New Foreword

On October 1, 2001 Axiom was withdrawn from the market and ended life as a commercial product. On September 3, 2002 Axiom was released under the Modified BSD license, including this document. On August 27, 2003 Axiom was released as free and open source software available for download from the Free Software Foundation's website, Savannah.

Work on Axiom has had the generous support of the Center for Algorithms and Interactive Scientific Computation (CAISS) at City College of New York. Special thanks go to Dr. Gilbert Baumslag for his support of the long term goal.

The online version of this documentation is roughly 1000 pages. In order to make printed versions we've broken it up into three volumes. The first volume is tutorial in nature. The second volume is for programmers. The third volume is reference material. We've also added a fourth volume for developers. All of these changes represent an experiment in print-on-demand delivery of documentation. Time will tell whether the experiment succeeded.

Axiom has been in existence for over thirty years. It is estimated to contain about three hundred man-years of research and has, as of September 3, 2003, 143 people listed in the credits. All of these people have contributed directly or indirectly to making Axiom available. Axiom is being passed to the next generation. I'm looking forward to future milestones.

With that in mind I've introduced the theme of the "30 year horizon". We must invent the tools that support the Computational Mathematician working 30 years from now. How will research be done when every bit of mathematical knowledge is online and instantly available? What happens when we scale Axiom by a factor of 100, giving us 1.1 million domains? How can we integrate theory with code? How will we integrate theorems and proofs of the mathematics with space-time complexity proofs and running code? What visualization tools are needed? How do we support the conceptual structures and semantics of mathematics in effective ways? How do we support results from the sciences? How do we teach the next generation to be effective Computational Mathematicians?

The "30 year horizon" is much nearer than it appears.

Tim Daly
CAISS, City College of New York
November 10, 2003 ((iHy))

Chapter 1

Numerical Analysis [4]

We can describe each number as x^* which has a machine-representable form which differs from the number x it is intended to represent. Quoting Householder we get:

$$x^* = \pm(x_1\beta^{-1} + x_2\beta^{-2} + \cdots + x_\lambda\beta^\lambda)\beta^\sigma$$

where β is the base, usually 2 or 10, λ is a positive integer, and σ is any integer, possibly zero. It may be that λ is fixed throughout the course of the computation, or it may vary, but in any case it is limited by practical considerations. Such a number will be called a representation. It may be that x^* is obtained by "rounding off" a number whose true value is x (for example, $x = 1/3$, $x^* = 0.33$), or that x^* is the result of measuring physically a quantity whose true value is x, or that x^* is the result of a computation intended to give an approximation to the quantity x.

Suppose one is interested in performing an operations ω upon a pair of numbers x and y. That is to say, $x\omega y$ may represent a product of x and y, a quotient of x by y, the yth power of x, ... In the numerical computation, however, one has only x^* and y^* upon which to operate, not x and y (or at least these are the quantitites upon which one does, in fact operate). Not only this, but often one does not even perform the strict operation ω, but rather a pseudo operation ω^*, which yields a rounded-off product, quotient, power, etc. Hence, instead of obtaining the desired result $x\omega y$, one obtains a result $x^*\omega^*y^*$.

The error in the result is therefore

$$x\omega y - x^*\omega^*y^* = (x\omega y - x^*\omega y^*) + (x^*\omega y^* - x^*\omega^*y^*)$$

Since x^* and y^* are numbers, the operation ω can be applied to them, and $x^*\omega y^*$ is well defined, except for special cases as when ω represents division and $y^* = 0$. But the expression in the first parenthesees on the right represents propagated error, and that in the second parentheses represents generated error, or round-off. Hence the total error in the result is the sum of the error propagated by the operation and that generated by the operation.

Householder notes that, given two operations ω and ϕ, it may be true that the operations are associative, e.g:

$$(x^*\omega y^*)\phi z^* = x^*\omega(y^*\phi z^*)$$

but if we expand these in terms of the above definitions of propogation and generation error we get two different expressions:

$$\begin{aligned}(x^*\omega y^*)\phi z^* - (x^*\omega^* y^*)\phi^* z^* &= [(x^*\omega y^*)\phi z^* - (x^*\omega^* y^*)\phi z^*] \\ &+ [(x^*\omega^* y^*)\phi z^* - (x^*\omega^* y^*)\phi^* z^*]\end{aligned}$$

$$\begin{aligned}x^*\omega(y^*\phi z^*) - x^*\omega^*(y^*\phi^* z^*) &= [x^*\omega(y^*\phi z^*) - x^*\omega(y^*\phi^* z^*)] \\ &+ [x^*\omega(y^*\phi^* z^*) - x^*\omega^*(y^*\phi^* z^*)]\end{aligned}$$

These are not always equal which implies that the strictly machine operations are not necessarily commutative.

Householder distinguishes a third class of error (besides propagation and generative) called residual errors. This occurs because some functions are approximated by infinite series. The finite computation of the series forces the truncation of the remaining terms causing these residual errors.

We will try to perform an analysis of each of the routines in this library for the given inputs to try to see the propagation errors and generation errors they introduce. Every effort will be made to minimize these errors. In particular, we will appeal to the machine generated code to see what approximations actually occur.

Chapter 2

Chapter Overview

Each routine in the Basic Linear Algebra Subroutine set (BLAS) has a prefix where:

- C - Complex
- D - Double Precision
- S - Real
- Z - Complex*16

Routines in level 2 and level 3 of BLAS use the prefix for type:

- GE - general
- GB - general band
- SY - symmetric
- HE - hermitian
- TR - triangular
- SB - symmetric band
- HB - hermetian band
- TB - triangular band
- SP - Sum packed
- HP - hermitian packed
- TP - triangular packed

For level 2 and level 3 BLAS options the options argument is CHARACTER*1 and may be passed as character strings. They mean:

- TRANx
  - **N**o transpose
  - **T**ranspose
  - **C**onjugate transpose (X, X^T, X^H)
- UPLO
  - **U**pper triangular
  - **L**ower triangular
- DIAG
  - **N**on-unit triangular
  - **U**nit triangular
- SIDE
  - **L**eft - A or op(A) on the left
  - **R**ight - A or op(A) on the right

For real matrices, TRANSx=T and TRANSx=C have the same meaning. For Hermitian matrices, TRANSx=T is not allowed. For complex symmetric matrices, TRANSx=H is not allowed.

There were 38 BLAS Level 1 routines defined in [**?**]. They are

- Dot product SDSDOT, DSDOT, DQ-IDOT DQ-ADOT C-UDOT C-CDOT DDOT SDOT
- Constant times a vector plus a vector CAXPY DAXPY SAXPY
- Set up Givens rotation DROTG SROTG
- Apply rotation DROT SROT
- Set up modified Givens rotation DROTMG SROTMG
- Apply modified rotation DROTM SROTM
- Copy x into y CCOPY DCOPY SCOPY
- Sway x and y CSWAP DSWAP SSWAP
- 2-norm (Euclidean length) SCNRM2 DNRM2 SNRM2
- Sum of absolute values SCASUM DASUM SASUM

- Constant times a vector CSSCAL CSCAL DSCAL SSCAL
- Index of maximum element ICAMAX IDAMAX ISAMAX

where

- I Integer
- S Single Precision
- D Double Precision
- C Single Precision Complex
- Q extended precision
- Z COMPLEX*16

Vector arguments are permitted to have a storage spacing between elements. This spacing is specified by an increment parameter. For example, suppose a vector x having components x_i, $i = 1, ldots, N$ is stored in a DOUBLE PRECISION array DX() with increment parameter INCX. If $INCX \geq 0$ then x_i is stored in $DX(1 + (i-1) * INCX)$. If $INCX < 0$ then x_i is stored in $DX(1 + (N-1) * |INCX|)$.

BlasLevelOne (BLAS1)

— package BLAS1 BlasLevelOne —

```
)abbrev package BLAS1 BlasLevelOne
++ Author: Timothy Daly
++ Date Created: 2010
++ Date March 24, 2010
++ Description:
++ This package provides an interface to the Blas library (level 1)
BlasLevelOne() : Exports == Implementation where

  SI   ==> SingleInteger
  INT  ==> Integer
  DF   ==> DoubleFloat
  SX   ==> PrimitiveArray(Float)
  DX   ==> PrimitiveArray(DoubleFloat)
  CDF  ==> Complex(DoubleFloat)
  LDX  ==> List(PrimitiveArray(DoubleFloat))
  PCDF ==> PrimitiveArray(Complex(DoubleFloat))
  PCF  ==> PrimitiveArray(Complex(Float))

  Exports == with

    dcabs1: CDF -> DF
      ++dcabs1(z) computes (+ (abs (realpart z)) (abs (imagpart z)))
```

```
  ++
  ++X t1:Complex DoubleFloat := complex(1.0,0)
  ++X dcabs1(t1)

dasum: (SI, DX, SI) -> DF
  ++dasum(n,array,incx) computes the sum of n elements in array
  ++using a stride of incx
  ++
  ++X dx:PRIMARR(DFLOAT):=[[1.0,2.0,3.0,4.0,5.0,6.0]]
  ++X dasum(6,dx,1)
  ++X dasum(3,dx,2)

daxpy: (SI, DF, DX, SI, DX, SI) -> DX
  ++daxpy(n,da,x,incx,y,incy) computes a y = a*x + y
  ++for each of the chosen elements of the vectors x and y
  ++and a constant multiplier a
  ++Note that the vector y is modified with the results.
  ++
  ++X x:PRIMARR(DFLOAT):=[[1.0,2.0,3.0,4.0,5.0,6.0]]
  ++X y:PRIMARR(DFLOAT):=[[1.0,2.0,3.0,4.0,5.0,6.0]]

  ++X dcopy(3,m,1,n,2)
  ++X n

ddot: (SI, DX, SI, DX, SI) -> DF
  ++ddot(n,x,incx,y,incy) computes the vector dot product
  ++of elements from the vector x and the vector y
  ++If the indicies are negative the elements are taken
  ++relative to the far end of the vector.
  ++
  ++X x:PRIMARR(DFLOAT):=[[1.0,2.0,3.0,4.0,5.0]]
  ++X y:PRIMARR(DFLOAT):=[[5.0,6.0,7.0,8.0,9.0]]
  ++X ddot(0,a,1,b,1) -- handle 0 elements ==> 0
```

```
  ++X ddot(3,a,1,b,1) -- (1,2,3) * (5,6,7) ==> 38.0
  ++X ddot(3,a,1,b,2) -- increment = 2 in b (1,2,3) * (5,7,9) ==> 46.0
  ++X ddot(3,a,2,b,1) -- increment = 2 in a (1,3,5) * (5,6,7) ==> 58.0
  ++X ddot(3,a,1,b,-2) -- increment = -2 in b (1,2,3) * (9,7,5) ==> 38.0
  ++X ddot(2,a,-2,b,1) -- increment = -2 in a (5,3,1) * (5,6,7) ==> 50.0
  ++X ddot(3,a,-2,b,-2) -- (5,3,1) * (9,7,5) ==> 71.0

dnrm2: (SI, DX, SI) -> DF
  ++dnrm2 takes the norm of the vector, ||x||
  ++
  ++X a:PRIMARR(DFLOAT):=[[3.0, -4.0, 5.0, -7.0, 9.0]]
  ++X dnrm2(3,a,1) -- 7.0710678118654755 = sqrt(3.0^2 + -4.0^2 + 5.0^2)
  ++X dnrm2(5,a,1) -- 13.416407864998739 = sqrt(180.0)
  ++X dnrm2(3,a,2) -- 10.72380529476361  = sqrt(115.0)

drotg: (DF, DF, DF, DF) -> DX
  ++drotg computes a 2D plane Givens rotation spanned by two
  ++coordinate axes.
  ++
  ++X a:MATRIX(DFLOAT):=[[6,5,0],[5,1,4],[0,4,3]]
  ++X drotg(elt(a,1,1),elt(a,1,2),0.0D0,0.0D0)

drot: (SI, DX, SI, DX, SI, DF, DF) -> LDX
  ++drot computes a 2D plane Givens rotation spanned by two
  ++coordinate axes. It modifies the arrays in place.
  ++The call drot(n,dx,incx,dy,incy,c,s) has the dx array which
  ++contains the y axis locations and dy which contains the
  ++y axis locations. They are rotated in parallel where
  ++c is the cosine of the angle and s is the sine of the angle and
  ++c^2+s^2 = 1
  ++
  ++X dx:PRIMARR(DFLOAT):=[[6,0, 1.0, 4.0, -1.0, -1.0]]
  ++X dy:PRIMARR(DFLOAT):=[[5.0, 1.0, -4.0, 4.0, -4.0]]
  ++X drot(5,dx,1,dy,1,0.707106781,0.707106781) -- rotate by 45 degrees
  ++X dx -- dx has been modified
  ++X dy -- dy has been modified
  ++X drot(5,dx,1,dy,1,0.707106781,-0.707106781) -- rotate by -45 degrees
  ++X dx -- dx has been modified
  ++X dy -- dy has been modified

dscal: (SI, DF, DX, SI) -> DX
  ++dscal scales each element of the vector by the scalar so
  ++dscal(n,da,dx,incx) = da*dx for n elements, incremented by incx
  ++Note that the dx array is modified in place.
  ++
  ++X dx:PRIMARR(DFLOAT):=[[1.0, 2.0, 3.0, 4.0, 5.0, 6.0]]
  ++X dscal(6,2.0,dx,1)
  ++X dx
  ++X dx:PRIMARR(DFLOAT):=[[1.0, 2.0, 3.0, 4.0, 5.0, 6.0]]
  ++X dscal(3,0.5,dx,1)
```

```
  ++X dx

dswap: (SI, DX, SI, DX, SI) -> LDX
  ++dswap swaps elements from the first vector with the second
  ++Note that the arrays are modified in place.
  ++
  ++X dx:PRIMARR(DFLOAT):=[[1.0, 2.0, 3.0, 4.0, 5.0, 6.0]]
  ++X dy:PRIMARR(DFLOAT):=[[1.0, 2.0, 3.0, 4.0, 5.0, 6.0]]
  ++X dswap(5,dx,1,dy,1)
  ++X dx:PRIMARR(DFLOAT):=[[1.0, 2.0, 3.0, 4.0, 5.0, 6.0]]
  ++X dy:PRIMARR(DFLOAT):=[[1.0, 2.0, 3.0, 4.0, 5.0, 6.0]]
  ++X dswap(3,dx,2,dy,2)
  ++X dx:PRIMARR(DFLOAT):=[[1.0, 2.0, 3.0, 4.0, 5.0, 6.0]]
  ++X dy:PRIMARR(DFLOAT):=[[1.0, 2.0, 3.0, 4.0, 5.0, 6.0]]
  ++X dswap(5,dx,1,dy,-1)

dzasum: (SI, PCDF, SI) -> DF
  ++dzasum takes the sum over all of the array where each
  ++element of the array sum is the sum of the absolute
  ++value of the real part and the absolute value of the
  ++imaginary part of each array element:
  ++   for i in array do sum = sum + (real(a(i)) + imag(a(i)))
  ++
  ++X d:PRIMARR(COMPLEX(DFLOAT)):=[[1.0+2.0*%i,-3.0+4.0*%i,5.0-6.0*%i]]
  ++X dzasum(3,d,1) -- 21.0
  ++X dzasum(3,d,2) -- 14.0
  ++X dzasum(-3,d,1) -- 0.0

dznrm2: (SI, PCDF, SI) -> DF
  ++dznrm2 returns the norm of a complex vector. It computes
  ++sqrt(sum(v*conjugate(v)))
  ++
  ++X a:PRIMARR(COMPLEX(DFLOAT))
  ++X a:=[[3.+4.*%i,-4.+5.*%i,5.+6.*%i,7.-8.*%i,-9.-2.*%i]]
  ++X dznrm2(5,a,1)   -- should be 18.028
  ++X dznrm2(3,a,2)   -- should be 13.077

=====================================================================

The dcabs1 routine computes the sum of the absolute value of the
real and imaginary parts of a complex number.

t1:Complex DoubleFloat := complex(1.0,0)
   1.

dcabs1(t1)
   1.

t2:Complex DoubleFloat := complex(1.0,1.0)
   1. + %i

dcabs1(t2)
   2.

t3:Complex DoubleFloat := complex(1.0,-1.0)
   1. - %i

dcabs1(t3)
   2.
```

```
t4:Complex DoubleFloat := complex(-1.0,-1.0)
   - 1. - %i

dcabs1(t4)
   2.

t5:Complex DoubleFloat := complex(-2.0,-2.0)
   - 2. - 2. %i

dcabs1(t5)
   4.

========================================================================
Man Page Details
========================================================================

The argument is:
\begin{itemize}
\item z - Complex DoubleFloat
\end{itemize}

The result is
\begin{itemize}
\item (+ (abs (realpart z)) (abs (imagpart z)))
\end{itemize}

```

———-

Axiom represents the type Complex(DoubleFloat) as a pair whose car is the real part and whose cdr is the imaginary part. This fact is used in this implementation.

This should really be a macro.

— **dcabs1.f** —

```
      double precision function dcabs1(z)
C ORIGINAL:
c      double complex z,zz
c      double precision t(2)

```

————-

lsame BLAS

The `lsame` function returns t if `ca` and
cb represent the same letter regardless of case.

This has been replaced everywhere with common lisp's char-equal function which compares characters ignoring case. The type (simple-array character (*)) has been replaced everywhere which character.

— lsame.f —

```
      LOGICAL          FUNCTION LSAME( CA, CB )
*
*  -- LAPACK auxiliary routine (version 3.0) --
*     Univ. of Tennessee, Univ. of California Berkeley, NAG Ltd.,
*     Courant Institute, Argonne National Lab, and Rice University
*     September 30, 1994
*
*     .. Scalar Arguments ..
      CHARACTER          CA, CB
*     ..
*
*  Purpose
*  =======
*
*  LSAME returns .TRUE. if CA is the same letter as CB regardless of
*  case.
*
*  Arguments
*  =========
*
*  CA      (input) CHARACTER*1
*  CB      (input) CHARACTER*1
*          CA and CB specify the single characters to be compared.
*
* =====================================================================
*
*     .. Intrinsic Functions ..
      INTRINSIC          ICHAR
*     ..
```

```
*     .. Local Scalars ..
      INTEGER            INTA, INTB, ZCODE
*     ..
*     .. Executable Statements ..
*
*     Test if the characters are equal
*
      LSAME = CA.EQ.CB
      IF( LSAME )
     $   RETURN
*
*     Now test for equivalence if both characters are alphabetic.
*
      ZCODE = ICHAR( 'Z' )
*
*     Use 'Z' rather than 'A' so that ASCII can be detected on Prime
*     machines, on which ICHAR returns a value with bit 8 set.
*     ICHAR('A') on Prime machines returns 193 which is the same as
*     ICHAR('A') on an EBCDIC machine.
*

\section{xerbla BLAS}
%\pagehead{xerbla}{xerbla}
%\pagepic{ps/v104algebraicfunction.ps}{AF}{1.00}

The {\tt xerbla} routine is an error handler.
It is called if an input parameter has an invalid value.

This function has been rewritten everywhere to use the common lisp error
function.

\begin{chunk}{xerbla.f}
      SUBROUTINE XERBLA( SRNAME, INFO )
*
*  -- LAPACK auxiliary routine (preliminary version) --
*     Univ. of Tennessee, Univ. of California Berkeley, NAG Ltd.,
*     Courant Institute, Argonne National Lab, and Rice University
*     February 29, 1992
*
*     .. Scalar Arguments ..
      CHARACTER*6        SRNAME
      INTEGER            INFO
*     ..
*
*  Purpose
*  =======
*
*  XERBLA  is an error handler for the LAPACK routines.
*  It is called by an LAPACK routine if an input parameter has an
*  invalid value.  A message is printed and execution stops.
*
*  Installers may consider modifying the STOP statement in order to
*  call system-specific exception-handling facilities.
*
*  Arguments
*  =========
*
*  SRNAME  (input) CHARACTER*6
```

```
*          The name of the routine which called XERBLA.
*
*  INFO    (input) INTEGER
*          The position of the invalid parameter in the parameter list
*          of the calling routine.
*
*
      WRITE( *, FMT = 9999 )SRNAME, INFO
*
*
* commented out by RLT
*      STOP
*
 9999 FORMAT( ' ** On entry to ', A6, ' parameter number ', I2, ' had ',
     $      'an illegal value' )
*
*     End of XERBLA
*
      END

\end{verbatim}

Man Page Details
========================================================================

Computes doublefloat $asum \leftarrow ||re(x)||_1 + ||im(x)||_1$

Arguments are:
\begin{itemize}
\item n - fixnum
\item dx - array doublefloat
\item incx - fixnum
\end{itemize}

Return values are:
\begin{itemize}
\item 1 nil
\item 2 nil
\item 3 nil
\end{itemize}

NAME
       DASUM  -  BLAS level one, sums the absolute values of the elements of a
       double precision vector

SYNOPSIS
       DOUBLE PRECISION FUNCTION DASUM ( n, x, incx )
           INTEGER                      n, incx
           DOUBLE PRECISION             x

AXIOM SIGNATURE:
       SI  ==> SingleInteger
       DF  ==> DoubleFloat
       DX  ==> PrimitiveArray(DoubleFloat)

       dasum: (SI, DX, SI) -> DF

DESCRIPTION
       This routine performs the following vector operation:

                          n
                 DASUM <-- Sum abs(x(i))
                          i=1
```

```
ARGUMENTS
       n       INTEGER. (input)
               Number of vector elements to be summed.
               if n <= 0, the result will be 0.0
               if n > length(x) then the whole array is summed.

       x       DOUBLE PRECISION. (input)
               Array of dimension (n-1) * abs(incx)+ 1.
               Vector that contains elements to be summed.

       incx    INTEGER. (input)
               Increment between elements of x.
               If incx <= 0, the results will be 0.0

RESULT:
       DASUM   DOUBLE PRECISION. (output)
               Sum of the absolute values of the elements of the vector x.
               If n <= 0, DASUM is set to 0.0

NOTES:
       Axiom uses 0-based arrays. Fortran uses 1-based arrays.

       if the index of the array exceeds the length of x
       then no additional elements are added. Thus,
       if x = #(1.0 2.0 3.0 4.0 5.0 6.0)
       then
        (dasum 3 a -1) =  0.0 ; neg incx
        (dasum 3 a 0)  =  0.0 ; zero incx
        (dasum -1 a 1) =  0.0 ; neg elements
        (dasum 0 a 1)  =  0.0 ; no elements
        (dasum 1 a 1)  =  1.0 ; 1.0
        (dasum 2 a 1)  =  3.0 ; 1.0+2.0
        (dasum 3 a 1)  =  6.0 ; 1.0+2.0+3.0
        (dasum 4 a 1)  = 10.0 ; 1.0+2.0+3.0+4.0
        (dasum 5 a 1)  = 15.0 ; 1.0+2.0+3.0+4.0+5.0
        (dasum 6 a 1)  = 21.0 ; 1.0+2.0+3.0+4.0+5.0+6.0
        (dasum 7 a 1)  = 21.0 ; 1.0+2.0+3.0+4.0+5.0+6.0
        (dasum 1 a 2)  =  1.0 ; 1.0
        (dasum 2 a 2)  =  4.0 ; 1.0+3.0
        (dasum 3 a 2)  =  9.0 ; 1.0+3.0+5.0
        (dasum 4 a 2)  =  9.0 ; 1.0+3.0+5.0
        (dasum 1 a 3)  =  1.0 ; 1.0
        (dasum 2 a 3)  =  5.0 ; 1.0+4.0
        (dasum 3 a 3)  =  5.0 ; 1.0+4.0
        (dasum 1 a 4)  =  1.0 ; 1.0
        (dasum 2 a 4)  =  6.0 ; 1.0+5.0

========================================================================
daxpy examples
========================================================================

For each of the following examples we assume that we have preset
the variables to the following values. Note that the daxpy function
will modify the second array. Each example assumes we have reset
the variables to these values.

a:PRIMARR(DFLOAT):=[ [ 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0] ]
b:PRIMARR(DFLOAT):=[ [ 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0] ]

then we compute the sum of the first 3 elements of each vector
and we show the steps of the computation with trailing comments.
The comments show which elements are changed and what the computation is.

daxpy(3,2.0,a,1,b,1) ==> [3.,6.,9.,4.,5.,6.,7.]
  dy(0)[3.0] = dy(0)[1.0] + ( da[2.0] * dx(0)[1.0] )
  dy(1)[6.0] = dy(1)[2.0] + ( da[2.0] * dx(1)[2.0] )
  dy(2)[9.0] = dy(2)[3.0] + ( da[2.0] * dx(2)[3.0] )

or we compute the first 7 elements of each vector

daxpy(7,2.0,a,1,b,1) ==> [3.,6.,9.,12.,15.,18.,21.]
  dy(0) [3.0] = dy(0)[1.0] + ( da[2.0] * dx(0)[1.0] )
  dy(1) [6.0] = dy(1)[2.0] + ( da[2.0] * dx(1)[2.0] )
  dy(2) [9.0] = dy(2)[3.0] + ( da[2.0] * dx(2)[3.0] )
  dy(3)[12.0] = dy(3)[4.0] + ( da[2.0] * dx(3)[4.0] )
  dy(4)[15.0] = dy(4)[5.0] + ( da[2.0] * dx(4)[5.0] )
  dy(5)[18.0] = dy(5)[6.0] + ( da[2.0] * dx(5)[6.0] )
```

```
  dy(6)[21.0] = dy(6)[7.0] + ( da[2.0] * dx(6)[7.0] )

or we compute the first 8 elements, which fails due to the fact that
the vectors are not long enough.

daxpy(8,2.0,a,1,b,1) ==> [1.,2.,3.,4.,5.,6.,7.]

or we compute the 3 elements, taking every 3rd element, giving the
index of 0, 3, 6

daxpy(3,2.0,a,3,b,3) ==> [3.,2.,3.,12.,5.,6.,21.]
  dy(0) [3.0] = dy(0)[1.0] + ( da[2.0] * dx(0)[1.0] )
  dy(3)[12.0] = dy(3)[4.0] + ( da[2.0] * dx(3)[4.0] )
  dy(6)[21.0] = dy(6)[7.0] + ( da[2.0] * dx(6)[7.0] )

or we compute 4 elements, taking every 2nd element, giving the
index of 0, 2, 4, 6

daxpy(4,2.0,a,2,b,2) ==> [3.,2.,9.,4.,15.,6.,21.]
  dy(0) [3.0] = dy(0)[1.0] + ( da[2.0] * dx(0)[1.0] )
  dy(2) [9.0] = dy(2)[3.0] + ( da[2.0] * dx(2)[3.0] )
  dy(4)[15.0] = dy(4)[5.0] + ( da[2.0] * dx(4)[5.0] )
  dy(6)[21.0] = dy(6)[7.0] + ( da[2.0] * dx(6)[7.0] )

or we compute 5 elements, taking every 2nd element, which fails
due to vector length

daxpy(5,2.0,a,2,b,2) ==> [1.,2.,3.,4.,5.,6.,7.]

or we compute 3 elements, taking every 2nd value, giving the
index of 0, 2, 4

daxpy(3,2.0,a,2,b,2) ==> [3.,2.,9.,4.,15.,6.,7.]
  dy(0) [3.0] = dy(0)[1.0] + ( da[2.0] * dx(0)[1.0] )
  dy(2) [9.0] = dy(2)[3.0] + ( da[2.0] * dx(2)[3.0] )
  dy(4)[15.0] = dy(4)[5.0] + ( da[2.0] * dx(4)[5.0] )

or we compute 3 elements, taking every 2nd value, giving the
index of 0, 2, 4 but with a negative multiplier

daxpy(3,-2.0,a,2,b,2) ==> [- 1.,2.,- 3.,4.,- 5.,6.,7.]
  dy(0)[-1.0] = dy(0)[1.0] + ( da[-2.0] * dx(0)[1.0] )
  dy(2)[-3.0] = dy(2)[3.0] + ( da[-2.0] * dx(2)[3.0] )
  dy(4)[-5.0] = dy(4)[5.0] + ( da[-2.0] * dx(4)[5.0] )

or we change the lengths of the input vectors, making them unequal.
So for the next two examples we assume the arrays look like:

a:PRIMARR(DFLOAT):=[ [ 1.0, 2.0, 3.0] ]
b:PRIMARR(DFLOAT):=[ [ 1.0, 2.0, 3.0, 4.0, 5.0] ]
```

```
We compute 3 elements, with a negative multiplier, and different increments
using an index for the 'a' array having values 0, 1, 2
using an index for the 'b' array having values 0, 2, 3

daxpy(3,-2.0,a,1,b,2) ==> [- 1.,2.,- 1.,4.,- 1.]
  dy(0)[-1.0] = dy(0)[1.0] + ( da[-2.0] * dx(0)[1.0] )
  dy(2)[-1.0] = dy(2)[3.0] + ( da[-2.0] * dx(1)[2.0] )
  dy(4)[-1.0] = dy(4)[5.0] + ( da[-2.0] * dx(2)[3.0] )

or we compute 3 elements with a multiplier of 0.0 which fails

daxpy(3,0.0,a,1,b,2) ==> [1.,2.,3.,4.,5.,6.,7.]

NAME
       DAXPY - BLAS level one axpy subroutine

SYNOPSIS
       SUBROUTINE DAXPY    ( n, alpha, x, incx, y, incy )

           INTEGER           n, incx, incy

           DOUBLE PRECISION  alpha, x, y

DESCRIPTION
       DAXPY  adds  a  scalar multiple of a double precision vector to another
       double precision vector.

       DAXPY computes a constant alpha times a vector x plus a vector y.   The
       result overwrites the initial values of vector y.

       This routine performs the following vector operation:

            y  <--  alpha*x + y

       incx and incy specify the increment between two consecutive
       elements of respectively vector x and y.

ARGUMENTS
       n       INTEGER. (input)
               Number  of  elements in the vectors.  If n <= 0, these routines
               return without any computation.

       alpha   DOUBLE PRECISION. (input)
               If alpha = 0 this routine returns without any computation.
```

```
       x       DOUBLE PRECISION, (input)
               Array of dimension (n-1) * |incx| + 1.  Contains the vector  to
               be scaled before summation.

       incx    INTEGER. (input)
               Increment between elements of x.
               If incx = 0, the results will be unpredictable.

       y       DOUBLE PRECISION, (input and output)
               array of dimension (n-1) * |incy| + 1.
               Before calling the routine, y contains the vector to be summed.
               After the routine ends, y contains the result of the summation.

       incy    INTEGER. (input)
               Increment between elements of y.
               If incy = 0, the results will be unpredictable.

RETURN VALUES
       When  n <= 0, double precision alpha = 0., this routine returns immedi-
       ately with no change in its arguments.
```

