Casting the Dark Web in a New Light:
A value-chain lens reveals a growing cyber attack ecosystem and new strategies for combating it.

Keman Huang, Michael Siegel, Keri Pearlson and Stuart Madnick

ABSTRACT
Cyber attacks are increasing in frequency, sophistication, and impact. Defending against them requires a new perspective on the attacks and the attackers. By applying a value-chain lens to the problem, we can better understand the dark web as an ecosystem in which well Orchestrated attacks are assembled by entrepreneurs and supported by well-organized service offerings. This casts new light on the dark web and suggests more effective and proactive responses to cyber attacks.

KEYWORDS: Cybersecurity, data security, hacking, security, privacy, Digital Business, IT Strategy, Financial Management & Risk, IT Governance & Leadership

We developed and validated the cyber-attack-as-a-service value chain model. We analyzed service samples in dark web markets and undertook an extensive survey of existing literature and publicly available reports. We also interviewed more than 30 cybersecurity executives, managers and researchers from Fortune 500 companies, and key cybersecurity solution providers.

We were focused on the Question: How can companies better defend themselves against the threat of cyber attack?
We learned that:

• Cyber crime has developed into a well-organized business ecosystem populated by service providers and attack creators.
• A value chain of primary and supporting services enables cyber criminals to out-innovate and out-pace the defense community.
• Companies can disrupt cyber crime by refocusing their defensive efforts on the cyber-attack-as-a-service value chain.

With cyber attacks increasingly threatening businesses, executives need new tools, techniques, and approaches to protect their organizations. Unfortunately, criminal innovation often outpaces their defensive efforts. In February 2019, the AV.TEST Institute, a research organization that focuses on IT security, registered more than 350,000 new malware samples per day, and according to Symantec’s 2019 Internet Security Threat Report, cyber attacks targeting supply chain vulnerabilities increased by 78% in 2018.1

Wide-scale attacks are becoming more common, too. In October 2016, a distributed-denial-of-service (DDoS) attack hit Dyn, a DNS provider, which, in turn, brought down companies such as PayPal, Twitter, Reddit, Amazon, Netflix, and Spotify. In 2017, the WannaCry and NotPetya ransomware attacks affected healthcare, education, manufacturing, and other sectors around the world. A report from the Department of Health in the UK revealed that WannaCry alone cost it £92 million. That same year, while the cyber defense community was working out how to fight ransomware, cryptojacking—the hijacking of other people’s machines to mine cryptocurrency—arose as a threat. Cryptojacking attacks detected by Symantec increased by 8,500% during 2017. During 2018, the value of cryptocurrencies plunged 90%, yet Symantec still blocked four times as many attacks as the previous year.

Attackers always seem to be one or two steps ahead of the defenders. Are they more technically adept, or do they have a magical recipe for innovation that enables them to move more quickly? If, as is commonly believed, hackers operated mainly as isolated individuals, they would need to be incredibly skilled and fast to create hacks at the frequency we’ve seen. However, when we conducted research in dark web markets, surveyed the literature of cyber attacks, and interviewed cybersecurity professionals, we found that the prevalence of the “fringe hacker” is a misconception.

Through this work, we found a useful lens for examining how cyber criminals innovate and operate. The Value Chain model, developed by Michael Porter, offers a process-based view of business. When applied to cyber crime, it reveals that the dark web—that part of the internet that has been intentionally hidden, is inaccessible through standard web browsers, and facilitates criminal activities—is serving as what Porter called a value system. That system includes a comprehensive cyber attack supply chain, which enables hackers and other providers to develop and sell the products and services needed to mount attacks at scale. Understanding how it works provides new, more effective avenues for combating attacks to companies, security service providers, and the defense community at large.

The Dark Web’s CAaaS Markeplaces
The dark web hosts various cyber-attack-as-a-service (CAaaS) marketplaces and forums that cater to a criminal ilk of technologists and businesspeople. Rather than orchestrate a hack themselves, the technologists can use the dark web to develop and sell the components needed to launch an attack as well as offer expertise and other services needed to complete an attack. The businesspeople buy these services and combine them to orchestrate attacks.

---

For example, when we surveyed the dark web in June 2017, we found personal profiles (the more personal, the more valuable) for sale: In one case, a pharmacy database with more than 50,000 customer profiles including email addresses was available for $1,000. Silent Bitcoin miners used for cryptojacking also were being sold for as little as EU2.25 (about $2). And criminals who wanted to launch phishing attacks needed to look no further than Dream Market, one of the largest dark web marketplaces, where they could purchase a phishing service, along with an SMTP server to replicate phishing emails, an automated mailer application to send the emails, fraudulent websites, and high-quality email lists of individuals and businesses. The collective cost: around $100 per month.

