Negative leap second: Climate change delays unusual step for time standard

In our technologically interconnected era, many devices and systems rely on sharing a certain awareness of precisely what time it is. While leap seconds have largely been absorbed into current mechanisms, experts say, a negative leap second — or, a minute with only 59 seconds — could pose an entirely new challenge.

They were created as a way to reconcile deviations between traditional astronomical time and the newer international reference based on atomic clocks, known as Coordinated Universal Time or UTC. It's a process that for years has been complicated by variations in the Earth's rotation.

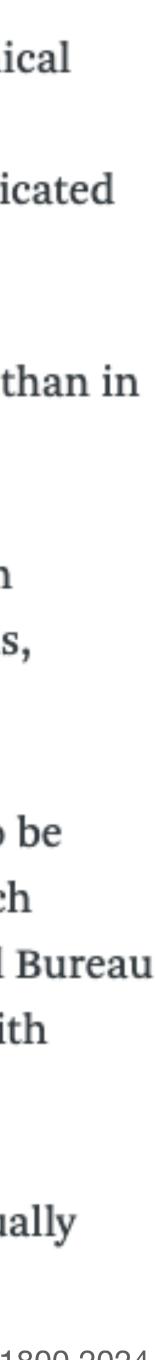

"By the 1960s, Earth was and had been decelerating, and so rotating more slowly than in the nineteenth century, which defined the atomic second," Agnew writes.

The first leap second was added in 1972. In the first decades, it became nearly an annual process. In the past 23 years, scientists have added only four leap seconds, according to Agnew.

"Since 1972, irregularities in Earth's movement have called for 27 leap seconds to be added — at irregular intervals and with a maximum of only 6 months' notice each time," said Patrizia Tavella, director of <u>the Time Department</u> at the International Bureau of Weights and Measures in France, <u>in a discussion</u> published in *Nature* along with Agnew's research.

The current problem, Agnew says, is that Earth's rotation now seems to be gradually getting faster than the established time standard can account for.

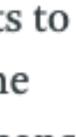

https://www.wbur.org/npr/1241674216/climate-change-time-negative-leap-second

And here's where things get a bit weird. Human-induced climate change actually acts to slow down the planet's rotation, Agnew says, because when ice melts at the poles, the planet gets a bit more oblong — wider at the equators — and less spherical. That means Earth spins a little slower, like when an ice skater holds their arms out, rather than pulling them in.

The net result for timekeepers, the new research says, is that climate change seems to have delayed the potential need for a negative leap second, at least for a bit.

https://www.wbur.org/npr/1241674216/climate-change-time-negative-leap-second

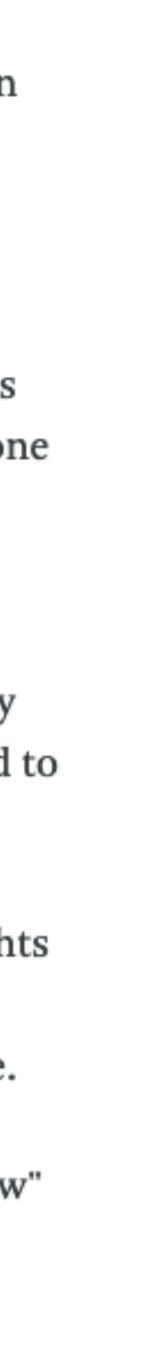

Leap seconds have had critics for a long minute, in part because of the havoc they can wreak on things like online reservation and retail systems. A couple years ago, <u>engineers at Meta railed against it</u>, stating, "Introducing new leap seconds is a risky practice that does more harm than good" and should be replaced.

Worth noting: "In 2012, <u>a leap second caused a major Facebook outage, as</u> Facebook's Linux servers became overloaded trying to work out why they had been transported one second into the past," <u>the Data Center Dynamics</u> website noted.

"Many systems now have software that can accept an additional second, but few if any allow for removing a second," Agnew said, "so that a negative leap second is expected to create many difficulties."

Other solutions could present themselves. In 2022, the General Conference on Weights and Measures <u>decided to eliminate</u> the leap second by 2035. The organization could decide to eliminate the potential of a negative leap second sooner than that deadline.