———-

— daxpy.f —

```
      subroutine daxpy(n,da,dx,incx,dy,incy)
c
c     constant times a vector plus a vector.
c     uses unrolled loops for increments equal to one.
c     jack dongarra, linpack, 3/11/78.
c     modified 12/3/93, array(1) declarations changed to array(*)
c
      double precision dx(*),dy(*),da
      integer i,incx,incy,ix,iy,m,mp1,n
c
      if(n.le.0)return
      if (da .eq. 0.0d0) return
      if(incx.eq.1.and.incy.eq.1)go to 20
c
c        code for unequal increments or equal increments
c          not equal to 1
c
      ix = 1
      iy = 1
      if(incx.lt.0)ix = (-n+1)*incx + 1
      if(incy.lt.0)iy = (-n+1)*incy + 1
      do 10 i = 1,n
```

```
        dy(iy) = dy(iy) + da*dx(ix)
        ix = ix + incx
        iy = iy + incy
   10 continue
      return
c
c        code for both increments equal to 1
c
c
c        clean-up loop
c
   20 m = mod(n,4)
      if( m .eq. 0 ) go to 40
      do 30 i = 1,m
        dy(i) = dy(i) + da*dx(i)

========================================================================
dcopy examples
========================================================================

Assume we have two arrays which we initialize to these values:
a:PRIMARR(DFLOAT):=[ [ 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0] ]

b:PRIMARR(DFLOAT):=[ [ 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0] ]

Note that after each call to dcopy the b array is modified.
The changed value is shown. We reset it after each bcopy but we
do not show that here.

dcopy(3,a,1,b,1) ==> [1.,2.,3.,0.,0.,0.,0.]

dcopy(7,a,1,b,1) ==> [1.,2.,3.,4.,5.,6.,7.]

dcopy(8,a,1,b,1) ==> [0.,0.,0.,0.,0.,0.,0.]

dcopy(3,a,3,b,3) ==> [1.,0.,0.,4.,0.,0.,7.]

dcopy(4,a,2,b,2) ==> [1.,0.,3.,0.,5.,0.,7.]

dcopy(5,a,2,b,2) ==> [0.,0.,0.,0.,0.,0.,0.]

dcopy(3,a,2,b,2) ==> [1.,0.,3.,0.,5.,0.,0.]

The arrays can be of different lengths:

a:PRIMARR(DFLOAT):=[ [ 1.0, 2.0, 3.0] ]
```

```
b:PRIMARR(DFLOAT):=[ [ 1.0, 2.0, 3.0, 4.0, 5.0] ]

dcopy(3,a,1,b,1) ==>  [1.,2.,3.,4.,5.]

dcopy(3,a,1,b,2) ==>  [1.,2.,2.,4.,3.]

a:PRIMARR(DFLOAT):=[ [ 1.0, 2.0, 3.0, 4.0, 5.0] ]

b:PRIMARR(DFLOAT):=[ [ 1.0, 2.0, 3.0] ]

dcopy(5,a,1,b,1) ==> [1.,2.,3.]

NAME
       DCOPY  -  BLAS level one, copies a double precision vector into another
       double precision vector

SYNOPSIS
       SUBROUTINE DCOPY    ( n, x, incx, y, incy )

           INTEGER           n, incx, incy

           DOUBLE PRECISION  x, y

DESCRIPTION
       DCOPY copies a double precision vector into  another  double  precision
       vector.  DCOPY copies a vector x, whose length is n to a vector y. incx
       and incy specify the increment  between  two  consecutive  elements  of
       respectively vector x and y.

       This routine performs the following vector operation:

            y  <--  x

       where x and y are double precision vectors.

ARGUMENTS
       n       INTEGER. (input)
               Number of vector elements to be copied.
               If n <= 0, this routine returns without computation.

       x       DOUBLE PRECISION, (input)
               Vector from which to copy.

       incx    INTEGER. (input)
```

```
               Increment between elements of x.
               If incx = 0, the y vector is unchanged

       y       DOUBLE PRECISION, (output)
               array of dimension (n-1) * |incy| + 1, result vector.

       incy    INTEGER. (input)
               Increment between elements of y.
               If incy = 0, the y vector is unchanged
```

NAME
       DDOT  -  BLAS  level one, computes a dot product (inner product) of two
       double precision vectors

SYNOPSIS
       DOUBLE PRECISION FUNCTION DDOT ( n, x, incx, y, incy )

           INTEGER                     n, incx, incy

           DOUBLE PRECISION            x, y

DESCRIPTION
       DDOT computes a dot product of two double precision vectors  (l  double
       precision inner product).
         2

       This routine performs the following vector operation:

                                                 n
               DDOT  <--  (transpose of x) * y  =  Sum  x(i)*y(i)
                                                 i=1
       where x and y are double precision vectors.

       If n <= 0, DDOT is set to 0.

ARGUMENTS
       n       INTEGER. (input)
               Number of elements in each vector.

       x       DOUBLE PRECISION. (input)
```

```
               Array of dimension (n-1) * |incx| + 1.
               Array x contains the first vector operand.

       incx    INTEGER. (input)
               Increment between elements of x.
               If incx = 0, the results will be unpredictable.

       y       DOUBLE PRECISION, (input)
               Array of dimension (n-1) * |incy| + 1.
               Array y contains the second vector operand.

       incy    INTEGER. (input)
               Increment between elements of y.  If incy = 0, the results will
               be unpredictable.

RETURN VALUES
       DDOT    DOUBLE PRECISION. Result (dot product). (output)

NOTES
       When  working  backward  (incx < 0 or incy < 0), each routine starts at
       the end of the vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

            y(1-incy * (n-1)), y(1-incy * (n-2)), ..., y(1)
```

dnrm2 examples
==========================================================================

DNRM2 is a BLAS level one which computes the Euclidean norm of a vector.

Given the vector [ 3.0, -4.0, 5.0, -7.0, 9.0 ]

dnrm2(3,a,1)
   = sqrt(3.0^2 + -4.0^2 + 5.0^2)
   = sqrt(50.0)
   = 7.0710678118654755

dnrm2(5,a,1)
   = sqrt(3.0^2 + -4.0^2 + 5.0^2 + -7.0^2 + 9.0^2)
   = sqrt(180.0)
   = 13.416407864998739

dnrm2(3,a,2)
   = sqrt(3.0^2 + 5.0^2 + 9.0^2)
   = sqrt(115.0)
   = 10.72380529476361

NAME
       DNRM2 - BLAS level one, computes the Euclidean norm of a vector

SYNOPSIS
       DOUBLE PRECISION FUNCTION DNRM2 ( n, x, incx )

           INTEGER                      n, incx
```

```
           DOUBLE PRECISION             x

DESCRIPTION
       DNRM2  computes the Euclidean (L2) norm of a double precision real vec-
       tor, as follows:

               DNRM2 <-- ||x||
                              2

       where x is a double precision real vector.

ARGUMENTS
       n       INTEGER. (input)
               Number of elements in the operand vector.

       x       DOUBLE PRECISION. (input)
               Array of dimension (n-1) * |incx| + 1.
               Array x contains the operand vector.

       incx    INTEGER. (input)
               Increment between elements of x.
               If incx = 0, the results will be unpredictable.

RETURN VALUES
       DNRM2   DOUBLE PRECISION. Result (Euclidean norm). (output)
               If n <= 0, DNRM2 is set to 0d0.

NOTES
       When working backward (incx < 0), each routine starts at the end of the
       vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)
```

========================================================================

A Givens rotation is a rotation in the plane spanned by two
coordinate axes, named after Wallace Givens. [REF-Wiki3]

A Givens rotation is represented by a matrix of the form

              +-                          -+
              | 1  ...  0  ...  0  ...  0 |
              | .   .   .   .   .   .   . |
              | .    .  .    .  .    .  . |
              | 0  ...  c  ... -s  ...  0 |
              | .   .   .   .   .   .   . |
G(i,j,theta) = | .    .  .    .  .    .  . |
              | 0  ...  s  ...  c  ...  0 |
              | .   .   .   .   .   .   . |
              | .    .  .    .  .    .  . |
              | 0  ...  0  ...  0  ...  1 |
              +-                          -+

where c = cos(theta) and s = sin(theta) appear at the intersections
of the ith, jth rows and columns. The non-zero elements of a Givens
matrix are given by:
```

```
g   = 1 for k != i,j
 kk
g   = c
 ii
g   = c              (sign of sine switches for j>i)
 jj
g   = -s
 ji
g   = s  for i > j
 ij
```

The product G(i,j,theta)*x represents the counterclockwise rotation
of the vector in the (i,j) plane of theta radians.

The main use of Givens rotations in numerical linear algebra is to
introduce zeros in vectors or matrices. This effect can be employed
for computing the QR decomposition of a matrix. One advantage over
the Householder tranformations is that they can easily be parallelized,
and another is that often for very sparse matrices they have a lower
operation count.

When a Givens rotation matrix, G(i,k,theta) multiplies another
matrix A from the left, GA, only rows i and j of A are affected.
Thus we restrict attention to the following problem. Given a and b,
find c=cos(theta) and s=sin(theta) such that

```
+-     -+ +- -+   +- -+
| c  -s | | a |   | r |
|       | |   | = |   |
| s   c | | b |   | 0 |
+-     -+ +- -+   +- -+
```

The solution is

```
r = sqrt(a^2+b^2)
c = a/r
s = -b/r
```

However, the computation for r may overflow or underflow. An alternative
formulation avoiding this problem [REF-GC96, p5.1.8] is implemented as the
hypot function in many programming languages.

As Anderson [REF-And00] discovered in improving LAPACK, a previously
overlooked numerical consideration is continuity. To achieve this
we require r to be positive.

```
   if (b = 0) then { c = copysign(1,a); s=0; r=abs(a) }
   else if (a = 0) then { c = 0; s = copysign(1,b); r = abs(b) }
   else if (abs(b) > abs(a)) then
     t = a/b
```

```
     u = copysign(sqrt(1+t*t),b)
     s = 1/u
     c = s*t
     r = b*u
   else
     t = b/a
     u = copysign(sqrt(1+t*t),a)
     c = 1/u
     s = c*t
     r = a*u

copysign can be implemented as x*sgn(y) using the sign function.

NAME
       DGROTG - BLAS level one rotation subroutines

SYNOPSIS
       SUBROUTINE DROTG    ( a, b, c, s )

           DOUBLE PRECISION  a, b, c, s

DESCRIPTION
       DROTG  computes  the  elements  of  a Givens plane rotation matrix such
       that:

             _      _     _   _    _   _
             | c  s |     | a |    | r |
             |-s  c | *   | b | =  | 0 |
             -      -     -   -    -   -

       where  r = +- sqrt ( a**2 + b**2 )  and c**2 + s**2 =1.

       The Givens plane rotation can be used to introduce zero elements into
       a matrix selectively.

ARGUMENTS
       a       (input and output) DOUBLE PRECISION

               First vector component.  On input, the first component  of  the
               vector to be rotated.  On output, a is overwritten by r, the
               first component of the vector in the rotated coordinate  system
               where:
```

```
            r = sign(sqrt(a**2 + b**2),a), if |a| > |b|

            r = sign(sqrt(a**2 + b**2),b), if |a| <= |b|

      b     (input and output) DOUBLE PRECISION
            Second vector component.

            On input, the second component of the vector to be rotated.  On
            output, b contains z, where:

                z=s    if  |a| >  |b|
                z=1/c  if  |a| <= |b|  and  c != 0  and r != 0
                z=1    if  |a| <= |b|  and  c  = 0  and r != 0
                z=0    if  r = 0

      c     (output) DOUBLE PRECISION
            Cosine of the angle of rotation:

                 c = a/r  if  r != 0
                 c = 1    if  r  = 0

      s     (output) DOUBLE PRECISION
            Sine of the angle of rotation:

                 s = b/r  if  r != 0
                 s = 0    if  r  = 0

NOTE
      The value of z, returned in b by DROTG, gives a compact  representation
      of  the rotation matrix, which can be used later to reconstruct c and s
      as in the following example:

           IF (B .EQ. 1. ) THEN
               C = 0.
               S = 1.
           ELSEIF( ABS( B) .LT. 1) THEN
               C = SQRT( 1. - B * B)
               S = B
           ELSE
               C = 1. / B
               S = SQRT( 1 - C * C)
           ENDIF
```

Double precision. Computes plane rotation. Arguments are:

- da - double-float

- db - double-float
- c - double-float
- s - double-float

Returns multiple values where:

- 1 da - double-float
- 2 db - double-float
- 3 c - double-float
- 4 s - double-float

— drotg.f —

```
      subroutine drotg(da,db,c,s)
c
c     construct givens plane rotation.
c     jack dongarra, linpack, 3/11/78.
c
      double precision da,db,c,s,roe,scale,r,z
c
      roe = db
      if( dabs(da) .gt. dabs(db) ) roe = da
      scale = dabs(da) + dabs(db)
      if( scale .ne. 0.0d0 ) go to 10

NAME
       DROT - BLAS level one, plane rotation subroutines

SYNOPSIS
       SUBROUTINE DROT    ( n, x, incx, y, incy, c, s )

           INTEGER          n, incx, incy

           DOUBLE PRECISION x, y, c, s
```

```
DESCRIPTION
       DROT   applies  a  plane  rotation matrix to a real sequence of ordered
       pairs:

            (x , y ), for all i = 1, 2, ..., n.
              i   i

ARGUMENTS
       n       INTEGER. (input)
               Number of ordered pairs (planar points in DROT) to be  rotated.
               If n <= 0, this routine returns without computation.

       x       DOUBLE PRECISION, (input and output)
               Array  of dimension (n-1) * |incx| + 1.  On input, array x con-
               tains the x-coordinate of each planar point to be rotated.   On
               output,  array x contains the x-coordinate of each rotated pla-
               nar point.

       incx    INTEGER. (input)
               Increment between elements of x.  If incx = 0, the results will
               be unpredictable.

       y       DOUBLE PRECISION, (input and output)
               array of dimension (n-1) * |incy| + 1.
               On  input,  array  y  contains  the y-coordinate of each planar
               point to be rotated.  On output, array y contains the y-coordi-
               nate of each rotated planar point.

       incy    INTEGER. (input)
               Increment between elements of y.  If incy = 0, the results will
               be unpredictable.

       c       DOUBLE PRECISION, Cosine of the angle of rotation.
               (input)

       s       DOUBLE PRECISION, Sine of the angle of rotation. (input)

NOTES
       This routine applies the following plane rotation to each pair
       of elements (x , y):
                                 i   i
            _      _       _       _     _       _
           | x(i) |  <--  | c   s |   .  | x(i) |
           | y(i) |       |-s   c |      | y(i) |
           -      -       -       -     -       -

            for i = 1,...,n
                                        2    2
       If coefficients c and s satisfy c  + s  = 1.0, the rotation matrix
```

```
       is orthogonal, and the transformation is called a Givens plane
       rotation. If c = 1 and s = 0, DROT returns without modifying any
       input parameters.

       To calculate the Givens coefficients c and s from a two-element
       vector to determine the angle of rotation, use SROTG(3S).

       When working backward (incx < 0 or incy < 0), each routine starts
       at the end of the vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

            y(1-incy * (n-1)), y(1-incy * (n-2)), ..., y(1)
```

NAME
       DSCAL - BLAS level one, scales a double precision vector

SYNOPSIS
       SUBROUTINE DSCAL    ( n, alpha, x, incx )

           INTEGER           n, incx

           DOUBLE PRECISION  alpha, x
```

```
DESCRIPTION
       DSCAL  scales a double precision vector with a double precision scalar.
       DSCAL scales the vector x of length n and increment incx  by  the  con-
       stant a.

       This routine performs the following vector operation:

                 x <-- alpha x

       where alpha is a double precisoin scalar, and x is a double precision
       vector.

ARGUMENTS
       n       INTEGER. (input)
               Number of elements in the vector.
               If n <= 0, this routine returns without computation.

       alpha   DOUBLE PRECISION scalar alpha. (input)

       x       DOUBLE PRECISION, (input and output)
               Array of dimension (n-1) * |incx| + 1. Vector to be scaled.

       incx    INTEGER. (input)
               Increment between elements of x.
               If incx = 0, the results will be unpredictable.
```

———-

— dscal.f —

```
      subroutine  dscal(n,da,dx,incx)
c
c     scales a vector by a constant.
c     uses unrolled loops for increment equal to one.
c     jack dongarra, linpack, 3/11/78.
c     modified 3/93 to return if incx .le. 0.
c     modified 12/3/93, array(1) declarations changed to array(*)
c
      double precision da,dx(*)
      integer i,incx,m,mp1,n,nincx
c
      if( n.le.0 .or. incx.le.0 )return
      if(incx.eq.1)go to 20
c
c        code for increment not equal to 1
c
      nincx = n*incx
      do 10 i = 1,nincx,incx
```

```
        dx(i) = da*dx(i)
   10 continue
      return
c
c        code for increment equal to 1
c
c
c        clean-up loop
c
   20 m = mod(n,5)
      if( m .eq. 0 ) go to 40
      do 30 i = 1,m

NAME
       DSWAP - BLAS level one, Swaps two double precision vectors

SYNOPSIS
       SUBROUTINE DSWAP    ( n, x, incx, y, incy )
```

```
      INTEGER           n, incx, incy

      DOUBLE PRECISION  x, y

DESCRIPTION
       DSWAP  swaps  two double precision vectors, it interchanges n values of
       vector x and vector y.  incx and incy specify the increment between two
       consecutive elements of respectively vector x and y.

       This routine performs the following vector operation:

            x <-> y

        where x and y are double precision vectors.

ARGUMENTS
       n       INTEGER. (input)
               Number of vector elements to be swapped.
               If n <= 0, this routine returns without computation.

       x       DOUBLE PRECISION, (input and output)
               Array of dimension (n-1) * |incx| + 1.

       incx    INTEGER. (input)
               Increment between elements of x.
               If incx = 0, the results will be unpredictable.

       y       DOUBLE PRECISION, (input and output)
               array of dimension (n-1) * |incy| + 1. Vector to be swapped.

       incy    INTEGER. (input)
               Increment between elements of y.  If incy = 0, the results will
               be unpredictable.

NOTES
       When  working  backward  (incx < 0 or incy < 0), each routine starts at
       the end of the vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

            y(1-incy * (n-1)), y(1-incy * (n-2)), ..., y(1)
```

— dswap.f —

```
      subroutine  dswap (n,dx,incx,dy,incy)
c
c     interchanges two vectors.
c     uses unrolled loops for increments equal one.
c     jack dongarra, linpack, 3/11/78.
c     modified 12/3/93, array(1) declarations changed to array(*)
c
      double precision dx(*),dy(*),dtemp
      integer i,incx,incy,ix,iy,m,mp1,n
c
      if(n.le.0)return
      if(incx.eq.1.and.incy.eq.1)go to 20
c
c       code for unequal increments or equal increments not equal
c         to 1
c
      ix = 1
      iy = 1
      if(incx.lt.0)ix = (-n+1)*incx + 1
      if(incy.lt.0)iy = (-n+1)*incy + 1
      do 10 i = 1,n
        dtemp = dx(ix)
        dx(ix) = dy(iy)
        dy(iy) = dtemp
        ix = ix + incx
        iy = iy + incy
   10 continue
      return
c
c       code for both increments equal to 1
c
c
c       clean-up loop
c
   20 m = mod(n,3)
      if( m .eq. 0 ) go to 40
      do 30 i = 1,m
        dtemp = dx(i)
        dx(i) = dy(i)
        dy(i) = dtemp
   30 continue
      if( n .lt. 3 ) return
   40 mp1 = m + 1
      do 50 i = mp1,n,3
        dtemp = dx(i)
        dx(i) = dy(i)
        dy(i) = dtemp
        dtemp = dx(i + 1)
        dx(i + 1) = dy(i + 1)
        dy(i + 1) = dtemp
```

```
        dtemp = dx(i + 2)
        dx(i + 2) = dy(i + 2)
        dy(i + 2) = dtemp
   50 continue
      return
      end
```

———-

There appears to be a bit of confusion using negative increments. The fortran code does not work as I would have guessed. I don't understand what it was intended to do.

NAME
       DZASUM - BLAS level one, sums the absolute values of the real and imag-
       inary parts of the elements of a double complex vector

SYNOPSIS
       DOUBLE PRECISION FUNCTION DZASUM ( n, x, incx )

           INTEGER                     n, incx

           DOUBLE COMPLEX              x

DESCRIPTION
       This routine performs the following vector operation:

                            n
                DZASUM <-- Sum abs( real(x(i)) ) + abs( aimag(x(i)) )
                           i=1

ARGUMENTS
       n       INTEGER. (input)
               Number of vector elements to be summed.

       x       DOUBLE COMPLEX. (input)
               Array of dimension (n-1) * abs(incx) + 1.
               Vector that contains elements to be summed.

       incx    INTEGER. (input)
```

```
              Increment between elements of x.
              If incx = 0, the results will be unpredictable.

RETURN VALUES
       DZASUM  DOUBLE PRECISION. (output)
              Sum of the absolute values of the real and imaginary  parts  of
              the elements of the vector x.
              If n <= 0, DZASUM is set to 0.

NOTES
       When working backward (incx < 0), each routine starts at the end of the
       vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)
```

```

Spad represents complex numbers as a pair where the car is the real part and the cons is the imaginary part. BLAS wants a complex number in fortran format. So we have a design choice to make. Either we could write all of the BLAS code using Spad internal representation or we could follow the BLAS code standard. I've decided to follow the BLAS code standard so we need to create thunks to do the data translation.

dznrm2 examples
=====================================================================

dznrm2 computes the complex norm of the input vector.
```

```
For each element it computes the sum
    a.i*conjugate(a.i)
for all i. Then it returns the square root of the final sum.

If the count or increment are negative, the result is 0.0

NAME
       DZNRM2 - BLAS level one, computes the Euclidean norm of a vector

SYNOPSIS
       DOUBLE PRECISION FUNCTION DZNRM2 ( n, x, incx )

           INTEGER                       n, incx
```

```
           DOUBLE COMPLEX                 x

DESCRIPTION
       DZNRM2  computes  the Euclidean (L2) norm of a double precision complex
       vector:

               DZNRM2 <-- ||x||
                                2

       where x is a double precision complex vector.

ARGUMENTS
       n       INTEGER (input)
               Number of elements in the operand vector.

       x       DOUBLE COMPLEX (input)
               Array of dimension (n-1) * |incx| + 1.
               Array x contains the operand vector.

       incx    INTEGER (input)
               Increment between elements of x.
               If incx = 0, the results will be unpredictable.

RETURN VALUES
       DZNRM2  DOUBLE PRECISION Result (Euclidean norm). (output)
               If n <= 0, DZNRM2 is set to 0d0.

NOTES
       When  working backward (incx < 0), DZNRM2 starts at the end of the vec-
       tor and moves backward, as follows:

               x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)
```

```

Spad represents complex numbers as a pair where the car is the real part and the cons is the imaginary part. BLAS wants a complex number in fortran format. So we have a design choice to make. Either we could write all of the BLAS code using Spad internal representation or we could follow the BLAS code standard. I've decided to follow the BLAS code standard so we need to create thunks to do the data translation.

