \prime}}\left(b_{q}+b_{-q}^{+}\right)\right. \\
& \left.\left.-\left\langle\mathrm{T}_{k+q, k^{\prime} ; k k^{\prime \prime}}\left(b_{q}+b_{-q}^{+}\right)\right\rangle\right]\right\} a_{k^{\prime}}^{+} a_{k^{\prime \prime}}, \tag{2.34}
\end{align*}
$$

where the last term in square brackets will also be found to vanish. By construction, $\langle V\rangle=0$.

Now, we collect all the term of $H_{0}$ and $V$, using the definitions and calculations of thermal averages of Appendix A. The zeroth-order Hamiltonian becomes

$$
\begin{equation*}
H_{0}=\sum_{k} \tilde{\epsilon}_{k} a_{k} a_{k}+\sum_{q} \omega_{q}\left(b_{q}^{+} b_{q}+\frac{1}{2}\right) \tag{2.35}
\end{equation*}
$$

where

$$
\begin{equation*}
\tilde{\epsilon}_{k}=\epsilon+\tilde{J}_{k}-N^{-1} \sum_{q}\left|A_{k}^{q}\right|^{2} \omega_{q} . \tag{2.36}
\end{equation*}
$$

From Eqs. (2.29), (A18), and (A24) the renormalized transfer integral is found after some manipulation to be given by

$$
\begin{equation*}
\widetilde{J}_{k}=\sum_{k^{\prime}}\left\langle\theta_{k}\right\rangle^{2}\left(\exp E^{0}\right)_{k k^{\prime}} J_{k^{\prime}} \tag{2.37}
\end{equation*}
$$

The perturbation becomes

$$
\begin{align*}
V= & \sum_{k k^{\prime} k^{\prime}}\left\{J_{k} \mathrm{~T}_{k k^{\prime} ; k k^{\prime \prime}}-2 N^{-1} \sum_{q} \omega_{q} f_{-k}^{q} A_{-k^{\prime}}^{-q} \mathrm{~T}_{k+q, k^{\prime} ; k_{1} k^{\prime \prime}-q}\right. \\
& \left.+N^{-1 / 2} \sum_{q} \omega_{q} f_{-k}^{q} \mathrm{~T}_{k+q, k^{\prime} ; k k^{\prime}}\left(b_{q}+b_{-q}^{+}\right)\right\} a_{k^{\prime}}^{+} a_{k}^{\prime \prime}, \tag{2.38}
\end{align*}
$$

where the second term can be regarded as modifying the transfer integral. ${ }^{21,22}$

## III. TRANSFORMATION PARAMETERS AND APPROXIMATIONS

Since Eq. (A25) gives the transformation parameters $A_{q}^{Q}$ implicitly in terms of an exponential matrix function, an exact algebraic solution seems unlikely to be easily obtained. In this section, we examine the properties of the coupling parameters $f_{q}^{Q}$ and reasonable approximations for them. We then argue that the $A_{q}^{Q}$ must behave similarly and proceed with the calculation. In Appendix B, a test of the approximations is made.

The local and nonlocal parts of the coupling parameters $f_{n-m}^{Q}$ can be separated according to ${ }^{12}$

$$
\begin{equation*}
f_{n-m}^{Q}=g_{Q} \delta_{n m}+\left[1-e^{i \mathbf{Q} \cdot\left(\mathbf{R}_{n}-\mathbf{R}_{m}\right)}\right] \phi_{n-m}^{Q} \tag{3.1}
\end{equation*}
$$

Here $\phi_{n-m}^{Q}$ is related to the derivative of $J_{n m}$ with respect to the relative displacements (translational, rotational, or mixed) at sites $n$ and $m$ in mode $Q$ of the phonon branch in question. From Eq. (2.4) it follows that

$$
\begin{align*}
& g_{Q}^{*}=g_{-Q},  \tag{3.2}\\
& \phi_{n-m}^{Q *}=-\phi_{m-n}^{-Q} . \tag{3.3}
\end{align*}
$$

With these results we find

$$
\begin{align*}
f_{q}^{q-q^{\prime}} & =g_{q-q^{\prime}}+\sum_{r}\left(e^{-i \mathbf{q} \cdot \mathbf{R}_{r}}-e^{-i q^{\prime} \cdot \mathbf{R}_{r}} \phi_{r}^{q-q^{\prime}}\right.  \tag{3.4}\\
& \equiv g_{q-q^{\prime}}-i\left(\phi_{q}^{q-q^{\prime}}-\phi_{q^{\prime}}^{q-q^{\prime}}\right) \tag{3.5}
\end{align*}
$$

where $g_{q-q^{\prime}}$ and $\phi_{q}^{q-q^{\prime}}$ are real if $g_{q}$ and $\phi_{r}^{q}$ are symmetric in $q$.

At least for optic modes, the dispersion in $g_{q}$ and $\phi_{r}^{q}$ should be small and these quantities can be replaced by suitable averages over $q$. For example, the Hamiltonian used by Sumi ${ }^{7}$ has coupling parameters independent of phonon wave vector. Then we obtain

$$
\begin{equation*}
f_{q}^{q-q^{\prime}} \approx g-i\left(\phi_{q}-\phi_{q^{\prime}}\right), \tag{3.6}
\end{equation*}
$$

where now $\phi_{q}$ is odd in $q$. This expression yields $g$ as either $f_{q}^{0}$ or the average of $f_{\lambda}^{q}$ over $q$. From Eqs. (2.32) and (3.6), we find that $A_{\lambda}^{0}=g$ for all $\lambda$. We then assume that $A_{\lambda}^{q}$ can be written by analogy with Eq. (3.6) as

$$
\begin{equation*}
A_{\lambda}^{q}=g-i \eta\left(\phi_{\lambda}-\phi_{\lambda-q}\right) \tag{3.7}
\end{equation*}
$$

this proves to be a self-consistent assumption to within a weakly $q$ dependent factor.

With these assumptions, the matrix $E^{Q}$ of Eq. (A24) has elements

$$
\begin{align*}
E_{\lambda q}^{Q}= & N^{-1}(2 n+1)\left[g-i \eta\left(\phi_{q-Q}-\phi_{\lambda-Q}\right)\right] \\
& \times\left[g+i \eta\left(\phi_{q}-\phi_{\lambda}\right)\right] \tag{3.8}
\end{align*}
$$

where we have also assumed that the weak dispersion allows $n_{q-\lambda}$ to be replaced by an average $n$. For $Q=0, \mathrm{E}^{Q}$ is real, with elements

$$
\begin{equation*}
E_{\lambda q}^{0}=N^{-1}(2 n+1)\left[g^{2}+\eta^{2}\left(\phi_{q}-\phi_{\lambda}\right)^{2}\right] . \tag{3.9}
\end{equation*}
$$

For later use it is convenient to expand Eq. (3.8) and collect together factors dependent on $\lambda$ and $\mathbf{q}$ together.

$$
\begin{align*}
E_{\lambda q}^{Q}= & N^{-1}(2 n+1)\left[g^{2}+V_{\lambda}^{Q}\right. \\
& \left.+V_{q}^{Q^{*}}-\eta^{2}\left(\phi_{\lambda} \phi_{q-Q}+\phi_{q} \phi_{\lambda-Q}\right)\right] \tag{3.10}
\end{align*}
$$

where

$$
\begin{equation*}
V_{\lambda}^{Q}=\eta^{2} \phi_{\lambda} \phi_{\lambda-Q}-i g \eta\left(\phi_{\lambda}-\phi_{\lambda-Q}\right) . \tag{3.11}
\end{equation*}
$$

In order to test the approximation of Eq. (3.7) we compute $A_{\lambda}^{0}$ in Appendix B, and in Sec. IV compare the values of $A_{\lambda}^{0}$ with $g$ for various values of the parameters. It is seen there that our assumption of Eq. (3.7) yields self-consistent results for all parameters.

