- To help us give partial credit, show your work and state any assumptions that you make.

Question 1	26 points
Question 2	36 points
Question 3	38 points

Name: _____

1. Consider the following autosomal *Drosophila*, traits caused by recessive alleles: bent wings (**bn**⁻), short legs (**sh**⁻), and orange eyes (**or**⁻). You cross two true breeding lines to produce F1 flies, all of which have the wild type phenotype (strait wings, long legs, and red eyes). F1 females are then mated to triply homozygous males with bent wings, short legs, and orange eyes. Among 100 progeny from this cross you observe the following phenotypes:

<u>Phenotype</u>	<u>Number</u>
strait wings, long legs, and red eyes	10
bent wings, short legs, and orange eyes	14
strait wings, short legs, and red eyes	26
bent wings, long legs, and orange eyes	30
strait wings, long legs, and orange eyes	8
bent wings, short legs, and red eyes	6
strait wings, short legs, and orange eyes	2
bent wings, long legs, and red eyes	4

(a 6 points) What were the genotypes of the two true breeding parental lines that were crossed?

(b 12 points) Draw a genetic map showing the order and relevant distances in cM of the **bn**, **sh**, and **or** markers.

Name: _____

(c 8 points) A colleague calls to tell you she plans to carry out the following two-factor cross. A true breeding line with bent wings will be crossed to a true breeding line with short legs (unless specified other traits appear normal). F1 flies will then be crossed to a true breeding strain with bent wings and short legs. Your colleague wants to know what proportion of the progeny from this cross will have bent wings and short legs. What would you tell her?

2. The pedigree shows inheritance of an X-linked recessive trait. (Assume the trait is completely penetrant).

(a 4 pts.) What is the probability that the female designated **1** is a carrier for the trait?

(b 6 pts.) If the child indicated by **?** is a boy, what is the probability he will be affected by the trait?

Name: _____

(c 6 pts.) If the child indicated by **?** is a girl, what is the probability she will be affected by the trait?

(d 8 pts.) If the child indicated by **?** is affected by the trait, what is the probability that the couple's next child will be affected by the trait?

(e 12 pts.) If the child indicated by **?** is not affected by the trait, calculate the new probability that the female designated **1** is a carrier for the trait.

Name: _____

3. You have isolated two different yeast mutants called *cys1⁻* and *cys2⁻* that cannot synthesize the amino acid cysteine and therefore require cysteine added to the medium for growth (i.e. they are Cys⁻).

(a 4 points) You mate a call *cys1⁻* mutant to a *cys2⁻* mutant. The resulting diploids don't require cysteine (i.e. they are Cys⁺). What does this tell you about the *cys1⁻* and *cys2⁻* mutations?

Next, you sporulate the diploid from part **(a)**. Among the 50 tetrads analyzed three different tetrad types are found

Type:	4 Cys ⁻	3 Cys ⁻ : 1 Cys ⁺	2 Cys ⁻ : 2 Cys ⁺
Number:	39	10	1

(b 6 points) Say that you want a *cys1⁻cys2⁻* double mutant. What is the easiest way to obtain such a mutant without further analysis?

(c 6 points) You choose one of the tetrads for further analysis and the four spores have the following properties: Spore 1 = MAT α Cys⁺, Spore 2 = MAT α Cys⁻, Spore 3 = MAT α Cys⁻, and Spore 4 = MAT α Cys⁻. You carry out the matings that are possible and find that the diploid produced by mating Spore 2 to Spore 3 is Cys⁻, while the diploid produced by mating Spore 2 to Spore 4 is Cys⁺. Which spore is the double mutant? Explain your reasoning.

Name: _____

(d 6 points) Given the number of tetrads of each type, what is the distance between the *cys1⁻* and *cys2⁻* mutations?

You have isolated a mutation that you call *cysX⁻* that activates an alternative pathway for cysteine synthesis. A *cysX⁻* mutation on its own is Cys⁺, and when a *cysX⁻* mutation is combined with a *cys1⁻* mutation, the double mutant is Cys⁺.

(e 8 points) Describe the cross you would perform and the interpretation of the outcome that you would use to determine whether *cysX⁻* is dominant or recessive?

(f 8 points) Say that *cysX⁻* is 5 cM away from *cys1⁻*. In a cross of a MAT α *cysX⁻* mutant to a MAT α *cys1⁻* mutant what types of tetrads (in terms of the proportion of Cys⁻ : Cys⁺) would you expect to find and how many of each type would you expect from a total of 50 tetrads?

Question 1 26 points

Question 2 36 points

Question 3 38 points

Name: _____

1. Consider the following autosomal *Drosophila* traits caused by recessive alleles: bent wings (**bn**⁻), short legs (**sh**⁻), and orange eyes (**or**⁻). You cross two true breeding lines to produce F1 flies, all of which have the wild type phenotype (strait wings, long legs, and red eyes). F1 females are then mated to triply homozygous males with bent wings, short legs, and orange eyes. Among 100 progeny from this cross you observe the following phenotypes:

<u>Phenotype</u>	<u>Number</u>
strait wings, long legs, and red eyes	10
bent wings, short legs, and orange eyes	14
strait wings, short legs, and red eyes	26
bent wings, long legs, and orange eyes	30
strait wings, long legs, and orange eyes	8
bent wings, short legs, and red eyes	6
strait wings, short legs, and orange eyes	2
bent wings, long legs, and red eyes	4

(a 6 points) What were the genotypes of the two true breeding parental lines that were crossed?