Agnew suggests the groups that determine UTC should adopt a new rule: "never allow" a negative leap second.

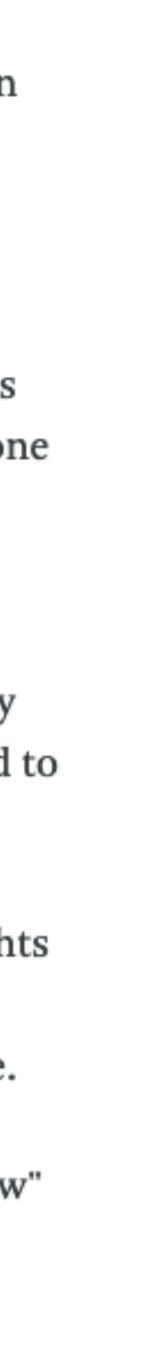

what assumptions are built into our systems? what happens when those assumptions are wrong? Leap seconds have had critics for a long minute, in part because of the havoc they can wreak on things like online reservation and retail systems. A couple years ago, <u>engineers at Meta railed against it</u>, stating, "Introducing new leap seconds is a risky practice that does more harm than good" and should be replaced.

Worth noting: "In 2012, <u>a leap second caused a major Facebook outage, as</u> Facebook's Linux servers became overloaded trying to work out why they had been transported one second into the past," <u>the Data Center Dynamics</u> website noted.

"Many systems now have software that can accept an additional second, but few if any allow for removing a second," Agnew said, "so that a negative leap second is expected to create many difficulties."

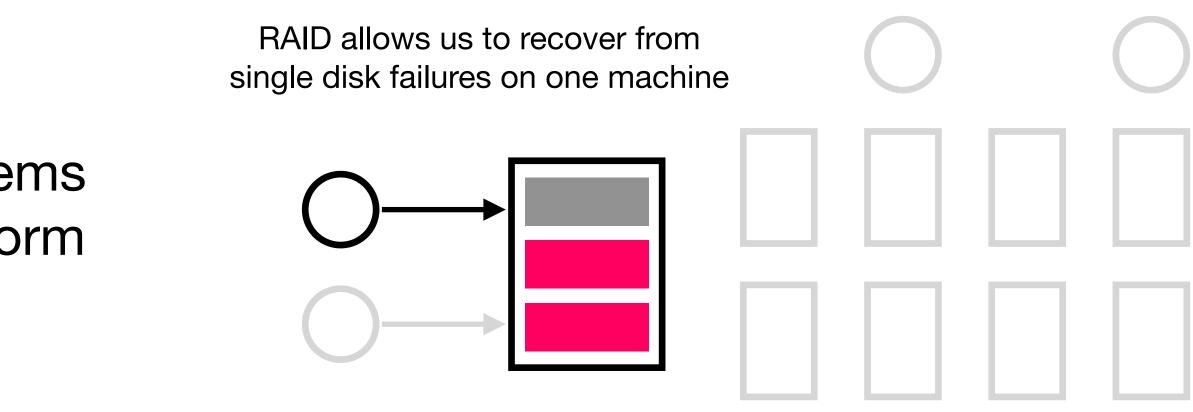

Other solutions could present themselves. In 2022, the General Conference on Weights and Measures <u>decided to eliminate</u> the leap second by 2035. The organization could decide to eliminate the potential of a negative leap second sooner than that deadline.

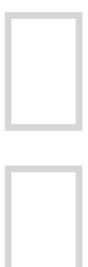

Agnew suggests the groups that determine UTC should adopt a new rule: "never allow" a negative leap second.

our goal is to build **reliable systems from unreliable components**. we want to build systems that serve many clients, store a lot of data, perform well, all while keeping availability high

> the high-level process of dealing with failures is to identify the faults, detect/contain the faults, and handle the faults. in lecture, we will build a **set of abstractions** to make that process more manageable

atomicity

transfer (bank, account_a, account_b, amount): bank[account_a] = bank[account_a] - amount bank[account_b] = bank[account_b] + amount

atomicity

atomicity

problem: account_a lost amount dollars, but **account_b** didn't gain **amount** dollars

atomicity

solution: make this action **atomic**. ensure that the system completes both steps or neither step.