Recently, artificial intelligence has been harnessed to create even more powerful CAaaS dark web offerings. With the help of AI, personal information collected from Twitter, Facebook, and other social media sites can be used to automatically generate phishing emails and posts with open rates as high as 60%. This is a higher rate than found in so-called spear phishing campaigns, in which attackers manually research victims and create targeted messages. In another example, in 2018, cybersecurity firm Darktrace reported spotting a never-before-seen attack that used rudimentary machine learning to observe, learn, and mimic patterns of normal user behavior inside a network.

The emergence of CAaaS marketplaces is a game-changing development that drastically reduces barriers and challenges in cyber crime: hackers and other dark web providers don’t need to perform attacks to realize benefits from their innovations, and their customers don’t need to be hackers to mount attacks. The “as-a-service” model distances developers from the attacks enabled by their products and services as they don’t need to be directly involved in the specific cyber attack activity. It helps them evade the grasp of authorities, as well, because many services in CAaaS marketplaces are not fundamentally illegal. For instance, a service that creates emails might not break any laws on its own but can still be used as part of a process for illegal phishing. Likewise for help desks, payment systems, and other services that can be used to support the development or launch of an attack. With all this open space and freedom, hackers can more easily create new modules. They also can steal and sell tools developed by others, such as the NSA.

The services offered are not randomly chosen but, rather, purposefully designed, innovative responses to business opportunities—sometimes with the help of cutting edge technologies. For example, Joker’s Stash, a large dark web marketplace that offers PPaaS (personal-profile-as-a-service), uses a blockchain-based DNS to make it more difficult for law enforcement agencies to trace and take down its systems. In another instance, in January 2018, a Reddit user named deepfakes used open-source AI to create fake porn videos featuring celebrities and politicians. Shortly after,FakeApp, a desktop application that makes it easy for anyone to generate their own fake porn videos, appeared—demonstrating just how effective AI

---

can be at improving attack and deception services, and making this technology a major concern.\textsuperscript{12}

Thus, we see cybercrime evolving from a nefarious hobby into a business ecosystem and value chain with a global scope. No wonder it is difficult, if not impossible, for the defense community to keep up.

The CAaaS Value Chain

When we examined the services available on the dark web, we looked for any activity that could help an attacker, reduce the cost of an attack, or increase the benefit derived from an attack, each time asking “What is the value added?” That exercise revealed a value chain of primary activities needed to create cyber attacks and support activities that make the attacks more efficient and effective (see “The Cyber Crime Ecosystem”).

The Cyber Crime Ecosystem

The dark web hosts a complete value chain of services designed to mount and support cyber attacks.

The primary activities of the value chain include the services needed to mount the attack: the discovery of vulnerabilities, the development and delivery of the weapons needed to exploit those vulnerabilities, and the execution of the cyber attack—whether a single action, a multi-step attack, or an advanced persistent threat in which attacks remain undetected for an extended period. Support activities facilitate the cyber attack business by reducing the cost and increasing the benefit of an attack. Life-cycle operations include activities that help select valuable attack targets, organize hackers, manage the distribution of proceeds, hide the operation from authorities, and if disrupted, recover the sidelined operation. Hacker human resources services include hiring, training, and managing trusted hackers. Marketing and delivery provides a trustworthy marketplace for service providers and buyers, a market-based pricing mechanism, and system for transferring funds. Technology support offers tools and functional operations such as customer service.
The CAaaS value chain exposes the links between the attack services available on the dark web, as well as the gaps in which opportunities to develop new services might arise. (Wherever there is a demand to make cyber attacks more efficient or profitable, we can assume service providers will be motivated to fulfill that demand.) Using this value chain model, we identified 24 key primary and supporting services for sale on the dark web. For example, security-checker-as-a-service (SCaaS) provides a simulated environment to evaluate and test whether exploitations can bypass cyber security defenses prior to an actual attack, and deception-as-a-service (DaaS) generates the fake websites, emails, and software used to mislead victims. Reputation-as-a-service (RaaS) generates ratings for each user based on their previous interactions and helps attackers find hackers on whom they can rely, and value-evaluation-as-a-service (VEaaS) helps users to verify the quality of stolen credit cards and establish their price. (See “Services in the CAaaS Ecosystem.”)
Services in the CAaaS Ecosystem

The ecosystem consists of 24 key primary and supporting services that can be combined in myriad ways to develop and mount attacks.