In order to determine $H_{0}$ explicitly, we must still compute $\widetilde{J}_{\lambda}$ and $A_{k}^{q}$ which require an evaluation of $\eta$. Because the expressions for all these quantities are quite complicated, the dependence of these terms on the bandwidth, phonon frequencies, and coupling parameters are best displayed as numerically computed figures, rather than mathematical expressions. We therefore relegate the algebra to the appendices and proceed to the numerical evaluations of Sec . IV. In Appendix $\mathbf{C}$, a self-consistent expression is derived for $\eta$ which is numerically evaluated in Sec. IV. Finally in Appendix $D$, we evaluate $\widetilde{J}_{\lambda}$, completing our evaluation of the terms in $H_{0}$.

## IV. NUMERICAL CALCULATIONS

## A. Coupling parameters

For numerical calculations it is necessary to specify a distribution for the nonlocal coupling parameters. In Ref. 1 we used Gaussian distributions of energy for analytical convenience. However, since the $\phi_{\lambda}$ are antisymmetric in $\lambda$, a pair of Gaussians would be required to represent the distribution, with maximum densities of states intermediate between the zone center and the zone boundary in opposite directions. For the present purposes it is therefore simpler to take

$$
\begin{equation*}
\phi_{\lambda}=\phi \sin \lambda . \tag{4.1}
\end{equation*}
$$

It follows that

$$
\begin{align*}
& N^{-1} \sum_{\lambda} \phi_{\lambda}^{2}=\frac{1}{2} \phi^{2},  \tag{4.2}\\
& N^{-1} \sum_{\lambda} \phi_{\lambda}^{4}=\frac{3}{8} \phi^{4}, \tag{4.3}
\end{align*}
$$

and hence

$$
\begin{align*}
& V^{0}=\frac{1}{2} \eta^{2} \phi^{2}  \tag{4.4}\\
& F^{0}=g^{2}+\eta^{2} \phi^{2}  \tag{4.5}\\
& G^{0}=\frac{1}{8} \eta^{4} \phi^{4}=\frac{1}{2}\left(V^{0}\right)^{2} \tag{4.6}
\end{align*}
$$

and so on.
The scaling parameter $\eta$ is obtained as the solution of Eq. (C33). In the limit of very weak local coupling $g \ll \phi$, $F^{0} \approx 2 V^{0}$ so that $X \approx 0$ but $g^{2} c_{ \pm} \approx 0$ also. Then Eq. (C33) reduces to

$$
\begin{equation*}
\eta=\exp \left[-\left(n+\frac{1}{2}\right) \phi^{2}\left(2-\eta^{2}\right) \eta^{2}\right] \tag{4.7}
\end{equation*}
$$

the solutions of which are plotted in Fig. 1 as a function of ( $\left.n+\frac{1}{2}\right) \phi^{2}$; solutions for $\eta^{2} \geqslant 2$ are excluded by continuity. It is seen that $\eta$ falls farther and farther below unity as $n$ and $\phi$ increase. However, for $n$ fixed, $\eta$ decreases slightly less rapidly than $\phi$ increases, so that the product $\eta \phi$ determining the transformation parameters increases steadily with $\phi$ (roughly like $\ln \phi$ ).

The solutions for $\eta$ as a function of $g$ for different values of $\phi$ are plotted for different temperatures in Figs. 2-4. The parameter $\eta$ shows varied by systematic behavior, decreasing from the initial value given in Fig. 1 for $g=0$ as $g$ increases. As $\phi$ increases, $\eta$ decreases for a given value of $g$, and as $T$ increases, $\eta$ decreases more rapidly with $g$ for a given value of $\phi$. In all cases, the product $\eta \phi$ determining the transformation parameters increases with increasing $\phi$, though less rapidly than $\phi$ itself.

Although in the present treatment the transformation parameters are not optimized in any variational sense, they can be regarded as effecting a compromise between the conflicting aspects of nonlocal coupling. On the one hand, elec-tron-phonon coupling tends to produce localization, but on the other hand, nonlocal coupling tends to increase the kinetic energy and so produce delocalization. ${ }^{23}$ Because of this equivocal nature of nonlocal coupling, $\eta$ must be less than unity.

Figures 2-4 also show the calculated values of the test

FIG. 1. Scaling parameter $\eta$ as a function of $(n+1 / 2) \phi^{2}$ for zero local coupling ( $g=0$ ).
parameter $\xi$ introduced in Appendix B. It is essentially unity for all values of $\phi$ and $T$ when $g \geqslant 1$, and deviates by no more than $15 \%$ for smaller values of $g$. The deviation from unity is larger for larger values of $\phi$; hence the approximate form assumed for $A_{\lambda}^{q}$ appears to be largely justified as far as this test goes.

## B. Polaron band

The states in the transformed zeroth-order Hamilton$\operatorname{ian} H_{0}$ have energies $\epsilon_{\lambda}$ given by Eq. (2.36), which with the present assumptions for $A_{\lambda}^{q}$ reduces to

$$
\begin{equation*}
\epsilon_{\lambda}=\epsilon+\widetilde{J}_{\lambda}-N^{-1} \sum_{q} \omega_{q}\left[g^{2}+\eta^{2}\left(\phi_{\lambda}-\phi_{\lambda-q}\right)^{2}\right] \tag{4.8}
\end{equation*}
$$

Using Eq. (4.1) for $\phi_{\lambda}$ and ignoring the dispersion in $\omega_{q}$ leads to

$$
\begin{equation*}
\epsilon_{\lambda}=\epsilon+\widetilde{J}_{\lambda}-\omega\left(g^{2}+\frac{1}{2} \eta^{2} \phi^{2}+\eta^{2} \phi^{2} \sin ^{2} \lambda\right) . \tag{4.9}
\end{equation*}
$$

FIG. 2. Test and scaling parameters $\xi$ and $\eta$ as functions of local coupling parameter $g$ for different nonlocal coupling parameters $\phi$ at $T / \omega=1$. The curves are marked with the value of $\phi$. The upper three curves show $\xi$, the second and third down corresponding to $\phi=1$ and $\phi=0.3$, respectively. The lower three curves show $\eta$.

FIG. 3. Same as Fig. 2 but at $T / \omega=3$.

The polaron transfer integral $\widetilde{J}_{\lambda}$ is given by Eq. (D5). For simplicity we assume

$$
\begin{equation*}
J_{\lambda}=J \cos \lambda, \tag{4.10}
\end{equation*}
$$

where $J$ is the bare transfer integral, in which case the parameter $M$ defined by Eq. (D4) is zero. Substitution for quantities determining $E_{\lambda}^{0}$ in Eq. (B6) then yields
$\widetilde{J}_{\lambda}=J \exp \left[-(2 n+1)\left(g^{2}+\frac{1}{2} \eta^{2} \phi^{2}+\eta^{2} \phi^{2} \sin ^{2} \lambda\right] \cos \lambda\right.$.
Equations (4.9) and (4.11) together can be written as

$$
\begin{align*}
\epsilon_{\lambda}= & \epsilon^{\prime}+J^{\prime} \exp \left[-(2 n+1) \eta^{2} \phi^{2} \sin ^{2} \lambda\right] \\
& \times \cos \lambda-\omega \eta^{2} \phi^{2} \sin ^{2} \lambda, \tag{4.12}
\end{align*}
$$

where

$$
\begin{align*}
& \epsilon^{\prime}=\epsilon-\omega\left(g^{2}+\frac{1}{2} \eta^{2} \phi^{2}\right),  \tag{4.13}\\
& J^{\prime}=J \exp \left[-(2 n+1)\left(g^{2}+\frac{1}{2} \eta^{2} \phi^{2}\right)\right] . \tag{4.14}
\end{align*}
$$

These expressions illustrate the conclusions reached at the end of Sec. III. The nonlocal coupling produces an additional polaron binding energy through the additional term in

FIG. 4. Same as Fig. 2 but at $T / \omega=5$.
$\eta^{2} \phi^{2}$ in $\epsilon^{\prime}$. The last term in Eq. (4.12) can also be regarded as an additional binding energy which is largest midway between the Brillouin zone center and the zone boundary. Similarly, the same factors produce an additional and nonuniform polaron band narrrowing.