atomicity

solution: make this action **atomic**. ensure that the system completes both steps or neither step.

current quest: update the bank transfer code to make this action atomic

atomicity

transfer (bank_file, account_a, account_b, amount): bank = read_accounts(bank_file) bank[account_a] = bank[account_a] - amount bank[account_b] = bank[account_b] + amount write_accounts(bank_file)

current quest: update the bank transfer code to make this action atomic idea: write to a file so that a crash in between lines 2 and 3 has no effect

atomicity

an action is atomic if it **happens** completely or not at all. if we can guarantee atomicity, it will be much easier to reason about failures

transfer (bank_file, account_a, account_b, amount): bank = read_accounts(bank_file) bank[account_a] = bank[account_a] - amount bank[account_b] = bank[account_b] + amount write_accounts(bank_file)

current quest: update the bank transfer code to make this action atomic idea: write to a file so that a crash in between lines 2 and 3 has no effect

atomicity

transfer (bank_file, account_a, account_b, amount): bank = read_accounts(bank_file) bank[account_a] = bank[account_a] - amount bank[account_b] = bank[account_b] + amount write accounts(bank_file)

if the system crashes here, upon recovery, it will appear as if the transfer didn't happen at all because we didn't make any updates to **bank_file**

current quest: update the bank transfer code to make this acti idea: write to a file so that a crash in between lines 2 and 3 has no effect

at	0	m	C	ity

	0	r	ר	C	7	+	ſ))	m	1	,	C	
-	U	1	5	U		C	U	, ,		C			

transfer (bank_file, account_a, account_b, amount): bank = read_accounts(bank_file) bank[account_a] = bank[account_a] - amount bank[account_b] = bank[account_b] + amount write_accounts(bank_file)

current quest: update the bank transfer code to make this action atomic idea: write to a file so that a crash in between lines 2 and 3 has no effect

atomicity

an action is atomic if it **happens** completely or not at all. if we can guarantee atomicity, it will be much easier to reason about failures

transfer (bank_file, account_a, account_b, amount): bank = read_accounts(bank_file) bank[account a] = bank[account a] - amount bank[account_b] = bank[account_b] + amount write_accounts(bank_file) ← crash! 💥

current quest: update the bank transfer code to make this action atomic idea: write to a file so that a crash in between lines 2 and 3 has no effect

atomicity

an action is atomic if it **happens** completely or not at all. if we can guarantee atomicity, it will be much easier to reason about failures

transfer (bank_file, account_a, account_b, amount): bank = read_accounts(bank_file) bank[account_a] = bank[account_a] - amount bank[account b] = bank[account b] + amount write_accounts(bank_file) ← crash! 💥

problem: a crash during write accounts() leaves **bank_file** in an intermediate state

current quest: update the bank transfer code to make this action atomic idea: write to a file so that a crash in between lines 2 and 3 has no effect

atomicity

an action is atomic if it **happens** completely or not at all. if we can guarantee atomicity, it will be much easier to reason about failures

transfer (bank_file, account_a, account_b, amount): bank = read_accounts(bank_file) bank[account a] = bank[account a] - amount bank[account b] = bank[account b] + amount write_accounts(tmp_file) rename(tmp_file, bank_file)

current quest: update the bank transfer code to make this action atomic idea: write to a temporary file so that a crash in between lines 2 and 3 has no effect, and neither does a crash during a write

atomicity

transfer (bank_file, account_a, account_b, amount): bank = read_accounts(bank_file) bank[account_a] = bank[account_a] - amount bank[account b] = bank[account b] + amount rename(tmp_file, bank_file)

current quest: update the bank transfer code to make this action atomic idea: write to a temporary file so that a crash in between lines 2 and 3 has no effect, and neither does a crash during a write

atomicity

transfer (bank_file, account_a, account_b, amount): bank = read accounts(bank file) bank[account_a] = bank[account_a] - amount bank[account b] = bank[account b] + amount rename(tmp_file, bank_file)

if the system crashes here, upon recovery, it will appear as if the transfer didn't happen at all because we didn't make any updates to **bank_file**. we don't read from tmp_file, so it's okay if it was left in an intermediate state

current quest: update the bank transfer code to make this action atomic idea: write to a temporary file so that a crash in between lines 2 and 3 has no effect, and neither does a crash during a write