NOTE: The Axiom internal representation of PRIMARR(COMPLEX(FLOAT)) is an array where each array element AE is

```
AE = (cons (cons (therealpart 0)) (cons (theimagpart 0)))
```

so we need (caar AE) and (cadr AE) to get the real and imag parts.

— BLAS 1 dznrm2 —

NAME
       ICAMAX - BLAS level one, maximum index function

SYNOPSIS
       INTEGER FUNCTION ICAMAX ( n, x, incx )

           INTEGER              n, incx

           COMPLEX              x

DESCRIPTION
       ICAMAX  searches a complex vector for the first occurrence of the maxi-
       mum absolute value.
```

```
       ICAMAX determines the first index i such that

       |Real(x )|+ |Imag(x ) | = MAX(|Real(x )| + | Imag(x )|): j = 1, ..., n
              i           i                 j             j
               where x  is an element of a complex vector.
                      j

ARGUMENTS
       n       INTEGER. (input)
               Number of elements to process in the vector to be searched.  If
               n <= 0, these routines return 0.

       x       COMPLEX. (input)
               Array of dimension (n-1) * |incx| + 1.
               Array x contains the vector to be searched.

       incx    INTEGER. (input)
               Increment between elements of x.

RETURN VALUES
       ICAMAX  INTEGER. (output)
               Return  the first index of the maximum absolute value of vector
               x.  The vector x has length n and increment incx.

NOTES
       When working backward (incx < 0), each routine starts at the end of the
       vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

       The largest absolute value is:

```

Spad represents complex numbers as a pair where the car is the real part and the cons is the imaginary part. BLAS wants a complex number in fortran format. So we have a design choice to make. Either we could write all of the BLAS code using Spad internal representation or we could follow the BLAS code standard. I've decided to follow the BLAS code standard so we need to create thunks to do the data translation.

NOTE: The Axiom internal representation of PRIMARR(COMPLEX(FLOAT)) is an array where each array element AE is

```
AE = (cons (cons (therealpart 0)) (cons (theimagpart 0)))
```

so we need (caar AE) and (cadr AE) to get the real and imag parts.

NOTE: Array indexing in Axiom is 0-based but Fortran is 1-based so the results are displaced by 1.

NAME
       IDAMAX - BLAS level one, maximum index function

SYNOPSIS
       INTEGER FUNCTION IDAMAX ( n, x, incx )

           INTEGER               n, incx

           DOUBLE PRECISION      x

DESCRIPTION
       IDAMAX  searches  a double precision vector for the first occurrence of
       the the maximum absolute value. The vector x has length n and increment
       incx.

ARGUMENTS
       n       INTEGER. (input)
               Number of elements to process in the vector to be searched.  If
               n <= 0, these routines return 0.

       x       DOUBLE PRECISION. (input)
               Array of dimension (n-1) * |incx| + 1.
               Array x contains the vector to be searched.

       incx    INTEGER. (input)
               Increment between elements of x.

RETURN VALUES
       IDAMAX  INTEGER. (output)
```

```
              Return the first index of the maximum absolute value of  vector
              x.  The vector x has length n and increment incx.

NOTES
       When working backward (incx < 0), each routine starts at the end of the
       vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

       The largest absolute value is:

            ABS (x(1+(index-1) * incx)) when incx > 0

            ABS (x(1+(n-index) * |incx|)) when incx < 0
```

— idamax.f —

NAME
       ISAMAX - BLAS level one, maximum index function
```

```
SYNOPSIS
       INTEGER FUNCTION ISAMAX ( n, x, incx )

           INTEGER               n, incx

           REAL                  x

DESCRIPTION
       ISAMAX searches a real vector for the first occurrence of the the maxi-
       mum absolute value. The vector x has length n and increment incx.

       ISAMAX returns the first index i such that
               |x | = MAX |x | : j = 1, ..., n
                 i          j
       where x  is an element of a real vector.
              j

ARGUMENTS
       n       INTEGER. (input)
               Number of elements to process in the vector to be searched.  If
               n <= 0, these routines return 0.

       x       REAL. (input)
               Array of dimension (n-1) * |incx| + 1.
               Array x contains the vector to be searched.

       incx    INTEGER. (input)
               Increment between elements of x.

RETURN VALUES
       ISAMAX  INTEGER. (output)
               Return  the first index of the maximum absolute value of vector
               x.  The vector x has length n and increment incx.

NOTES
       When working backward (incx < 0), each routine starts at the end of the
       vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

       The largest absolute value is:

            ABS (x(1+(index-1) * incx)) when incx > 0

            ABS (x(1+(n-index) * |incx|)) when incx < 0

            _______-

```

Spad represents complex numbers as a pair where the car is the real part and the cons is the imaginary part. BLAS wants a complex number in fortran format. So we have a design choice to make. Either we could write all of the BLAS code using Spad internal representation or we could follow the BLAS code standard. I've decided to follow the BLAS code standard so we need to create thunks to do the data translation.

NAME
       IZAMAX - BLAS level one, maximum index function

SYNOPSIS
       INTEGER FUNCTION IZAMAX ( n, x, incx )

           INTEGER              n, incx

           DOUBLE COMPLEX       x

DESCRIPTION
       IZAMAX searches a double complex vector for the first occurrence of the
       maximum absolute value.

       IZAMAX determines the first index i such that

       |Real(x )|+ |Imag(x ) | = MAX(|Real(x )| + | Imag(x )|): j = 1, ..., n
```

```
             i          i                j            j
              where x  is an element of a double complex vector.
                     j

ARGUMENTS
       n       INTEGER. (input)
               Number of elements to process in the vector to be searched.  If
               n <= 0, these routines return 0.

       x       DOUBLE COMPLEX. (input)
               Array of dimension (n-1) * |incx| + 1.
               Array x contains the vector to be searched.

       incx    INTEGER. (input)
               Increment between elements of x.

RETURN VALUES
       IZAMAX  INTEGER. (output)
               Return  the first index of the maximum absolute value of vector
               x.  The vector x has length n and increment incx.

NOTES
       When working backward (incx < 0), each routine starts at the end of the
       vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

       The largest absolute value is:

            ABS (x(1+(index-1) * incx)) when incx > 0

            ABS (x(1+(n-index) * |incx|)) when incx < 0

```

Spad represents complex numbers as a pair where the car is the real part and the cons is the imaginary part. BLAS wants a complex number in fortran format. So we have a design choice to make. Either we could write all of the BLAS code using Spad internal representation or we could follow the BLAS code standard. I've decided to follow the BLAS code standard so we need to create thunks to do the data translation.

NOTE: The Axiom internal representation of PRIMARR(COMPLEX(DFLOAT)) is an array where each array element AE is

```
AE = (cons (therealpart 0)) (cons (theimagpart 0))
```

so we need (car AE) and (cdr AE) to get the real and imag parts.

NOTE: Array indexing in Axiom is 0-based but Fortran is 1-based so the results are displaced by 1.

— BLAS 1 izamax —

```

NAME
       ZAXPY - BLAS level one axpy subroutine

SYNOPSIS
       SUBROUTINE ZAXPY    ( n, alpha, x, incx, y, incy )

           INTEGER           n, incx, incy

           DOUBLE COMPLEX    alpha, x, y

DESCRIPTION
       ZAXPY adds a scalar multiple of a double complex vector to another dou-
       ble complex vector.

       ZAXPY computes a constant alpha times a vector x plus a vector y.   The
       result overwrites the initial values of vector y.

       This routine performs the following vector operation:

            y  <--  alpha*x + y

       incx and incy specify the increment between two consecutive
       elements of respectively vector x and y.

ARGUMENTS
       n       INTEGER. (input)
               Number  of  elements in the vectors.  If n <= 0, these routines
               return without any computation.

       alpha   DOUBLE COMPLEX. (input)
               If alpha = 0 this routine returns without any computation.

       x       DOUBLE COMPLEX. (input)
               Array of dimension (n-1) * |incx| + 1.  Contains the vector  to
               be scaled before summation.

       incx    INTEGER. (input)
               Increment between elements of x.
               If incx = 0, the results will be unpredictable.
```

```
       y       DOUBLE COMPLEX. (input and output)
               array of dimension (n-1) * |incy| + 1.
               Before calling the routine, y contains the vector to be summed.
               After the routine ends, y contains the result of the summation.

       incy    INTEGER. (input)
               Increment between elements of y.
               If incy = 0, the results will be unpredictable.

NOTES
       This  routine  is  Level  1  Basic  Linear Algebra Subprograms (Level 1
       BLAS).

       When working backward (incx < 0 or incy < 0), each  routine  starts  at
       the end of the vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

            y(1-incy * (n-1)), y(1-incy * (n-2)), ..., y(1)

RETURN VALUES
       When  n  <=  0, double complex alpha = 0 = 0.+0.i, this routine returns
       immediately with no change in its arguments.
```

———-

Computes (complex double-float) $y \leftarrow \alpha x + y$

Arguments are:

- n - fixnum
- da - (complex double-float)
- dx - array (complex double-float)
- incx - fixnum
- dy - array (complex double-float)
- incy - fixnum

Axiom delivers PRIMARR(COMPLEX(DFLOAT)) as a list of pairs. We create a thunk function zaxpySpad which creates an array of complex double-float objects required by zaxpy.

The zaxpy function is defined to modify the second array. So the thunk function has to setf this information back into the original array.

The zaxpySpad function could be more efficient if it only copied elements that were modified. This was not done because of the overhead of figuring out which elements this could be under all possible arguments.

NAME
       ZCOPY  -  BLAS  level  one, copies a double complex vector into another
       double complex vector

SYNOPSIS
       SUBROUTINE ZCOPY    ( n, x, incx, y, incy )

           INTEGER           n, incx, incy

           DOUBLE COMPLEX    x, y

DESCRIPTION
       ZCOPY copies a double complex vector into another double  complex  vec-
       tor.   ZCOPY  copies  a vector x, whose length is n to a vector y. incx
       and incy specify the increment  between  two  consecutive  elements  of
       respectively vector x and y.

       This routine performs the following vector operation:

            y  <--  x

       where x and y are double complex vectors.

ARGUMENTS
       n       INTEGER. (input)
               Number of vector elements to be copied.
               If n <= 0, this routine returns without computation.
```

```
       x       DOUBLE COMPLEX, (input)
               Vector from which to copy.

       incx    INTEGER. (input)
               Increment between elements of x.
               If incx = 0, the results will be unpredictable.

       y       DOUBLE COMPLEX, (output)
               array of dimension (n-1) * |incy| + 1, result vector.

       incy    INTEGER. (input)
               Increment between elements of y.  If incy = 0, the results will
               be unpredictable.

NOTES
       When  working  backward  (incx < 0 or incy < 0), each routine starts at
       the end of the vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

            y(1-incy * (n-1)), y(1-incy * (n-2)), ..., y(1)
```

NAME
       ZDOTC  - BLAS level one, computes the hermitian dot product of vector x
       and vector y.

SYNOPSIS
       DOUBLE COMPLEX FUNCTION ZDOTC ( n, x, incx, y, incy )

           INTEGER                     n, incx, incy

           COMPLEX*16                  x, y
```

```
DESCRIPTION
       ZDOTC computes a dot product of the conjugate of a complex  vector  and
       another     complex     vector     (1     complex    inner    product).
       2

       ZDOTC computes a dot product of the conjugate of a complex  vector  and
       another     complex     vector     (1     complex    inner    product).
       2

       This routine performs the following vector operation:

            ZDOTC  <--  (conjugate transpose of x) * y
                            n
                        =  Sum  (complex conjugate of x(i))*y(i)
                           i=1
                                                H
       where x and y are complex vectors, and x is the conjugate
       transpose of x.

       If n <= 0, ZDOTC is set to 0.

ARGUMENTS
       n       INTEGER. (input)
               Number of elements in each vector.

       x       COMPLEX*16. (input)
               Array of dimension (n-1) * |incx| + 1.
               Array x contains the first vector operand.

       incx    INTEGER. (input)
               Increment between elements of x.
               If incx = 0, the results will be unpredictable.

       y       COMPLEX*16. (input)
               Array of dimension (n-1) * |incy| + 1.
               Array y contains the second vector operand.

       incy    INTEGER. (input)
               Increment between elements of y.
               If incy = 0, the results will be unpredictable.

RETURN VALUES
       ZDOTC    DOUBLE COMPLEX. Result (dot product). (output)

NOTES
       When  working  backward  (incx < 0 or incy < 0), each routine starts at
       the end of the vector and moves backward, as follows:
```

```
           x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

           y(1-incy * (n-1)), y(1-incy * (n-2)), ..., y(1)
```

NAME
       ZDOTU - BLAS level one, computes computes a dot product (inner product)
       of two complex vectors

SYNOPSIS
       DOUBLE COMPLEX FUNCTION ZDOTU ( n, x, incx, y, incy )

           INTEGER                     n, incx, incy

           COMPLEX*16                  x, y
```

```
DESCRIPTION
       ZDOTU computes a dot product of two complex vectors.

       This routine performs the following vector operation:

                                                    n
               ZDOTU  <--  (transpose of x) * y  =  Sum  x(i)*y(i)
                                                   i=1
                                        T
       where x and y are real vectors, and x is the transpose of
       x.

       If n <= 0, ZDOTU is set to 0.

ARGUMENTS
       n       INTEGER. (input)
               Number of elements in each vector.

       x       COMPLEX*16. (input)
               Array of dimension (n-1) * |incx| + 1.
               Array x contains the first vector operand.

       incx    INTEGER. (input)
               Increment between elements of x.
               If incx = 0, the results will be unpredictable.

       y       COMPLEX*16. (input)
               Array of dimension (n-1) * |incy| + 1.
               Array y contains the second vector operand.

       incy    INTEGER. (input)
               Increment between elements of y.
               If incy = 0, the results will be unpredictable.

RETURN VALUES
       ZDOTU   DOUBLE COMPLEX. Result (dot product). (output)

NOTES
       When  working  backward  (incx < 0 or incy < 0), each routine starts at
       the end of the vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

            y(1-incy * (n-1)), y(1-incy * (n-2)), ..., y(1)
```

NAME
       ZDSCAL - BLAS level one, Scales a double complex vector

SYNOPSIS
       SUBROUTINE ZDSCAL    ( n, alpha, x, incx )

           INTEGER            n, incx

           DOUBLE COMPLEX     x

           DOUBLE PRECISION   alpha

DESCRIPTION
       ZDSCAL  scales  a double complex vector with a double precision scalar.
       ZDSCAL scales the vector x of length n and increment incx by  the  con-
       stant alpha.

       This routine performs the following vector operation:

                 x <-- alpha x

       where alpha is a double precision scalar, and x is a double complex
       vector.

ARGUMENTS
       n       INTEGER. (input)
```

```
              Number of elements in the vector.
              If n <= 0, this routine returns without computation.

       alpha  DOUBLE PRECISION. (input)
              Value used to scale vector

       x      DOUBLE COMPLEX. (input and output)
              Array  of dimension (n-1) * abs(incx) + 1. Vector to be scaled.

       incx   INTEGER. (input)
              Increment between elements of x.
              If incx = 0, the results will be unpredictable.

NOTES
       When  working  backward  (incx < 0 or incy < 0), each routine starts at
       the end of the vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

NAME
       ZROTG - Extensions to BLAS level one rotation subroutines

SYNOPSIS
           SUBROUTINE ZROTG ( a, b, c, s )

           DOUBLE COMPLEX
                       a, b, s

           DOUBLE PRECISION
                       c

DESCRIPTION
       ZROTG  computes  the  elements  of  a Givens plane rotation matrix such
       that:

            _             _    _   _    _   _
           |      c    s  |    | a |    | r |
           |-congj(s)  c  | *  | b | =  | 0 |
           -              -    -   -    -   -

       where r = (a / sqrt(conjg(a)*a)) * sqrt ( conjg(a)*a + conjg(b)*b ) ,
       and the notation conjg(z) represents the complex conjugate of z.

       The Givens plane rotation can be used to introduce zero elements into
       a matrix selectively.
```

```
ARGUMENTS
       a       (input and output) DOUBLE COMPLEX

               First vector component.

               On input, the first component of the vector to be rotated.  On
               output,  a is overwritten by the unique complex number r, whose
               size in the complex plane is the Euclidean norm of the  complex
               vector  (a,b),  and whose direction in the complex plane is the
               same as that of the original complex element a.

                   if |a| != 0
                   r = a / |a| * sqrt( conjg(a)*a + conjg(b)*b )

                   if |a| = 0
                   r = b

       b       (input) DOUBLE COMPLEX

               Second vector component.

               The second component of the vector to be rotated.

       c       (output) DOUBLE PRECISION

               Cosine of the angle of rotation.

                   if |a| != 0
                   c = |a| /  sqrt( conjg(a)*a + conjg(b)*b )

                   if |a| = 0
                   c = 0

       s       (output) DOUBLE COMPLEX
               Sine of the angle of rotation.

                   if |a| != 0
                   c=a/|a|*conjg(b)/sqrt(conjg(a)*a+conjg(b)*b)

                   if |a| = 0
                   s = ( 1.0 , 0.0 )
```

(Complex Double-Float). Computes plane rotation. Arguments are:

- da - (complex double-float)
- db - (complex double-float)
- c - double-float
- s - (complex double-float)

Returns multiple values where:

- 1 da - ca
- 2 db - nil
- 3 c - c
- 4 s - s

NAME
       ZSCAL - BLAS level one, Scales a double complex vector

SYNOPSIS
       SUBROUTINE ZSCAL    ( n, alpha, x, incx )

           INTEGER            n, incx

           DOUBLE COMPLEX     x, alpha

DESCRIPTION
       ZSCAL  scales  a  double  complex  vector with a double complex scalar.
       ZSCAL scales the vector x of length n and increment incx  by  the  con-
       stant alpha.

       This routine performs the following vector operation:

                 x <-- alpha x

       where alpha is a double complex scalar, and x is a double complex
       vector.

ARGUMENTS
       n       INTEGER. (input)
               Number of elements in the vector.
               If n <= 0, this routine returns without computation.

       alpha   DOUBLE COMPLEX. (input)
               Value used to scale vector

       x       DOUBLE COMPLEX. (input and output)
               Array  of dimension (n-1) * abs(incx) + 1. Vector to be scaled.

       incx    INTEGER. (input)
               Increment between elements of x.
               If incx = 0, the results will be unpredictable.

NOTES
```

```
       When  working  backward  (incx < 0 or incy < 0), each routine starts at
       the end of the vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

NAME
       ZSWAP - BLAS level one, Swaps two double complex vectors

SYNOPSIS
       SUBROUTINE ZSWAP    ( n, x, incx, y, incy )

           INTEGER           n, incx, incy

           DOUBLE COMPLEX    x, y

DESCRIPTION
       ZSWAP  swaps  two  double  complex vectors, it interchanges n values of
       vector x and vector y.  incx and incy specify the increment between two
       consecutive elements of respectively vector x and y.

       This routine performs the following vector operation:

                 x <-> y

            where x and y are double complex vectors.

ARGUMENTS
       n       INTEGER. (input)
               Number of vector elements to be swapped.
               If n <= 0, this routine returns without computation.

       x       DOUBLE COMPLEX, (input and output)
               Array of dimension (n-1) * |incx| + 1.

       incx    INTEGER. (input)
               Increment between elements of x.
               If incx = 0, the results will be unpredictable.

       y       DOUBLE COMPLEX, (input and output)
               array of dimension (n-1) * |incy| + 1. Vector to be swapped.

       incy    INTEGER. (input)
               Increment between elements of y.  If incy = 0, the results will
               be unpredictable.

NOTES
```

When working backward (incx < 0 or incy < 0), each routine starts at the end of the vector and moves backward, as follows:

x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

y(1-incy * (n-1)), y(1-incy * (n-2)), ..., y(1)

========================================================================

 NAME
      DGBMV - perform one of the matrix-vector operations   y :=
      alpha*A*x + beta*y, or y := alpha*A'*x + beta*y,
```

```
SYNOPSIS
     SUBROUTINE DGBMV ( TRANS, M, N, KL, KU, ALPHA, A, LDA, X,
                        INCX, BETA, Y, INCY )

         DOUBLE       PRECISION ALPHA, BETA

         INTEGER      INCX, INCY, KL, KU, LDA, M, N

         CHARACTER*1  TRANS

         DOUBLE       PRECISION A( LDA, * ), X( * ), Y( * )

PURPOSE
     DGBMV  performs one of the matrix-vector operations

     where alpha and beta are scalars, x and y are vectors and A
     is an m by n band matrix, with kl sub-diagonals and ku
     super-diagonals.

PARAMETERS
     TRANS  - CHARACTER*1.
            On entry, TRANS specifies the operation to be per-
            formed as follows:

            TRANS = 'N' or 'n'   y := alpha*A*x + beta*y.

            TRANS = 'T' or 't'   y := alpha*A'*x + beta*y.

            TRANS = 'C' or 'c'   y := alpha*A'*x + beta*y.

            Unchanged on exit.

     M      - INTEGER.
            On entry, M specifies the number of rows of the
            matrix A.  M must be at least zero.  Unchanged on
            exit.

     N      - INTEGER.
            On entry, N specifies the number of columns of the
            matrix A.  N must be at least zero.  Unchanged on
            exit.

     KL     - INTEGER.
            On entry, KL specifies the number of sub-diagonals of
            the matrix A. KL must satisfy  0 .le. KL.  Unchanged
            on exit.

     KU     - INTEGER.
            On entry, KU specifies the number of super-diagonals
            of the matrix A. KU must satisfy  0 .le. KU.
```

```
       Unchanged on exit.

ALPHA  - DOUBLE PRECISION.
       On entry, ALPHA specifies the scalar alpha.
       Unchanged on exit.

A      - DOUBLE PRECISION array of DIMENSION ( LDA, n ).
       Before entry, the leading ( kl + ku + 1 ) by n part
       of the array A must contain the matrix of coeffi-
       cients, supplied column by column, with the leading
       diagonal of the matrix in row ( ku + 1 ) of the
       array, the first super-diagonal starting at position
       2 in row ku, the first sub-diagonal starting at posi-
       tion 1 in row ( ku + 2 ), and so on.  Elements in the
       array A that do not correspond to elements in the
       band matrix (such as the top left ku by ku triangle)
       are not referenced.  The following program segment
       will transfer a band matrix from conventional full
       matrix storage to band storage:

       DO 20, J = 1, N K = KU + 1 - J DO 10, I = MAX( 1, J -
       KU ), MIN( M, J + KL ) A( K + I, J ) = matrix( I, J )
       10    CONTINUE 20 CONTINUE

       Unchanged on exit.

LDA    - INTEGER.
       On entry, LDA specifies the first dimension of A as
       declared in the calling (sub) program. LDA must be at
       least ( kl + ku + 1 ).  Unchanged on exit.

X      - DOUBLE PRECISION array of DIMENSION at least
       ( 1 + ( n - 1 )*abs( INCX ) ) when TRANS = 'N' or 'n'
       and at least ( 1 + ( m - 1 )*abs( INCX ) ) otherwise.
       Before entry, the incremented array X must contain
       the vector x.  Unchanged on exit.

INCX   - INTEGER.
       On entry, INCX specifies the increment for the ele-
       ments of X. INCX must not be zero.  Unchanged on
       exit.

BETA   - DOUBLE PRECISION.
       On entry, BETA specifies the scalar beta. When BETA
       is supplied as zero then Y need not be set on input.
       Unchanged on exit.

Y      - DOUBLE PRECISION array of DIMENSION at least
       ( 1 + ( m - 1 )*abs( INCY ) ) when TRANS = 'N' or 'n'
```

```
            and at least ( 1 + ( n - 1 )*abs( INCY ) ) otherwise.
            Before entry, the incremented array Y must contain
            the vector y. On exit, Y is overwritten by the
            updated vector y.

      INCY   - INTEGER.
            On entry, INCY specifies the increment for the ele-
            ments of Y. INCY must not be zero.  Unchanged on
            exit.
```

 NAME
      DGEMV - perform one of the matrix-vector operations   y :=
      alpha*A*x + beta*y, or y := alpha*A'*x + beta*y,

 SYNOPSIS
      SUBROUTINE DGEMV ( TRANS, M, N, ALPHA, A, LDA, X, INCX,
                         BETA, Y, INCY )

          DOUBLE       PRECISION ALPHA, BETA

          INTEGER      INCX, INCY, LDA, M, N

          CHARACTER*1  TRANS

          DOUBLE       PRECISION A( LDA, * ), X( * ), Y( * )

 PURPOSE
      DGEMV  performs one of the matrix-vector operations

      where alpha and beta are scalars, x and y are vectors and A
      is an m by n matrix.
```

```
PARAMETERS
     TRANS  - CHARACTER*1.
            On entry, TRANS specifies the operation to be per-
            formed as follows:

            TRANS = 'N' or 'n'   y := alpha*A*x + beta*y.

            TRANS = 'T' or 't'   y := alpha*A'*x + beta*y.

            TRANS = 'C' or 'c'   y := alpha*A'*x + beta*y.

            Unchanged on exit.

     M      - INTEGER.
            On entry, M specifies the number of rows of the
            matrix A.  M must be at least zero.  Unchanged on
            exit.

     N      - INTEGER.
            On entry, N specifies the number of columns of the
            matrix A.  N must be at least zero.  Unchanged on
            exit.

     ALPHA  - DOUBLE PRECISION.
            On entry, ALPHA specifies the scalar alpha.
            Unchanged on exit.

     A      - DOUBLE PRECISION array of DIMENSION ( LDA, n ).
            Before entry, the leading m by n part of the array A

            must contain the matrix of coefficients.  Unchanged
            on exit.

     LDA    - INTEGER.
            On entry, LDA specifies the first dimension of A as
            declared in the calling (sub) program. LDA must be at
            least max( 1, m ).  Unchanged on exit.

     X      - DOUBLE PRECISION array of DIMENSION at least
            ( 1 + ( n - 1 )*abs( INCX ) ) when TRANS = 'N' or 'n'
            and at least ( 1 + ( m - 1 )*abs( INCX ) ) otherwise.
            Before entry, the incremented array X must contain
            the vector x.  Unchanged on exit.

     INCX   - INTEGER.
            On entry, INCX specifies the increment for the ele-
            ments of X. INCX must not be zero.  Unchanged on
            exit.

     BETA   - DOUBLE PRECISION.
```

```
            On entry, BETA specifies the scalar beta. When BETA
            is supplied as zero then Y need not be set on input.
            Unchanged on exit.

      Y     - DOUBLE PRECISION array of DIMENSION at least
            ( 1 + ( m - 1 )*abs( INCY ) ) when TRANS = 'N' or 'n'
            and at least ( 1 + ( n - 1 )*abs( INCY ) ) otherwise.
            Before entry with BETA non-zero, the incremented
            array Y must contain the vector y. On exit, Y is
            overwritten by the updated vector y.

      INCY  - INTEGER.
            On entry, INCY specifies the increment for the ele-
            ments of Y. INCY must not be zero.  Unchanged on
            exit.