The wave vector dependent binding energy may change the band structure qualitatively as well as quantitatively. ${ }^{17}$ Differentiation of $\epsilon_{\lambda}$ with respect to $\lambda$ shows that the band has extrema at the zone center and the zone boundary, as usual, and also at wave vectors satisfying

$$
\begin{align*}
& J^{\prime} \exp \left[-(2 n+1) \eta^{2} \phi^{2} \sin ^{2} \lambda\right] \\
& \quad \times\left[1+(2 n+1) 2 \eta^{2} \phi^{2} \cos ^{2} \lambda\right]+2 \omega \eta^{2} \phi^{2} \cos \lambda=0 \tag{4.15}
\end{align*}
$$

The first term here takes the signs of $J$ ' and hence of $J$ (which determines whether the bottom of the bare band is at the zone center or the zone boundary), while the second terms takes both positive and negative signs as $\lambda$ varies. The equation therefore has a real solution provided $J^{\prime}$ is not too large compared with $\omega \eta^{2} \phi^{2}$, a situation favored by small $J$, large $\omega$, and large $\phi$. The additional extremum is the new band minimum, which moves in from the zone boundary or out from the zone center (according as $J$ is positive or negative), leaving these as local maxima. As $J$ becomes smaller, the minimum moves closer to the point $\lambda=\pi / 2$, midway between the center and the boundary.

The changes can also be understood directly from Eq. (4.12) for $\epsilon_{\lambda}$. The last term on the right-hand side lowers the energy, and produces a new minimum provided it increases in magnitude faster than the second term on the right-hand side-which is the condition expressed by Eq. (4.15). One consequence of these changes is an additional peak in the density of polaron states at the new minimum, together with a widening of the band. This contrasts with the local polaron transformation which always narrows the band.

The band structure is illustrated in Figs. 5-7. Figure 5 shows how the band structure changes with $\phi$ for fixed values of $J, g$, and $T$. The quantity plotted is $\epsilon_{\lambda}^{\prime}=\left(\epsilon_{\lambda}-\epsilon^{\prime}\right) / \omega$, which equals $J^{\prime} / \omega$ for $\lambda=0$ and $-J^{\prime} / \omega$ for $\lambda=\pi$. The val-

FIG. 5. Polaron band structure and nonlocal coupling. Reduced energy $\epsilon^{\prime}=\left[\varepsilon_{\lambda}-\varepsilon^{\prime}\right) / \omega$ as function of wave vector $\lambda$ for different nonlocal coupling parameters $\phi$, marked on the curves; $J / \omega / 1, g=1, T / \omega=1$.

FIG. 6. Polaron band shape and transfer integral. Relative energy $\epsilon_{\lambda}^{\prime \prime}=\left(\epsilon_{\lambda}-\epsilon^{\prime}\right) / J^{\prime}$ as a function of wave vector $\lambda$ for different transfer integrals $J$, marked on the curves; $g=1, \phi=1, T / \omega=1$.
ue of $J^{\prime}$ decreases slightly as $\phi$ increases, through the increase in the product $\eta \phi$, and the condition for a new band minimum is satisfied before $\phi$ reaches 1 . For $\phi=3$ the minimum is deeper and close to $\lambda=\pi / 2$, making the bandwidth nearly double its value for $\phi=0$. This effect is particularly marked because $J^{\prime} \approx 0.1 \omega$ whereas the extra binding energy varies like $\omega$; for smaller $g$ and lower $T, J^{\prime}$ is larger and the band shape changes less markedly, acquiring a new minimum only for a very large $\phi$, while for larger $g$ and higher $T, J^{\prime}$ is smaller and the band has a new minimum for all but the smallest $\phi$.

Figure 6 shows how the band shape changes with $J$ for fixed values of $g, \phi$, and $T$. The quantity plotted is $\epsilon_{\lambda}^{\prime \prime}=\left(\epsilon_{\lambda}-\epsilon^{\prime}\right) / J^{\prime}$ in order to make the changes more readily comparable than if an absolute energy scale were used. As $J$ decreases, a new band minimum develops, deepens, and moves towards $\lambda=\pi / 2$. The changes are more marked than when $\phi$ changes because there is no offsetting change in $\phi$.

FIG. 7. Polaron band shape and temperature. Relative energy $\epsilon^{\prime \prime}=\left(\epsilon_{\lambda}-\epsilon^{\prime}\right) / J^{\prime}$ as a function of wave vector $\lambda$ for different temperatures $T / \omega$, marked on the curves; $J / \omega=1, g=1, \phi=0.3$.

Figure 7 shows how the band shape, again plotted as $\epsilon_{\lambda}^{\prime \prime}$, changes with $T$ for fixed values of $J, g$, and $\phi$. As $T$ increases, $J^{\prime}$ decreases faster than $\eta$ does, and a new band minimum develops as before. The effects in Figs. 6 and 7, like those in Fig. 5, are less marked for other parameter sets, which tend to produce a new minimum for practically all values or for practically none. It is to be expected that the main qualitative changes should occur for parameters all of the same magnitude. $(J / \omega \approx 1, T / \omega \approx 1, g \approx 1, \phi \approx 1)$ as in the figures.

## V. DISCUSSION

We have shown here the consequences of applying a nonlocal polaron transformation to a model Hamiltonian incorporating both local and nonlocal coupling. With a view to applications in transport theory, the transformed Hamiltonian has been partitioned according to our previous prescription. ${ }^{1}$ Various differences from pure local coupling are seen, all in the direction of greater complexity. To ensure a perturbation which can reasonably be treated as small in transport theory, a temperature-dependent transformation is required, more like the variationally optimized local transformation than the simple explicit clothing with constant transformation parameters used before. ${ }^{1}$ Even to evaluate the transformation parameters for nonlocal coupling has required approximations, though it is hoped that these are of only minor and quantitative significance, as suggested by the test parameter $\xi$.

The rest of this paper has concentrated on the nature of the polaron states. Nonlocal coupling displays ambivalence between binding and transfer effects. Even for a simple bare band structure and a simple distribution of coupling parameters, the band structure may change significantly in width, shape, and density of states. This has consequences for transport theorys, where obtaining tractable results has often depended on using simple model densities of polaron states which may be qualitatively unsuitable with nonlocal coupling.

Transport depends also on correlation functions of the form $\left\langle V_{k k^{\prime}}(t) V_{q q^{\prime}}\right\rangle$. The perturbation $V$ has not been discussed here in detail. For weak nonlocal coupling, the polaron transformation becomes purely local, and the first two terms in $V$ can be interpreted as involving a modified transfer integral which may be bigger or smaller than $J$ itself, depending on the relative signs of local and nonlocal coupling. This agrees with previous work in this limit, ${ }^{21,24}$ which in turn agrees with other results on transport. ${ }^{12}$ One consequence of the form of $V$ is that the polaron hopping and scattering rates are no longer governed by the same parameter as the polaron velocities once there is nonlocal coupling for local coupling $J$ governs all these quantities. The detailed application of the present results to transport is in hand.