atomicity

transfer (bank_file, account_a, account_b, amount): bank = read_accounts(bank_file) bank[account a] = bank[account a] - amount bank[account b] = bank[account b] + amount write_accounts(tmp_file) rename(tmp_file, bank_file)

current quest: update the bank transfer code to make this action atomic idea: write to a temporary file so that a crash in between lines 2 and 3 has no effect, and neither does a crash during a write

atomicity

transfer (bank_file, account_a, account_b, amount): bank = read_accounts(bank_file) bank[account_a] = bank[account_a] - amount bank[account b] = bank[account b] + amount write_accounts(tmp_file) rename(tmp_file, bank_file) ← crash! 💥

current quest: update the bank transfer code to make this action atomic idea: write to a temporary file so that a crash in between lines 2 and 3 has no effect, and neither does a crash during a write

atomicity

transfer (bank_file, account_a, account_b, amount): bank = read accounts(bank_file) bank[account_a] = bank[account_a] - amount bank[account b] = bank[account b] + amount write_accounts(tmp_file) rename(tmp_file, bank_file) ← crash! 💥

problem: a crash during **rename()** potentially leaves **bank_file** in an intermediate state

current quest: update the bank transfer code to make this action atomic idea: write to a temporary file so that a crash in between lines 2 and 3 has no effect, and neither does a crash during a write

atomicity

transfer (bank_file, account_a, account_b, amount): bank = read accounts(bank_file) bank[account_a] = bank[account_a] - amount bank[account b] = bank[account b] + amount write_accounts(tmp_file) rename(tmp_file, bank_file) ← crash! 💥

solution: make rename() atomic

current quest: update the bank transfer code to make this action atomic idea: write to a temporary file so that a crash in between lines 2 and 3 has no effect, and neither does a crash during a write

atomicity

transfer (bank_file, account_a, account_b, amount): bank = read accounts(bank_file) bank[account_a] = bank[account_a] - amount bank[account b] = bank[account b] + amount write_accounts(tmp_file)

solution: make rename() atomic

making rename() atomic is more feasible than making write_accounts() atomic; we'll see why as we go along

current quest: update the bank transfer code to make this action atomic idea: write to a temporary file so that a crash in between lines 2 and 3 has no effect, and neither does a crash during a write

atomicity

an action is atomic if it **happens** completely or not at all. if we can guarantee atomicity, it will be much easier to reason about failures

current quest: ensure that rename is atomic, so that our approach to the bank transfer code works

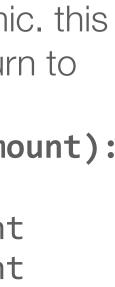

atomicity

an action is atomic if it **happens** completely or not at all. if we can guarantee atomicity, it will be much easier to reason about failures

we're in an interlude, working on making rename atomic. this is the bank transfer code, which we'll eventually return to

transfer (bank_file, account_a, account_b, amount): bank = read_accounts(bank_file) bank[account_a] = bank[account_a] - amount bank[account_b] = bank[account_b] + amount write_accounts(tmp_file) rename(tmp_file, bank_file)

refcount: 1	refcount: 1

rename(tmp_file, orig_file): tmp inode = lookup(tmp file) // = 2 orig inode = lookup(orig_file) // = 1

orig_file dirent = tmp_inode — crash! 💥 remove tmp_file dirent (here, or anywhere after this) decref(orig_inode) rename happened,

but refcounts might be wrong

current quest: ensure that rename is atomic, so that our approach to the bank transfer code works

v data : [..]

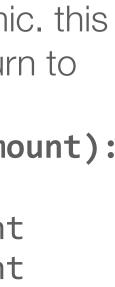

atomicity

an action is atomic if it **happens** completely or not at all. if we can guarantee atomicity, it will be much easier to reason about failures

we're in an interlude, working on making rename atomic. this is the bank transfer code, which we'll eventually return to

```
transfer (bank_file, account_a, account_b, amount):
    bank = read_accounts(bank_file)
    bank[account_a] = bank[account_a] - amount
    bank[account_b] = bank[account_b] + amount
    write_accounts(tmp_file)
    rename(tmp_file, bank_file)
```

solution: recover from failure

(clean things up)

recover(disk): for inode in disk.inodes: inode.refcount = find_all_refs(disk.root_dir, inode) if exists(tmp_file): unlink(tmp_file)

current quest: ensure that rename is atomic, so that our approach to the bank transfer code works