<table>
<thead>
<tr>
<th>Service Name</th>
<th>Description</th>
<th>Value Chain Activities</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vulnerability Discovery as a Service</td>
<td>Discover vulnerabilities within the target system</td>
<td>Primary</td>
</tr>
<tr>
<td>Exploit as a Service</td>
<td>Create Exploit for the vulnerability</td>
<td>Primary</td>
</tr>
<tr>
<td>Deception as a Service</td>
<td>Provide fake information to mislead targets</td>
<td>Primary</td>
</tr>
<tr>
<td>Payload as a Service</td>
<td>Provide malicious payload such as virus, worm, ransomware etc.</td>
<td>Primary</td>
</tr>
<tr>
<td>Exploit Package as a Service</td>
<td>Combine exploits into exploit kits</td>
<td>Support</td>
</tr>
<tr>
<td>Obfuscate as a Service</td>
<td>Provide obfuscation strategies and technologies to reduce being detected</td>
<td>Support</td>
</tr>
<tr>
<td>Security Checker as a Service</td>
<td>Verify whether can bypass the defensive system</td>
<td>Support</td>
</tr>
<tr>
<td>Repackage as a Service</td>
<td>Repack different elements to increase effectiveness of an attack</td>
<td>Support</td>
</tr>
<tr>
<td>Botnet as a Service</td>
<td>Provide botnet</td>
<td>Primary</td>
</tr>
<tr>
<td>Traffic Redirection as a Service</td>
<td>Redirect traffic to the specific address</td>
<td>Primary</td>

<tr>
<td>Reputation Escalation as a Service</td>
<td>Craft a fake reputation for a given target</td>
<td>Support</td>
</tr>
<tr>
<td>Personal Profile as a Service</td>
<td>Offer personal profile like passport, social security number, credit card etc. about targets</td>
<td>Support</td>
</tr>
<tr>
<td>Domain Knowledge as a Service</td>
<td>Offer domain knowledge about the target</td>
<td>Support</td>
</tr>
<tr>
<td>Tool Pool as a Service</td>
<td>Provide toolkits or platforms to support cyber attack</td>
<td>Support</td>
</tr>
<tr>
<td>Target Selection as a Service</td>
<td>Identify the valuable targets for attack</td>
<td>Support</td>
</tr>
<tr>
<td>Money Laundering as a Service</td>
<td>Provide money laundering network to clean the illegal money</td>
<td>Support</td>
</tr>
<tr>
<td>Money Mule Recruiting as a Service</td>
<td>Recruit money mules to establish money laundering network</td>
<td>Support</td>
</tr>
<tr>
<td>Reputation as a Service</td>
<td>Provide reputation system for underground users</td>
<td>Support</td>
</tr>
<tr>
<td>Value Evaluation as a Service</td>
<td>Evaluate or price the provided service or good</td>
<td>Support</td>
</tr>
<tr>
<td>Marketplace as a Service</td>
<td>Provide the marketplace for underground trading</td>
<td>Support</td>
</tr>
<tr>
<td>Hacker Training as a Service</td>
<td>Train hackers in specific skills</td>
<td>Support</td>
</tr>
<tr>
<td>Hacker Recruiting as a Service</td>
<td>Recruit suitable hackers for cyber attacks</td>
<td>Support</td>
</tr>
</tbody>
</table>

We identified the inputs, outputs, and supports for each service in the CAaaS ecosystem. Then we identified potential combinations of services, based on the interactions among their inputs, outputs, and supports, to demonstrate how they can be used to mount attacks (see “Using
CAaaS for a Ransomware Attack”). Together, these services comprise a comprehensive supply chain of attack capabilities.

**Using CAaaS for a Ransomware Attack**

Here are some ways that services available on the dark web can be assembled to mount a complete ransomware attack.

![Diagram showing the components of a ransomware attack]

**Success Begets Success**

Within the cyber-attack-as-a-service value chain, a successful attack can enhance the entire chain’s ability to rapidly generate new attacks. For example, after a group named The Shadow Brokers stole EternalBlue and DoublePulsar, vulnerability exploitation tools developed by the NSA, in a cyber attack in August 2016, the tools enabled new services such as TPaaS (tool-pool-as-a-service) and became part of the arsenal used in the WannaCry ransomware attacks in May 2017.\(^\text{13}\)

In other cases, successful attacks can set the stage for follow-on attacks. For example, compromised machines can be infected with malware that create botnets, which, in turn, then reach out to other machines and infect them.