## APPENDIX A: EVALUATION OF THERMAL AVERAGES

It is necessary to evaluate the thermal averages not only to complete the specification of $H_{0}$ and $V$ but also to obtain a
useful equation determining the $A \underset{\lambda}{q}$. This is complicated by the need to take matrix elements of two exponential functions separately while taking their thermal average simultaneously. We require averages like

$$
\begin{equation*}
\left\langle\theta_{k k^{\prime}}^{+}, \theta_{q q^{\prime}}\right\rangle=\left\langle(\exp S)_{k^{\prime} k}(\exp -S)_{q q^{\prime}}\right\rangle \tag{A1}
\end{equation*}
$$

The two exponents differ only in signs, and hence commute, so that they can be combined into a single exponent as

$$
\begin{equation*}
\left\langle\theta_{k k^{\prime}}^{+}, \theta_{q q^{\prime}}\right\rangle=\left\langle\exp \left(\mathrm{S}-\mathrm{S}^{\prime}\right)\right\rangle_{k^{\prime} k ; q q^{\prime}}, \tag{A2}
\end{equation*}
$$

where the $k^{\prime} k$ matrix element of all functions of $S$ is implied and the $q q^{\prime}$ matrix element of all functions of $\mathrm{S}^{\prime}$. Now $\mathrm{S}=\mathrm{T}-\mathrm{U}$, where

$$
\begin{align*}
& T_{k k^{\prime}}=N^{-1 / 2} A_{-k^{\prime}}^{k-k^{\prime}} b_{-k+k^{\prime}}^{+}  \tag{A3}\\
& U_{k k^{\prime}}=N^{-1 / 2} A_{-k^{\prime}}^{k-k^{\prime}} b_{k-k^{\prime}} \tag{A4}
\end{align*}
$$

so that with similar definitions for $T^{\prime}$ and $U^{\prime}$ from $S^{\prime}$ we find

$$
\begin{equation*}
\left\langle\theta_{k k^{\prime}}^{+}, \theta_{q q^{\prime}}\right\rangle=\left\langle\exp \left[\left(\mathrm{T}-\mathrm{T}^{\prime}\right)-\left(\mathrm{U}-\mathrm{U}^{\prime}\right)\right]\right\rangle_{k^{\prime} k ; q q^{\prime}} \tag{A5}
\end{equation*}
$$

Here $T-T^{\prime}$ involves only creation operators and $\left(U-U^{\prime}\right)$ only annihilation operators; these two matrix operators are Hermitian conjugates which commute with their commutator and hence satisfy the relation for operators $L$ of this type

$$
\begin{equation*}
\left\langle\exp \left(L^{+}-L\right)\right\rangle=\exp -\frac{1}{2}\left\langle\left(L^{+} L+L L^{+}\right)\right\rangle, \tag{A6}
\end{equation*}
$$

where the exponent now conserves the number of phonons.
The exponent in Eq. (A5) can then be written as a sum of exponents which with Eq. (A6) can be factorized to yield

$$
\begin{align*}
\left\langle\theta_{k k^{\prime}}^{+}, \theta_{q q^{\prime}}\right\rangle= & {[\exp \langle\mathrm{TU}+\mathrm{TU}\rangle]_{k^{\prime} k^{\prime}} } \\
& \times\left[\exp \frac{1}{2}\left\langle T U^{\prime}+U U^{\prime}+\mathrm{T}+\mathrm{T}^{\prime} U+U T^{\prime}\right\rangle\right]_{k^{\prime} k ; q q^{\prime}} \\
& \times\left[\exp \frac{1}{2}\left\langle\mathrm{~T}^{\prime} U^{\prime}+U^{\prime} T^{\prime}\right\rangle\right]_{q^{\prime} q^{\prime}}, \tag{A7}
\end{align*}
$$

where momentum conservation makes the first and last factors diagonal. These factors can be seen to be the thermal averages of $\theta_{k^{\prime} k^{\prime}}^{+}$and $\theta_{q^{\prime} q^{\prime}}$ separately, and are evaluated as

$$
\begin{align*}
\left\langle\theta_{-k}^{+}\right\rangle & \equiv\left[\exp -\frac{1}{2}\langle\mathrm{TU}+\mathrm{UT}\rangle\right]_{k k}=\left\langle\theta_{-k}\right\rangle  \tag{A8}\\
& =\exp \left[-N^{-1} \sum_{q}\left(n_{q}+\frac{1}{2}\right)\left|A_{-k}^{-q}\right|^{2}\right] \tag{A9}
\end{align*}
$$

with $n_{q}=\left[\exp \left(\beta \omega_{q}\right]-1\right]^{-1}$ and $\beta=1 / k_{B} T$. This expression resembles the Franck-Condon factor obtained for local coupling, apart from the dependence on $k$.

In the middle factor of Eq. (A7) the order of primed and unprimed matrix operators affects the thermal average, with terms like $T U^{\prime}$ giving contributions proportional to $n$ and terms like U'T giving contributions proportional to $n+1$. Their sum gives contributions proportional to $2 n+1$, so that it suffices to study $\langle\exp$ TU'〉 and then replace $n$ by $2 n+1$ everywhere. The zeroth-order term is

$$
\begin{equation*}
\delta_{k^{\prime} k} \delta_{q q^{\prime}}=\delta_{k k^{\prime}} \delta_{k-k^{\prime}, q-q^{\prime}} \tag{A10}
\end{equation*}
$$

where the factor $\delta_{k-k^{\prime}, q-q^{\prime}}$ expected from Eq. (2.27) has been extracted. The first-order term is

$$
\begin{align*}
\left\langle T U^{\prime}\right\rangle_{k^{\prime} k ; q q^{\prime}} & =\left\langle T_{k^{\prime} k} U_{q q^{\prime}}\right\rangle  \tag{A11}\\
& =N^{-1} n_{k-k^{\prime}} \cdot A_{-k}^{k^{\prime}-k} A_{-q}^{q-q^{\prime}} \delta_{k-k^{\prime}, q-q^{\prime}}, \tag{A12}
\end{align*}
$$

where relabeling using the symmetry of the $A_{k}^{q}$ gives

$$
\left\langle T U^{\prime}\right\rangle_{k^{\prime} k_{;} q q^{\prime}}=N^{-1} n_{k-k^{\prime}}\left(A_{-k^{\prime}}^{k-k^{\prime}}\right)^{*} A_{-k^{\prime}+k-q}^{k-k^{\prime}} \delta_{k-k^{\prime}, q-q^{\prime}}
$$

(A13)
The total contribution is therefore $D_{k k^{\prime}}^{k-q} \delta_{k-k^{\prime}, q-q^{\prime}}$; where the matrix $\mathrm{D}^{Q}$ has elements

$$
\begin{equation*}
D{ }_{k k^{\prime}}^{Q}=N^{-1}\left(2 n_{k-k^{\prime}}+1\right)\left(A_{-k^{\prime}}^{k-k^{\prime}}\right)^{*} A_{-k^{\prime}+Q}^{k-k^{\prime}} \tag{A14}
\end{equation*}
$$

The second-order term depends on

$$
\begin{align*}
& {\left[\left\langle T U^{\prime}\right\rangle^{2}\right]_{k^{\prime} ; ; q q^{\prime}}=\sum_{K Q}\left\langle T_{k^{\prime} K}\left\langle T_{K k} U_{q Q}\right\rangle u_{Q q^{\prime}}\right\rangle}  \tag{A15}\\
& =\sum_{k}\left[N^{-1} n_{k-K}\left(A_{-K}^{k-K}\right)^{*} A_{-K+k-q}^{k-K}\right] \\
& \quad \times\left[N^{-1} n_{K-k^{\prime}}\left(A_{-k^{\prime}}^{K-k^{\prime}}\right)^{*} A_{-k^{\prime}+k-q}^{K-k^{\prime}}\right] \delta_{k-k^{\prime}, q-q^{\prime}}, \tag{A16}
\end{align*}
$$

leading to a total contribution depending on

$$
\begin{equation*}
\sum_{K} D_{k K}^{k-q} D_{K k^{\prime}}^{k-q} \delta_{k-k^{\prime}, q-q^{\prime}}=\left(\mathrm{D}^{k-q}\right)_{k k^{\prime}}^{2}, \delta_{k-k^{\prime}, q-q^{\prime}} \tag{A17}
\end{equation*}
$$