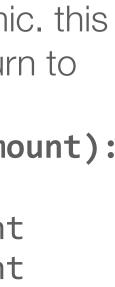

atomicity

an action is atomic if it **happens** completely or not at all. if we can guarantee atomicity, it will be much easier to reason about failures

we're in an interlude, working on making rename atomic. this is the bank transfer code, which we'll eventually return to

transfer (bank_file, account_a, account_b, amount): bank = read accounts(bank_file) bank[account_a] = bank[account_a] - amount bank[account_b] = bank[account_b] + amount write_accounts(tmp_file) rename(tmp_file, bank_file)

solution: recover from failure

(clean things up)

recover(disk): for inode in disk.inodes: inode.refcount = find_all_refs(disk.root_dir, inode) if exists(tmp_file): unlink(tmp_file)

having a recovery process means that we don't have to worry about getting everything completely correct before the failure happens; we have a chance to clean things up afterwards

current quest: ensure that rename is atomic, so that our approach to the bank transfer code works

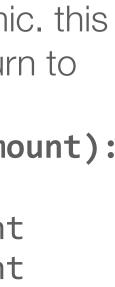

atomicity

an action is atomic if it **happens** completely or not at all. if we can guarantee atomicity, it will be much easier to reason about failures

we're in an interlude, working on making rename atomic. this is the bank transfer code, which we'll eventually return to

transfer (bank_file, account_a, account_b, amount): bank = read_accounts(bank_file) bank[account_a] = bank[account_a] - amount bank[account_b] = bank[account_b] + amount write_accounts(tmp_file) rename(tmp_file, bank_file)

transfer (bank_file, account_a, account_b, amount): bank = read_accounts(bank_file) bank[account_a] = bank[account_a] - amount bank[account_b] = bank[account_b] + amount write_accounts(tmp_file) rename(tmp_file, bank_file)

atomicity

an action is atomic if it **happens** completely or not at all. if we can guarantee atomicity, it will be much easier to reason about failures

transfer (bank_file, account_a, account_b, amount): bank = read accounts(bank_file) bank[account a] = bank[account a] - amount bank[account b] = bank[account_b] + amount write_accounts(tmp_file) rename(tmp_file, bank_file)

renaming the file — specifically modifying bank_file's directory entry — is the commit point. if the system crashes before the commit point, it's as if the operation didn't happen; if it crashes after the commit point, the operation must complete. the commit point itself must also be atomic.

atomicity

an action is atomic if it **happens** completely or not at all. if we can guarantee atomicity, it will be much easier to reason about failures

transfer (bank_file, account_a, account_b, amount): bank = read_accounts(bank_file) bank[account_a] = bank[account_a] - amount bank[account_b] = bank[account_b] + amount write_accounts(tmp_file) rename(tmp_file, bank_file)

atomicity

an action is atomic if it **happens** completely or not at all. if we can guarantee atomicity, it will be much easier to reason about failures

isolation

transfer (bank_file, account_a, account_b, amount): bank = read accounts(bank_file) bank[account_a] = bank[account_a] - amount bank[account b] = bank[account b] + amount write_accounts(tmp_file) rename(tmp_file, bank_file)

isolation deals with concurrency, and we've seen that. couldn't we just put locks around everything?

isn't that what locks are for?

atomicity

an action is atomic if it **happens** completely or not at all. if we can guarantee atomicity, it will be much easier to reason about failures

isolation

```
transfer (bank_file, account_a, account_b, amount):
    acquire(lock)
    bank = read_accounts(bank file)
    bank[account_a] = bank[account_a] - amount
    bank[account_b] = bank[account_b] + amount
    write accounts(tmp_file)
    rename(tmp_file, bank_file)
    release(lock)
```

isolation deals with concurrency, and we've seen that. couldn't we just put locks around everything?

isn't that what locks are for?