 NAME
      DGER - perform the rank 1 operation   A := alpha*x*y' + A,

 SYNOPSIS
      SUBROUTINE DGER ( M, N, ALPHA, X, INCX, Y, INCY, A, LDA )

          DOUBLE      PRECISION ALPHA

          INTEGER     INCX, INCY, LDA, M, N

          DOUBLE      PRECISION A( LDA, * ), X( * ), Y( * )

 PURPOSE
      DGER   performs the rank 1 operation

      where alpha is a scalar, x is an m element vector, y is an n
      element vector and A is an m by n matrix.

 PARAMETERS
      M      - INTEGER.
               On entry, M specifies the number of rows of the
               matrix A.  M must be at least zero.  Unchanged on
               exit.

      N      - INTEGER.
               On entry, N specifies the number of columns of the
               matrix A.  N must be at least zero.  Unchanged on
               exit.

      ALPHA  - DOUBLE PRECISION.
               On entry, ALPHA specifies the scalar alpha.
               Unchanged on exit.

      X      - DOUBLE PRECISION array of dimension at least
```

```
              ( 1 + ( m - 1 )*abs( INCX ) ).  Before entry, the
              incremented array X must contain the m element vector
              x.  Unchanged on exit.

      INCX    - INTEGER.
              On entry, INCX specifies the increment for the ele-
              ments of X. INCX must not be zero.  Unchanged on
              exit.

      Y       - DOUBLE PRECISION array of dimension at least
              ( 1 + ( n - 1 )*abs( INCY ) ).  Before entry, the
              incremented array Y must contain the n element vector
              y.  Unchanged on exit.

      INCY    - INTEGER.
              On entry, INCY specifies the increment for the ele-
              ments of Y. INCY must not be zero.  Unchanged on

              exit.

      A       - DOUBLE PRECISION array of DIMENSION ( LDA, n ).
              Before entry, the leading m by n part of the array A
              must contain the matrix of coefficients. On exit, A
              is overwritten by the updated matrix.

      LDA     - INTEGER.
              On entry, LDA specifies the first dimension of A as
              declared in the calling (sub) program. LDA must be at
              least max( 1, m ).  Unchanged on exit.
```

 NAME
      DSBMV - perform the matrix-vector operation   y := alpha*A*x
      + beta*y,

 SYNOPSIS
      SUBROUTINE DSBMV ( UPLO, N, K, ALPHA, A, LDA, X, INCX, BETA,
                         Y, INCY )

          DOUBLE       PRECISION ALPHA, BETA

          INTEGER      INCX, INCY, K, LDA, N

          CHARACTER*1  UPLO

          DOUBLE       PRECISION A( LDA, * ), X( * ), Y( * )

 PURPOSE
      DSBMV  performs the matrix-vector  operation

      where alpha and beta are scalars, x and y are n element vec-
      tors and A is an n by n symmetric band matrix, with k
      super-diagonals.
```

```
PARAMETERS
     UPLO   - CHARACTER*1.
            On entry, UPLO specifies whether the upper or lower
            triangular part of the band matrix A is being sup-
            plied as follows:

            UPLO = 'U' or 'u'   The upper triangular part of A is
            being supplied.

            UPLO = 'L' or 'l'   The lower triangular part of A is
            being supplied.

            Unchanged on exit.

     N      - INTEGER.
            On entry, N specifies the order of the matrix A.  N
            must be at least zero.  Unchanged on exit.

     K      - INTEGER.
            On entry, K specifies the number of super-diagonals
            of the matrix A. K must satisfy  0 .le. K.  Unchanged
            on exit.

     ALPHA  - DOUBLE PRECISION.
            On entry, ALPHA specifies the scalar alpha.
            Unchanged on exit.

     A      - DOUBLE PRECISION array of DIMENSION ( LDA, n ).

            Before entry with UPLO = 'U' or 'u', the leading ( k
            + 1 ) by n part of the array A must contain the upper
            triangular band part of the symmetric matrix, sup-
            plied column by column, with the leading diagonal of
            the matrix in row ( k + 1 ) of the array, the first
            super-diagonal starting at position 2 in row k, and
            so on. The top left k by k triangle of the array A is
            not referenced.  The following program segment will
            transfer the upper triangular part of a symmetric
            band matrix from conventional full matrix storage to
            band storage:

            DO 20, J = 1, N M = K + 1 - J DO 10, I = MAX( 1, J -
            K ), J A( M + I, J ) = matrix( I, J ) 10    CONTINUE
            20 CONTINUE

            Before entry with UPLO = 'L' or 'l', the leading ( k
            + 1 ) by n part of the array A must contain the lower
            triangular band part of the symmetric matrix, sup-
            plied column by column, with the leading diagonal of
```

```
        the matrix in row 1 of the array, the first sub-
        diagonal starting at position 1 in row 2, and so on.
        The bottom right k by k triangle of the array A is
        not referenced.  The following program segment will
        transfer the lower triangular part of a symmetric
        band matrix from conventional full matrix storage to
        band storage:

        DO 20, J = 1, N M = 1 - J DO 10, I = J, MIN( N, J + K
        ) A( M + I, J ) = matrix( I, J ) 10    CONTINUE 20
        CONTINUE

        Unchanged on exit.

LDA     - INTEGER.
        On entry, LDA specifies the first dimension of A as
        declared in the calling (sub) program. LDA must be at
        least ( k + 1 ).  Unchanged on exit.

X       - DOUBLE PRECISION array of DIMENSION at least
        ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
        incremented array X must contain the vector x.
        Unchanged on exit.

INCX    - INTEGER.
        On entry, INCX specifies the increment for the ele-
        ments of X. INCX must not be zero.  Unchanged on
        exit.

BETA    - DOUBLE PRECISION.
        On entry, BETA specifies the scalar beta.  Unchanged
        on exit.

Y       - DOUBLE PRECISION array of DIMENSION at least
        ( 1 + ( n - 1 )*abs( INCY ) ).  Before entry, the
        incremented array Y must contain the vector y. On
        exit, Y is overwritten by the updated vector y.

INCY    - INTEGER.
        On entry, INCY specifies the increment for the ele-
        ments of Y. INCY must not be zero.  Unchanged on
        exit.

 NAME
      DSPMV - perform the matrix-vector operation   y := alpha*A*x
      + beta*y,

 SYNOPSIS
      SUBROUTINE DSPMV ( UPLO, N, ALPHA, AP, X, INCX, BETA, Y,
                         INCY )
```

```
          DOUBLE       PRECISION ALPHA, BETA

          INTEGER      INCX, INCY, N

          CHARACTER*1  UPLO

          DOUBLE       PRECISION AP( * ), X( * ), Y( * )

PURPOSE
     DSPMV  performs the matrix-vector operation

     where alpha and beta are scalars, x and y are n element vec-
     tors and A is an n by n symmetric matrix, supplied in packed
     form.

PARAMETERS
     UPLO   - CHARACTER*1.
              On entry, UPLO specifies whether the upper or lower
              triangular part of the matrix A is supplied in the
              packed array AP as follows:

              UPLO = 'U' or 'u'   The upper triangular part of A is
              supplied in AP.

              UPLO = 'L' or 'l'   The lower triangular part of A is
              supplied in AP.

              Unchanged on exit.

     N      - INTEGER.
              On entry, N specifies the order of the matrix A.  N
              must be at least zero.  Unchanged on exit.

     ALPHA  - DOUBLE PRECISION.
              On entry, ALPHA specifies the scalar alpha.
              Unchanged on exit.

     AP     - DOUBLE PRECISION array of DIMENSION at least
              ( ( n*( n + 1 ) )/2 ).  Before entry with UPLO = 'U'
              or 'u', the array AP must contain the upper triangu-
              lar part of the symmetric matrix packed sequentially,
              column by column, so that AP( 1 ) contains a( 1, 1 ),
              AP( 2 ) and AP( 3 ) contain a( 1, 2 ) and a( 2, 2 )

              respectively, and so on.  Before entry with UPLO =
              'L' or 'l', the array AP must contain the lower tri-
              angular part of the symmetric matrix packed sequen-
              tially, column by column, so that AP( 1 ) contains a(
              1, 1 ), AP( 2 ) and AP( 3 ) contain a( 2, 1 ) and a(
```

```
            3, 1 ) respectively, and so on.  Unchanged on exit.

      X     - DOUBLE PRECISION array of dimension at least
            ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
            incremented array X must contain the n element vector
            x.  Unchanged on exit.

      INCX  - INTEGER.
            On entry, INCX specifies the increment for the ele-
            ments of X. INCX must not be zero.  Unchanged on
            exit.

      BETA  - DOUBLE PRECISION.
            On entry, BETA specifies the scalar beta. When BETA
            is supplied as zero then Y need not be set on input.
            Unchanged on exit.

      Y     - DOUBLE PRECISION array of dimension at least
            ( 1 + ( n - 1 )*abs( INCY ) ).  Before entry, the
            incremented array Y must contain the n element vector
            y. On exit, Y is overwritten by the updated vector y.

      INCY  - INTEGER.
            On entry, INCY specifies the increment for the ele-
            ments of Y. INCY must not be zero.  Unchanged on
            exit.

 NAME
      DSPR2 - perform the symmetric rank 2 operation   A :=
      alpha*x*y' + alpha*y*x' + A,

 SYNOPSIS
      SUBROUTINE DSPR2 ( UPLO, N, ALPHA, X, INCX, Y, INCY, AP )

          DOUBLE       PRECISION ALPHA

          INTEGER      INCX, INCY, N

          CHARACTER*1  UPLO

          DOUBLE       PRECISION AP( * ), X( * ), Y( * )

 PURPOSE
      DSPR2  performs the symmetric rank 2 operation

      where alpha is a scalar, x and y are n element vectors and A
      is an n by n symmetric matrix, supplied in packed form.

 PARAMETERS
      UPLO   - CHARACTER*1.
               On entry, UPLO specifies whether the upper or lower
               triangular part of the matrix A is supplied in the
               packed array AP as follows:

               UPLO = 'U' or 'u'   The upper triangular part of A is
               supplied in AP.

               UPLO = 'L' or 'l'   The lower triangular part of A is
               supplied in AP.

               Unchanged on exit.
```

```
N      - INTEGER.
       On entry, N specifies the order of the matrix A.  N
       must be at least zero.  Unchanged on exit.

ALPHA  - DOUBLE PRECISION.
       On entry, ALPHA specifies the scalar alpha.
       Unchanged on exit.

X      - DOUBLE PRECISION array of dimension at least
       ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
       incremented array X must contain the n element vector
       x.  Unchanged on exit.

INCX   - INTEGER.
       On entry, INCX specifies the increment for the ele-
       ments of X. INCX must not be zero.  Unchanged on

       exit.

Y      - DOUBLE PRECISION array of dimension at least
       ( 1 + ( n - 1 )*abs( INCY ) ).  Before entry, the
       incremented array Y must contain the n element vector
       y.  Unchanged on exit.

INCY   - INTEGER.
       On entry, INCY specifies the increment for the ele-
       ments of Y. INCY must not be zero.  Unchanged on
       exit.

AP     - DOUBLE PRECISION array of DIMENSION at least
       ( ( n*( n + 1 ) )/2 ).  Before entry with  UPLO = 'U'
       or 'u', the array AP must contain the upper triangu-
       lar part of the symmetric matrix packed sequentially,
       column by column, so that AP( 1 ) contains a( 1, 1 ),
       AP( 2 ) and AP( 3 ) contain a( 1, 2 ) and a( 2, 2 )
       respectively, and so on. On exit, the array AP is
       overwritten by the upper triangular part of the
       updated matrix.  Before entry with UPLO = 'L' or 'l',
       the array AP must contain the lower triangular part
       of the symmetric matrix packed sequentially, column
       by column, so that AP( 1 ) contains a( 1, 1 ), AP( 2
       ) and AP( 3 ) contain a( 2, 1 ) and a( 3, 1 ) respec-
       tively, and so on. On exit, the array AP is overwrit-
       ten by the lower triangular part of the updated
       matrix.

 NAME
      DSPR - perform the symmetric rank 1 operation   A :=
      alpha*x*x' + A,

 SYNOPSIS
      SUBROUTINE DSPR ( UPLO, N, ALPHA, X, INCX, AP )

          DOUBLE      PRECISION ALPHA

          INTEGER     INCX, N

          CHARACTER*1 UPLO

          DOUBLE      PRECISION AP( * ), X( * )

 PURPOSE
      DSPR    performs the symmetric rank 1 operation

      where alpha is a real scalar, x is an n element vector and A
      is an n by n symmetric matrix, supplied in packed form.

 PARAMETERS
      UPLO   - CHARACTER*1.
               On entry, UPLO specifies whether the upper or lower
               triangular part of the matrix A is supplied in the
               packed array AP as follows:

               UPLO = 'U' or 'u'   The upper triangular part of A is
               supplied in AP.

               UPLO = 'L' or 'l'   The lower triangular part of A is
               supplied in AP.

               Unchanged on exit.
```

```
      N      - INTEGER.
             On entry, N specifies the order of the matrix A.  N
             must be at least zero.  Unchanged on exit.

      ALPHA  - DOUBLE PRECISION.
             On entry, ALPHA specifies the scalar alpha.
             Unchanged on exit.

      X      - DOUBLE PRECISION array of dimension at least
             ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
             incremented array X must contain the n element vector
             x.  Unchanged on exit.

      INCX   - INTEGER.
             On entry, INCX specifies the increment for the ele-
             ments of X. INCX must not be zero.  Unchanged on

             exit.

      AP     - DOUBLE PRECISION array of DIMENSION at least
             ( ( n*( n + 1 ) )/2 ).  Before entry with  UPLO = 'U'
             or 'u', the array AP must contain the upper triangu-
             lar part of the symmetric matrix packed sequentially,
             column by column, so that AP( 1 ) contains a( 1, 1 ),
             AP( 2 ) and AP( 3 ) contain a( 1, 2 ) and a( 2, 2 )
             respectively, and so on. On exit, the array AP is
             overwritten by the upper triangular part of the
             updated matrix.  Before entry with UPLO = 'L' or 'l',
             the array AP must contain the lower triangular part
             of the symmetric matrix packed sequentially, column
             by column, so that AP( 1 ) contains a( 1, 1 ), AP( 2
             ) and AP( 3 ) contain a( 2, 1 ) and a( 3, 1 ) respec-
             tively, and so on. On exit, the array AP is overwrit-
             ten by the lower triangular part of the updated
             matrix.

 NAME
      DSYMV - perform the matrix-vector operation   y := alpha*A*x
      + beta*y,

 SYNOPSIS
      SUBROUTINE DSYMV ( UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y,
                         INCY )

          DOUBLE       PRECISION ALPHA, BETA

          INTEGER      INCX, INCY, LDA, N

          CHARACTER*1  UPLO

          DOUBLE       PRECISION A( LDA, * ), X( * ), Y( * )

 PURPOSE
      DSYMV  performs the matrix-vector  operation

      where alpha and beta are scalars, x and y are n element vec-
      tors and A is an n by n symmetric matrix.

 PARAMETERS
      UPLO   - CHARACTER*1.
               On entry, UPLO specifies whether the upper or lower
               triangular part of the array A is to be referenced as
               follows:

               UPLO = 'U' or 'u'   Only the upper triangular part of
               A is to be referenced.

               UPLO = 'L' or 'l'   Only the lower triangular part of
               A is to be referenced.

               Unchanged on exit.

      N      - INTEGER.
```

```
         On entry, N specifies the order of the matrix A.  N
         must be at least zero.  Unchanged on exit.

ALPHA  - DOUBLE PRECISION.
         On entry, ALPHA specifies the scalar alpha.
         Unchanged on exit.

A      - DOUBLE PRECISION array of DIMENSION ( LDA, n ).
         Before entry with  UPLO = 'U' or 'u', the leading n
         by n upper triangular part of the array A must con-
         tain the upper triangular part of the symmetric
         matrix and the strictly lower triangular part of A is
         not referenced.  Before entry with UPLO = 'L' or 'l',
         the leading n by n lower triangular part of the array

         A must contain the lower triangular part of the sym-
         metric matrix and the strictly upper triangular part
         of A is not referenced.  Unchanged on exit.

LDA    - INTEGER.
         On entry, LDA specifies the first dimension of A as
         declared in the calling (sub) program. LDA must be at
         least max( 1, n ).  Unchanged on exit.

X      - DOUBLE PRECISION array of dimension at least
         ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
         incremented array X must contain the n element vector
         x.  Unchanged on exit.

INCX   - INTEGER.
         On entry, INCX specifies the increment for the ele-
         ments of X. INCX must not be zero.  Unchanged on
         exit.

BETA   - DOUBLE PRECISION.
         On entry, BETA specifies the scalar beta. When BETA
         is supplied as zero then Y need not be set on input.
         Unchanged on exit.

Y      - DOUBLE PRECISION array of dimension at least
         ( 1 + ( n - 1 )*abs( INCY ) ).  Before entry, the
         incremented array Y must contain the n element vector
         y. On exit, Y is overwritten by the updated vector y.

INCY   - INTEGER.
         On entry, INCY specifies the increment for the ele-
         ments of Y. INCY must not be zero.  Unchanged on
         exit.

 NAME
      DSYR2 - perform the symmetric rank 2 operation   A :=
      alpha*x*y' + alpha*y*x' + A,

 SYNOPSIS
      SUBROUTINE DSYR2 ( UPLO, N, ALPHA, X, INCX, Y, INCY, A, LDA
                       )

          DOUBLE       PRECISION ALPHA

          INTEGER      INCX, INCY, LDA, N

          CHARACTER*1  UPLO

          DOUBLE       PRECISION A( LDA, * ), X( * ), Y( * )

 PURPOSE
      DSYR2  performs the symmetric rank 2 operation

      where alpha is a scalar, x and y are n element vectors and A
      is an n by n symmetric matrix.

 PARAMETERS
      UPLO   - CHARACTER*1.
               On entry, UPLO specifies whether the upper or lower
               triangular part of the array A is to be referenced as
               follows:

               UPLO = 'U' or 'u'   Only the upper triangular part of
               A is to be referenced.

               UPLO = 'L' or 'l'   Only the lower triangular part of
               A is to be referenced.

               Unchanged on exit.

      N      - INTEGER.
               On entry, N specifies the order of the matrix A.  N
               must be at least zero.  Unchanged on exit.

      ALPHA  - DOUBLE PRECISION.
               On entry, ALPHA specifies the scalar alpha.
               Unchanged on exit.
```

```
      X      - DOUBLE PRECISION array of dimension at least
             ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
             incremented array X must contain the n element vector
             x.  Unchanged on exit.

      INCX   - INTEGER.
             On entry, INCX specifies the increment for the

             elements of X. INCX must not be zero.  Unchanged on
             exit.

      Y      - DOUBLE PRECISION array of dimension at least
             ( 1 + ( n - 1 )*abs( INCY ) ).  Before entry, the
             incremented array Y must contain the n element vector
             y.  Unchanged on exit.

      INCY   - INTEGER.
             On entry, INCY specifies the increment for the ele-
             ments of Y. INCY must not be zero.  Unchanged on
             exit.

      A      - DOUBLE PRECISION array of DIMENSION ( LDA, n ).
             Before entry with  UPLO = 'U' or 'u', the leading n
             by n upper triangular part of the array A must con-
             tain the upper triangular part of the symmetric
             matrix and the strictly lower triangular part of A is
             not referenced. On exit, the upper triangular part of
             the array A is overwritten by the upper triangular
             part of the updated matrix.  Before entry with UPLO =
             'L' or 'l', the leading n by n lower triangular part
             of the array A must contain the lower triangular part
             of the symmetric matrix and the strictly upper tri-
             angular part of A is not referenced. On exit, the
             lower triangular part of the array A is overwritten
             by the lower triangular part of the updated matrix.

      LDA    - INTEGER.
             On entry, LDA specifies the first dimension of A as
             declared in the calling (sub) program. LDA must be at
             least max( 1, n ).  Unchanged on exit.

 NAME
      DSYR - perform the symmetric rank 1 operation   A :=
      alpha*x*x' + A,

 SYNOPSIS
      SUBROUTINE DSYR ( UPLO, N, ALPHA, X, INCX, A, LDA )

          DOUBLE      PRECISION ALPHA

          INTEGER     INCX, LDA, N
```

```
          CHARACTER*1 UPLO

          DOUBLE      PRECISION A( LDA, * ), X( * )

PURPOSE
     DSYR   performs the symmetric rank 1 operation

     where alpha is a real scalar, x is an n element vector and A
     is an n by n symmetric matrix.

PARAMETERS
     UPLO   - CHARACTER*1.
            On entry, UPLO specifies whether the upper or lower
            triangular part of the array A is to be referenced as
            follows:

            UPLO = 'U' or 'u'   Only the upper triangular part of
            A is to be referenced.

            UPLO = 'L' or 'l'   Only the lower triangular part of
            A is to be referenced.

            Unchanged on exit.

     N      - INTEGER.
            On entry, N specifies the order of the matrix A.  N
            must be at least zero.  Unchanged on exit.

     ALPHA  - DOUBLE PRECISION.
            On entry, ALPHA specifies the scalar alpha.
            Unchanged on exit.

     X      - DOUBLE PRECISION array of dimension at least
            ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
            incremented array X must contain the n element vector
            x.  Unchanged on exit.

     INCX   - INTEGER.
            On entry, INCX specifies the increment for the ele-
            ments of X. INCX must not be zero.  Unchanged on

            exit.

     A      - DOUBLE PRECISION array of DIMENSION ( LDA, n ).
            Before entry with  UPLO = 'U' or 'u', the leading n
            by n upper triangular part of the array A must con-
            tain the upper triangular part of the symmetric
            matrix and the strictly lower triangular part of A is
            not referenced. On exit, the upper triangular part of
            the array A is overwritten by the upper triangular
```

```
           part of the updated matrix.  Before entry with UPLO =
           'L' or 'l', the leading n by n lower triangular part
           of the array A must contain the lower triangular part
           of the symmetric matrix and the strictly upper tri-
           angular part of A is not referenced. On exit, the
           lower triangular part of the array A is overwritten
           by the lower triangular part of the updated matrix.

     LDA   - INTEGER.
           On entry, LDA specifies the first dimension of A as
           declared in the calling (sub) program. LDA must be at
           least max( 1, n ).  Unchanged on exit.
```

 NAME
      DTBMV - perform one of the matrix-vector operations   x :=
      A*x, or x := A'*x,

 SYNOPSIS
      SUBROUTINE DTBMV ( UPLO, TRANS, DIAG, N, K, A, LDA, X, INCX
                       )

          INTEGER      INCX, K, LDA, N

          CHARACTER*1  DIAG, TRANS, UPLO

          DOUBLE       PRECISION A( LDA, * ), X( * )

 PURPOSE
      DTBMV  performs one of the matrix-vector operations

      where x is an n element vector and  A is an n by n unit, or
      non-unit, upper or lower triangular band matrix, with ( k +
      1 ) diagonals.

 PARAMETERS
      UPLO   - CHARACTER*1.
               On entry, UPLO specifies whether the matrix is an
               upper or lower triangular matrix as follows:

               UPLO = 'U' or 'u'   A is an upper triangular matrix.

               UPLO = 'L' or 'l'   A is a lower triangular matrix.

               Unchanged on exit.

      TRANS  - CHARACTER*1.
               On entry, TRANS specifies the operation to be per-
               formed as follows:

               TRANS = 'N' or 'n'   x := A*x.
```

TRANS = 'T' or 't' x := A'*x.

TRANS = 'C' or 'c' x := A'*x.

Unchanged on exit.

DIAG - CHARACTER*1.
On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N - INTEGER.
On entry, N specifies the order of the matrix A. N must be at least zero. Unchanged on exit.

K - INTEGER.
On entry with UPLO = 'U' or 'u', K specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', K specifies the number of sub-diagonals of the matrix A. K must satisfy 0 .le. K. Unchanged on exit.

A - DOUBLE PRECISION array of DIMENSION (LDA, n).
Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

DO 20, J = 1, N M = K + 1 - J DO 10, I = MAX(1, J - K), J A(M + I, J) = matrix(I, J) 10 CONTINUE 20 CONTINUE

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal

```
           of the matrix in row 1 of the array, the first sub-
           diagonal starting at position 1 in row 2, and so on.
           The bottom right k by k triangle of the array A is
           not referenced.  The following program segment will
           transfer a lower triangular band matrix from conven-
           tional full matrix storage to band storage:

           DO 20, J = 1, N M = 1 - J DO 10, I = J, MIN( N, J + K
           ) A( M + I, J ) = matrix( I, J ) 10    CONTINUE 20
           CONTINUE

           Note that when DIAG = 'U' or 'u' the elements of the
           array A corresponding to the diagonal elements of the
           matrix are not referenced, but are assumed to be
           unity.  Unchanged on exit.

     LDA   - INTEGER.
           On entry, LDA specifies the first dimension of A as
           declared in the calling (sub) program. LDA must be at
           least ( k + 1 ).  Unchanged on exit.

     X     - DOUBLE PRECISION array of dimension at least
           ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
           incremented array X must contain the n element vector
           x. On exit, X is overwritten with the transformed
           vector x.