By induction the $n$ th-order term follows similarly from $\left(\mathrm{D}^{k-q}\right)^{n}$, so that Eq. (2.41) can be written as

$$
\begin{equation*}
\left\langle\theta_{k k^{\prime}}^{+}, \theta_{q q^{\prime}}\right\rangle=\left\langle\theta_{-k^{\prime}}\right\rangle\left(\exp D^{k-q}\right)_{k k^{\prime}}\left\langle\theta_{-q^{\prime}}\right\rangle \delta_{k-k^{\prime}, q-q^{\prime}} . \tag{A18}
\end{equation*}
$$

Extensions of these methods show how the remaining thermal averages in $H_{0}$ and $V$ give zero contribution as already asserted. From Eq. (A6) and results in Ref. 16 we deduce that

$$
\begin{align*}
& \left\langle\exp \left[\left(T-T^{\prime}\right)-\left(U-U^{\prime}\right)\right]\left(b+b^{+}\right)\right\rangle \\
& \quad=\left[\langle T b\rangle-\left\langle U b^{+}\right\rangle\right]\left\langle\exp \left[\left(T-T^{\prime}\right)-\left(U-U^{\prime}\right)\right]\right\rangle \\
& \quad \quad-\left\langle\exp \left[\left(T-T^{\prime}\right)-\left(U-U^{\prime}\right)\right]\right\rangle\left[\left\langle T^{\prime} b\right\rangle-\left\langle U^{\prime} b^{+}\right\rangle\right] \tag{A19}
\end{align*}
$$

and hence that

$$
\begin{align*}
& \left\langle\theta_{k^{+}+q, k}^{+} \theta_{k^{\prime} k}\left(b_{q}+b_{-q}^{+}\right)\right\rangle \\
& =\sum_{\kappa}\left\{\left[\left\langle T_{k K} b_{q}\right\rangle-\left\langle U_{k K} b_{-q}^{+}\right\rangle\right]\left\langle\theta_{k^{\prime}+q K}^{+} \theta_{k^{\prime} k}\right\rangle\right. \\
& \left.-\left\langle\theta_{k^{\prime}+q, k}^{+} \theta_{k^{\prime} K}\right\rangle\left[\left\langle T_{K k} b_{q}\right\rangle-\left\langle U_{K k} b_{-q}^{+}\right\rangle\right]\right\}  \tag{A20}\\
& =N^{-1 / 2}\left[A_{-k}^{-q}\left\langle\theta_{k^{\prime}+q, k} \theta_{k^{\prime}, k-q}\right\rangle\right. \\
& \left.-A_{-q-q}^{-q}\left\langle\theta_{k^{\prime}+q, k+q} \theta_{k^{\prime} k}\right\rangle\right] . \tag{A21}
\end{align*}
$$

When Eq. (A21 is substituted in Eq. (2.33), Eq. (2.32) can be used to evaluate the sum over $k^{\prime}$, yielding a term proportional to

$$
\begin{equation*}
\sum_{q} \omega_{q}\left(A_{-k}^{-q} A_{-k+q}^{q}-A_{-k-q}^{q} A_{-k}^{q}\right) . \tag{A22}
\end{equation*}
$$

Since $\omega_{q}$ is even in $q$, the second sum is made equal and opposite to the first by changing the summation variable to $-q$, and so the term vanishes. The last term in Eq. (2.34) for $V$ vanishes similarly, consisting from Eq. (2.31) of two parts, one like that just discussed and the other proportional to $\left\langle b_{q}+b_{-q}^{+}\right\rangle$.

We now collect the foregoing results. The choice of Eq. (2.32) for the transformation coefficients can be written as

$$
\begin{equation*}
A_{k}^{q}=\sum_{k^{\prime}} f_{k^{\prime}}^{q}\left\langle\theta_{k-q}\right\rangle\left(\exp D^{q}\right)_{q-k^{\prime}, q-k}\left\langle\theta_{k}\right\rangle \tag{A23}
\end{equation*}
$$

By introducing the matrix $\mathrm{E}^{q}$ with elements
$E_{k k^{\prime}}^{q}=D_{q-k^{\prime}, q-k}^{q}=N^{-1}\left(2 n_{k-k^{\prime}}+1\right)\left(A_{k-q}^{k-k^{\prime}}\right) *\left(A_{k}^{k-k^{\prime}}\right)$,
we obtain alternatively

$$
\begin{equation*}
A_{k}^{q}=\sum_{k} f_{k^{\prime}}^{q}\left\langle\theta_{k-q}\right\rangle\left(\exp \mathrm{E}^{q}\right)_{k k} \cdot\left\langle\theta_{k}\right\rangle \tag{A25}
\end{equation*}
$$

The new matrix also enables Eq. (A9) to be written as

$$
\begin{equation*}
\left\langle\theta_{k}\right\rangle=\exp \left[-\frac{1}{2} \sum_{k^{\prime}} E_{k k^{\prime}}^{0}\right] \tag{A26}
\end{equation*}
$$

## APPENDIX B: TEST OF APROXIMATIONS

One simple test of the approximations is to use them in Eq. (A25) to calculate $A_{\lambda}^{0}$ and compare with the exact value g. From Eq. (A25),

$$
\begin{equation*}
A_{\lambda}^{0}=\left\langle\theta_{\lambda}^{2}\right\rangle \sum_{q}\left(\exp \mathrm{E}^{0}\right)_{\lambda q} f_{q}^{0} \tag{B1}
\end{equation*}
$$

where, since $f_{q}^{0}=g$, we find

$$
\begin{equation*}
\xi=A_{\lambda}^{0} g^{-1}=\left\langle\theta_{\lambda}\right\rangle^{2} \sum_{q}\left(\exp E^{0}\right\rangle_{\lambda q} \tag{B2}
\end{equation*}
$$

From Eqs. (A9) and (3.7) we have at once

$$
\begin{equation*}
\left\langle\theta_{\lambda}\right\rangle^{2}=\exp \left[-(2 n+1)\left(g^{2}+V^{0}+\eta^{2} \phi_{\lambda}^{2}\right)\right] \tag{B3}
\end{equation*}
$$

where

$$
\begin{equation*}
V^{0} \equiv \eta^{2} N^{-1} \sum_{q} \phi_{q}^{2}=N^{-1} \sum_{\lambda} V_{\lambda}^{0} . \tag{B4}
\end{equation*}
$$