atomicity

an action is atomic if it **happens** completely or not at all. if we can guarantee atomicity, it will be much easier to reason about failures

isolation

```
transfer (bank_file, account_a, account_b, amount):
    acquire(lock)
    bank = read_accounts(bank file)
    bank[account_a] = bank[account_a] - amount
    bank[account_b] = bank[account_b] + amount
    write accounts(tmp_file)
    rename(tmp_file, bank_file)
    release(lock)
```

isolation deals with concurrency, and we've seen that. couldn't we just put locks around everything?

isn't that what locks are for?

this particular strategy will perform poorly

would force a single transfer at a time

locks sometimes require global reasoning, which is messy

eventually, we'll incorporate locks, but in a systematic way

atomicity

an action is atomic if it **happens** completely or not at all. if we can guarantee atomicity, it will be much easier to reason about failures

isolation

transactions provide atomicity and isolation

atomicity

an action is atomic if it **happens** completely or not at all. if we can guarantee atomicity, it will be much easier to reason about failures

isolation

transactions provide atomicity and isolation

Transaction 1

begin transfer(A, B, 20) withdraw(B, 10) end

Transaction 2

begin transfer(B, C, 5) deposit(A, 5) end

atomicity

an action is atomic if it **happens** completely or not at all. if we can guarantee atomicity, it will be much easier to reason about failures

isolation

transactions provide atomicity and isolation

Transaction 1

begin transfer(A, B, 20) withdraw(B, 10) end

Transaction 2

begin transfer(B, C, 5) deposit(A, 5) end

atomicity and isolation — and thus, transactions — make it easier to reason about failures (and concurrency)

atomicity

an action is atomic if it **happens** completely or not at all. if we can guarantee atomicity, it will be much easier to reason about failures

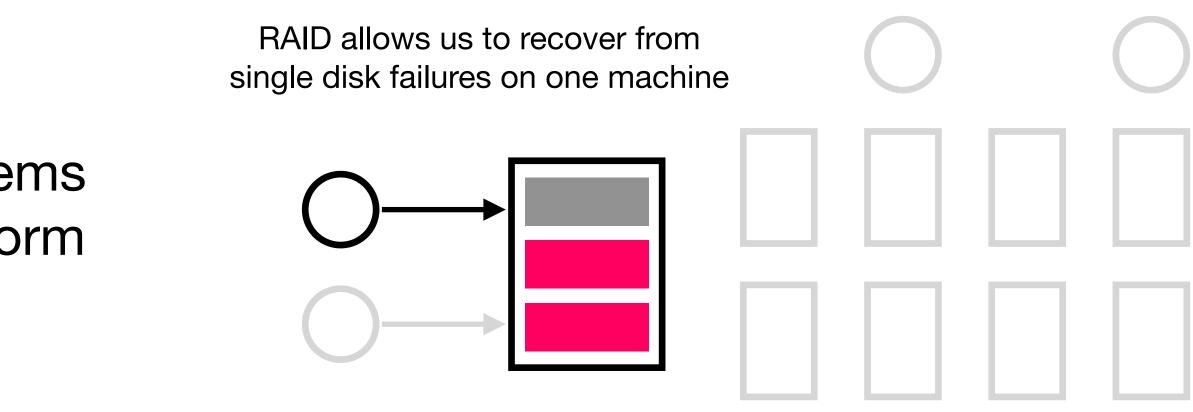

isolation

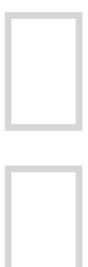

isolation refers to how and when the effects of one action (A1) are visible to another (A2). *in lecture*, we will aim to get a high level of isolation, where A1 and A2 appear to have executed serially, even if they are actually executed in parallel.