We can determine the genotypes of the parental flies by looking at the two highest classes of progeny in the F2. These classes are the Parental Classes. Based on these classes, we can determine that the original true-breeding strains were

bn⁻/bn⁻ sh⁺/sh⁺ or⁻/or⁻ and bn⁺/bn⁺ sh⁻/sh⁻ or⁺/or⁺

(b 12 points) Draw a genetic map showing the order and relevant distances in cM of the **bn**, **sh**, and **or** markers.

There are three possible orders for these genes along the chromosome.

or bn sh or sh bn sh or bn

Since we know what the parental genotypes are, we can draw the three possible F1 chromosome arrangements.

$$\begin{array}{ccc} \frac{or^- \quad bn^- \quad sh^+}{or^+ \quad bn^+ \quad sh^-} & \frac{or^- \quad sh^+ \quad bn^-}{or^+ \quad sh^- \quad bn^+} & \frac{sh^+ \quad or^- \quad bn^-}{sh^- \quad or^+ \quad bn^+} \end{array}$$

The smallest class of F2 progeny represents the Double-Crossover class. These progeny resulted from a double crossover event during meiosis of the F1 parent.

Double Crossover Class 1 Straight wings, short legs, orange eyes

Double Crossover Class 2 Bent wings, long legs, red eyes

Only the following order can generate these classes via a double crossover event.

$$\begin{array}{ccc} \frac{sh^+ \quad or^- \quad bn^-}{sh^- \quad or^+ \quad bn^+} & & \frac{sh^+ \quad or^+ \quad bn^-}{sh^- \quad or^- \quad bn^+} \end{array}$$

To calculate the distance between each of the markers we must add up the total number of recombinant progeny for that interval and divide by the total number of progeny.

The distance between sh and or is:

$$(10 + 14 + 4 + 2) / 100 \times 100 = 30 \text{ cM}$$

The distance between or and bn is:

$$(8 + 6 + 4 + 2) / 100 \times 100 = 20 \text{ cM}$$

The cumulative map distance between sh and bn is 50 cM

HOWEVER, if you were to calculate the distance between sh and bn by ignoring the "or" locus, you would end up with:

$$(10 + 14 + 8 + 6) / 100 \times 100 = 38 \text{ cM}$$

The correct map should be the following:

$$sh \text{ } \underline{\hspace{1cm}} \text{ 30cM } \underline{\hspace{1cm}} \text{ or } \underline{\hspace{1cm}} \text{ 20cM } \underline{\hspace{1cm}} \text{ bn}$$

Name: _____

(c 8 points) A colleague calls to tell you she plans to carry out the following two-factor cross. A true breeding line with bent wings will be crossed to a true breeding line with short legs (unless specified other traits appear normal). F1 flies will then be crossed to a true breeding strain with bent wings and short legs. Your colleague wants to know what proportion of the progeny from this cross will have bent wings and short legs. What would you tell her?

It is very important to realize that this question is dealing with a two-factor cross and not a three-factor cross. Although we have shown the cumulative map distance between "bn" and "sh" is 50 cM via a three-factor cross, the observable map distance in a two-factor cross will only be 38 cM.

This means that 38% of the F2 progeny will be recombinant progeny. One half of these progeny will inherit the sh- bn- chromosome.

Therefore, $38 / 2 = 19\%$ of the F2 progeny will have short wings and bent legs.

F1

$$\begin{array}{c} \text{sh}^+ \\ \hline \text{sh}^- \end{array} \times \begin{array}{c} \text{bn}^- \\ \hline \text{bn}^+ \end{array} \quad \times \quad \begin{array}{c} \text{sh}^- \\ \hline \text{sh}^- \end{array} \begin{array}{c} \text{bn}^- \\ \hline \text{bn}^- \end{array}$$

F2

$$\begin{array}{c} \text{sh}^+ \\ \hline \text{sh}^- \end{array} \begin{array}{c} \text{bn}^- \\ \hline \text{bn}^- \end{array} \quad 62 / 2 = 31\% \text{ Bent wings}$$

$$\begin{array}{c} \text{sh}^- \\ \hline \text{sh}^- \end{array} \begin{array}{c} \text{bn}^+ \\ \hline \text{bn}^- \end{array} \quad 62 / 2 = 31\% \text{ Short legs}$$

$$\begin{array}{c} \text{sh}^+ \\ \hline \text{sh}^- \end{array} \begin{array}{c} \text{bn}^+ \\ \hline \text{bn}^- \end{array} \quad 38 / 2 = 19\% \text{ Wild-type}$$

$$\begin{array}{c} \text{sh}^- \\ \hline \text{sh}^- \end{array} \begin{array}{c} \text{bn}^- \\ \hline \text{bn}^- \end{array} \quad 38 / 2 = 19\% \text{ Short legs and Bent wings}$$

Name: _____

2. The pedigree shows inheritance of an X-linked recessive trait. (Assume the trait is completely penetrant).

(a 4 pts.) What is the probability that the female designated **1** is a carrier for the trait?