We therefore require
$\sum_{q}\left(\exp E^{0}\right)_{\lambda q}=\sum_{q}\left(\delta_{\lambda q}+E_{\lambda q}+\frac{1}{2} \sum_{q^{\prime}} E_{\lambda q^{\prime}}^{0} E_{q^{\prime} q}^{0}+\cdots\right)$.
Here $\Sigma_{q} \delta_{\lambda q}=1$ and
$\sum_{q} E_{\lambda q}^{0}=(2 n+1)\left(g^{2}+V^{0}+\eta^{2} \phi_{\lambda}^{2}\right) \equiv(2 n+1) E_{\lambda}^{0}$.
The next term involves

$$
\begin{align*}
\sum_{q q^{\prime}} E_{\lambda q^{\prime}}^{0} E_{q^{\prime} q}^{0} & =(2 n+1) \sum_{q^{\prime}} E_{\lambda q^{\prime}}^{0} E_{q^{\prime}}^{0}  \tag{B7}\\
& =(2 n+1)^{2}\left(F^{0} E_{\lambda}^{0}+G^{0}\right), \tag{B8}
\end{align*}
$$

where

$$
\begin{align*}
& F^{0}=g^{2}+2 V^{0}  \tag{B9}\\
& G^{0}=W^{0}-\left(V^{0}\right)^{2}  \tag{B10}\\
& W^{0}=\eta^{4} N^{-1} \sum_{q} \phi_{q}^{4} \tag{B11}
\end{align*}
$$

are all positive quantities. It follows from these results that a factor $E_{\lambda}^{0}$ in one order gives rise to a factor $(2 n+1)\left(F^{0} E_{\lambda}^{0}+G\right)$ in the next order, while a constant factor $G^{0}$ gives rise to a factor $(2 n+1) G^{0} E_{\lambda}^{0}$. We can therefore write

$$
\begin{equation*}
\sum_{q}\left(E^{0}\right)_{\lambda q}^{r}=(2 n+1)^{r}\left(u_{r} E_{\lambda}^{0}+v_{r}\right), \tag{B12}
\end{equation*}
$$

where the coefficients $u_{r}$ and $v_{r}$ satisfy

$$
\begin{align*}
& u_{r+1}=F_{u_{r}}^{0}+v_{r},  \tag{B13}\\
& v_{r+1}=G_{u_{r}}^{0} \tag{B14}
\end{align*}
$$

subject to $u_{0}=0, v_{0}=1 ; u_{1}=1, v_{1}=0 ; u_{2}=F^{0}, v_{2}=G^{0}$.
The difference equations (B13) and (B14) are solved by assuming $u_{r} \propto x^{r}$, which is valid provided

$$
\begin{equation*}
x_{ \pm}=\frac{1}{2}\left\{F^{0} \pm\left[\left(F^{0}\right)^{2}+4 G^{0}\right]^{1 / 2}\right\} \equiv \frac{1}{2}\left(F^{0} \pm H^{0}\right), \tag{B15}
\end{equation*}
$$

where, since $G^{0} \geqslant 0, H^{0} \geqslant F^{0}$. The general solution is then the linear combination $u_{r}=u_{+} x_{+}^{r}+u_{-} x_{-}^{r}$. The boundary conditions yield $u_{+}=1 / H=-u_{-}$, with the solutions for $n \geqslant 0$;
$u_{r}=\left(H^{0}\right)^{-1}\left\{\left[\frac{1}{2}\left(F^{0}+H^{0}\right)\right]^{r}-\left[\frac{1}{2}\left(F^{0}-H^{0}\right)\right]^{r}\right\}$,
$v_{r}=G^{0}\left(H^{0}\right)^{-1}\left\{\left[\frac{1}{2}\left(F^{0}+H^{0}\right)\right]^{r-1}-\left[\frac{1}{2}\left(F^{0}-H^{0}\right)\right]^{r-1}\right\}$.

The solutions enable the series for $\Sigma_{q}\left(\exp E^{0}\right)_{\lambda q}$ to be summed, with the result

$$
\begin{align*}
& \sum_{q}\left(\exp E^{0}\right)_{\lambda q} \\
&=\left(H^{0}\right)^{-1}\left\{e^{(n+1 / 2)\left(F^{0}+H^{0}\right)}\left[E_{\lambda}^{0}-\frac{1}{2}\left(F^{0}-H^{0}\right)\right]\right. \\
&\left.\quad-e^{(n+1 / 2)\left(F^{0}+H^{0}\right)}\left[E_{\lambda}^{0}-\frac{1}{2}\left(F^{0}-H^{0}\right)\right]\right\}, \tag{B18}
\end{align*}
$$

where $G^{0}$ has been replaced by $\left[\left(H^{0}\right)^{2}-\left(F^{0}\right)^{2}\right] / 4$. The factor $\xi$ is obtained by multiplying this exponential by $\left\langle\theta_{\lambda}\right\rangle^{2}$, which from Eqs. (B3) and (B4) is $\exp \left[-(2 n+1) E_{\lambda}^{0}\right.$.]

We therefore obtain an expression for $\xi$, which should be independent of $\lambda$, but in fact depends on $E_{\lambda}^{0}$. We eliminate this dependence by replacing $E_{\lambda}^{0}$ by its average over $\lambda$, which is $F^{0}$. Then

$$
\begin{align*}
\xi= & \left(1 / 2 H^{0}\right)\left[\left(F^{0}+H^{0}\right) e^{-(n+1 / 2)\left(F^{0}-H^{0}\right)}\right. \\
& \left.-\left(F^{0}-H^{0}\right) e^{-(n+1 / 2)\left(F^{0}+H^{0}\right)}\right] . \tag{B19}
\end{align*}
$$

In the limit of diagonal coupling, $G^{0} \rightarrow 0$ and $H^{0} \rightarrow F^{0}$, so that $\xi \rightarrow 1$ as required to obtain previous results. In general, Eq. (B19) gives $\xi$ in terms of $\eta$ and averages over the distribution of coupling parameters. Values of $\xi$ calculated as a test of the assumption Eq. (3.7) are presented in Sec. IV A, Figs. 2-4, which show that the deviations from unity are small, and thus the approximations are reasonable.

## APPENDIX C: EVALUATION OF $\eta$

We obtain the scaling parameter $\eta$ from Eq. (3.7) which implies

$$
\begin{equation*}
\eta\left(\phi_{\lambda}-\phi_{\lambda-Q}\right)=\operatorname{Re}\left(i A \frac{Q}{\lambda}\right) . \tag{C1}
\end{equation*}
$$

From Eqs. (A25) and (3.6), this means

$$
\begin{align*}
\eta\left(\phi_{\lambda}-\phi_{\lambda-Q}\right)= & \left\langle\theta_{\lambda-Q}\right\rangle\left\langle\theta_{\lambda}\right\rangle\left\{-g \operatorname{Im}\left[\sum_{q}\left(\exp \mathrm{E}^{Q}\right)_{\lambda q}\right]\right. \\
& \left.+\operatorname{Re}\left[\sum_{q}\left(\exp \mathrm{E}^{Q}\right)_{\lambda_{q}}\right]\left(\phi_{q-} \phi_{q-Q}\right)\right\} \tag{C2}
\end{align*}
$$

The evaluation of $\Sigma_{q}\left(\exp E^{Q}\right)_{\lambda q}$ proceeds much as for $Q=0$. In particular,

$$
\begin{equation*}
\sum_{q} E_{\lambda q}^{Q}=(2 n+1)\left(g^{2}+V^{Q}+V_{\lambda}^{Q}\right) \equiv(2 n+1) E_{\lambda}^{Q} \tag{C3}
\end{equation*}
$$

where $V^{Q}$ is a generalization of $V^{0}$ :

$$
\begin{equation*}
V^{Q}=\eta^{2} N^{-1} \sum_{q} \phi_{q} \phi_{q-Q}=N^{-1} \sum_{\lambda} V_{\lambda}^{Q} \tag{C4}
\end{equation*}
$$