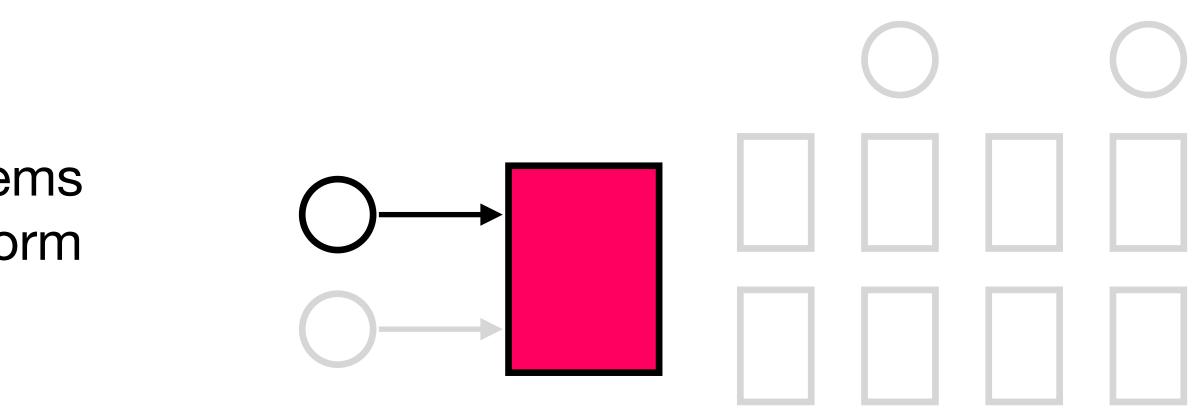

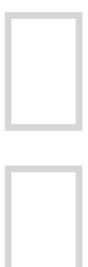

> the high-level process of dealing with failures is to identify the faults, detect/contain the faults, and handle the faults. in lecture, we will build a **set of abstractions** to make that process more manageable

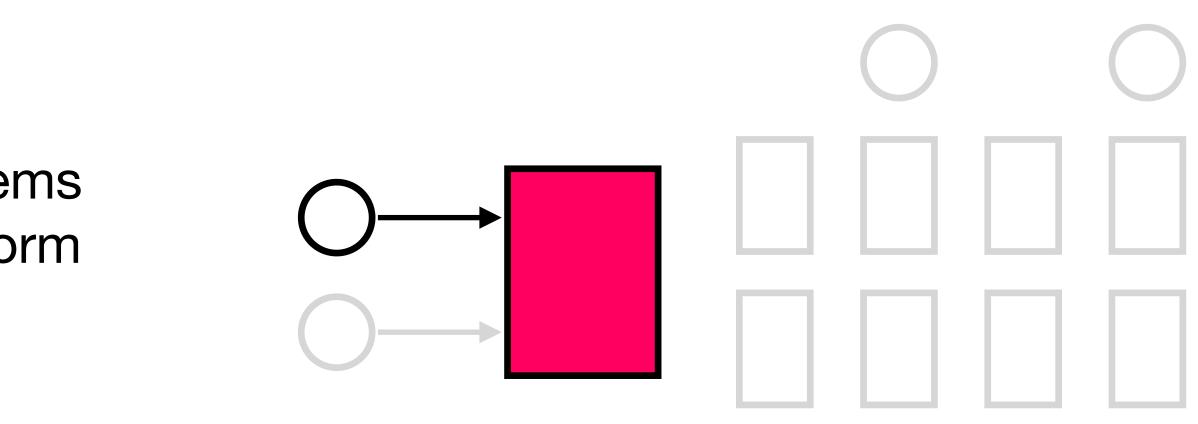

> the high-level process of dealing with failures is to identify the faults, detect/contain the faults, and handle the faults. in lecture, we will build a **set of abstractions** to make that process more manageable

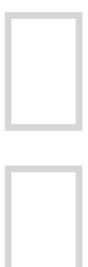

transactions — which provide **atomicity** and **isolation** — make it easier for us to reason about failures

our job in lecture is to understand how a system *implements* transactions. how do our systems guarantee atomicity? how do they guarantee isolation?