Given that male #3 is affected, female #2 must be a carrier. As a result, the probability that female #1 is a carrier is $\frac{1}{2}$.

(b 6 pts.) If the child indicated by **?** is a boy, what is the probability he will be affected by the trait?

$$P(\text{boy ? affected}) = P(\text{\#1 is a carrier}) \times P(\text{boy ? receives } X^{\text{rec}} \text{ from mom})$$

$$= \frac{1}{2} \times \frac{1}{2} = \frac{1}{4}$$

(c 6 pts.) If the child indicated by **?** is a girl, what is the probability she will be affected by the trait?

$$P(\text{girl ? affected}) = P(\text{\#1 is a carrier}) \times P(\text{girl ? receives } X^{\text{rec}} \text{ from mom}) \times P(\text{girl ? receives } X^{\text{rec}} \text{ from dad})$$

$$= \frac{1}{2} \times \frac{1}{2} \times 1 = 1/4$$

Name: _____

(d 8 pts.) If the child indicated by ? is affected by the trait, what is the probability that the couple's next child will be affected by the trait?

If the child indicated by ? is affected, then female #1 must be a carrier. Thus, the probability that the next child is affected is $\frac{1}{2}$.

(e 12 pts.) If the child indicated by ? is not affected by the trait, calculate the new probability that the female designated 1 is a carrier for the trait.

Bayes Theorem can be used to compute this conditional probability.

X = #1 is a carrier

Y = the child isn't affected

$$P(Y/X) = \frac{1}{2}$$

$$P(X) = \frac{1}{2}$$

$$P(Y/\text{not } X) = 1$$

$$P(\text{not } X) = 1/2$$

$$P(X | Y) = p(Y | X) \cdot p(X) / [p(Y | X) \cdot p(X) + p(Y | \text{not } X) \cdot p(\text{not } X)]$$

$$P(X/Y) = \frac{(1/2 \times 1/2)}{[(1/2 \times 1/2) + (1 \times 1/2)]}$$

$$P(X/Y) = 1/3$$

After the birth of a child without the trait, the probability that female #1 is a carrier is reduced from 50% to 33.33%.

Name: _____

3. You have isolated two different yeast mutants called *cys1⁻* and *cys2⁻* that cannot synthesize the amino acid cysteine and therefore require cysteine added to the medium for growth (i.e. they are Cys⁻).

(a 4 points) You mate a *cys1⁻* mutant to a *cys2⁻* mutant. The resulting diploids don't require cysteine (i.e. they are Cys⁺). What does this tell you about the *cys1⁻* and *cys2⁻* mutations?

This result is indicative of complementation between *cys1* and *cys2*. Therefore, the mutations are in different genes.

Next, you sporulate the diploid from part (a). Among the 50 tetrads analyzed three different tetrad types are found

Type:	4 Cys ⁻	3 Cys ⁻ : 1 Cys ⁺	2 Cys ⁻ : 2 Cys ⁺
Number:	39	10	1

(b 6 points) Say that you want a *cys1⁻cys2⁻* double mutant. What is the easiest way to obtain such a mutant without further analysis?

The double crossover event creating the NPD tetrad resulted in the production of two Cys⁻ and two Cys⁺ spores. The two Cys⁻ spores (*cys1⁻cys2⁻*) are double mutants.

(c 6 points) You choose one of the tetrads for further analysis and the four spores have the following properties: Spore 1 = MAT α Cys⁺, Spore 2 = MAT α Cys⁻, Spore 3 = MAT α Cys⁻, and Spore 4 = MAT α Cys⁻. You carry out the matings that are possible and find that the diploid produced by mating Spore 2 to Spore 3 is Cys⁻, while the diploid produced by mating Spore 2 to Spore 4 is Cys⁺. Which spore is the double mutant? Explain your reasoning.

Spore 3 is the double mutant. The cross between spore 2 (Cys⁻) and spore 4 (Cys⁻) generated a Cys⁺ diploid. This is complementation and indicates that spores 2 and 4 are single mutants carrying mutations in different genes. Since we know spore 1 is Cys⁺, it is not a mutant. This leaves spore 3 as the double mutant.

Name: _____

(d 6 points) Given the number of tetrads of each type, what is the distance between the *cys1⁻* and *cys2⁻* mutations?

$$\begin{aligned}\text{Map Distance (cM)} &= 100 \times \frac{TT + 6 \text{ (NPD)}}{2 \sum \text{TETRADS}} \\ &= 100 \times [16 / 100] \\ &= 16 \text{ cM}\end{aligned}$$

You have isolated a mutation that you call *cysX⁻* that activates an alternative pathway for cysteine synthesis. A *cysX⁻* mutation on its own is Cys⁺, and when a *cysX⁻* mutation is combined with a *cys1⁻* mutation, the double mutant is Cys⁺.