Note that $V^{Q}$ is real, while $V_{\lambda}^{Q}$ has an imaginary part which contributes to Eq. (C2). the next order term yields

$$
\begin{equation*}
\sum_{q q^{\prime}} E_{\lambda q^{\prime}}^{Q} E_{q^{\prime} q}^{Q}=(2 n+1)^{2}\left(F^{Q} E_{\lambda}^{Q}+G^{Q}+I \eta^{2} \phi_{\lambda} \phi_{\lambda-Q}\right) \tag{C5}
\end{equation*}
$$

where

$$
\begin{align*}
& F^{Q}=g^{2}+V^{0}+V^{Q}  \tag{C6}\\
& G^{Q}=W^{Q}-V^{0} V^{Q}+I g^{2}  \tag{C7}\\
& W^{Q}=\eta^{4} N^{-1} \sum_{q} \phi_{q}^{2} \phi_{q-Q}^{2}  \tag{C8}\\
& I=V^{Q}-V^{0} \tag{C9}
\end{align*}
$$

As $Q \rightarrow 0, I \rightarrow 0$, and these equations reduce to Eqs. (B10)(B13). However, the additional factor in $\phi_{\lambda} \phi_{\lambda-Q}$ for nonzero $Q$ means that the third-order term is needed to complete the recursive specification of higher terms. The result is
$\sum_{q}\left(E^{Q}\right)_{\lambda q}^{3}=(2 n+1)^{3}\left(K E_{i}^{0}+L+F^{Q} I \eta^{2} \phi_{\lambda} \phi_{\lambda-Q}\right)$,
where

$$
\begin{align*}
& K=\left(F^{Q}\right)^{2}+G^{Q}+I V^{Q}  \tag{Cl1}\\
& L=F^{Q} G^{Q}+I\left[W^{Q}-\left(V^{Q}\right)^{2}\right] \tag{C12}
\end{align*}
$$

We can therefore write

$$
\begin{equation*}
\sum_{q}\left(E^{Q}\right)_{\lambda q}^{r}=(2 n+1)^{r}\left(u_{r} E_{\lambda}^{Q}+v_{r}+w_{r} \eta^{2} \phi_{\lambda} \phi_{\lambda-Q}\right) \tag{C13}
\end{equation*}
$$

where the coefficients satisfy

$$
\begin{align*}
& u_{r+1}=F^{Q} u_{r}+v_{r}+V^{Q} w_{r}  \tag{C14}\\
& v_{r+1}=G^{Q} u_{r}+\left[W^{Q}-\left(V^{Q}\right)^{2}\right] w_{r}  \tag{C15}\\
& w_{r+1}=I u_{r} \tag{C16}
\end{align*}
$$

These equations have the solution

$$
\begin{equation*}
u_{r}=c_{1} x_{1}^{r}+c_{2} x_{2}^{r}+c_{3} x_{3}^{r} \tag{C17}
\end{equation*}
$$

where the $x_{i}$ are the roots of

$$
\begin{equation*}
x^{3}-F^{Q} x^{2}-\left(G^{Q}+I V^{Q}\right) x-\left[W^{Q}-\left(V^{Q}\right)^{2}\right] I=0 \tag{C18}
\end{equation*}
$$

and the boundary conditions determining the $c_{i}$ are $u_{0}=0$, $u_{1}=1, u_{2}=F^{Q}$. Algebraic solution of cubic equations is complicated, so for the time being we leave the $x_{i}$ and $c_{i}$ undetermined. For Eq. (C2) we require the imaginary part of $\Sigma_{q}\left(\exp E^{Q}\right)_{\lambda q}$, from which Eq. (C13) comes from that of $E_{\lambda}^{Q}$. Through Eqs. (C3) and (3.11) we obtain

$$
\begin{equation*}
-\operatorname{Im}\left[\sum_{q}\left(\exp \mathrm{E}^{Q}\right)_{\lambda q}\right]=g \eta\left(\phi_{\lambda} \phi_{\lambda-Q}\right) \times \sum_{i=1} c_{i} \exp (2 n+1) x_{i} \tag{C19}
\end{equation*}
$$

In the evaluation of the final term in Eq. (C3), we first obtain simply $\phi_{\lambda}-\phi_{\lambda-Q}$. The next term is

$$
\begin{align*}
& \sum_{z} E_{\bar{\lambda} q}^{Q}\left(\phi_{q}-\phi_{q-Q}\right) \\
& \quad=-(2 n+1) \eta I\left[2 i g+\eta\left(\phi_{\lambda}-\phi_{\lambda-Q}\right)\right] \tag{C20}
\end{align*}
$$ so that in the $r$ th-order term the coefficient of $\left(\phi_{\lambda}-\phi_{\lambda-\mathrm{Q}}\right)$ is $\left[-(2 n+1) \eta^{2} I\right]^{r}$. The term independent of $\lambda$ on the righthand side of Eq. (C20) gives rise to a series of terms like those in Eq. (C13), but the constant contributed in each order by the $\left(\phi_{\lambda}-\phi_{\lambda-Q}\right)$ in the preceding order means that the coefficients now obey the inhomogeneous equation

$$
\begin{align*}
u_{r+3} & -F^{Q} u_{r+2}-\left(G^{Q}+I V^{Q}\right) u_{r+1} \\
& -\left[W^{Q}-\left(V^{Q}\right)^{2}\right] I u_{r}=i Y\left(-\eta^{2} I\right)^{r+2} \tag{C21}
\end{align*}
$$

where $y=2 g / \eta$. This has solutions

$$
\begin{equation*}
u_{r}=d_{1} x_{1}^{r}+d_{2} x_{2}^{r}+d_{3} x_{3}^{r}+i Z\left(-\eta^{2} I\right)^{r} \tag{C22}
\end{equation*}
$$

where the $x_{i}$ solve the previous homogeneous equation and the new coefficients $d_{i}$ are fixed by the boundary conditions $u_{0}=0, u_{1}=0, u_{2}=-i Y \eta^{2} I$. The term $Z\left(-y^{2} I\right)^{r}$ in Eq. (C22) is a particular solution of Eq. (C21),

$$
\begin{align*}
Z= & Y\left(-Y^{2} I^{2}\left\{\left(-\eta^{2} I\right)^{3}-F^{Q}\left(-\eta^{2} I\right)^{2}\right.\right. \\
& -\left(G^{Q}+I V^{Q}\right)\left(-\eta^{2} I\right)-\left(\left[W^{Q}-\left(V^{Q}\right)^{2}\right] I\right\}^{-1} \tag{C23}
\end{align*}
$$

Since the initial nonzero value $u_{2}$ is imaginary, so are the coefficients $d_{i}$, which we rewrite as $i e_{i}$. Then real contributions to Eq. (C2) come from the imaginary part of $E_{\lambda}^{Q}$ and directly from the terms in $\left(\phi_{\lambda}-\phi_{\lambda-Q}\right)$, giving

$$
\begin{gather*}
\left(\phi_{\lambda}-\phi_{\lambda-\Omega}\right)\left\{g \eta \sum_{i=1}^{3} e_{i} e^{(2 n+1) x_{i}}+(1+g \lambda Z)\right. \\
\left.\times \exp \left[-(2 n+1) \eta^{2} I\right]\right\} \tag{C24}
\end{gather*}
$$

Combining this result with Eq. (C19) in Eq. (C2), we obtain

$$
\begin{align*}
\eta= & \left\langle\theta_{\lambda-Q}\right\rangle\left\langle\theta_{\lambda}\right\rangle\left(g \eta \sum_{i=1}^{3}\left(g c_{i}+e_{i}\right) e^{(2 n+1) x_{i}}\right. \\
& \left.+(1+g \eta Z) \exp \left[-(2 n+1) \eta^{2} I\right]\right\} \tag{C25}
\end{align*}
$$