     INCX  - INTEGER.
           On entry, INCX specifies the increment for the ele-
           ments of X. INCX must not be zero.  Unchanged on
           exit.
```

 NAME
      DTBSV - solve one of the systems of equations   A*x = b, or
      A'*x = b,

 SYNOPSIS
```

```
     SUBROUTINE DTBSV ( UPLO, TRANS, DIAG, N, K, A, LDA, X, INCX
                      )

         INTEGER      INCX, K, LDA, N

         CHARACTER*1  DIAG, TRANS, UPLO

         DOUBLE       PRECISION A( LDA, * ), X( * )

PURPOSE
     DTBSV  solves one of the systems of equations

     where b and x are n element vectors and A is an n by n unit,
     or non-unit, upper or lower triangular band matrix, with ( k
     + 1 ) diagonals.

     No test for singularity or near-singularity is included in
     this routine. Such tests must be performed before calling
     this routine.

PARAMETERS
     UPLO   - CHARACTER*1.
            On entry, UPLO specifies whether the matrix is an
            upper or lower triangular matrix as follows:

            UPLO = 'U' or 'u'   A is an upper triangular matrix.

            UPLO = 'L' or 'l'   A is a lower triangular matrix.

            Unchanged on exit.

     TRANS  - CHARACTER*1.
            On entry, TRANS specifies the equations to be solved
            as follows:

            TRANS = 'N' or 'n'   A*x = b.

            TRANS = 'T' or 't'   A'*x = b.

            TRANS = 'C' or 'c'   A'*x = b.

            Unchanged on exit.

     DIAG   - CHARACTER*1.
            On entry, DIAG specifies whether or not A is unit
            triangular as follows:

            DIAG = 'U' or 'u'   A is assumed to be unit triangu-
            lar.
```

```
          DIAG = 'N' or 'n'   A is not assumed to be unit tri-
          angular.

          Unchanged on exit.

N         - INTEGER.
          On entry, N specifies the order of the matrix A.  N
          must be at least zero.  Unchanged on exit.

K         - INTEGER.
          On entry with UPLO = 'U' or 'u', K specifies the
          number of super-diagonals of the matrix A.  On entry
          with UPLO = 'L' or 'l', K specifies the number of
          sub-diagonals of the matrix A.  K must satisfy  0
          .le. K.  Unchanged on exit.

A         - DOUBLE PRECISION array of DIMENSION ( LDA, n ).
          Before entry with UPLO = 'U' or 'u', the leading ( k
          + 1 ) by n part of the array A must contain the upper
          triangular band part of the matrix of coefficients,
          supplied column by column, with the leading diagonal
          of the matrix in row ( k + 1 ) of the array, the
          first super-diagonal starting at position 2 in row k,
          and so on. The top left k by k triangle of the array
          A is not referenced.  The following program segment
          will transfer an upper triangular band matrix from
          conventional full matrix storage to band storage:

          DO 20, J = 1, N M = K + 1 - J DO 10, I = MAX( 1, J -
          K ), J A( M + I, J ) = matrix( I, J ) 10    CONTINUE
          20 CONTINUE

          Before entry with UPLO = 'L' or 'l', the leading ( k
          + 1 ) by n part of the array A must contain the lower
          triangular band part of the matrix of coefficients,
          supplied column by column, with the leading diagonal
          of the matrix in row 1 of the array, the first sub-
          diagonal starting at position 1 in row 2, and so on.
          The bottom right k by k triangle of the array A is
          not referenced.  The following program segment will
          transfer a lower triangular band matrix from conven-
          tional full matrix storage to band storage:

          DO 20, J = 1, N M = 1 - J DO 10, I = J, MIN( N, J + K
          ) A( M + I, J ) = matrix( I, J ) 10    CONTINUE 20
          CONTINUE

          Note that when DIAG = 'U' or 'u' the elements of the
          array A corresponding to the diagonal elements of the
```

```
            matrix are not referenced, but are assumed to be
            unity.  Unchanged on exit.

      LDA    - INTEGER.
             On entry, LDA specifies the first dimension of A as
             declared in the calling (sub) program. LDA must be at
             least ( k + 1 ).  Unchanged on exit.

      X      - DOUBLE PRECISION array of dimension at least
             ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
             incremented array X must contain the n element
             right-hand side vector b. On exit, X is overwritten
             with the solution vector x.

      INCX   - INTEGER.
             On entry, INCX specifies the increment for the ele-
             ments of X. INCX must not be zero.  Unchanged on
             exit.
```

 NAME
      DTPMV - perform one of the matrix-vector operations   x :=
      A*x, or x := A'*x,

 SYNOPSIS
      SUBROUTINE DTPMV ( UPLO, TRANS, DIAG, N, AP, X, INCX )

          INTEGER      INCX, N

          CHARACTER*1  DIAG, TRANS, UPLO

          DOUBLE       PRECISION AP( * ), X( * )

 PURPOSE
      DTPMV  performs one of the matrix-vector operations
```

```
     where x is an n element vector and  A is an n by n unit, or
     non-unit, upper or lower triangular matrix, supplied in
     packed form.

 PARAMETERS
      UPLO   - CHARACTER*1.
               On entry, UPLO specifies whether the matrix is an
               upper or lower triangular matrix as follows:

               UPLO = 'U' or 'u'   A is an upper triangular matrix.

               UPLO = 'L' or 'l'   A is a lower triangular matrix.

               Unchanged on exit.

      TRANS  - CHARACTER*1.
               On entry, TRANS specifies the operation to be per-
               formed as follows:

               TRANS = 'N' or 'n'   x := A*x.

               TRANS = 'T' or 't'   x := A'*x.

               TRANS = 'C' or 'c'   x := A'*x.

               Unchanged on exit.

      DIAG   - CHARACTER*1.
               On entry, DIAG specifies whether or not A is unit
               triangular as follows:

               DIAG = 'U' or 'u'   A is assumed to be unit triangu-
               lar.

               DIAG = 'N' or 'n'   A is not assumed to be unit

               triangular.

               Unchanged on exit.

      N      - INTEGER.
               On entry, N specifies the order of the matrix A.  N
               must be at least zero.  Unchanged on exit.

      AP     - DOUBLE PRECISION array of DIMENSION at least
               ( ( n*( n + 1 ) )/2 ).  Before entry with  UPLO = 'U'
               or 'u', the array AP must contain the upper triangu-
               lar matrix packed sequentially, column by column, so
               that AP( 1 ) contains a( 1, 1 ), AP( 2 ) and AP( 3 )
               contain a( 1, 2 ) and a( 2, 2 ) respectively, and so
```

```
            on.  Before entry with UPLO = 'L' or 'l', the array
            AP must contain the lower triangular matrix packed
            sequentially, column by column, so that AP( 1 ) con-
            tains a( 1, 1 ), AP( 2 ) and AP( 3 ) contain a( 2, 1
            ) and a( 3, 1 ) respectively, and so on.  Note that
            when  DIAG = 'U' or 'u', the diagonal elements of A
            are not referenced, but are assumed to be unity.
            Unchanged on exit.

      X     - DOUBLE PRECISION array of dimension at least
            ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
            incremented array X must contain the n element vector
            x. On exit, X is overwritten with the transformed
            vector x.

      INCX  - INTEGER.
            On entry, INCX specifies the increment for the ele-
            ments of X. INCX must not be zero.  Unchanged on
            exit.
```

 NAME
      DTPSV - solve one of the systems of equations   A*x = b, or
      A'*x = b,

 SYNOPSIS
      SUBROUTINE DTPSV ( UPLO, TRANS, DIAG, N, AP, X, INCX )

          INTEGER      INCX, N

          CHARACTER*1  DIAG, TRANS, UPLO

          DOUBLE       PRECISION AP( * ), X( * )

 PURPOSE
      DTPSV  solves one of the systems of equations

      where b and x are n element vectors and A is an n by n unit,
      or non-unit, upper or lower triangular matrix, supplied in
      packed form.

      No test for singularity or near-singularity is included in
      this routine. Such tests must be performed before calling
```

```
     this routine.

 PARAMETERS
     UPLO   - CHARACTER*1.
            On entry, UPLO specifies whether the matrix is an
            upper or lower triangular matrix as follows:

            UPLO = 'U' or 'u'   A is an upper triangular matrix.

            UPLO = 'L' or 'l'   A is a lower triangular matrix.

            Unchanged on exit.

     TRANS  - CHARACTER*1.
            On entry, TRANS specifies the equations to be solved
            as follows:

            TRANS = 'N' or 'n'   A*x = b.

            TRANS = 'T' or 't'   A'*x = b.

            TRANS = 'C' or 'c'   A'*x = b.

            Unchanged on exit.

     DIAG   - CHARACTER*1.
            On entry, DIAG specifies whether or not A is unit
            triangular as follows:

            DIAG = 'U' or 'u'   A is assumed to be unit triangu-
            lar.

            DIAG = 'N' or 'n'   A is not assumed to be unit tri-
            angular.

            Unchanged on exit.

     N      - INTEGER.
            On entry, N specifies the order of the matrix A.  N
            must be at least zero.  Unchanged on exit.

     AP     - DOUBLE PRECISION array of DIMENSION at least
            ( ( n*( n + 1 ) )/2 ).  Before entry with  UPLO = 'U'
            or 'u', the array AP must contain the upper triangu-
            lar matrix packed sequentially, column by column, so
            that AP( 1 ) contains a( 1, 1 ), AP( 2 ) and AP( 3 )
            contain a( 1, 2 ) and a( 2, 2 ) respectively, and so
            on.  Before entry with UPLO = 'L' or 'l', the array
            AP must contain the lower triangular matrix packed
            sequentially, column by column, so that AP( 1 ) con-
```

```
            tains a( 1, 1 ), AP( 2 ) and AP( 3 ) contain a( 2, 1
            ) and a( 3, 1 ) respectively, and so on.  Note that
            when  DIAG = 'U' or 'u', the diagonal elements of A
            are not referenced, but are assumed to be unity.
            Unchanged on exit.

      X     - DOUBLE PRECISION array of dimension at least
            ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
            incremented array X must contain the n element
            right-hand side vector b. On exit, X is overwritten
            with the solution vector x.

      INCX  - INTEGER.
            On entry, INCX specifies the increment for the ele-
            ments of X. INCX must not be zero.  Unchanged on
            exit.
```

 NAME
      DTRMV - perform one of the matrix-vector operations   x :=
      A*x, or x := A'*x,

 SYNOPSIS
      SUBROUTINE DTRMV ( UPLO, TRANS, DIAG, N, A, LDA, X, INCX )

          INTEGER      INCX, LDA, N

          CHARACTER*1  DIAG, TRANS, UPLO

          DOUBLE       PRECISION A( LDA, * ), X( * )

 PURPOSE
      DTRMV  performs one of the matrix-vector operations

      where x is an n element vector and  A is an n by n unit, or
      non-unit, upper or lower triangular matrix.

 PARAMETERS
      UPLO   - CHARACTER*1.
               On entry, UPLO specifies whether the matrix is an
```

```
         upper or lower triangular matrix as follows:

         UPLO = 'U' or 'u'   A is an upper triangular matrix.

         UPLO = 'L' or 'l'   A is a lower triangular matrix.

         Unchanged on exit.

TRANS  - CHARACTER*1.
         On entry, TRANS specifies the operation to be per-
         formed as follows:

         TRANS = 'N' or 'n'   x := A*x.

         TRANS = 'T' or 't'   x := A'*x.

         TRANS = 'C' or 'c'   x := A'*x.

         Unchanged on exit.

DIAG   - CHARACTER*1.
         On entry, DIAG specifies whether or not A is unit
         triangular as follows:

         DIAG = 'U' or 'u'   A is assumed to be unit triangu-
         lar.

         DIAG = 'N' or 'n'   A is not assumed to be unit tri-
         angular.

         Unchanged on exit.

N      - INTEGER.
         On entry, N specifies the order of the matrix A.  N
         must be at least zero.  Unchanged on exit.

A      - DOUBLE PRECISION array of DIMENSION ( LDA, n ).
         Before entry with  UPLO = 'U' or 'u', the leading n
         by n upper triangular part of the array A must con-
         tain the upper triangular matrix and the strictly
         lower triangular part of A is not referenced.  Before
         entry with UPLO = 'L' or 'l', the leading n by n
         lower triangular part of the array A must contain the
         lower triangular matrix and the strictly upper tri-
         angular part of A is not referenced.  Note that when
         DIAG = 'U' or 'u', the diagonal elements of A are not
         referenced either, but are assumed to be unity.
         Unchanged on exit.

LDA    - INTEGER.
```

```
           On entry, LDA specifies the first dimension of A as
           declared in the calling (sub) program. LDA must be at
           least max( 1, n ).  Unchanged on exit.

     X     - DOUBLE PRECISION array of dimension at least
           ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
           incremented array X must contain the n element vector
           x. On exit, X is overwritten with the transformed
           vector x.

     INCX  - INTEGER.
           On entry, INCX specifies the increment for the ele-
           ments of X. INCX must not be zero.  Unchanged on
           exit.

 NAME
      DTRSV - solve one of the systems of equations   A*x = b, or
```

```
     A'*x = b,

SYNOPSIS
     SUBROUTINE DTRSV ( UPLO, TRANS, DIAG, N, A, LDA, X, INCX )

         INTEGER      INCX, LDA, N

         CHARACTER*1  DIAG, TRANS, UPLO

         DOUBLE       PRECISION A( LDA, * ), X( * )

PURPOSE
     DTRSV  solves one of the systems of equations

     where b and x are n element vectors and A is an n by n unit,
     or non-unit, upper or lower triangular matrix.

     No test for singularity or near-singularity is included in
     this routine. Such tests must be performed before calling
     this routine.

PARAMETERS
     UPLO   - CHARACTER*1.
            On entry, UPLO specifies whether the matrix is an
            upper or lower triangular matrix as follows:

            UPLO = 'U' or 'u'   A is an upper triangular matrix.

            UPLO = 'L' or 'l'   A is a lower triangular matrix.

            Unchanged on exit.

     TRANS  - CHARACTER*1.
            On entry, TRANS specifies the equations to be solved
            as follows:

            TRANS = 'N' or 'n'   A*x = b.

            TRANS = 'T' or 't'   A'*x = b.

            TRANS = 'C' or 'c'   A'*x = b.

            Unchanged on exit.

     DIAG   - CHARACTER*1.
            On entry, DIAG specifies whether or not A is unit
            triangular as follows:

            DIAG = 'U' or 'u'   A is assumed to be unit
```

```
            triangular.

            DIAG = 'N' or 'n'   A is not assumed to be unit tri-
            angular.

            Unchanged on exit.

      N     - INTEGER.
            On entry, N specifies the order of the matrix A.  N
            must be at least zero.  Unchanged on exit.

      A     - DOUBLE PRECISION array of DIMENSION ( LDA, n ).
            Before entry with  UPLO = 'U' or 'u', the leading n
            by n upper triangular part of the array A must con-
            tain the upper triangular matrix and the strictly
            lower triangular part of A is not referenced.  Before
            entry with UPLO = 'L' or 'l', the leading n by n
            lower triangular part of the array A must contain the
            lower triangular matrix and the strictly upper tri-
            angular part of A is not referenced.  Note that when
            DIAG = 'U' or 'u', the diagonal elements of A are not
            referenced either, but are assumed to be unity.
            Unchanged on exit.

      LDA   - INTEGER.
            On entry, LDA specifies the first dimension of A as
            declared in the calling (sub) program. LDA must be at
            least max( 1, n ).  Unchanged on exit.

      X     - DOUBLE PRECISION array of dimension at least
            ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
            incremented array X must contain the n element
            right-hand side vector b. On exit, X is overwritten
            with the solution vector x.

      INCX  - INTEGER.
            On entry, INCX specifies the increment for the ele-
            ments of X. INCX must not be zero.  Unchanged on
            exit.

 NAME
      ZGBMV - perform one of the matrix-vector operations   y :=
      alpha*A*x + beta*y, or y := alpha*A'*x + beta*y, or   y :=
      alpha*conjg( A' )*x + beta*y,

 SYNOPSIS
      SUBROUTINE ZGBMV ( TRANS, M, N, KL, KU, ALPHA, A, LDA, X,
                         INCX, BETA, Y, INCY )

          COMPLEX*16   ALPHA, BETA

          INTEGER      INCX, INCY, KL, KU, LDA, M, N

          CHARACTER*1  TRANS

          COMPLEX*16   A( LDA, * ), X( * ), Y( * )

 PURPOSE
      ZGBMV  performs one of the matrix-vector operations

      where alpha and beta are scalars, x and y are vectors and A
      is an m by n band matrix, with kl sub-diagonals and ku
      super-diagonals.

 PARAMETERS
```

```
TRANS  - CHARACTER*1.
       On entry, TRANS specifies the operation to be per-
       formed as follows:

       TRANS = 'N' or 'n'   y := alpha*A*x + beta*y.

       TRANS = 'T' or 't'   y := alpha*A'*x + beta*y.

       TRANS = 'C' or 'c'   y := alpha*conjg( A' )*x +
       beta*y.

       Unchanged on exit.

M      - INTEGER.
       On entry, M specifies the number of rows of the
       matrix A.  M must be at least zero.  Unchanged on
       exit.

N      - INTEGER.
       On entry, N specifies the number of columns of the
       matrix A.  N must be at least zero.  Unchanged on
       exit.

KL     - INTEGER.
       On entry, KL specifies the number of sub-diagonals of
       the matrix A. KL must satisfy  0 .le. KL.  Unchanged

       on exit.

KU     - INTEGER.
       On entry, KU specifies the number of super-diagonals
       of the matrix A. KU must satisfy  0 .le. KU.
       Unchanged on exit.

ALPHA  - COMPLEX*16      .
       On entry, ALPHA specifies the scalar alpha.
       Unchanged on exit.

A      - COMPLEX*16       array of DIMENSION ( LDA, n ).
       Before entry, the leading ( kl + ku + 1 ) by n part
       of the array A must contain the matrix of coeffi-
       cients, supplied column by column, with the leading
       diagonal of the matrix in row ( ku + 1 ) of the
       array, the first super-diagonal starting at position
       2 in row ku, the first sub-diagonal starting at posi-
       tion 1 in row ( ku + 2 ), and so on.  Elements in the
       array A that do not correspond to elements in the
       band matrix (such as the top left ku by ku triangle)
       are not referenced.  The following program segment
       will transfer a band matrix from conventional full
```

```
            matrix storage to band storage:

            DO 20, J = 1, N K = KU + 1 - J DO 10, I = MAX( 1, J -
            KU ), MIN( M, J + KL ) A( K + I, J ) = matrix( I, J )
            10    CONTINUE 20 CONTINUE

            Unchanged on exit.

      LDA   - INTEGER.
            On entry, LDA specifies the first dimension of A as
            declared in the calling (sub) program. LDA must be at
            least ( kl + ku + 1 ).  Unchanged on exit.

      X     - COMPLEX*16       array of DIMENSION at least
            ( 1 + ( n - 1 )*abs( INCX ) ) when TRANS = 'N' or 'n'
            and at least ( 1 + ( m - 1 )*abs( INCX ) ) otherwise.
            Before entry, the incremented array X must contain
            the vector x.  Unchanged on exit.

      INCX  - INTEGER.
            On entry, INCX specifies the increment for the ele-
            ments of X. INCX must not be zero.  Unchanged on
            exit.

      BETA  - COMPLEX*16      .
            On entry, BETA specifies the scalar beta. When BETA
            is supplied as zero then Y need not be set on input.
            Unchanged on exit.

      Y     - COMPLEX*16       array of DIMENSION at least
            ( 1 + ( m - 1 )*abs( INCY ) ) when TRANS = 'N' or 'n'
            and at least ( 1 + ( n - 1 )*abs( INCY ) ) otherwise.
            Before entry, the incremented array Y must contain
            the vector y. On exit, Y is overwritten by the
            updated vector y.

      INCY  - INTEGER.
            On entry, INCY specifies the increment for the ele-
            ments of Y. INCY must not be zero.  Unchanged on
            exit.

 NAME
      ZGEMV - perform one of the matrix-vector operations   y :=
      alpha*A*x + beta*y, or y := alpha*A'*x + beta*y, or   y :=
      alpha*conjg( A' )*x + beta*y,

 SYNOPSIS
      SUBROUTINE ZGEMV ( TRANS, M, N, ALPHA, A, LDA, X, INCX,
                         BETA, Y, INCY )

          COMPLEX*16   ALPHA, BETA

          INTEGER      INCX, INCY, LDA, M, N

          CHARACTER*1  TRANS

          COMPLEX*16   A( LDA, * ), X( * ), Y( * )

 PURPOSE
```

```
     ZGEMV  performs one of the matrix-vector operations

     where alpha and beta are scalars, x and y are vectors and A
     is an m by n matrix.

 PARAMETERS
     TRANS  - CHARACTER*1.
            On entry, TRANS specifies the operation to be per-
            formed as follows:

            TRANS = 'N' or 'n'   y := alpha*A*x + beta*y.

            TRANS = 'T' or 't'   y := alpha*A'*x + beta*y.

            TRANS = 'C' or 'c'   y := alpha*conjg( A' )*x +
            beta*y.

            Unchanged on exit.

     M      - INTEGER.
            On entry, M specifies the number of rows of the
            matrix A.  M must be at least zero.  Unchanged on
            exit.

     N      - INTEGER.
            On entry, N specifies the number of columns of the
            matrix A.  N must be at least zero.  Unchanged on
            exit.

     ALPHA  - COMPLEX*16      .
            On entry, ALPHA specifies the scalar alpha.
            Unchanged on exit.

     A      - COMPLEX*16       array of DIMENSION ( LDA, n ).
            Before entry, the leading m by n part of the array A
            must contain the matrix of coefficients.  Unchanged
            on exit.

     LDA    - INTEGER.
            On entry, LDA specifies the first dimension of A as
            declared in the calling (sub) program. LDA must be at
            least max( 1, m ).  Unchanged on exit.

     X      - COMPLEX*16       array of DIMENSION at least
            ( 1 + ( n - 1 )*abs( INCX ) ) when TRANS = 'N' or 'n'
            and at least ( 1 + ( m - 1 )*abs( INCX ) ) otherwise.
            Before entry, the incremented array X must contain
            the vector x.  Unchanged on exit.

     INCX   - INTEGER.
```

```
            On entry, INCX specifies the increment for the ele-
            ments of X. INCX must not be zero.  Unchanged on
            exit.

      BETA   - COMPLEX*16      .
            On entry, BETA specifies the scalar beta. When BETA
            is supplied as zero then Y need not be set on input.
            Unchanged on exit.

      Y      - COMPLEX*16       array of DIMENSION at least
            ( 1 + ( m - 1 )*abs( INCY ) ) when TRANS = 'N' or 'n'
            and at least ( 1 + ( n - 1 )*abs( INCY ) ) otherwise.
            Before entry with BETA non-zero, the incremented
            array Y must contain the vector y. On exit, Y is
            overwritten by the updated vector y.

      INCY   - INTEGER.
            On entry, INCY specifies the increment for the ele-
            ments of Y. INCY must not be zero.  Unchanged on
            exit.

 NAME
      ZGERC - perform the rank 1 operation   A := alpha*x*conjg(
      y' ) + A,

 SYNOPSIS
      SUBROUTINE ZGERC ( M, N, ALPHA, X, INCX, Y, INCY, A, LDA )

          COMPLEX*16   ALPHA

          INTEGER      INCX, INCY, LDA, M, N

          COMPLEX*16   A( LDA, * ), X( * ), Y( * )

 PURPOSE
      ZGERC  performs the rank 1 operation

      where alpha is a scalar, x is an m element vector, y is an n
      element vector and A is an m by n matrix.

 PARAMETERS
      M      - INTEGER.
               On entry, M specifies the number of rows of the
```

```
          matrix A.  M must be at least zero.  Unchanged on
          exit.

N         - INTEGER.
          On entry, N specifies the number of columns of the
          matrix A.  N must be at least zero.  Unchanged on
          exit.

ALPHA     - COMPLEX*16      .
          On entry, ALPHA specifies the scalar alpha.
          Unchanged on exit.

X         - COMPLEX*16       array of dimension at least
          ( 1 + ( m - 1 )*abs( INCX ) ).  Before entry, the
          incremented array X must contain the m element vector
          x.  Unchanged on exit.

INCX      - INTEGER.
          On entry, INCX specifies the increment for the ele-
          ments of X. INCX must not be zero.  Unchanged on
          exit.

Y         - COMPLEX*16       array of dimension at least
          ( 1 + ( n - 1 )*abs( INCY ) ).  Before entry, the
          incremented array Y must contain the n element vector
          y.  Unchanged on exit.

INCY      - INTEGER.
          On entry, INCY specifies the increment for the

          elements of Y. INCY must not be zero.  Unchanged on
          exit.

A         - COMPLEX*16       array of DIMENSION ( LDA, n ).
          Before entry, the leading m by n part of the array A
          must contain the matrix of coefficients. On exit, A
          is overwritten by the updated matrix.

LDA       - INTEGER.
          On entry, LDA specifies the first dimension of A as
          declared in the calling (sub) program. LDA must be at
          least max( 1, m ).  Unchanged on exit.

NAME
     ZGERU - perform the rank 1 operation   A := alpha*x*y' + A,

SYNOPSIS
     SUBROUTINE ZGERU ( M, N, ALPHA, X, INCX, Y, INCY, A, LDA )

         COMPLEX*16   ALPHA

         INTEGER      INCX, INCY, LDA, M, N

         COMPLEX*16   A( LDA, * ), X( * ), Y( * )

PURPOSE
     ZGERU  performs the rank 1 operation

     where alpha is a scalar, x is an m element vector, y is an n
     element vector and A is an m by n matrix.

PARAMETERS
     M      - INTEGER.
              On entry, M specifies the number of rows of the
              matrix A.  M must be at least zero.  Unchanged on
              exit.

     N      - INTEGER.
              On entry, N specifies the number of columns of the
              matrix A.  N must be at least zero.  Unchanged on
              exit.

     ALPHA  - COMPLEX*16      .
              On entry, ALPHA specifies the scalar alpha.
              Unchanged on exit.

     X      - COMPLEX*16       array of dimension at least
              ( 1 + ( m - 1 )*abs( INCX ) ).  Before entry, the
              incremented array X must contain the m element vector
              x.  Unchanged on exit.

     INCX   - INTEGER.
              On entry, INCX specifies the increment for the ele-
              ments of X. INCX must not be zero.  Unchanged on
              exit.

     Y      - COMPLEX*16       array of dimension at least
              ( 1 + ( n - 1 )*abs( INCY ) ).  Before entry, the
              incremented array Y must contain the n element vector
              y.  Unchanged on exit.

     INCY   - INTEGER.
```

```
            On entry, INCY specifies the increment for the ele-
            ments of Y. INCY must not be zero.  Unchanged on

            exit.

      A     - COMPLEX*16       array of DIMENSION ( LDA, n ).
            Before entry, the leading m by n part of the array A
            must contain the matrix of coefficients. On exit, A
            is overwritten by the updated matrix.