Cyber attacks can also expose new vulnerabilities to be exploited. For instance, personally identifiable information (PII)—such as Social Security numbers, digital images, and geolocation and biometric data collected from data breaches and social media and sold on the dark web—provides fodder for subsequent attacks. One example is the so-called whaling phishing attack, which uses PPaaS (personal-profile-as-a-service), TSaaS (target-selection-as-a-service), and DaaS (deception-as-a-service) to impersonate senior executives, such as CEOs and CFOs, to gain access to corporate funds and sensitive data.

There are many other examples of new services, automatically-generating attacks, and new vulnerabilities that follow from initial attacks. These enable the dark web ecosystem to grow and expand quickly, making it difficult for organizations to keep up appropriate defenses.

**Making Money in the CAaaS Ecosystem**

There are two basic paths to business success in the CAaaS value chain: Service providers rely on their technical skills to create and sell new services, while the attack creators design and launch successful attacks utilizing those services.

The service providers use several different pricing models. In many cases, their offerings are available for a one-time fee for unlimited use. For example, in June 2016, a Microsoft Office zero-day vulnerability (that is, a vulnerability not previously discovered and with no known fix), was priced at $30,031 in Bitcoin in a dark web market. A one-day vulnerability (that is, a vulnerability for which a patch is available but often not deployed), cost about $648.10, including the exploit.

Some service providers adopt more creative, pay-for-results pricing models. For example, malware is sometimes sold on a pay-per-install basis, in which buyers only pay a fee, typically in the $0.02 to $0.10 range, if and when the malware is successfully installed on a victim’s machine.\(^\text{14}\) There are profit-sharing pricing schemes: “GandCrab” ransomware offers a partner program in which members share 40% of the profits with the developers.\(^\text{15}\) There are also subscription models in which users receive updates and improvements in return for an ongoing fee: The ShadowBrokers Dump Service is a “zero-day vulnerabilities and exploits” service that offers monthly subscribers access to continually-updated lists of vulnerabilities, tools, and datasets.

In contrast to service providers, attack creators are often business-savvy managers, not tech gurus. They conceive attacks and then use the services in the CAaaS value chain to execute them.

To create and execute a ransomware attack (as shown in “Using CAaaS for a Ransomware Attack”), a attack creator can buy the Neutrino exploit kit packaged with a ransomware payload (complete with customer support), the bulletproof servers to host the exploit kit and ransomware payload, a botnet as the infrastructure, an obfuscation service to make it more difficult for an anti-malware solution to detect the attack, and a traffic redirection service to bring victims to the servers. If the creator encounters problems running the attack, he or she can hire a hacker with previous ransomware experience to solve technical issues. In addition, the creator can hire a service to collect the ransom in cryptocurrency and a money laundering service to safely obtain it.

Based on prices we’ve observed on the dark web, the combination of services described above would likely cost the attack creator about $13,000 per month, plus a 40% commission on any gains processed through a money-laundering service. Based on Angler revenue reported by

\(^{15}\) “Behind the veil – GandCrab Ransomware Partner Program,” LMNTRIX Lab, Feb 3, 2018, https://www.lmntrix.com/Lab/Lab_info.php?id=95
Cisco in 2017 and an understanding of advanced defensive efforts, it is reasonable to assume that such an attack would redirect 900,000 users per month to the servers hosting the exploit kit and ransomware payload.\footnote{“Cisco 2016 Annual Security Report” Cisco Security Research, 2016.} If only 10% of the 900,000 users were frozen out of their machines and 0.5% of the victims paid a $300 ransom, the attack would earn $81,000 per month for the attackers after money laundering commissions. Overall, the attack would produce an ROI of more than 500%.

**Changing the Defensive Playbook**

Examining cyber attacks through the lens of a value chain reveals organized businesspeople using proven business models within a well-defined ecosystem governed by the dictates of supply and demand. This CAaaS ecosystem makes mounting targeted, scalable cyber attacks quicker, cheaper, and more difficult to stop. But understanding all that helps organizations reimagine how to combat cyber attacks. They can fight back in the following ways:

1. **Expand the focus of cyber threat intelligence.**

Many cyber threat intelligence services collect data from enterprise IT environments to detect potential cyber threats. There is some investigation of the dark web, but it is usually limited to harvesting threat information and alerting potential targets. Investigators, for example, can find out whether a company’s data is being traded in a dark web marketplace or whether its machines are part of botnets. But rarely do threat intelligence processes look at services provided in these marketplaces.