(e 8 points) Describe the cross you would perform and the interpretation of the outcome that you would use to determine whether *cysX⁻* is dominant or recessive?

cysX⁻ cys1⁻ (haploid) × *cysX⁺ cys1⁻* (haploid) > *cysX⁻ cysX⁺; cys1⁻ cys1⁻* (diploid)

If diploid is *cys⁺*, then *cysX⁻* is dominant to *cysX⁺*

If diploid is *cys⁻*, then *cysX⁻* is recessive to *cysX⁺*

(f 8 points) Say that *cysX*⁻ is 5 cM away from *cys1*⁻. In a cross of a MATa *cysX*⁻ mutant to a MATα *cys1*⁻ mutant what types of tetrads (in terms of the proportion of Cys⁻ : Cys⁺) would you expect to find and how many of each type would you expect from a total of 50 tetrads?

PD(45)	NPD(0)	TT(5)
<i>cysX</i> ⁻ <i>cys1</i> ⁺	<i>cysX</i> ⁻ <i>cys1</i> ⁻	<i>cysX</i> ⁻ <i>cys1</i> ⁻
<i>cysX</i> ⁻ <i>cys1</i> ⁺	<i>cysX</i> ⁻ <i>cys1</i> ⁻	<i>cysX</i> ⁻ <i>cys1</i> ⁺
<i>cysX</i> ⁺ <i>cys1</i> ⁻	<i>cysX</i> ⁺ <i>cys1</i> ⁺	<i>cysX</i> ⁺ <i>cys1</i> ⁺
<i>cysX</i> ⁺ <i>cys1</i> ⁻	<i>cysX</i> ⁺ <i>cys1</i> ⁺	<i>cysX</i> ⁺ <i>cys1</i> ⁻
<u>2<i>cys</i>⁺ : 2<i>cys</i>⁻</u>	<u>4<i>cys</i>⁺</u>	<u>3<i>cys</i>⁺ : 1<i>cys</i>⁻</u>

Out of 50 tetrads, 0 NPD would be expected. The frequency of a double crossover is .05 x .05 = 0.0025. Of these double crossovers, only $\frac{1}{4}$ represent NPDs. Thus, only one in 1600 tetrads would be expected to be NPD.

$$\text{Map Distance (cM)} = 100 \times \frac{\text{TT} + 6 (\text{NPD})}{2 \sum \text{TETRADS}}$$

$$5 = 100 \times [((\text{TT} + (6 \times 0)) / (2 \times 50))]$$

TT = 5. Thus, the 45 remaining tetrads are PD.

7.03 Exam 2

Question 1	28 points
Question 2	39 points
Question 3	33 points

Name: _____

1. (a 12 pts.) The sequences of the three stop codons are: 5'UAG3', 5'UAA3', and 5'UGA3'. Give the sequences of the codon portion of the four tRNA genes that can be mutated by a transition mutation to generate a nonsense suppressing allele. (A transition is a mutation of a G•C to A•T or an A•T to G•C). For your answer, write out the DNA sequence of the anti-codon portion of the gene for each tRNA (be sure to label the 5' and 3' ends of both DNA strands).

Consider the following segment from the middle of a gene coding sequence with the translated amino acids indicated below each codon.

5' ... TGG CCC TTG GAT AGC ... 3'
... Trp-Pro-Leu-Asp-Ser ...

You isolate a single base pair insertion creating a frameshift mutation. The additional base is underlined and the resulting amino acid sequence is shown.

5' ... TGG CCC TTG GGA TAG C ... 3'
... Trp-Pro-Leu-Gly-Stop

(b 8 pts.) Briefly explain why a nonsense suppressing tRNA mutation can not correct this mutation.

Name: _____

(c 8 pts.) You isolate a mutation in tRNA^{pro} that carries an additional base in the anticodon loop of the tRNA (the normal anticodon sequence is 5' GGG 3' whereas your mutation has the anticodon sequence 5' AGGG 3'). This type of tRNA mutation is known as a frameshift suppressor. Write out the amino acid sequence from the segment of the protein that is produced when the frameshift is suppressed by the tRNA^{pro} frameshift suppressor mutation.

2. A LacI^S mutation alters the Lac repressor so that it cannot bind to inducer molecules such as IPTG, thus causing repression of the Lac operon even when inducer is present. Starting with an F- LacI^S strain, which makes white colonies on X-gal plates, you isolate a number of revertants that form blue colonies. After mating each revertant to a strain carrying an F' with a wild type Lac operon (including the LacI gene) you find that the revertants are of two types.

(a 8 pts.) Type 1 revertants exhibit constitutive Lac operon expression but show normally regulated expression when they carry F' Lac. What type of mutation is the most likely cause of the type 1 revertants? Be as specific as you can.

(b 8 pts.) Type 2 revertants exhibit constitutive Lac operon expression even when they carry F' Lac. What type of mutation is the most likely cause of the type 2 revertants? Be as specific as you can.

Name: _____

(c 8 pts.) Which type of revertant would you expect to be the more frequent? Explain your reasoning.