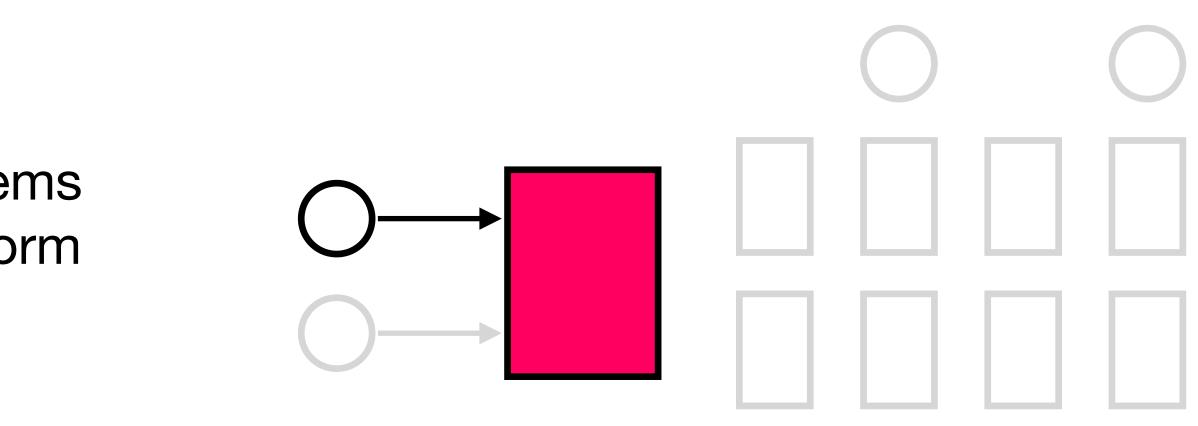

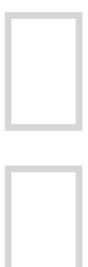

transactions — which provide **atomicity** and **isolation** — make it easier for us to reason about failures

our job in lecture is to understand how a system *implements* transactions. how do our systems guarantee atomicity? how do they guarantee isolation?

atomicity: we have this working for one user and one file via *shadow copies*, but they perform poorly

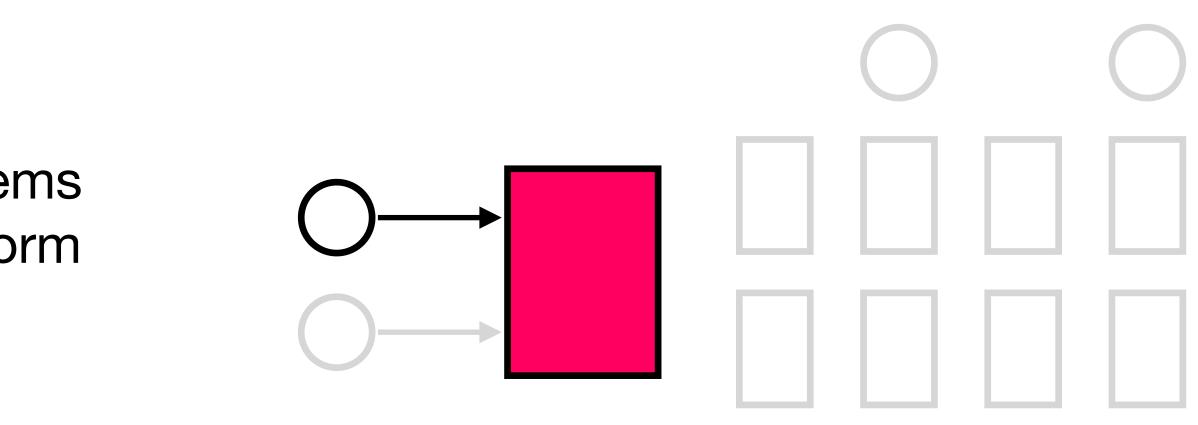

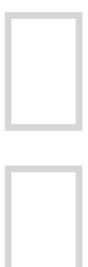

transactions — which provide **atomicity** and **isolation** — make it easier for us to reason about failures

our job in lecture is to understand how a system *implements* transactions. how do our systems guarantee atomicity? how do they guarantee isolation?

atomicity: we have this working for one user and one file via *shadow copies*, but they perform poorly

isolation: we don't really have this yet coarse-grained locks perform poorly; fine-grained locks are difficult to reason about

transactions provide atomicity and isolation, both of which make it easier for us to reason about failures because we don't have to deal with intermediate states.

shadow copies are one way to achieve atomicity. they work in certain cases, but perform poorly: requiring us to copy an entire file even for small changes — and don't allow for concurrency.

our main goal for the next few lectures is to *implement* transactions. how do we get the underlying system to provide atomicity and isolation so that this abstraction can exist?

we haven't covered how one would use shadow copies in general (e.g., outside of the world of banking). and we won't; next time, we'll work on a scheme that is superior in every way