      LDA   - INTEGER.
            On entry, LDA specifies the first dimension of A as
            declared in the calling (sub) program. LDA must be at
            least max( 1, m ).  Unchanged on exit.
```

 NAME
      ZHBMV - perform the matrix-vector operation   y := alpha*A*x
      + beta*y,

 SYNOPSIS
      SUBROUTINE ZHBMV ( UPLO, N, K, ALPHA, A, LDA, X, INCX, BETA,
                         Y, INCY )

          COMPLEX*16   ALPHA, BETA

          INTEGER      INCX, INCY, K, LDA, N

          CHARACTER*1  UPLO

          COMPLEX*16   A( LDA, * ), X( * ), Y( * )

 PURPOSE
      ZHBMV  performs the matrix-vector  operation

      where alpha and beta are scalars, x and y are n element vec-
      tors and A is an n by n hermitian band matrix, with k
      super-diagonals.

 PARAMETERS
      UPLO   - CHARACTER*1.
               On entry, UPLO specifies whether the upper or lower
               triangular part of the band matrix A is being sup-
               plied as follows:

               UPLO = 'U' or 'u'   The upper triangular part of A is
               being supplied.

               UPLO = 'L' or 'l'   The lower triangular part of A is
               being supplied.
```

```
        Unchanged on exit.

N       - INTEGER.
        On entry, N specifies the order of the matrix A.  N
        must be at least zero.  Unchanged on exit.

K       - INTEGER.
        On entry, K specifies the number of super-diagonals
        of the matrix A. K must satisfy  0 .le. K.  Unchanged
        on exit.

ALPHA   - COMPLEX*16      .
        On entry, ALPHA specifies the scalar alpha.
        Unchanged on exit.

A       - COMPLEX*16       array of DIMENSION ( LDA, n ).

        Before entry with UPLO = 'U' or 'u', the leading ( k
        + 1 ) by n part of the array A must contain the upper
        triangular band part of the hermitian matrix, sup-
        plied column by column, with the leading diagonal of
        the matrix in row ( k + 1 ) of the array, the first
        super-diagonal starting at position 2 in row k, and
        so on. The top left k by k triangle of the array A is
        not referenced.  The following program segment will
        transfer the upper triangular part of a hermitian
        band matrix from conventional full matrix storage to
        band storage:

        DO 20, J = 1, N M = K + 1 - J DO 10, I = MAX( 1, J -
        K ), J A( M + I, J ) = matrix( I, J ) 10    CONTINUE
        20 CONTINUE

        Before entry with UPLO = 'L' or 'l', the leading ( k
        + 1 ) by n part of the array A must contain the lower
        triangular band part of the hermitian matrix, sup-
        plied column by column, with the leading diagonal of
        the matrix in row 1 of the array, the first sub-
        diagonal starting at position 1 in row 2, and so on.
        The bottom right k by k triangle of the array A is
        not referenced.  The following program segment will
        transfer the lower triangular part of a hermitian
        band matrix from conventional full matrix storage to
        band storage:

        DO 20, J = 1, N M = 1 - J DO 10, I = J, MIN( N, J + K
        ) A( M + I, J ) = matrix( I, J ) 10    CONTINUE 20
        CONTINUE

        Note that the imaginary parts of the diagonal ele-
```

```
           ments need not be set and are assumed to be zero.
           Unchanged on exit.

     LDA   - INTEGER.
           On entry, LDA specifies the first dimension of A as
           declared in the calling (sub) program. LDA must be at
           least ( k + 1 ).  Unchanged on exit.

     X     - COMPLEX*16       array of DIMENSION at least
           ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
           incremented array X must contain the vector x.
           Unchanged on exit.

     INCX  - INTEGER.
           On entry, INCX specifies the increment for the ele-
           ments of X. INCX must not be zero.  Unchanged on
           exit.

     BETA  - COMPLEX*16      .

           On entry, BETA specifies the scalar beta.  Unchanged
           on exit.

     Y     - COMPLEX*16       array of DIMENSION at least
           ( 1 + ( n - 1 )*abs( INCY ) ).  Before entry, the
           incremented array Y must contain the vector y. On
           exit, Y is overwritten by the updated vector y.

     INCY  - INTEGER.
           On entry, INCY specifies the increment for the ele-
           ments of Y. INCY must not be zero.  Unchanged on
           exit.

 NAME
      ZHEMV - perform the matrix-vector operation   y := alpha*A*x
      + beta*y,

 SYNOPSIS
      SUBROUTINE ZHEMV ( UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y,
```

```
                    INCY )

         COMPLEX*16   ALPHA, BETA

         INTEGER      INCX, INCY, LDA, N

         CHARACTER*1  UPLO

         COMPLEX*16   A( LDA, * ), X( * ), Y( * )

PURPOSE
     ZHEMV  performs the matrix-vector  operation

     where alpha and beta are scalars, x and y are n element vec-
     tors and A is an n by n hermitian matrix.

PARAMETERS
     UPLO   - CHARACTER*1.
            On entry, UPLO specifies whether the upper or lower
            triangular part of the array A is to be referenced as
            follows:

            UPLO = 'U' or 'u'   Only the upper triangular part of
            A is to be referenced.

            UPLO = 'L' or 'l'   Only the lower triangular part of
            A is to be referenced.

            Unchanged on exit.

     N      - INTEGER.
            On entry, N specifies the order of the matrix A.  N
            must be at least zero.  Unchanged on exit.

     ALPHA  - COMPLEX*16      .
            On entry, ALPHA specifies the scalar alpha.
            Unchanged on exit.

     A      - COMPLEX*16       array of DIMENSION ( LDA, n ).
            Before entry with  UPLO = 'U' or 'u', the leading n
            by n upper triangular part of the array A must con-
            tain the upper triangular part of the hermitian
            matrix and the strictly lower triangular part of A is
            not referenced.  Before entry with UPLO = 'L' or 'l',
            the leading n by n lower triangular part of the array

            A must contain the lower triangular part of the her-
            mitian matrix and the strictly upper triangular part
            of A is not referenced.  Note that the imaginary
            parts of the diagonal elements need not be set and
```

```
*           are assumed to be zero.  Unchanged on exit.
*
*     LDA    - INTEGER.
*           On entry, LDA specifies the first dimension of A as
*           declared in the calling (sub) program. LDA must be at
*           least max( 1, n ).  Unchanged on exit.
*
*     X      - COMPLEX*16       array of dimension at least
*           ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
*           incremented array X must contain the n element vector
*           x.  Unchanged on exit.
*
*     INCX   - INTEGER.
*           On entry, INCX specifies the increment for the ele-
*           ments of X. INCX must not be zero.  Unchanged on
*           exit.
*
*     BETA   - COMPLEX*16      .
*           On entry, BETA specifies the scalar beta. When BETA
*           is supplied as zero then Y need not be set on input.
*           Unchanged on exit.
*
*     Y      - COMPLEX*16       array of dimension at least
*           ( 1 + ( n - 1 )*abs( INCY ) ).  Before entry, the
*           incremented array Y must contain the n element vector
*           y. On exit, Y is overwritten by the updated vector y.
*
*     INCY   - INTEGER.
*           On entry, INCY specifies the increment for the ele-
*           ments of Y. INCY must not be zero.  Unchanged on
*           exit.

NAME
     ZHER2 - perform the hermitian rank 2 operation   A :=
     alpha*x*conjg( y' ) + conjg( alpha )*y*conjg( x' ) + A,

SYNOPSIS
     SUBROUTINE ZHER2 ( UPLO, N, ALPHA, X, INCX, Y, INCY, A, LDA
                      )

         COMPLEX*16   ALPHA

         INTEGER      INCX, INCY, LDA, N

         CHARACTER*1  UPLO

         COMPLEX*16   A( LDA, * ), X( * ), Y( * )

PURPOSE
     ZHER2  performs the hermitian rank 2 operation

     where alpha is a scalar, x and y are n element vectors and A
     is an n by n hermitian matrix.

PARAMETERS
     UPLO   - CHARACTER*1.
            On entry, UPLO specifies whether the upper or lower
            triangular part of the array A is to be referenced as
            follows:

            UPLO = 'U' or 'u'   Only the upper triangular part of
            A is to be referenced.

            UPLO = 'L' or 'l'   Only the lower triangular part of
            A is to be referenced.

            Unchanged on exit.

     N      - INTEGER.
            On entry, N specifies the order of the matrix A.  N
            must be at least zero.  Unchanged on exit.

     ALPHA  - COMPLEX*16      .
            On entry, ALPHA specifies the scalar alpha.
            Unchanged on exit.

     X      - COMPLEX*16       array of dimension at least
            ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
            incremented array X must contain the n element vector
            x.  Unchanged on exit.

     INCX   - INTEGER.
```

```
          On entry, INCX specifies the increment for the

          elements of X. INCX must not be zero.  Unchanged on
          exit.

      Y   - COMPLEX*16       array of dimension at least
          ( 1 + ( n - 1 )*abs( INCY ) ).  Before entry, the
          incremented array Y must contain the n element vector
          y.  Unchanged on exit.

      INCY - INTEGER.
          On entry, INCY specifies the increment for the ele-
          ments of Y. INCY must not be zero.  Unchanged on
          exit.

      A   - COMPLEX*16       array of DIMENSION ( LDA, n ).
          Before entry with  UPLO = 'U' or 'u', the leading n
          by n upper triangular part of the array A must con-
          tain the upper triangular part of the hermitian
          matrix and the strictly lower triangular part of A is
          not referenced. On exit, the upper triangular part of
          the array A is overwritten by the upper triangular
          part of the updated matrix.  Before entry with UPLO =
          'L' or 'l', the leading n by n lower triangular part
          of the array A must contain the lower triangular part
          of the hermitian matrix and the strictly upper tri-
          angular part of A is not referenced. On exit, the
          lower triangular part of the array A is overwritten
          by the lower triangular part of the updated matrix.
          Note that the imaginary parts of the diagonal ele-
          ments need not be set, they are assumed to be zero,
          and on exit they are set to zero.

      LDA  - INTEGER.
          On entry, LDA specifies the first dimension of A as
          declared in the calling (sub) program. LDA must be at
          least max( 1, n ).  Unchanged on exit.

 NAME
      ZHER - perform the hermitian rank 1 operation   A :=
      alpha*x*conjg( x' ) + A,

 SYNOPSIS
      SUBROUTINE ZHER ( UPLO, N, ALPHA, X, INCX, A, LDA )

          DOUBLE      PRECISION ALPHA

          INTEGER     INCX, LDA, N

          CHARACTER*1 UPLO

          COMPLEX*16  A( LDA, * ), X( * )

 PURPOSE
      ZHER   performs the hermitian rank 1 operation

      where alpha is a real scalar, x is an n element vector and A
      is an n by n hermitian matrix.

 PARAMETERS
```

```
UPLO   - CHARACTER*1.
       On entry, UPLO specifies whether the upper or lower
       triangular part of the array A is to be referenced as
       follows:

       UPLO = 'U' or 'u'   Only the upper triangular part of
       A is to be referenced.

       UPLO = 'L' or 'l'   Only the lower triangular part of
       A is to be referenced.

       Unchanged on exit.

N      - INTEGER.
       On entry, N specifies the order of the matrix A.  N
       must be at least zero.  Unchanged on exit.

ALPHA  - DOUBLE PRECISION.
       On entry, ALPHA specifies the scalar alpha.
       Unchanged on exit.

X      - COMPLEX*16       array of dimension at least
       ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
       incremented array X must contain the n element vector
       x.  Unchanged on exit.

INCX   - INTEGER.
       On entry, INCX specifies the increment for the ele-
       ments of X. INCX must not be zero.  Unchanged on

       exit.

A      - COMPLEX*16       array of DIMENSION ( LDA, n ).
       Before entry with  UPLO = 'U' or 'u', the leading n
       by n upper triangular part of the array A must con-
       tain the upper triangular part of the hermitian
       matrix and the strictly lower triangular part of A is
       not referenced. On exit, the upper triangular part of
       the array A is overwritten by the upper triangular
       part of the updated matrix.  Before entry with UPLO =
       'L' or 'l', the leading n by n lower triangular part
       of the array A must contain the lower triangular part
       of the hermitian matrix and the strictly upper tri-
       angular part of A is not referenced. On exit, the
       lower triangular part of the array A is overwritten
       by the lower triangular part of the updated matrix.
       Note that the imaginary parts of the diagonal ele-
       ments need not be set, they are assumed to be zero,
       and on exit they are set to zero.
```

```
      LDA    - INTEGER.
             On entry, LDA specifies the first dimension of A as
             declared in the calling (sub) program. LDA must be at
             least max( 1, n ).  Unchanged on exit.
```

 NAME
      ZHPMV - perform the matrix-vector operation   y := alpha*A*x
      + beta*y,

 SYNOPSIS
      SUBROUTINE ZHPMV ( UPLO, N, ALPHA, AP, X, INCX, BETA, Y,
                         INCY )

          COMPLEX*16   ALPHA, BETA

          INTEGER      INCX, INCY, N

          CHARACTER*1  UPLO

          COMPLEX*16   AP( * ), X( * ), Y( * )

 PURPOSE
      ZHPMV  performs the matrix-vector operation

      where alpha and beta are scalars, x and y are n element vec-
      tors and A is an n by n hermitian matrix, supplied in packed
      form.

 PARAMETERS
      UPLO   - CHARACTER*1.
               On entry, UPLO specifies whether the upper or lower
               triangular part of the matrix A is supplied in the
               packed array AP as follows:

               UPLO = 'U' or 'u'   The upper triangular part of A is
               supplied in AP.

               UPLO = 'L' or 'l'   The lower triangular part of A is
               supplied in AP.

               Unchanged on exit.

      N      - INTEGER.
               On entry, N specifies the order of the matrix A.  N
```

```
       must be at least zero.  Unchanged on exit.

ALPHA  - COMPLEX*16      .
       On entry, ALPHA specifies the scalar alpha.
       Unchanged on exit.

AP     - COMPLEX*16       array of DIMENSION at least
       ( ( n*( n + 1 ) )/2 ).  Before entry with UPLO = 'U'
       or 'u', the array AP must contain the upper triangu-
       lar part of the hermitian matrix packed sequentially,
       column by column, so that AP( 1 ) contains a( 1, 1 ),
       AP( 2 ) and AP( 3 ) contain a( 1, 2 ) and a( 2, 2 )

       respectively, and so on.  Before entry with UPLO =
       'L' or 'l', the array AP must contain the lower tri-
       angular part of the hermitian matrix packed sequen-
       tially, column by column, so that AP( 1 ) contains a(
       1, 1 ), AP( 2 ) and AP( 3 ) contain a( 2, 1 ) and a(
       3, 1 ) respectively, and so on.  Note that the ima-
       ginary parts of the diagonal elements need not be set
       and are assumed to be zero.  Unchanged on exit.

X      - COMPLEX*16       array of dimension at least
       ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
       incremented array X must contain the n element vector
       x.  Unchanged on exit.

INCX   - INTEGER.
       On entry, INCX specifies the increment for the ele-
       ments of X. INCX must not be zero.  Unchanged on
       exit.

BETA   - COMPLEX*16      .
       On entry, BETA specifies the scalar beta. When BETA
       is supplied as zero then Y need not be set on input.
       Unchanged on exit.

Y      - COMPLEX*16       array of dimension at least
       ( 1 + ( n - 1 )*abs( INCY ) ).  Before entry, the
       incremented array Y must contain the n element vector
       y. On exit, Y is overwritten by the updated vector y.

INCY   - INTEGER.
       On entry, INCY specifies the increment for the ele-
       ments of Y. INCY must not be zero.  Unchanged on
       exit.

 NAME
      ZHPR2 - perform the hermitian rank 2 operation   A :=
      alpha*x*conjg( y' ) + conjg( alpha )*y*conjg( x' ) + A,
```

```
SYNOPSIS
     SUBROUTINE ZHPR2 ( UPLO, N, ALPHA, X, INCX, Y, INCY, AP )

         COMPLEX*16   ALPHA

         INTEGER      INCX, INCY, N

         CHARACTER*1  UPLO

         COMPLEX*16   AP( * ), X( * ), Y( * )

PURPOSE
     ZHPR2  performs the hermitian rank 2 operation

     where alpha is a scalar, x and y are n element vectors and A
     is an n by n hermitian matrix, supplied in packed form.

PARAMETERS
     UPLO   - CHARACTER*1.
            On entry, UPLO specifies whether the upper or lower
            triangular part of the matrix A is supplied in the
            packed array AP as follows:

            UPLO = 'U' or 'u'   The upper triangular part of A is
            supplied in AP.

            UPLO = 'L' or 'l'   The lower triangular part of A is
            supplied in AP.

            Unchanged on exit.

     N      - INTEGER.
            On entry, N specifies the order of the matrix A.  N
            must be at least zero.  Unchanged on exit.

     ALPHA  - COMPLEX*16      .
            On entry, ALPHA specifies the scalar alpha.
            Unchanged on exit.

     X      - COMPLEX*16       array of dimension at least
            ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
            incremented array X must contain the n element vector
            x.  Unchanged on exit.

     INCX   - INTEGER.
            On entry, INCX specifies the increment for the ele-
            ments of X. INCX must not be zero.  Unchanged on

            exit.
```

```
      Y      - COMPLEX*16       array of dimension at least
             ( 1 + ( n - 1 )*abs( INCY ) ).  Before entry, the
             incremented array Y must contain the n element vector
             y.  Unchanged on exit.

      INCY   - INTEGER.
             On entry, INCY specifies the increment for the ele-
             ments of Y. INCY must not be zero.  Unchanged on
             exit.

      AP     - COMPLEX*16       array of DIMENSION at least
             ( ( n*( n + 1 ) )/2 ).  Before entry with  UPLO = 'U'
             or 'u', the array AP must contain the upper triangu-
             lar part of the hermitian matrix packed sequentially,
             column by column, so that AP( 1 ) contains a( 1, 1 ),
             AP( 2 ) and AP( 3 ) contain a( 1, 2 ) and a( 2, 2 )
             respectively, and so on. On exit, the array AP is
             overwritten by the upper triangular part of the
             updated matrix.  Before entry with UPLO = 'L' or 'l',
             the array AP must contain the lower triangular part
             of the hermitian matrix packed sequentially, column
             by column, so that AP( 1 ) contains a( 1, 1 ), AP( 2
             ) and AP( 3 ) contain a( 2, 1 ) and a( 3, 1 ) respec-
             tively, and so on. On exit, the array AP is overwrit-
             ten by the lower triangular part of the updated
             matrix.  Note that the imaginary parts of the diago-
             nal elements need not be set, they are assumed to be
             zero, and on exit they are set to zero.

 NAME
      ZHPR - perform the hermitian rank 1 operation   A :=
      alpha*x*conjg( x' ) + A,

 SYNOPSIS
```

```
     SUBROUTINE ZHPR ( UPLO, N, ALPHA, X, INCX, AP )

         DOUBLE      PRECISION ALPHA

         INTEGER     INCX, N

         CHARACTER*1 UPLO

         COMPLEX*16  AP( * ), X( * )

PURPOSE
     ZHPR    performs the hermitian rank 1 operation

     where alpha is a real scalar, x is an n element vector and A
     is an n by n hermitian matrix, supplied in packed form.

PARAMETERS
     UPLO   - CHARACTER*1.
            On entry, UPLO specifies whether the upper or lower
            triangular part of the matrix A is supplied in the
            packed array AP as follows:

            UPLO = 'U' or 'u'   The upper triangular part of A is
            supplied in AP.

            UPLO = 'L' or 'l'   The lower triangular part of A is
            supplied in AP.

            Unchanged on exit.

     N      - INTEGER.
            On entry, N specifies the order of the matrix A.  N
            must be at least zero.  Unchanged on exit.

     ALPHA  - DOUBLE PRECISION.
            On entry, ALPHA specifies the scalar alpha.
            Unchanged on exit.

     X      - COMPLEX*16       array of dimension at least
            ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
            incremented array X must contain the n element vector
            x.  Unchanged on exit.

     INCX   - INTEGER.
            On entry, INCX specifies the increment for the ele-
            ments of X. INCX must not be zero.  Unchanged on

            exit.

     AP     - COMPLEX*16       array of DIMENSION at least
```

```
           ( ( n*( n + 1 ) )/2 ).  Before entry with  UPLO = 'U'
           or 'u', the array AP must contain the upper triangu-
           lar part of the hermitian matrix packed sequentially,
           column by column, so that AP( 1 ) contains a( 1, 1 ),
           AP( 2 ) and AP( 3 ) contain a( 1, 2 ) and a( 2, 2 )
           respectively, and so on. On exit, the array AP is
           overwritten by the upper triangular part of the
           updated matrix.  Before entry with UPLO = 'L' or 'l',
           the array AP must contain the lower triangular part
           of the hermitian matrix packed sequentially, column
           by column, so that AP( 1 ) contains a( 1, 1 ), AP( 2
           ) and AP( 3 ) contain a( 2, 1 ) and a( 3, 1 ) respec-
           tively, and so on. On exit, the array AP is overwrit-
           ten by the lower triangular part of the updated
           matrix.  Note that the imaginary parts of the diago-
           nal elements need not be set, they are assumed to be
           zero, and on exit they are set to zero.

 NAME
      ZTBMV - perform one of the matrix-vector operations   x :=
      A*x, or x := A'*x, or x := conjg( A' )*x,

 SYNOPSIS
      SUBROUTINE ZTBMV ( UPLO, TRANS, DIAG, N, K, A, LDA, X, INCX
                       )

          INTEGER      INCX, K, LDA, N

          CHARACTER*1  DIAG, TRANS, UPLO

          COMPLEX*16   A( LDA, * ), X( * )

 PURPOSE
      ZTBMV  performs one of the matrix-vector operations

      where x is an n element vector and  A is an n by n unit, or
      non-unit, upper or lower triangular band matrix, with ( k +
      1 ) diagonals.

 PARAMETERS
      UPLO   - CHARACTER*1.
               On entry, UPLO specifies whether the matrix is an
               upper or lower triangular matrix as follows:

               UPLO = 'U' or 'u'   A is an upper triangular matrix.

               UPLO = 'L' or 'l'   A is a lower triangular matrix.

               Unchanged on exit.

      TRANS  - CHARACTER*1.
               On entry, TRANS specifies the operation to be per-
               formed as follows:

               TRANS = 'N' or 'n'   x := A*x.

               TRANS = 'T' or 't'   x := A'*x.

               TRANS = 'C' or 'c'   x := conjg( A' )*x.

               Unchanged on exit.

      DIAG   - CHARACTER*1.
```

```
          On entry, DIAG specifies whether or not A is unit
          triangular as follows:

          DIAG = 'U' or 'u'   A is assumed to be unit triangu-
          lar.

          DIAG = 'N' or 'n'   A is not assumed to be unit tri-
          angular.

          Unchanged on exit.

N         - INTEGER.
          On entry, N specifies the order of the matrix A.  N
          must be at least zero.  Unchanged on exit.

K         - INTEGER.
          On entry with UPLO = 'U' or 'u', K specifies the
          number of super-diagonals of the matrix A.  On entry
          with UPLO = 'L' or 'l', K specifies the number of
          sub-diagonals of the matrix A.  K must satisfy  0
          .le. K.  Unchanged on exit.

A         - COMPLEX*16       array of DIMENSION ( LDA, n ).
          Before entry with UPLO = 'U' or 'u', the leading ( k
          + 1 ) by n part of the array A must contain the upper
          triangular band part of the matrix of coefficients,
          supplied column by column, with the leading diagonal
          of the matrix in row ( k + 1 ) of the array, the
          first super-diagonal starting at position 2 in row k,
          and so on. The top left k by k triangle of the array
          A is not referenced.  The following program segment
          will transfer an upper triangular band matrix from
          conventional full matrix storage to band storage:

          DO 20, J = 1, N M = K + 1 - J DO 10, I = MAX( 1, J -
          K ), J A( M + I, J ) = matrix( I, J ) 10    CONTINUE
          20 CONTINUE

          Before entry with UPLO = 'L' or 'l', the leading ( k
          + 1 ) by n part of the array A must contain the lower
          triangular band part of the matrix of coefficients,
          supplied column by column, with the leading diagonal
          of the matrix in row 1 of the array, the first sub-
          diagonal starting at position 1 in row 2, and so on.
          The bottom right k by k triangle of the array A is
          not referenced.  The following program segment will
          transfer a lower triangular band matrix from conven-
          tional full matrix storage to band storage:

          DO 20, J = 1, N M = 1 - J DO 10, I = J, MIN( N, J + K
```

```
            ) A( M + I, J ) = matrix( I, J ) 10    CONTINUE 20
            CONTINUE

            Note that when DIAG = 'U' or 'u' the elements of the
            array A corresponding to the diagonal elements of the
            matrix are not referenced, but are assumed to be
            unity.  Unchanged on exit.

      LDA   - INTEGER.
            On entry, LDA specifies the first dimension of A as
            declared in the calling (sub) program. LDA must be at
            least ( k + 1 ).  Unchanged on exit.

      X     - COMPLEX*16       array of dimension at least
            ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
            incremented array X must contain the n element vector
            x. On exit, X is overwritten with the transformed
            vector x.

      INCX  - INTEGER.
            On entry, INCX specifies the increment for the ele-
            ments of X. INCX must not be zero.  Unchanged on
            exit.

 NAME
      ZTBSV - solve one of the systems of equations   A*x = b, or
      A'*x = b, or conjg( A' )*x = b,

 SYNOPSIS
      SUBROUTINE ZTBSV ( UPLO, TRANS, DIAG, N, K, A, LDA, X, INCX
                       )

          INTEGER      INCX, K, LDA, N

          CHARACTER*1  DIAG, TRANS, UPLO

          COMPLEX*16   A( LDA, * ), X( * )

 PURPOSE
      ZTBSV  solves one of the systems of equations

      where b and x are n element vectors and A is an n by n unit,
      or non-unit, upper or lower triangular band matrix, with ( k
      + 1 ) diagonals.

      No test for singularity or near-singularity is included in
      this routine. Such tests must be performed before calling
      this routine.

 PARAMETERS
      UPLO   - CHARACTER*1.
```

```
         On entry, UPLO specifies whether the matrix is an
         upper or lower triangular matrix as follows:

         UPLO = 'U' or 'u'   A is an upper triangular matrix.

         UPLO = 'L' or 'l'   A is a lower triangular matrix.

         Unchanged on exit.

TRANS  - CHARACTER*1.
         On entry, TRANS specifies the equations to be solved
         as follows:

         TRANS = 'N' or 'n'   A*x = b.

         TRANS = 'T' or 't'   A'*x = b.

         TRANS = 'C' or 'c'   conjg( A' )*x = b.

         Unchanged on exit.

DIAG   - CHARACTER*1.
         On entry, DIAG specifies whether or not A is unit
         triangular as follows:

         DIAG = 'U' or 'u'   A is assumed to be unit triangu-
         lar.

         DIAG = 'N' or 'n'   A is not assumed to be unit tri-
         angular.

         Unchanged on exit.

N      - INTEGER.
         On entry, N specifies the order of the matrix A.  N
         must be at least zero.  Unchanged on exit.

K      - INTEGER.
         On entry with UPLO = 'U' or 'u', K specifies the
         number of super-diagonals of the matrix A.  On entry
         with UPLO = 'L' or 'l', K specifies the number of
         sub-diagonals of the matrix A.  K must satisfy  0
         .le. K.  Unchanged on exit.