(d 15 pts.) You have a Tn5 insertion that is linked to the $LacI^S$ mutation. You grow P1 on an otherwise wild-type strain that carries the Tn5 insertion and then use this lysate to infect one of your type 1 revertant strains, selecting for kanamycin resistance (Kan^r). Among 100 Kan^r transductants, you find that 60 show normally regulated Lac expression, 35 are constitutive and 5 are uninducible. Draw a genetic map showing the relative positions of the Tn5 insertion and the $LacI^S$ and Lac revertant mutations. For your answer give the distances between the Tn5 insertion and each of the relevant mutations expressed as a cotransduction frequency. (Assume that quadruple crossovers are too rare to be present in the 100 transductants you analyze).

Name: _____

3. You are studying the regulation of synthesis of the amino acid tryptophan in a new bacterial species and you find that the first enzyme in the pathway for tryptophan synthesis (the product of the TrpA gene) is synthesized when there is no tryptophan in the medium, but is not synthesized when tryptophan is present.

(a 9 pts.) You mutagenize the bacteria by generating a collection of random insertions of the transposon Tn5 into the bacterial chromosome. By screening for altered regulation of tryptophan synthesis, you find an insertion mutation, designated Trp1⁻, which gives *uninducible* expression of TrpA even when tryptophan is absent from the medium. Transduction experiments show that the Tn5 insertion is not linked to the TrpA gene. Classify the Trp1⁻ mutation in terms of its likely genetic properties taking into account the type of mutation usually caused by a transposon insertion (explain your reasoning). Propose the type of regulatory function probably encoded by the wild type Trp1 gene. Finally, diagram a model to explain the effects of tryptophan and the wild type Trp1 gene on TrpA expression, assuming a linear pathway.

(b 9 pts.) You isolate a second Tn5 insertion mutation, designated Trp2⁻, which shows *constitutive* TrpA expression even in the presence of tryptophan. The Tn5 insertion in Trp2⁻ is *not* linked either to Trp1⁻ or to TrpA. Diagram the *two* possible models for linear regulatory pathways for TrpA that account for the behavior of the Trp1 and Trp2 genes. For each model include a role for tryptophan.

Name: _____

(c 6 pts.) Next you combine a Trp1^- with a Trp2^- mutation and find that the double mutant gives *uninducible* TrpA expression. Which model from part (b) is consistent with this new observation?

(d 9 pts.) Finally, you mutagenize the wild type Trp1 gene with a chemical mutagen and find that while most Trp1 gene mutations cause *uninducible* TrpA expression, certain rare alleles give *constitutive* expression. You designate one of these rare constitutive alleles Trp1^* . Using an F' that carries the wild type Trp1 region of the chromosome, you find that the Trp1^* allele is dominant. Propose a molecular description of the type of mutation Trp1^* might be in the context of your overall model for TrpA regulation.

Question 1	34 points
Question 2	36 points
Question 3	30 points

Name: _____

1. You are studying how yeast cells grow on sucrose and you find that both sucrose and glucose regulate expression of the *SUC1* gene, which encodes an enzyme for sucrose breakdown. *SUC1* is not expressed in cells grown without sucrose, but is induced when sucrose is added to the growth medium. In cells grown in medium that contains both sucrose and glucose, *SUC1* is not expressed. You have isolated mutations in three different genes that alter *SUC1* regulation, called **A⁻**, **B⁻** and **C⁻**. All three mutations are recessive and none of the mutations are linked to one another or to *SUC1*. *SUC1* expression in wild type yeast and each of the three mutants are shown below.

	<u><i>SUC1</i> expression</u>		
	– sucrose	+ sucrose	+ sucrose & glucose
Wild type	–	+	–
A⁻	+	+	–
B⁻	–	–	–
C⁻	–	+	+

(a 6 pts.) For each of the three genes, state whether it affects regulation by sucrose or glucose and whether it is a positive activator or a negative regulator.

Gene **A**

Gene **B**

Gene **C**

Name: _____

You cross an **A⁻** mutant to a **B⁻** mutant. After tetrads are dissected and evaluated for *SUC1* expression in either the presence or absence of sucrose, (no glucose is present in this experiment) the following tetrad types are observed.

<u>Type 1</u>	<u>Type 2</u>	<u>Type3</u>
constitutive	constitutive	constitutive
constitutive	constitutive	constitutive
regulated	regulated	uninducible
uninducible	regulated	uninducible

(b 8 pts.) What is the phenotype of the **A⁻ B⁻** double mutant? Explain how you arrived at your answer.

(c 10 pts.) Draw a model showing the interactions between the different regulatory factors encoded by **A** and **B**. Be sure to include the *SUC1* gene and to indicate where and how sucrose acts.

Name: _____

Next, you construct a set of deletions within the promoter region of the *SUC1* gene (+1 indicates the first transcribed nucleotide). The ability of each of these deletions to express *SUC1* in cells grown on different sugars is shown below.

	-300	-250	-200	-150	-100	-50	+1	- sucrose	+ sucrose	+ sucrose & glucose
1)	_____	_____	_____	_____	_____	_____	_____	-	+	-
2)	_____	_____	_____	_____	_____	_____	_____	-	+	+
3)	_____	_____	_____	_____	_____	_____	_____	-	-	-
4)	_____	_____	_____	_____	_____	_____	_____	-	+	-
5)	_____	_____	_____	_____	_____	_____	_____	-	+	-
6)	_____	_____	_____	_____	_____	_____	_____	-	-	-

(d 5 pts.) The DNA sequence of gene **C** reveals that this gene is likely to encode a DNA-binding protein. Assuming that the product of gene **C** binds to the promoter region of the *SUC1* gene, where is it most likely to bind? Explain your reasoning.