Although the factors $\left(\phi_{\lambda}-\phi_{\lambda-Q}\right)$ cancel, this expression for $\eta$ still contains a dependence on $\lambda$ and $\mathbf{Q}$. As with $\xi$, we eliminate this dependence by replacing the various quantities in Eq. (C25) by their averages over $\lambda$ and $\mathbf{Q}$. Thus in $\left\langle\theta_{\lambda-Q}\right\rangle$ and $\left\langle\theta_{\lambda}\right\rangle, E_{\lambda-Q}^{0}$ and $E_{\lambda}^{0}$ are both replaced by $F^{0}$; $V^{Q}$ is replaced by zero, so that $F^{Q}$ is replaced by $F^{0}-V^{0}$ and $I$ by $-V^{0}$; and $W^{0}$ is replaced by $\left(V^{0}\right)^{2}$, so that $G^{Q}$ is replaced by $V^{0}\left(F^{0}-V^{0}\right)$. These replacements not only make $\eta$ a constant as originally postulated, but also simplify the averages over the $\phi_{q}$ required in the treatment by eliminating power of $\phi_{q} \phi_{q^{\prime}}$, for $q^{\prime} \neq q$. Furthermore, the replacements allow a factorization of Eq. (C18), which reduces to

$$
\begin{equation*}
\left(x+V^{0}\right)\left[x^{2}-F^{0} x+\left(V^{0}\right)^{2}\right]=0 \tag{C26}
\end{equation*}
$$

It follows that $x_{1}=-V^{0}$ and
$x_{2,3}=\frac{1}{2}\left\{F^{0} \pm\left[\left(F^{0}\right)^{2}-4\left(V^{0}\right)^{2}\right]^{1 / 2}\right\}=\frac{1}{2}\left(F^{0} \pm X\right)$,
where $X$ is real because from Eq. (B9) $F^{0} \geqslant 2 V^{0}$. The coefficients $c_{i}$ are then obtained as

$$
\begin{align*}
& c_{1}=\left(F^{0}+2 V^{0}\right)^{-1}  \tag{C28}\\
& C_{2,3}=\left[\left(F^{0}+2 V^{0}\right)^{-1} \pm X^{-1}\right] / 2 \tag{C29}
\end{align*}
$$

The quantity $Z$ in Eq. (C24) reduces to

$$
\begin{align*}
& Z=Y \eta^{4} /\left(\eta^{2}+1\right)\left[\left(\eta^{4}+1\right) V^{0}-\eta^{2} F^{0}\right],  \tag{C30}\\
& e_{1}=Y \eta^{2} /\left(\eta^{2}+1\right)\left(F^{0}+2 V^{0}\right),  \tag{C31}\\
& e_{2,3}=-Y V^{0} \eta^{2} \frac{\left[\left(\eta^{2}+1\right)\left(F^{0}+2 V^{0}\right)^{-1} \pm\left(\eta^{2}-1\right) X^{-1}\right]}{2\left[\left(\eta^{4}+1\right) V^{0}-\eta^{2} F^{0}\right]} \tag{C32}
\end{align*}
$$

With these results we find

$$
\begin{align*}
\eta= & (1+g \eta Z) \exp \left[-(2 n+1)\left(F^{0}-\eta^{2} V^{0}\right)\right] \\
& +g^{2} \eta\left\{\left(F^{0}+2 V^{0}\right)^{-1}\left[2 \eta\left(\eta^{2}+1\right)^{-1}\right]\right\} \\
& \quad \times \exp \left\{-(2 n+1)\left(F^{0}+V\right)\right\} \\
& +\frac{1}{2} \sum_{ \pm} c_{ \pm} \exp \left[-(n+1 / 2)\left(F^{0} \mp X\right)\right], \quad(\mathrm{C} 33) \tag{C33}
\end{align*}
$$

where

$$
\begin{gather*}
c_{ \pm}=\left[1-\frac{2 \eta V^{0}\left(\eta^{2}+1\right)}{\left(\eta^{4}+1\right) V^{0}-\eta^{2} F^{0}}\right]\left(F^{0}+2 V^{0}\right)^{-1} \\
\pm\left[1-\frac{2 \eta V^{0}\left(\eta^{2}-1\right)}{\left(\eta^{4}+1\right) V^{0}-\eta^{2} F^{0}}\right] X^{-1} \tag{C34}
\end{gather*}
$$

and it must be remembered that $F^{0}, V^{0}, X$, and $Z$ depend on $\eta$. This equation is solved numerically for $\eta$ in Sec. IV.

## APPENDIX D: EVALUATION OF $\widetilde{J}_{\lambda}$

The expression for $\widetilde{J}_{\lambda}$ given in Eq. (2.37) can be evaluated by techniques similar to those used for $A_{\lambda}^{Q}$. We make use of the fact that $J_{\lambda}$ is even in $\lambda$ and that

$$
\begin{equation*}
\sum_{\lambda} J_{\lambda}=0 \tag{D1}
\end{equation*}
$$

because $J_{r s}$ is purely nonlocal ( $J_{r r}=0$ ). Then in evaluating $\Sigma_{\mu}\left(\exp E^{0}\right)_{\lambda \mu} J_{\mu}$, the first term in $J_{\lambda}$ and the second is, from Eq. (3.9),

$$
\begin{equation*}
\sum_{\mu} E_{\lambda \mu}^{0} J_{\mu}=N^{-1}(2 n+1) \sum_{\mu}\left[g^{2}+\eta^{2}\left(\phi_{\lambda}-\phi_{\mu}\right)^{2}\right] J_{\mu} \tag{D2}
\end{equation*}
$$

The terms in $g^{2}$ and $\phi_{\lambda}^{2}$ vanish by Eq. (D1) and that in $\phi_{\lambda} \phi_{\mu}$ by symmetry, leaving

$$
\begin{equation*}
N^{-1}(2 n+1) \sum_{\mu} \eta^{2} \phi_{\mu}^{2} J_{\mu} \equiv(2 n+1) \eta^{2} M \tag{D3}
\end{equation*}
$$

We note that in the simple case where $\phi_{\mu}=\phi \sin \mu$ and $J_{\mu}=J \cos \mu, M$ is zero, so that presumably $M$ is often small.

By arguments analogous to those used previously, it follows that

$$
\begin{equation*}
\sum_{\mu}\left(E^{0}\right)_{\lambda \mu}^{r+1} J_{\mu}=(2 n+1)^{r+1}\left(u_{r} E_{\lambda}^{0}+v_{r}\right) \eta^{2} M \tag{D4}
\end{equation*}
$$

with boundary conditions $u_{0}=0, v_{0}=1, u_{1}=1, v_{1}=0$. These yield the previous solutions (B16) and (B17). With $\left\langle\phi_{\lambda}\right\rangle^{2}$ from Eqs. (B3) and (B6) we finally obtain

$$
\begin{align*}
\widetilde{J}_{\lambda}= & {\left[\exp -(2 n+1) E_{\lambda}^{0}\right]\left(J_{\lambda}-\left(E_{\lambda}^{0}-F^{0}\right) \eta^{2} M / G^{0}\right.} \\
& +\left(\eta^{2} M / 2 G^{0} H^{0}\right)\left\{e^{(n+1 / 2)\left(F^{0}+H^{0}\right)}\right. \\
& \times\left(H^{0}-F^{0}\right)\left(E_{\lambda}^{0}-\frac{1}{2} F^{0}-H^{0}\right) e^{(n+1 / 2)\left(F^{0}-H^{0}\right)} \\
& \left.\left.\times\left(H^{0}+F^{0}\right)\left[E_{\lambda}^{0}-\frac{1}{2}\left(F^{0}+H^{0}\right)\right]\right\}\right) \tag{D5}
\end{align*}
$$

Even when $M$ is zero, $\widetilde{J}_{\lambda}$ can differ from $J_{\lambda}$ in a complicated way. From Eq. (B6) it can be seen that there is a uniform band narowing caused by both local and nonlocal coupling plus further narrowing and distortion caused by nonlocal coupling which is greatest in regions intermediate between the Brillouin zone center and the zone boundary.