Because many of today’s cyber attacks are created by linking services, the emergence of new services can alert defenders and potential targets to the kinds of attacks that may brewing. For example, the spike in data breach incidents over the past few years suggests that we will likely see an increase in services offering personal profiles and, thus, in the number and kinds of attacks that use personal profiles. Monitoring and investigating these services can yield insights into new and more effective defense mechanisms.

Furthermore, since we know that the demand exists for services that will enhance the business case for attackers and that providers will work to fill that demand, we should be able to identify and potentially block emerging attack vectors. For example, when cryptojacking services like Coinhive, CryptoLoot, and JSEcoin emerged in dark web markets and the price of cryptocurrency skyrocketed in late 2017, we could have expected the increase of cryptojacking attacks that occurred in early 2018.

2. **Pursue a good offense as the best defense.**

Cyber strategy in most organizations is mainly reactive. Companies defend themselves after successful attacks have been launched. A value-chain-based view of attacks enables a more proactive strategy: We can switch to playing offense by disrupting the CAaaS ecosystem.
Understanding that attacks are created by combining services reveals new avenues for undermining them. For example, defenders can flood the cyber attack ecosystem with deceptive services, making the dark web less attractive for cybercriminals seeking to purchase services.\(^{17}\) This happened in 2017 when Dutch police infiltrated Hansa, one of the largest dark web markets at the time, and collected information for a month before acting against the service providers and attack creators using it. The operation not only shut down Hansa but also had the knock-on effect of eroding trust in other dark web markets.\(^{18}\)

Another offensive strategy is to disrupt select services that are frequently used to create attack vectors, thereby making it difficult and risky to orchestrate an attack. For example, by monitoring and infiltrating botnet services, law enforcement agencies can anticipate and prevent attacks that use them. Likewise, infiltrating cryptocurrency-based money laundering services could deter attackers by making it difficult for them to access their illegal gains.

### 3. Create a cyber defense service value chain.

If cyber criminals can create a value chain that makes it easier and more profitable to launch attacks, why can’t we build a defensive value chain? Cyber attack defense cannot be relegated to law enforcement agencies alone. Instead, it requires an ecosystem aimed at combating cybercrime that includes many actors—individuals, corporations, software and hardware providers, cyber security solution providers, infrastructure operators, financial systems, and governments—working together.

Ideally, for instance, we would see governments supporting the creation of a defensive value chain with policy, regulation, and cultural norms. Infrastructure operators, such as the internet service providers, would use their advantaged monitoring position to disrupt the delivery of cyber attacks. Financial institutions would act to block the monetary activities of cybercriminals, including their money-laundering networks and cryptocurrency monetization activities.

Granted, bringing together such disparate parties with so many interests is a Herculean task, and it’s not entirely clear how it should be approached. One possibility is to better align the capabilities needed to combat cybercrime with financial incentives to act. If organizations demonstrate sufficient demand and willingness to pay for cyber-defense-as-a-service—so it can essentially compete with cyber-attacks-as-a-service for providers and resources—a robust defense ecosystem is more likely to materialize.

No matter how it is accomplished, however, collecting defense services into a value chain would likely motivate more service providers to create and sell as-a-service cyber defense offerings, expanding the menu of activities that could be assembled by defenders to thwart attacks. Fighting fire with fire would be far more effective than today’s splintered efforts.

---

4. Approach defense as a business problem first, not a technology problem.

When business leaders ask, “How can we prepare for unknown cyber attacks?” they often assume that attackers are using new and perhaps unknown technologies. Although this is sometimes true, frequently the attackers and defenders use the same technologies: DDoS attacks, for example, use technology originally developed for software system stress testing. Ironically, many technologies used in attacks were initially developed by the defensive research community to block other kinds of attacks.

Moreover, today’s cyber attacks are often orchestrated by clever businesspeople who target organizations with something of value to steal or disrupt. So they should be treated like other business threats. Risk management tools and techniques can shed additional light on what’s driving the attacks, help identify vulnerabilities that attackers may prey upon, and enable potential targets to anticipate next moves. Organizations also can use their managerial expertise in business processes, operations, and strategies to help create a more complete perspective on cyber attacks. Protecting the business and detecting, responding to, and recovering from attacks is not solely the responsibility of technology experts.

As cyber attacks are becoming more frequent, dynamic, and damaging, it is clear that the current defensive mindset is not adequate to stem the tide. We need to shift our view of cybercrime from that of a chaotic, random set of events to that of a structured, often predictable set of business engagements and processes. Understanding cybercrime as an orchestration of services available on the dark web offers new insights into potential threats and effective ways of fighting them. It’s long past time to start beating the bad guys at their own game.