(e 5 pts.) In general, upstream activation sequences function normally regardless of their distance from the start of transcription. Which of the deletion mutants shown above show this to be true for the upstream activation sequence that responds to sucrose activation?

Name: _____

2. (a 12 pts.) Recently your lab has become interested in the function of a mouse gene called *myb*. To determine when and where *myb* is expressed during development you decide to construct a reporter for *myb* expression that can be examined in developing mice. Describe the basic procedure that you would use to produce a useful reporter for *myb* expression. For your answer include such specifics as cell type(s), a diagram of the DNA construct, the site of integration, and any additional breeding steps needed to obtain mice useful for your study.

(b 8 pts.) From the procedure above you obtain two different lines of mice carrying integrated *myb* reporter constructs. You cross heterozygous mice from Line 1 to one another and score how many of the resulting progeny carry the reporter construct and how many don't. You repeat the procedure for Line 2. The results of these two crosses are shown below.

	Contain Reporter	Do not contain Reporter
Progeny from Line 1 heterozygotes:	74	24
Progeny from Line 2 heterozygotes:	41	23

Provide an explanation for this data, keeping in mind that you did the same number of crosses for each line, but obtained fewer progeny overall from the Line 2 crosses.

Name: _____

(c 10 pts.) With Line 1, you design a screen looking for regulators of *myb* expression, after mutagenesis with a chemical mutagen. You find a mutant mouse (M) that has increased expression of your construct. The regulatory mutant M is genetically recessive and after extensive mapping experiments, you narrow down the location of the regulatory mutation to a region that contains two genes, TF1 and Db. Describe how you would construct a useful mouse model to test the idea that Db is a regulator of *myb* expression. For your answer include the cell type(s) you would target, a diagram of the DNA construct, the site of integration, and any additional breeding steps needed to get mice useful for your study.

Name: _____

(d 8 pts.) Using any mice generated in parts **a-c**, describe how you would carry out breeding experiments to test whether the mutation M is an allele of the Db gene. For your answer, include possible results and how you would interpret them.

3. (a 6 pts.) Consider a blood antigen called D. The allele for this antigen is dominant (i.e. individuals who are either D/d or D/D will express the antigen). If 84% of a population in Hardy-Weinberg equilibrium expresses the D antigen, what percent of the population are heterozygous for the D allele?

(b 6 pts.) The population in part (a) mixes in equal numbers with a population in which all of the individuals express the blood antigen. After one generation of random interbreeding between the two populations what percent of the population will express the antigen?

Name: _____

(c 9 pts.) You find an isolated population in which an unusual allele for the blood antigen (called d^*) is quite prevalent. By analyzing the DNA from this population you find that 18% of the population has genotype D/d^* , but none of the thousands of individuals examined has genotype d^*/d^* . Explain this result by assuming that d^* is a balanced polymorphism. For your answer calculate parameters h (the heterozygous advantage for d^*) and S (the selective disadvantage of d^*/d^*).

(d 9 pts.) Consider a population in which 1% of matings are between second cousins, but all other matings are between unrelated individuals (second cousins have great grandparents in common). If half of the individuals with a recessive trait have parents that are second cousins, what is the (approximate) allele frequency for the trait.

Question 1 34 points:_____

Question 2 36 points:_____

Question 3 30 points:_____

Total :_____

Name: _____

1. You are studying how yeast cells grow on sucrose and you find that both sucrose and glucose regulate expression of the *SUC1* gene, which encodes an enzyme for sucrose breakdown. *SUC1* is not expressed in cells grown without sucrose, but is induced when sucrose is added to the growth medium. In cells grown in medium that contains both sucrose and glucose, *SUC1* is not expressed. You have isolated mutations in three different genes that alter *SUC1* regulation, called **A⁻**, **B⁻** and **C⁻**. All three mutations are recessive and none of the mutations are linked to one another or to *SUC1*. *SUC1* expression in wild type yeast and each of the three mutants are shown below.

	<u><i>SUC1</i> expression</u>		
	- sucrose	+ sucrose	+ sucrose & glucose
Wild type	-	+	-
A⁻	+	+	-
B⁻	-	-	-
C⁻	-	+	+

(a 6 pts.) For each of the three genes, state whether it affects regulation by sucrose or glucose and whether it is a positive activator or a negative regulator.

Gene **A**

Sucrose - negative regulator

Gene **B**

Sucrose - positive regulator

Gene **C**

Glucose - negative regulator

Name: _____

You cross an **A⁻** mutant to a **B⁻** mutant. After tetrads are dissected and evaluated for *SUC1* expression in either the presence or absence of sucrose, (no glucose is present in this experiment) the following tetrad types are observed.

<u>Type 1</u>	<u>Type 2</u>	<u>Type 3</u>
constitutive	constitutive	constitutive
constitutive	constitutive	constitutive
regulated	regulated	uninducible
uninducible	regulated	uninducible

(b 8 pts.) What is the phenotype of the **A⁻ B⁻** double mutant? Explain how you arrived at your answer.