A      - COMPLEX*16       array of DIMENSION ( LDA, n ).
         Before entry with UPLO = 'U' or 'u', the leading ( k
         + 1 ) by n part of the array A must contain the upper
         triangular band part of the matrix of coefficients,
         supplied column by column, with the leading diagonal
         of the matrix in row ( k + 1 ) of the array, the
```

first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

DO 20, J = 1, N M = K + 1 - J DO 10, I = MAX(1, J - K), J A(M + I, J) = matrix(I, J) 10 CONTINUE 20 CONTINUE

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

DO 20, J = 1, N M = 1 - J DO 10, I = J, MIN(N, J + K) A(M + I, J) = matrix(I, J) 10 CONTINUE 20 CONTINUE

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the

matrix are not referenced, but are assumed to be unity. Unchanged on exit.

LDA - INTEGER.
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least (k + 1). Unchanged on exit.

X - COMPLEX*16 array of dimension at least (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element right-hand side vector b. On exit, X is overwritten with the solution vector x.

INCX - INTEGER.
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

 NAME
      ZTPMV - perform one of the matrix-vector operations   x :=
      A*x, or x := A'*x, or x := conjg( A' )*x,
```

```
SYNOPSIS
     SUBROUTINE ZTPMV ( UPLO, TRANS, DIAG, N, AP, X, INCX )

         INTEGER      INCX, N

         CHARACTER*1  DIAG, TRANS, UPLO

         COMPLEX*16   AP( * ), X( * )

PURPOSE
     ZTPMV  performs one of the matrix-vector operations

     where x is an n element vector and  A is an n by n unit, or
     non-unit, upper or lower triangular matrix, supplied in
     packed form.

PARAMETERS
     UPLO   - CHARACTER*1.
            On entry, UPLO specifies whether the matrix is an
            upper or lower triangular matrix as follows:

            UPLO = 'U' or 'u'   A is an upper triangular matrix.

            UPLO = 'L' or 'l'   A is a lower triangular matrix.

            Unchanged on exit.

     TRANS  - CHARACTER*1.
            On entry, TRANS specifies the operation to be per-
            formed as follows:

            TRANS = 'N' or 'n'   x := A*x.

            TRANS = 'T' or 't'   x := A'*x.

            TRANS = 'C' or 'c'   x := conjg( A' )*x.

            Unchanged on exit.

     DIAG   - CHARACTER*1.
            On entry, DIAG specifies whether or not A is unit
            triangular as follows:

            DIAG = 'U' or 'u'   A is assumed to be unit triangu-
            lar.

            DIAG = 'N' or 'n'   A is not assumed to be unit

            triangular.
```

```
            Unchanged on exit.

      N     - INTEGER.
            On entry, N specifies the order of the matrix A.  N
            must be at least zero.  Unchanged on exit.

      AP    - COMPLEX*16       array of DIMENSION at least
            ( ( n*( n + 1 ) )/2 ).  Before entry with  UPLO = 'U'
            or 'u', the array AP must contain the upper triangu-
            lar matrix packed sequentially, column by column, so
            that AP( 1 ) contains a( 1, 1 ), AP( 2 ) and AP( 3 )
            contain a( 1, 2 ) and a( 2, 2 ) respectively, and so
            on.  Before entry with UPLO = 'L' or 'l', the array
            AP must contain the lower triangular matrix packed
            sequentially, column by column, so that AP( 1 ) con-
            tains a( 1, 1 ), AP( 2 ) and AP( 3 ) contain a( 2, 1
            ) and a( 3, 1 ) respectively, and so on.  Note that
            when  DIAG = 'U' or 'u', the diagonal elements of A
            are not referenced, but are assumed to be unity.
            Unchanged on exit.

      X     - COMPLEX*16       array of dimension at least
            ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
            incremented array X must contain the n element vector
            x. On exit, X is overwritten with the transformed
            vector x.

      INCX  - INTEGER.
            On entry, INCX specifies the increment for the ele-
            ments of X. INCX must not be zero.  Unchanged on
            exit.

 NAME
      ZTPSV - solve one of the systems of equations   A*x = b, or
      A'*x = b, or conjg( A' )*x = b,

 SYNOPSIS
      SUBROUTINE ZTPSV ( UPLO, TRANS, DIAG, N, AP, X, INCX )

          INTEGER      INCX, N

          CHARACTER*1  DIAG, TRANS, UPLO

          COMPLEX*16   AP( * ), X( * )

 PURPOSE
      ZTPSV  solves one of the systems of equations

      where b and x are n element vectors and A is an n by n unit,
      or non-unit, upper or lower triangular matrix, supplied in
      packed form.

      No test for singularity or near-singularity is included in
      this routine. Such tests must be performed before calling
      this routine.

 PARAMETERS
      UPLO   - CHARACTER*1.
               On entry, UPLO specifies whether the matrix is an
               upper or lower triangular matrix as follows:

               UPLO = 'U' or 'u'   A is an upper triangular matrix.

               UPLO = 'L' or 'l'   A is a lower triangular matrix.
```

```
         Unchanged on exit.

TRANS  - CHARACTER*1.
         On entry, TRANS specifies the equations to be solved
         as follows:

         TRANS = 'N' or 'n'   A*x = b.

         TRANS = 'T' or 't'   A'*x = b.

         TRANS = 'C' or 'c'   conjg( A' )*x = b.

         Unchanged on exit.

DIAG   - CHARACTER*1.
         On entry, DIAG specifies whether or not A is unit
         triangular as follows:

         DIAG = 'U' or 'u'   A is assumed to be unit triangu-
         lar.

         DIAG = 'N' or 'n'   A is not assumed to be unit tri-
         angular.

         Unchanged on exit.

N      - INTEGER.
         On entry, N specifies the order of the matrix A.  N
         must be at least zero.  Unchanged on exit.

AP     - COMPLEX*16       array of DIMENSION at least
         ( ( n*( n + 1 ) )/2 ).  Before entry with  UPLO = 'U'
         or 'u', the array AP must contain the upper triangu-
         lar matrix packed sequentially, column by column, so
         that AP( 1 ) contains a( 1, 1 ), AP( 2 ) and AP( 3 )
         contain a( 1, 2 ) and a( 2, 2 ) respectively, and so
         on.  Before entry with UPLO = 'L' or 'l', the array
         AP must contain the lower triangular matrix packed
         sequentially, column by column, so that AP( 1 ) con-
         tains a( 1, 1 ), AP( 2 ) and AP( 3 ) contain a( 2, 1
         ) and a( 3, 1 ) respectively, and so on.  Note that
         when  DIAG = 'U' or 'u', the diagonal elements of A
         are not referenced, but are assumed to be unity.
         Unchanged on exit.

X      - COMPLEX*16       array of dimension at least
         ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
         incremented array X must contain the n element
         right-hand side vector b. On exit, X is overwritten
         with the solution vector x.
```

```
      INCX   - INTEGER.
             On entry, INCX specifies the increment for the ele-
             ments of X. INCX must not be zero.  Unchanged on
             exit.
```

 NAME
      ZTRMV - perform one of the matrix-vector operations   x :=
      A*x, or x := A'*x, or x := conjg( A' )*x,

 SYNOPSIS
      SUBROUTINE ZTRMV ( UPLO, TRANS, DIAG, N, A, LDA, X, INCX )

          INTEGER      INCX, LDA, N

          CHARACTER*1  DIAG, TRANS, UPLO

          COMPLEX*16   A( LDA, * ), X( * )

 PURPOSE
      ZTRMV  performs one of the matrix-vector operations

      where x is an n element vector and  A is an n by n unit, or
      non-unit, upper or lower triangular matrix.

 PARAMETERS
      UPLO   - CHARACTER*1.
               On entry, UPLO specifies whether the matrix is an
               upper or lower triangular matrix as follows:

               UPLO = 'U' or 'u'   A is an upper triangular matrix.

               UPLO = 'L' or 'l'   A is a lower triangular matrix.

               Unchanged on exit.

      TRANS  - CHARACTER*1.
               On entry, TRANS specifies the operation to be per-
               formed as follows:

               TRANS = 'N' or 'n'   x := A*x.

               TRANS = 'T' or 't'   x := A'*x.

               TRANS = 'C' or 'c'   x := conjg( A' )*x.

               Unchanged on exit.

      DIAG   - CHARACTER*1.
               On entry, DIAG specifies whether or not A is unit
```

```
       triangular as follows:

       DIAG = 'U' or 'u'   A is assumed to be unit triangu-
       lar.

       DIAG = 'N' or 'n'   A is not assumed to be unit tri-
       angular.

       Unchanged on exit.

N      - INTEGER.
       On entry, N specifies the order of the matrix A.  N
       must be at least zero.  Unchanged on exit.

A      - COMPLEX*16       array of DIMENSION ( LDA, n ).
       Before entry with  UPLO = 'U' or 'u', the leading n
       by n upper triangular part of the array A must con-
       tain the upper triangular matrix and the strictly
       lower triangular part of A is not referenced.  Before
       entry with UPLO = 'L' or 'l', the leading n by n
       lower triangular part of the array A must contain the
       lower triangular matrix and the strictly upper tri-
       angular part of A is not referenced.  Note that when
       DIAG = 'U' or 'u', the diagonal elements of A are not
       referenced either, but are assumed to be unity.
       Unchanged on exit.

LDA    - INTEGER.
       On entry, LDA specifies the first dimension of A as
       declared in the calling (sub) program. LDA must be at
       least max( 1, n ).  Unchanged on exit.

X      - COMPLEX*16       array of dimension at least
       ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
       incremented array X must contain the n element vector
       x. On exit, X is overwritten with the transformed
       vector x.

INCX   - INTEGER.
       On entry, INCX specifies the increment for the ele-
       ments of X. INCX must not be zero.  Unchanged on
       exit.

 NAME
      ZTRSV - solve one of the systems of equations   A*x = b, or
      A'*x = b, or conjg( A' )*x = b,

 SYNOPSIS
      SUBROUTINE ZTRSV ( UPLO, TRANS, DIAG, N, A, LDA, X, INCX )

          INTEGER      INCX, LDA, N

          CHARACTER*1  DIAG, TRANS, UPLO

          COMPLEX*16   A( LDA, * ), X( * )

 PURPOSE
      ZTRSV  solves one of the systems of equations
```

```
     where b and x are n element vectors and A is an n by n unit,
     or non-unit, upper or lower triangular matrix.

     No test for singularity or near-singularity is included in
     this routine. Such tests must be performed before calling
     this routine.

PARAMETERS
     UPLO   - CHARACTER*1.
            On entry, UPLO specifies whether the matrix is an
            upper or lower triangular matrix as follows:

            UPLO = 'U' or 'u'   A is an upper triangular matrix.

            UPLO = 'L' or 'l'   A is a lower triangular matrix.

            Unchanged on exit.

     TRANS  - CHARACTER*1.
            On entry, TRANS specifies the equations to be solved
            as follows:

            TRANS = 'N' or 'n'   A*x = b.

            TRANS = 'T' or 't'   A'*x = b.

            TRANS = 'C' or 'c'   conjg( A' )*x = b.

            Unchanged on exit.

     DIAG   - CHARACTER*1.
            On entry, DIAG specifies whether or not A is unit
            triangular as follows:

            DIAG = 'U' or 'u'   A is assumed to be unit

            triangular.

            DIAG = 'N' or 'n'   A is not assumed to be unit tri-
            angular.

            Unchanged on exit.

     N      - INTEGER.
            On entry, N specifies the order of the matrix A.  N
            must be at least zero.  Unchanged on exit.

     A      - COMPLEX*16       array of DIMENSION ( LDA, n ).
            Before entry with  UPLO = 'U' or 'u', the leading n
```

```
            by n upper triangular part of the array A must con-
            tain the upper triangular matrix and the strictly
            lower triangular part of A is not referenced.  Before
            entry with UPLO = 'L' or 'l', the leading n by n
            lower triangular part of the array A must contain the
            lower triangular matrix and the strictly upper tri-
            angular part of A is not referenced.  Note that when
            DIAG = 'U' or 'u', the diagonal elements of A are not
            referenced either, but are assumed to be unity.
            Unchanged on exit.

      LDA   - INTEGER.
            On entry, LDA specifies the first dimension of A as
            declared in the calling (sub) program. LDA must be at
            least max( 1, n ).  Unchanged on exit.

      X     - COMPLEX*16       array of dimension at least
            ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
            incremented array X must contain the n element
            right-hand side vector b. On exit, X is overwritten
            with the solution vector x.

      INCX  - INTEGER.
            On entry, INCX specifies the increment for the ele-
            ments of X. INCX must not be zero.  Unchanged on
            exit.

 NAME
      DGEMM - perform one of the matrix-matrix operations   C :=
      alpha*op( A )*op( B ) + beta*C,
```

```
SYNOPSIS
     SUBROUTINE DGEMM ( TRANSA, TRANSB, M, N, K, ALPHA, A, LDA,
                     B, LDB, BETA, C, LDC )

         CHARACTER*1  TRANSA, TRANSB

         INTEGER      M, N, K, LDA, LDB, LDC

         DOUBLE       PRECISION ALPHA, BETA

         DOUBLE       PRECISION A( LDA, * ), B( LDB, * ), C( LDC,
                      * )

PURPOSE
     DGEMM  performs one of the matrix-matrix operations

     where  op( X ) is one of

        op( X ) = X   or   op( X ) = X',

     alpha and beta are scalars, and A, B and C are matrices,
     with op( A ) an m by k matrix,  op( B )  a  k by n matrix
     and  C an m by n matrix.

PARAMETERS
     TRANSA - CHARACTER*1.  On entry, TRANSA specifies the form
     of op( A ) to be used in the matrix multiplication as fol-
     lows:

     TRANSA = 'N' or 'n',  op( A ) = A.

     TRANSA = 'T' or 't',  op( A ) = A'.

     TRANSA = 'C' or 'c',  op( A ) = A'.

     Unchanged on exit.

     TRANSB - CHARACTER*1.  On entry, TRANSB specifies the form
     of op( B ) to be used in the matrix multiplication as fol-
     lows:

     TRANSB = 'N' or 'n',  op( B ) = B.

     TRANSB = 'T' or 't',  op( B ) = B'.

     TRANSB = 'C' or 'c',  op( B ) = B'.

     Unchanged on exit.

     M      - INTEGER.
```

```
             On entry,  M  specifies  the number  of rows  of the
             matrix op( A )  and of the  matrix  C.  M  must  be
             at least  zero.  Unchanged on exit.

     N       - INTEGER.
             On entry,  N  specifies the number  of columns of the
             matrix op( B ) and the number of columns of the
             matrix C. N must be at least zero.  Unchanged on
             exit.

     K       - INTEGER.
             On entry,  K  specifies  the number of columns of the
             matrix op( A ) and the number of rows of the matrix
             op( B ). K must be at least  zero.  Unchanged on
             exit.

     ALPHA   - DOUBLE PRECISION.
             On entry, ALPHA specifies the scalar alpha.
             Unchanged on exit.

ka is
     A       -
              DOUBLE PRECISION array of DIMENSION ( LDA, ka ), where
             k  when  TRANSA = 'N' or 'n',  and is  m  otherwise.
             Before entry with  TRANSA = 'N' or 'n',  the leading
             m by k part of the array  A  must contain the matrix
             A,  otherwise the leading  k by m  part of the array
             A  must contain  the matrix A.  Unchanged on exit.

     LDA     - INTEGER.
             On entry, LDA specifies the first dimension of A as
             declared in the calling (sub) program. When  TRANSA =
             'N' or 'n' then LDA must be at least  max( 1, m ),
             otherwise  LDA must be at least  max( 1, k ).
             Unchanged on exit.

kb is
     B       -
              DOUBLE PRECISION array of DIMENSION ( LDB, kb ), where
             n  when  TRANSB = 'N' or 'n',  and is  k  otherwise.
             Before entry with  TRANSB = 'N' or 'n',  the leading
             k by n part of the array  B  must contain the matrix
             B,  otherwise the leading  n by k  part of the array
             B  must contain  the matrix B.  Unchanged on exit.

     LDB     - INTEGER.
             On entry, LDB specifies the first dimension of B as
             declared in the calling (sub) program. When  TRANSB =
             'N' or 'n' then LDB must be at least  max( 1, k ),
```

```
            otherwise  LDB must be at least  max( 1, n ).
            Unchanged on exit.

      BETA   - DOUBLE PRECISION.
            On entry,  BETA  specifies the scalar  beta.  When
            BETA  is supplied as zero then C need not be set on
            input.  Unchanged on exit.

      C      - DOUBLE PRECISION array of DIMENSION ( LDC, n ).
            Before entry, the leading  m by n  part of the array
            C must contain the matrix  C,  except when  beta  is
            zero, in which case C need not be set on entry.  On
            exit, the array  C  is overwritten by the  m by n
            matrix ( alpha*op( A )*op( B ) + beta*C ).

      LDC    - INTEGER.
            On entry, LDC specifies the first dimension of C as
            declared in  the  calling  (sub)  program.   LDC
            must  be  at  least max( 1, m ).  Unchanged on exit.

 NAME
      DSYMM - perform one of the matrix-matrix operations   C :=
      alpha*A*B + beta*C,

 SYNOPSIS
      SUBROUTINE DSYMM ( SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB,
                      BETA, C, LDC )

          CHARACTER*1  SIDE, UPLO

          INTEGER      M, N, LDA, LDB, LDC

          DOUBLE       PRECISION ALPHA, BETA

          DOUBLE       PRECISION A( LDA, * ), B( LDB, * ), C( LDC,
                       * )

 PURPOSE
      DSYMM  performs one of the matrix-matrix operations

      or

         C := alpha*B*A + beta*C,

      where alpha and beta are scalars,  A is a symmetric matrix
      and  B and C are  m by n matrices.

 PARAMETERS
      SIDE   - CHARACTER*1.
             On entry,  SIDE  specifies whether  the  symmetric
             matrix  A appears on the  left or right  in the
             operation as follows:

             SIDE = 'L' or 'l'   C := alpha*A*B + beta*C,

             SIDE = 'R' or 'r'   C := alpha*B*A + beta*C,

             Unchanged on exit.
```

```
     UPLO   - CHARACTER*1.
            On  entry,   UPLO  specifies  whether  the  upper  or
            lower triangular  part  of  the  symmetric  matrix
            A  is  to  be referenced as follows:

            UPLO = 'U' or 'u'   Only the upper triangular part of
            the symmetric matrix is to be referenced.

            UPLO = 'L' or 'l'   Only the lower triangular part of
            the symmetric matrix is to be referenced.

            Unchanged on exit.

     M      - INTEGER.
            On entry,  M  specifies the number of rows of the
            matrix  C.  M  must be at least zero.  Unchanged on
            exit.

     N      - INTEGER.
            On entry, N specifies the number of columns of the
            matrix C.  N  must be at least zero.  Unchanged on
            exit.

     ALPHA  - DOUBLE PRECISION.
            On entry, ALPHA specifies the scalar alpha.
            Unchanged on exit.

ka is
     A      -
             DOUBLE PRECISION array of DIMENSION ( LDA, ka ), where
            m  when  SIDE = 'L' or 'l'  and is  n otherwise.
            Before entry  with  SIDE = 'L' or 'l',  the  m by m
            part of the array  A  must contain the  symmetric
            matrix,  such that when  UPLO = 'U' or 'u', the lead-
            ing m by m upper triangular part of the array  A
            must contain the upper triangular part of the  sym-
            metric matrix and the  strictly  lower triangular
            part of  A  is not referenced,  and when  UPLO = 'L'
            or 'l', the leading  m by m  lower triangular part
            of the  array  A must  contain  the  lower triangular
            part  of the  symmetric matrix and the  strictly
            upper triangular part of  A  is not referenced.
            Before entry  with  SIDE = 'R' or 'r',  the  n by n
            part of the array  A  must contain the  symmetric
            matrix,  such that when  UPLO = 'U' or 'u', the lead-
            ing n by n upper triangular part of the array  A
            must contain the upper triangular part of the  sym-
            metric matrix and the  strictly  lower triangular
            part of  A  is not referenced,  and when  UPLO = 'L'
            or 'l', the leading  n by n  lower triangular part
```

```
           of the  array  A must  contain  the  lower triangular
           part  of the  symmetric matrix and the  strictly
           upper triangular part of  A  is not referenced.
           Unchanged on exit.

     LDA   - INTEGER.
           On entry, LDA specifies the first dimension of A as
           declared in the calling (sub) program.  When  SIDE =
           'L' or 'l'  then LDA must be at least  max( 1, m ),
           otherwise  LDA must be at least  max( 1, n ).
           Unchanged on exit.

     B     - DOUBLE PRECISION array of DIMENSION ( LDB, n ).
           Before entry, the leading  m by n part of the array
           B  must contain the matrix B.  Unchanged on exit.

     LDB   - INTEGER.
           On entry, LDB specifies the first dimension of B as
           declared in  the  calling  (sub)  program.   LDB
           must  be  at  least max( 1, m ).  Unchanged on exit.

     BETA  - DOUBLE PRECISION.
           On entry,  BETA  specifies the scalar  beta.  When
           BETA  is supplied as zero then C need not be set on
           input.  Unchanged on exit.

     C     - DOUBLE PRECISION array of DIMENSION ( LDC, n ).
           Before entry, the leading  m by n  part of the array
           C must contain the matrix  C,  except when  beta  is
           zero, in which case C need not be set on entry.  On
           exit, the array  C  is overwritten by the  m by n
           updated matrix.

     LDC   - INTEGER.
           On entry, LDC specifies the first dimension of C as
           declared in  the  calling  (sub)  program.   LDC
           must  be  at  least max( 1, m ).  Unchanged on exit.

           Level 3 Blas routine.

 NAME
      DSYR2K - perform one of the symmetric rank 2k operations   C
      := alpha*A*B' + alpha*B*A' + beta*C,

 SYNOPSIS
      SUBROUTINE DSYR2K( UPLO, TRANS, N, K, ALPHA, A, LDA, B, LDB,
                         BETA, C, LDC )

          CHARACTER*1    UPLO, TRANS

          INTEGER        N, K, LDA, LDB, LDC

          DOUBLE         PRECISION ALPHA, BETA

          DOUBLE         PRECISION A( LDA, * ), B( LDB, * ), C(
                         LDC, * )

 PURPOSE
      DSYR2K  performs one of the symmetric rank 2k operations

      or

         C := alpha*A'*B + alpha*B'*A + beta*C,

      where  alpha and beta  are scalars, C is an  n by n  sym-
      metric matrix and  A and B  are  n by k  matrices  in the
      first  case  and  k by n matrices in the second case.

 PARAMETERS
      UPLO   - CHARACTER*1.
               On  entry,   UPLO  specifies  whether  the  upper  or
               lower triangular  part  of the  array  C  is to be
               referenced  as follows:

               UPLO = 'U' or 'u'   Only the  upper triangular part
```

```
            of  C is to be referenced.

            UPLO = 'L' or 'l'   Only the  lower triangular part
            of  C is to be referenced.

            Unchanged on exit.

      TRANS  - CHARACTER*1.
            On entry,  TRANS  specifies the operation to be per-
            formed as follows:

            TRANS = 'N' or 'n'   C := alpha*A*B' + alpha*B*A' +
            beta*C.

            TRANS = 'T' or 't'   C := alpha*A'*B + alpha*B'*A +
            beta*C.

            TRANS = 'C' or 'c'   C := alpha*A'*B + alpha*B'*A +
            beta*C.

            Unchanged on exit.

      N      - INTEGER.
            On entry,  N specifies the order of the matrix C.  N
            must be at least zero.  Unchanged on exit.

      K      - INTEGER.
            On entry with  TRANS = 'N' or 'n',  K  specifies  the
            number of  columns  of the  matrices  A and B,  and
            on  entry  with TRANS = 'T' or 't' or 'C' or 'c',  K
            specifies  the  number of rows of the matrices  A and
            B.  K must be at least  zero.  Unchanged on exit.

      ALPHA  - DOUBLE PRECISION.
            On entry, ALPHA specifies the scalar alpha.
            Unchanged on exit.

ka is
      A      -
             DOUBLE PRECISION array of DIMENSION ( LDA, ka ), where
            k  when  TRANS = 'N' or 'n',  and is  n  otherwise.
            Before entry with  TRANS = 'N' or 'n',  the  leading
            n by k part of the array  A  must contain the matrix
            A,  otherwise the leading  k by n  part of the array
            A  must contain  the matrix A.  Unchanged on exit.

      LDA    - INTEGER.
            On entry, LDA specifies the first dimension of A as
            declared in  the  calling  (sub)  program.   When
            TRANS = 'N' or 'n' then  LDA must be at least  max(
```

```
          1, n ), otherwise  LDA must be at least  max( 1, k ).
          Unchanged on exit.

kb is
     B      -
             DOUBLE PRECISION array of DIMENSION ( LDB, kb ), where
          k  when  TRANS = 'N' or 'n',  and is  n  otherwise.
          Before entry with  TRANS = 'N' or 'n',  the  leading
          n by k part of the array  B  must contain the matrix
          B,  otherwise the leading  k by n  part of the array
          B  must contain  the matrix B.  Unchanged on exit.

     LDB    - INTEGER.
          On entry, LDB specifies the first dimension of B as
          declared in  the  calling  (sub)  program.   When
          TRANS = 'N' or 'n' then  LDB must be at least  max(
          1, n ), otherwise  LDB must be at least  max( 1, k ).
          Unchanged on exit.

     BETA   - DOUBLE PRECISION.
          On entry, BETA specifies the scalar beta.  Unchanged
          on exit.

     C      - DOUBLE PRECISION array of DIMENSION ( LDC, n ).
          Before entry  with  UPLO = 'U' or 'u',  the leading
          n by n upper triangular part of the array C must con-
          tain the upper triangular part  of the  symmetric
          matrix  and the strictly lower triangular part of C
          is not referenced.  On exit, the upper triangular
          part of the array  C is overwritten by the upper tri-
          angular part of the updated matrix.  Before entry
          with  UPLO = 'L' or 'l',  the leading  n by n lower
          triangular part of the array C must contain the lower
          triangular part  of the  symmetric matrix  and the
          strictly upper triangular part of C is not refer-
          enced.  On exit, the lower triangular part of the
          array  C is overwritten by the lower triangular part
          of the updated matrix.

     LDC    - INTEGER.
          On entry, LDC specifies the first dimension of C as
          declared in  the  calling  (sub)  program.   LDC
          must  be  at  least max( 1, n ).  Unchanged on exit.

 NAME
      DSYRK - perform one of the symmetric rank k operations   C
      := alpha*A*A' + beta*C,

 SYNOPSIS
      SUBROUTINE DSYRK ( UPLO, TRANS, N, K, ALPHA, A, LDA, BETA,
                         C, LDC )

          CHARACTER*1  UPLO, TRANS

          INTEGER      N, K, LDA, LDC

          DOUBLE       PRECISION ALPHA, BETA

          DOUBLE       PRECISION A( LDA, * ), C( LDC, * )

 PURPOSE
      DSYRK  performs one of the symmetric rank k operations

      or

         C := alpha*A'*A + beta*C,

      where  alpha and beta  are scalars, C is an  n by n  sym-
      metric matrix and  A  is an  n by k  matrix in the first
      case and a  k by n  matrix in the second case.

 PARAMETERS
      UPLO   - CHARACTER*1.
               On  entry,   UPLO  specifies  whether  the  upper  or
```

```
           lower triangular  part  of the  array  C  is to be
           referenced  as follows:

           UPLO = 'U' or 'u'   Only the  upper triangular part
           of  C is to be referenced.

           UPLO = 'L' or 'l'   Only the  lower triangular part
           of  C is to be referenced.

           Unchanged on exit.

     TRANS  - CHARACTER*1.
           On entry,  TRANS  specifies the operation to be per-
           formed as follows:

           TRANS = 'N' or 'n'   C := alpha*A*A' + beta*C.

           TRANS = 'T' or 't'   C := alpha*A'*A + beta*C.

           TRANS = 'C' or 'c'   C := alpha*A'*A + beta*C.

           Unchanged on exit.

     N      - INTEGER.
           On entry,  N specifies the order of the matrix C.  N
           must be at least zero.  Unchanged on exit.

     K      - INTEGER.
           On entry with  TRANS = 'N' or 'n',  K  specifies  the
           number of  columns   of  the   matrix   A,   and  on
           entry   with TRANS = 'T' or 't' or 'C' or 'c',  K
           specifies  the  number of rows of the matrix  A.  K
           must be at least zero.  Unchanged on exit.