Based on the spore phenotypes, the Type 2 tetrads must be the NPD tetrads. The spores within the NPD tetrad show either a regulated or constitutive phenotype. The regulated phenotype corresponds to an A⁺ B⁺ genotype. Thus, the spores showing the constitutive phenotype must have the double mutant genotype (A⁻ B⁻).

(c 10 pts.) Draw a model showing the interactions between the different regulatory factors encoded by **A** and **B**. Be sure to include the *SUC1* gene and to indicate where and how sucrose acts.

Sucrose and gene B are net activators of *SUC1* expression, while gene A is a net negative regulator.

Name: _____

Next, you construct a set of deletions within the promoter region of the *SUC1* gene (+1 indicates the first transcribed nucleotide). The ability of each of these deletions to express *SUC1* in cells grown on different sugars is shown below.

	-300	-250	-200	-150	-100	-50	+1	- sucrose	+ sucrose	+ sucrose & glucose
1)	_____	_____	_____	_____	_____	_____	_____	-	+	-
2)	_____	_____	_____	_____	_____	_____	_____	-	+	+
3)	_____	_____	_____	_____	_____	_____	_____	-	-	-
4)	_____	_____	_____	_____	_____	_____	_____	-	+	-
5)	_____	_____	_____	_____	_____	_____	_____	-	+	-
6)	_____	_____	_____	_____	_____	_____	_____	-	-	-

(d 5 pts.) The DNA sequence of gene **C** reveals that this gene is likely to encode a DNA-binding protein. Assuming that the product of gene **C** binds to the promoter region of the *SUC1* gene, where is it most likely to bind? Explain your reasoning.

The deletion 2 mutant shows *SUC1* expression in the presence of glucose. This suggests that the nucleotide region -250 to -200 is the site where the *Gene C* regulatory protein binds.

In addition, the deletion 2 mutant and the *Gene C* mutant exhibit the identical phenotype, which suggests that the deleted -250 to -200 region is the binding site for the *Gene C* regulatory product.

(e 5 pts.) In general, upstream activation sequences function normally regardless of their distance from the start of transcription. Which of the deletion mutants shown above show this to be true for the upstream activation sequence that responds to sucrose activation?

The results above show that the UAS responsive to sucrose lies in the -200 to -150 region. Deletion mutants 4 & 5 show wild-type regulation and reduce the distance between the UAS and promoter and support the hypothesis that a UAS can function normally despite its distance from the transcription start site.

Name: _____

2. (a 12 pts.) Recently your lab has become interested in the function of a mouse gene called *myb*. To determine when and where *myb* is expressed during development you decide to construct a reporter for *myb* expression that can be examined in developing mice. Describe the basic procedure that you would use to produce a useful reporter for *myb* expression. For your answer include such specifics as cell type(s), a diagram of the DNA construct, the site of integration, and any additional breeding steps needed to obtain mice useful for your study.

A transgenic approach or knock-in approach would be effective.

For the transgenic approach, a gene fusion consisting of the *myb* promoter ligated to the LacZ or GFP coding region (P_{myb} - LacZ or P_{myb} - GFP) could be introduced into a wild-type fertilized egg by micro-injection. This transgene would insert randomly into the genome. No additional breeding would be required. This transgenic mouse would serve as an effective model to monitor the spatial and temporal pattern of *myb* gene expression during development.

For the knock-in approach, the endogenous *myb* gene could be replaced with a reporter gene such as lacZ or GFP under control of the *myb* promoter.

The DNA construct, which would replace the endogenous *myb* gene through homologous recombination, would contain the LacZ gene and an anti-biotic resistance gene. DNA homologous to the 5' and 3' regions of the *myb* gene would border these two genes. In addition, a gene encoding thymidine kinase would be placed outside of the homologous 5' and 3' regions of the *myb* gene.

After selecting for homologous recombination of the construct into wild-type embryonic stem cells in culture, the knock-in cells would be introduced into an embryo, which would be injected into the uterus.

The chimeric offspring would be mated with wild-type mice in order to yield heterozygous mice (KI/+). These heterozygous mice would serve as effective models to monitor the spatial and temporal pattern of *myb* expression during development.

(b 8 pts.) From the procedure above you obtain two different lines of mice carrying integrated *myb* reporter constructs. You cross heterozygous mice from Line 1 to one another and score how many of the resulting progeny carry the reporter construct and how many don't. You repeat the procedure for Line 2. The results of these two crosses are shown below.

	Contain Reporter	Do not contain Reporter
Progeny from Line 1 heterozygotes:	74	24
Progeny from Line 2 heterozygotes:	41	23

Provide an explanation for this data, keeping in mind that you did the same number of crosses for each line, but obtained fewer progeny overall from the Line 2 crosses.

The absence of homozygous recessives in line 2 suggests that the reporter gene fusion inserted into an essential gene resulting in a loss of function mutation. The absence of a functional allele of this essential gene in homozygous recessives is lethal.

An alternative explanation is that two copies of the reporter gene fusion in homozygous recessives somehow are lethal due to some sort of toxicity.

Name: _____

(c 10 pts.) With Line 1, you design a screen looking for regulators of *myb* expression. After mutagenesis with a chemical mutagen, you find a mutant mouse (M) that has increased expression of your construct. The regulatory mutant M is genetically recessive and after extensive mapping experiments, you narrow down the location of the regulatory mutation to a region that contains two genes, TF1 and Db. Describe how you would construct a useful mouse model to test the idea that Db is a regulator of *myb* expression. For your answer include the cell type(s) you would target, a diagram of the DNA construct, the site of integration, and any additional breeding steps needed to get mice useful for your study.

A knockout or transgenic could be used.

For the knockout approach, the construct illustrated below would homologously recombine into the Db gene of wild-type embryonic stem cells.

After producing chimeric mice, they would be crossed with wild-type mice to generate heterozygous offspring (KO/+). The resulting heterozygous offspring would be mated among themselves to yield homozygous knockout mice (KO/KO). The homozygous knockout could be used to determine if Db is a regulator of *myb*.

For the transgenic approach, a wild-type Db allele would be injected into a MM fertilized egg through micro-injection. The wild-type Db allele would insert randomly into the MM mutant genome. No additional breeding steps would be required.

The phenotype of the transgenic mouse would enable the role of Db in *myb* expression to be determined.

Name: _____

(d 8 pts.) Using any mice generated in parts **a-c**, describe how you would carry out breeding experiments to test whether the mutation **M** is an allele of the **Db** gene. For your answer, include possible results and how you would interpret them.

The following cross could be performed -

$$\begin{array}{c} \text{KO/KO} \times \text{M/M} \\ \downarrow \\ \text{KO/M} \end{array}$$

and the phenotype of the **KO/M** mice would be examined.

If no complementation occurs, then **M** is an allele of the **Db** gene.

If complementation occurs, then **M** is an allele of a gene other than **Db**.

Another cross could be performed -

$$\text{M/M} \times \text{Transgenic Mouse}$$

If the progeny show a wild-type phenotype, then **M** is an allele of the **Db** gene.

3. (a 6 pts.) Consider a blood antigen called D. The allele for this antigen is dominant (i.e. individuals who are either D/d or D/D will express the antigen). If 84% of a population in Hardy-Weinberg equilibrium expresses the D antigen, what percent of the population are heterozygous for the D allele?

$$f(D/D) + f(D/d) = .84; \text{ Since } f(D/D) + f(D/d) + f(d/d) = 1, f(d/d) = 1 - .84 = .16$$

$$f(d/d) = .16, \text{ so the frequency of } d = .4$$

$$D + d = 1, \text{ so the frequency of } D = 1 - .4 = .6$$

$$f(D/d) = 2 (D) (d) = 2 \times .6 \times .4 = .48$$

(b 6 pts.) The population in part **(a)** mixes in equal numbers with a population in which all of the individuals express the blood antigen. After one generation of random interbreeding between the two populations what percent of the population will express the antigen?

	<u>f(D)</u>	<u>f(d)</u>
Population 1	.6	.4
Population 2	1	~0, so $d^2 = 0$

$$\begin{aligned} \text{Mixed Population: } D_{\text{new}} &= (.5) f(D_{\text{population 1}}) + (.5) f(D_{\text{population 2}}) \\ &= (.5) .6 + (.5) 1 \\ &= .8 \end{aligned}$$

$$\text{Mixed Population: } D + d = 1, \text{ so } d = .2$$

$$\begin{aligned} f(\text{individuals that express antigen}) &= f(D/D) + f(D/d) \\ &= .64 + .32 = .96 \end{aligned}$$

Name: _____

(c 9 pts.) You find an isolated population in which an unusual allele for the blood antigen (called d^*) is quite prevalent. By analyzing the DNA from this population you find that 18% of the population has genotype D/d^* , but none of the thousands of individuals examined has genotype d^*/d^* . Explain this result by assuming that d^* is a balanced polymorphism. For your answer calculate parameters h (the heterozygous advantage for d^*) and S (the selective disadvantage of d^*/d^*).

$$d^* = \frac{1}{2} f(D/d^*) + f(d^*/d^*) ; \text{ Since } f(d^*/d^*) = 0, d^* = \frac{1}{2} f(D/d^*)$$

$$d^* = \frac{1}{2} f(D/d^*) = 1/2 (.18) = .09$$

$$\text{OR } f(D/D) = .82 = D^2, \text{ so } D = .905 \text{ and } d^* = 1 - .905 = .095$$

$$Sq = h; \quad S=1, \text{ so } q = h = .09 \text{ or } .095$$

(d 9 pts.) Consider a population in which 1% of matings are between second cousins, yet all other matings are between unrelated individuals (second cousins have great grandparents in common). If half of the individuals with a recessive trait have parents that are second cousins, what is the (approximate) allele frequency for the trait.

The inbreeding coefficient for second cousins is $1/64$ ($F = 1/64$).

$$f(a/a) = .01 (Fq) + .99 (q^2)$$

$$\frac{1}{2} f(a/a) = .01 (Fq)$$

$$.02 (Fq) = .01 (Fq) + .99 (q^2)$$

$$.99 q = .01 (1/64)$$

$$q = 1.58 \times 10^{-4}$$