     ALPHA  - DOUBLE PRECISION.
           On entry, ALPHA specifies the scalar alpha.
           Unchanged on exit.

ka is
     A      -
            DOUBLE PRECISION array of DIMENSION ( LDA, ka ), where
           k  when  TRANS = 'N' or 'n',  and is  n  otherwise.
           Before entry with  TRANS = 'N' or 'n',  the  leading
           n by k part of the array  A  must contain the matrix
           A,  otherwise the leading  k by n  part of the array
           A  must contain  the matrix A.  Unchanged on exit.

     LDA    - INTEGER.
           On entry, LDA specifies the first dimension of A as
           declared in  the  calling  (sub)  program.   When
```

```
            TRANS = 'N' or 'n' then  LDA must be at least  max(
            1, n ), otherwise  LDA must be at least  max( 1, k ).
            Unchanged on exit.

      BETA  - DOUBLE PRECISION.
            On entry, BETA specifies the scalar beta.  Unchanged
            on exit.

      C     - DOUBLE PRECISION array of DIMENSION ( LDC, n ).
            Before entry  with  UPLO = 'U' or 'u',  the leading
            n by n upper triangular part of the array C must con-
            tain the upper triangular part  of the  symmetric
            matrix  and the strictly lower triangular part of C
            is not referenced.  On exit, the upper triangular
            part of the array  C is overwritten by the upper tri-
            angular part of the updated matrix.  Before entry
            with  UPLO = 'L' or 'l',  the leading  n by n lower
            triangular part of the array C must contain the lower
            triangular part  of the  symmetric matrix  and the
            strictly upper triangular part of C is not refer-
            enced.  On exit, the lower triangular part of the
            array  C is overwritten by the lower triangular part
            of the updated matrix.

      LDC   - INTEGER.
            On entry, LDC specifies the first dimension of C as
            declared in  the  calling  (sub)  program.   LDC
            must  be  at  least max( 1, n ).  Unchanged on exit.

 NAME
      DTRMM - perform one of the matrix-matrix operations   B :=
      alpha*op( A )*B, or B := alpha*B*op( A ),

 SYNOPSIS
      SUBROUTINE DTRMM ( SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A,
                         LDA, B, LDB )

          CHARACTER*1  SIDE, UPLO, TRANSA, DIAG

          INTEGER      M, N, LDA, LDB

          DOUBLE       PRECISION ALPHA

          DOUBLE       PRECISION A( LDA, * ), B( LDB, * )

 PURPOSE
      DTRMM  performs one of the matrix-matrix operations

      where  alpha  is a scalar,  B  is an m by n matrix,  A  is a
      unit, or non-unit,  upper or lower triangular matrix  and
      op( A )  is one  of
```

```
        op( A ) = A   or   op( A ) = A'.

PARAMETERS
     SIDE   - CHARACTER*1.
            On entry,  SIDE specifies whether  op( A ) multiplies
            B from the left or right as follows:

            SIDE = 'L' or 'l'   B := alpha*op( A )*B.

            SIDE = 'R' or 'r'   B := alpha*B*op( A ).

            Unchanged on exit.

     UPLO   - CHARACTER*1.
            On entry, UPLO specifies whether the matrix A is an
            upper or lower triangular matrix as follows:

            UPLO = 'U' or 'u'   A is an upper triangular matrix.

            UPLO = 'L' or 'l'   A is a lower triangular matrix.

            Unchanged on exit.

            TRANSA - CHARACTER*1.  On entry, TRANSA specifies the
            form of op( A ) to be used in the matrix multiplica-
            tion as follows:

            TRANSA = 'N' or 'n'   op( A ) = A.

            TRANSA = 'T' or 't'   op( A ) = A'.

            TRANSA = 'C' or 'c'   op( A ) = A'.

            Unchanged on exit.

     DIAG   - CHARACTER*1.
            On entry, DIAG specifies whether or not A is unit
            triangular as follows:

            DIAG = 'U' or 'u'   A is assumed to be unit triangu-
            lar.

            DIAG = 'N' or 'n'   A is not assumed to be unit tri-
            angular.

            Unchanged on exit.

     M      - INTEGER.
            On entry, M specifies the number of rows of B. M must
```

```
           be at least zero.  Unchanged on exit.

     N     - INTEGER.
           On entry, N specifies the number of columns of B.  N
           must be at least zero.  Unchanged on exit.

     ALPHA - DOUBLE PRECISION.
           On entry,  ALPHA specifies the scalar  alpha. When
           alpha is zero then  A is not referenced and  B need
           not be set before entry.  Unchanged on exit.

is m
     A     -
            DOUBLE PRECISION array of DIMENSION ( LDA, k ), where k
           when  SIDE = 'L' or 'l'  and is  n  when  SIDE = 'R'
           or 'r'.  Before entry  with  UPLO = 'U' or 'u',  the
           leading  k by k upper triangular part of the array  A
           must contain the upper triangular matrix  and the
           strictly lower triangular part of A is not refer-
           enced.  Before entry  with  UPLO = 'L' or 'l',  the
           leading  k by k lower triangular part of the array  A
           must contain the lower triangular matrix  and the
           strictly upper triangular part of A is not refer-
           enced.  Note that when  DIAG = 'U' or 'u',  the diag-
           onal elements of A  are not referenced either,  but
           are assumed to be  unity.  Unchanged on exit.

     LDA   - INTEGER.
           On entry, LDA specifies the first dimension of A as
           declared in the calling (sub) program.  When  SIDE =
           'L' or 'l'  then LDA  must be at least  max( 1, m ),
           when  SIDE = 'R' or 'r' then LDA must be at least

           max( 1, n ).  Unchanged on exit.

     B     - DOUBLE PRECISION array of DIMENSION ( LDB, n ).
           Before entry,  the leading  m by n part of the array
           B must contain the matrix  B,  and  on exit  is
           overwritten  by the transformed matrix.

     LDB   - INTEGER.
           On entry, LDB specifies the first dimension of B as
           declared in  the  calling  (sub)  program.   LDB
           must  be  at  least max( 1, m ).  Unchanged on exit.

 NAME
      DTRSM - solve one of the matrix equations   op( A )*X =
      alpha*B, or X*op( A ) = alpha*B,

 SYNOPSIS
      SUBROUTINE DTRSM ( SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A,
                         LDA, B, LDB )

          CHARACTER*1  SIDE, UPLO, TRANSA, DIAG

          INTEGER      M, N, LDA, LDB

          DOUBLE       PRECISION ALPHA

          DOUBLE       PRECISION A( LDA, * ), B( LDB, * )

 PURPOSE
      DTRSM  solves one of the matrix equations

      where alpha is a scalar, X and B are m by n matrices, A is a
      unit, or non-unit,  upper or lower triangular matrix  and
      op( A )  is one  of
```

```
        op( A ) = A   or   op( A ) = A'.

     The matrix X is overwritten on B.

 PARAMETERS
     SIDE   - CHARACTER*1.
            On entry, SIDE specifies whether op( A ) appears on
            the left or right of X as follows:

            SIDE = 'L' or 'l'   op( A )*X = alpha*B.

            SIDE = 'R' or 'r'   X*op( A ) = alpha*B.

            Unchanged on exit.

     UPLO   - CHARACTER*1.
            On entry, UPLO specifies whether the matrix A is an
            upper or lower triangular matrix as follows:

            UPLO = 'U' or 'u'   A is an upper triangular matrix.

            UPLO = 'L' or 'l'   A is a lower triangular matrix.

            Unchanged on exit.

            TRANSA - CHARACTER*1.  On entry, TRANSA specifies the
            form of op( A ) to be used in the matrix multiplica-
            tion as follows:

            TRANSA = 'N' or 'n'   op( A ) = A.

            TRANSA = 'T' or 't'   op( A ) = A'.

            TRANSA = 'C' or 'c'   op( A ) = A'.

            Unchanged on exit.

     DIAG   - CHARACTER*1.
            On entry, DIAG specifies whether or not A is unit
            triangular as follows:

            DIAG = 'U' or 'u'   A is assumed to be unit triangu-
            lar.

            DIAG = 'N' or 'n'   A is not assumed to be unit tri-
            angular.

            Unchanged on exit.
```

```
     M      - INTEGER.
              On entry, M specifies the number of rows of B. M must
              be at least zero.  Unchanged on exit.

     N      - INTEGER.
              On entry, N specifies the number of columns of B.  N
              must be at least zero.  Unchanged on exit.

     ALPHA  - DOUBLE PRECISION.
              On entry,  ALPHA specifies the scalar  alpha. When
              alpha is zero then  A is not referenced and  B need
              not be set before entry.  Unchanged on exit.

is m
     A      -
              DOUBLE PRECISION array of DIMENSION ( LDA, k ), where k
              when  SIDE = 'L' or 'l'  and is  n  when  SIDE = 'R'
              or 'r'.  Before entry  with  UPLO = 'U' or 'u',  the
              leading  k by k upper triangular part of the array  A
              must contain the upper triangular matrix  and the
              strictly lower triangular part of A is not refer-
              enced.  Before entry  with  UPLO = 'L' or 'l',  the
              leading  k by k lower triangular part of the array  A
              must contain the lower triangular matrix  and the
              strictly upper triangular part of A is not refer-
              enced.  Note that when  DIAG = 'U' or 'u',  the diag-
              onal elements of A  are not referenced either,  but
              are assumed to be  unity.  Unchanged on exit.

     LDA    - INTEGER.
              On entry, LDA specifies the first dimension of A as
              declared in the calling (sub) program.  When  SIDE =

              'L' or 'l'  then LDA  must be at least  max( 1, m ),
              when  SIDE = 'R' or 'r' then LDA must be at least
              max( 1, n ).  Unchanged on exit.

     B      - DOUBLE PRECISION array of DIMENSION ( LDB, n ).
              Before entry,  the leading  m by n part of the array
              B must contain  the  right-hand  side  matrix  B,
              and  on exit  is overwritten by the solution matrix
              X.

     LDB    - INTEGER.
              On entry, LDB specifies the first dimension of B as
              declared in  the  calling  (sub)  program.   LDB
              must  be  at  least max( 1, m ).  Unchanged on exit.

 NAME
      ZGEMM - perform one of the matrix-matrix operations   C :=
      alpha*op( A )*op( B ) + beta*C,

 SYNOPSIS
      SUBROUTINE ZGEMM ( TRANSA, TRANSB, M, N, K, ALPHA, A, LDA,
                         B, LDB, BETA, C, LDC )

          CHARACTER*1  TRANSA, TRANSB

          INTEGER      M, N, K, LDA, LDB, LDC

          COMPLEX*16   ALPHA, BETA

          COMPLEX*16   A( LDA, * ), B( LDB, * ), C( LDC, * )

 PURPOSE
      ZGEMM  performs one of the matrix-matrix operations

      where  op( X ) is one of

         op( X ) = X   or   op( X ) = X'   or   op( X ) = conjg(
      X' ),

      alpha and beta are scalars, and A, B and C are matrices,
      with op( A ) an m by k matrix,  op( B )  a  k by n matrix
      and  C an m by n matrix.

 PARAMETERS
      TRANSA - CHARACTER*1.  On entry, TRANSA specifies the form
      of op( A ) to be used in the matrix multiplication as fol-
```

```
     lows:

     TRANSA = 'N' or 'n',  op( A ) = A.

     TRANSA = 'T' or 't',  op( A ) = A'.

     TRANSA = 'C' or 'c',  op( A ) = conjg( A' ).

     Unchanged on exit.

     TRANSB - CHARACTER*1.  On entry, TRANSB specifies the form
     of op( B ) to be used in the matrix multiplication as fol-
     lows:

     TRANSB = 'N' or 'n',  op( B ) = B.

     TRANSB = 'T' or 't',  op( B ) = B'.

     TRANSB = 'C' or 'c',  op( B ) = conjg( B' ).

     Unchanged on exit.

     M      - INTEGER.
              On entry,  M  specifies  the number  of rows  of the
              matrix op( A )  and of the  matrix  C.  M  must  be
              at least  zero.  Unchanged on exit.

     N      - INTEGER.
              On entry,  N  specifies the number  of columns of the
              matrix op( B ) and the number of columns of the
              matrix C. N must be at least zero.  Unchanged on
              exit.

     K      - INTEGER.
              On entry,  K  specifies  the number of columns of the
              matrix op( A ) and the number of rows of the matrix
              op( B ). K must be at least  zero.  Unchanged on
              exit.

     ALPHA  - COMPLEX*16      .
              On entry, ALPHA specifies the scalar alpha.
              Unchanged on exit.

ka is
     A      -
              COMPLEX*16       array of DIMENSION ( LDA, ka ), where
              k  when  TRANSA = 'N' or 'n',  and is  m  otherwise.
              Before entry with  TRANSA = 'N' or 'n',  the leading
              m by k part of the array  A  must contain the matrix
              A,  otherwise the leading  k by m  part of the array
```

```
            A  must contain  the matrix A.  Unchanged on exit.

     LDA    - INTEGER.
            On entry, LDA specifies the first dimension of A as
            declared in the calling (sub) program. When  TRANSA =
            'N' or 'n' then LDA must be at least  max( 1, m ),
            otherwise  LDA must be at least  max( 1, k ).
            Unchanged on exit.

kb is
     B      -
             COMPLEX*16       array of DIMENSION ( LDB, kb ), where
            n  when  TRANSB = 'N' or 'n',  and is  k  otherwise.
            Before entry with  TRANSB = 'N' or 'n',  the leading
            k by n part of the array  B  must contain the matrix
            B,  otherwise the leading  n by k  part of the array
            B  must contain  the matrix B.  Unchanged on exit.

     LDB    - INTEGER.
            On entry, LDB specifies the first dimension of B as
            declared in the calling (sub) program. When  TRANSB =
            'N' or 'n' then LDB must be at least  max( 1, k ),

            otherwise  LDB must be at least  max( 1, n ).
            Unchanged on exit.

     BETA   - COMPLEX*16      .
            On entry,  BETA  specifies the scalar  beta.  When
            BETA  is supplied as zero then C need not be set on
            input.  Unchanged on exit.

     C      - COMPLEX*16       array of DIMENSION ( LDC, n ).
            Before entry, the leading  m by n  part of the array
            C must contain the matrix  C,  except when  beta  is
            zero, in which case C need not be set on entry.  On
            exit, the array  C  is overwritten by the  m by n
            matrix ( alpha*op( A )*op( B ) + beta*C ).

     LDC    - INTEGER.
            On entry, LDC specifies the first dimension of C as
            declared in  the  calling  (sub)  program.   LDC
            must  be  at  least max( 1, m ).  Unchanged on exit.

 NAME
      ZHEMM - perform one of the matrix-matrix operations   C :=
      alpha*A*B + beta*C,

 SYNOPSIS
      SUBROUTINE ZHEMM ( SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB,
                         BETA, C, LDC )

          CHARACTER*1  SIDE, UPLO

          INTEGER      M, N, LDA, LDB, LDC

          COMPLEX*16   ALPHA, BETA

          COMPLEX*16   A( LDA, * ), B( LDB, * ), C( LDC, * )

 PURPOSE
      ZHEMM  performs one of the matrix-matrix operations

      or

         C := alpha*B*A + beta*C,

      where alpha and beta are scalars, A is an hermitian matrix
      and  B and C are m by n matrices.

 PARAMETERS
      SIDE   - CHARACTER*1.
               On entry,  SIDE  specifies whether  the  hermitian
               matrix  A appears on the  left or right  in the
               operation as follows:

               SIDE = 'L' or 'l'   C := alpha*A*B + beta*C,

               SIDE = 'R' or 'r'   C := alpha*B*A + beta*C,

               Unchanged on exit.

      UPLO   - CHARACTER*1.
               On  entry,   UPLO  specifies  whether  the  upper  or
               lower triangular  part  of  the  hermitian  matrix
               A  is  to  be referenced as follows:
```

```
           UPLO = 'U' or 'u'   Only the upper triangular part of
           the hermitian matrix is to be referenced.

           UPLO = 'L' or 'l'   Only the lower triangular part of
           the hermitian matrix is to be referenced.

           Unchanged on exit.

     M     - INTEGER.
           On entry,  M  specifies the number of rows of the
           matrix  C.  M  must be at least zero.  Unchanged on
           exit.

     N     - INTEGER.
           On entry, N specifies the number of columns of the
           matrix C.  N  must be at least zero.  Unchanged on
           exit.

     ALPHA - COMPLEX*16      .
           On entry, ALPHA specifies the scalar alpha.
           Unchanged on exit.

ka is
     A     -
            COMPLEX*16       array of DIMENSION ( LDA, ka ), where
           m  when  SIDE = 'L' or 'l'  and is n  otherwise.
           Before entry  with  SIDE = 'L' or 'l',  the  m by m
           part of the array  A  must contain the  hermitian
           matrix,  such that when  UPLO = 'U' or 'u', the lead-
           ing m by m upper triangular part of the array  A
           must contain the upper triangular part of the  hermi-
           tian matrix and the  strictly  lower triangular part
           of  A  is not referenced,  and when  UPLO = 'L' or
           'l', the leading  m by m  lower triangular part  of
           the  array  A must  contain  the  lower triangular
           part  of the  hermitian matrix and the  strictly
           upper triangular part of  A  is not referenced.
           Before entry  with  SIDE = 'R' or 'r',  the  n by n
           part of the array  A  must contain the  hermitian
           matrix,  such that when  UPLO = 'U' or 'u', the lead-
           ing n by n upper triangular part of the array  A
           must contain the upper triangular part of the  hermi-
           tian matrix and the  strictly  lower triangular part
           of  A  is not referenced,  and when  UPLO = 'L' or
           'l', the leading  n by n  lower triangular part  of
           the  array  A must  contain  the  lower triangular
           part  of the  hermitian matrix and the  strictly
           upper triangular part of  A  is not referenced.  Note
           that the imaginary parts  of the diagonal elements
```

```
           need not be set, they are assumed to be zero.
           Unchanged on exit.

     LDA   - INTEGER.
           On entry, LDA specifies the first dimension of A as
           declared in the  calling (sub) program. When  SIDE =
           'L' or 'l'  then LDA must be at least  max( 1, m ),
           otherwise  LDA must be at least max( 1, n ).
           Unchanged on exit.

     B     - COMPLEX*16       array of DIMENSION ( LDB, n ).

           Before entry, the leading  m by n part of the array
           B  must contain the matrix B.  Unchanged on exit.

     LDB   - INTEGER.
           On entry, LDB specifies the first dimension of B as
           declared in  the  calling  (sub)  program.   LDB
           must  be  at  least max( 1, m ).  Unchanged on exit.

     BETA  - COMPLEX*16      .
           On entry,  BETA  specifies the scalar  beta.  When
           BETA  is supplied as zero then C need not be set on
           input.  Unchanged on exit.

     C     - COMPLEX*16       array of DIMENSION ( LDC, n ).
           Before entry, the leading  m by n  part of the array
           C must contain the matrix  C,  except when  beta  is
           zero, in which case C need not be set on entry.  On
           exit, the array  C  is overwritten by the  m by n
           updated matrix.

     LDC   - INTEGER.
           On entry, LDC specifies the first dimension of C as
           declared in  the  calling  (sub)  program.   LDC
           must  be  at  least max( 1, m ).  Unchanged on exit.

 NAME
      ZHER2K - perform one of the hermitian rank 2k operations   C
      := alpha*A*conjg( B' ) + conjg( alpha )*B*conjg( A' ) +
      beta*C,

 SYNOPSIS
      SUBROUTINE ZHER2K( UPLO, TRANS, N, K, ALPHA, A, LDA, B, LDB,
                         BETA, C, LDC )

          CHARACTER*1    UPLO, TRANS

          INTEGER        N, K, LDA, LDB, LDC

          DOUBLE         PRECISION BETA

          COMPLEX*16     ALPHA

          COMPLEX*16     A( LDA, * ), B( LDB, * ), C( LDC, * )

 PURPOSE
      ZHER2K  performs one of the hermitian rank 2k operations
```

```
     or

        C := alpha*conjg( A' )*B + conjg( alpha )*conjg( B' )*A +
     beta*C,

     where  alpha and beta  are scalars with  beta  real,  C is
     an  n by n hermitian matrix and  A and B  are  n by k
     matrices in the first case and  k by n  matrices in the
     second case.

PARAMETERS
     UPLO   - CHARACTER*1.
              On  entry,   UPLO  specifies  whether  the  upper  or
              lower triangular  part  of the  array  C  is to be
              referenced  as follows:

              UPLO = 'U' or 'u'   Only the  upper triangular part
              of  C is to be referenced.

              UPLO = 'L' or 'l'   Only the  lower triangular part
              of  C is to be referenced.

              Unchanged on exit.

     TRANS  - CHARACTER*1.
              On entry,  TRANS  specifies the operation to be per-
              formed as follows:

              TRANS = 'N' or 'n'    C := alpha*A*conjg( B' )

              + conjg( alpha )*B*conjg( A' ) + beta*C.

              TRANS = 'C' or 'c'    C := alpha*conjg( A' )*B
              + conjg( alpha )*conjg( B' )*A + beta*C.

              Unchanged on exit.

     N      - INTEGER.
              On entry,  N specifies the order of the matrix C.  N
              must be at least zero.  Unchanged on exit.

     K      - INTEGER.
              On entry with  TRANS = 'N' or 'n',  K  specifies  the
              number of  columns  of the  matrices  A and B,  and
              on  entry  with TRANS = 'C' or 'c',  K  specifies
              the number of rows of the matrices  A and B.  K must
              be at least zero.  Unchanged on exit.

     ALPHA  - COMPLEX*16      .
              On entry, ALPHA specifies the scalar alpha.
```

```
            Unchanged on exit.

ka is
     A      -
             COMPLEX*16       array of DIMENSION ( LDA, ka ), where
            k  when  TRANS = 'N' or 'n',  and is  n  otherwise.
            Before entry with  TRANS = 'N' or 'n',  the  leading
            n by k part of the array  A  must contain the matrix
            A,  otherwise the leading  k by n  part of the array
            A  must contain  the matrix A.  Unchanged on exit.

     LDA    - INTEGER.
            On entry, LDA specifies the first dimension of A as
            declared in  the  calling  (sub)  program.   When
            TRANS = 'N' or 'n' then  LDA must be at least  max(
            1, n ), otherwise  LDA must be at least  max( 1, k ).
            Unchanged on exit.

kb is
     B      -
             COMPLEX*16       array of DIMENSION ( LDB, kb ), where
            k  when  TRANS = 'N' or 'n',  and is  n  otherwise.
            Before entry with  TRANS = 'N' or 'n',  the  leading
            n by k part of the array  B  must contain the matrix
            B,  otherwise the leading  k by n  part of the array
            B  must contain  the matrix B.  Unchanged on exit.

     LDB    - INTEGER.
            On entry, LDB specifies the first dimension of B as
            declared in  the  calling  (sub)  program.   When
            TRANS = 'N' or 'n' then  LDB must be at least  max(
            1, n ), otherwise  LDB must be at least  max( 1, k ).

            Unchanged on exit.

     BETA   - DOUBLE PRECISION.
            On entry, BETA specifies the scalar beta.  Unchanged
            on exit.

     C      - COMPLEX*16       array of DIMENSION ( LDC, n ).
            Before entry  with  UPLO = 'U' or 'u',  the leading
            n by n upper triangular part of the array C must con-
            tain the upper triangular part  of the  hermitian
            matrix  and the strictly lower triangular part of C
            is not referenced.  On exit, the upper triangular
            part of the array  C is overwritten by the upper tri-
            angular part of the updated matrix.  Before entry
            with  UPLO = 'L' or 'l',  the leading  n by n lower
            triangular part of the array C must contain the lower
            triangular part  of the  hermitian matrix  and the
```

```
            strictly upper triangular part of C is not refer-
            enced.  On exit, the lower triangular part of the
            array  C is overwritten by the lower triangular part
            of the updated matrix.  Note that the imaginary parts
            of the diagonal elements need not be set,  they are
            assumed to be zero,  and on exit they are set to
            zero.

      LDC    - INTEGER.
             On entry, LDC specifies the first dimension of C as
             declared in  the  calling  (sub)  program.   LDC
             must  be  at  least max( 1, n ).  Unchanged on exit.

 NAME
```

```
     ZHERK - perform one of the hermitian rank k operations   C
     := alpha*A*conjg( A' ) + beta*C,

SYNOPSIS
     SUBROUTINE ZHERK ( UPLO, TRANS, N, K, ALPHA, A, LDA, BETA,
                        C, LDC )

         CHARACTER*1  UPLO, TRANS

         INTEGER      N, K, LDA, LDC

         DOUBLE       PRECISION ALPHA, BETA

         COMPLEX*16   A( LDA, * ), C( LDC, * )

PURPOSE
     ZHERK  performs one of the hermitian rank k operations

     or

        C := alpha*conjg( A' )*A + beta*C,

     where  alpha and beta  are  real scalars,  C is an  n by n
     hermitian matrix and  A  is an  n by k  matrix in the  first
     case and a  k by n matrix in the second case.

PARAMETERS
     UPLO   - CHARACTER*1.
            On  entry,   UPLO  specifies  whether  the  upper  or
            lower triangular  part  of the  array  C  is to be
            referenced  as follows:

            UPLO = 'U' or 'u'   Only the  upper triangular part
            of  C is to be referenced.

            UPLO = 'L' or 'l'   Only the  lower triangular part
            of  C is to be referenced.

            Unchanged on exit.

     TRANS  - CHARACTER*1.
            On entry,  TRANS  specifies the operation to be per-
            formed as follows:

            TRANS = 'N' or 'n'   C := alpha*A*conjg( A' ) +
            beta*C.

            TRANS = 'C' or 'c'   C := alpha*conjg( A' )*A +
            beta*C.
```

```
           Unchanged on exit.

     N     - INTEGER.
           On entry,  N specifies the order of the matrix C.  N
           must be at least zero.  Unchanged on exit.

     K     - INTEGER.
           On entry with  TRANS = 'N' or 'n',  K  specifies  the
           number of  columns   of  the   matrix   A,   and  on
           entry   with TRANS = 'C' or 'c',  K  specifies  the
           number of rows of the matrix A.  K must be at least
           zero.  Unchanged on exit.

     ALPHA - DOUBLE PRECISION.
           On entry, ALPHA specifies the scalar alpha.
           Unchanged on exit.

ka is
     A     -
            COMPLEX*16       array of DIMENSION ( LDA, ka ), where
           k  when  TRANS = 'N' or 'n',  and is  n  otherwise.
           Before entry with  TRANS = 'N' or 'n',  the  leading
           n by k part of the array  A  must contain the matrix
           A,  otherwise the leading  k by n  part of the array
           A  must contain  the matrix A.  Unchanged on exit.

     LDA   - INTEGER.
           On entry, LDA specifies the first dimension of A as
           declared in  the  calling  (sub)  program.   When
           TRANS = 'N' or 'n' then  LDA must be at least  max(
           1, n ), otherwise  LDA must be at least  max( 1, k ).
           Unchanged on exit.

     BETA  - DOUBLE PRECISION.
           On entry, BETA specifies the scalar beta.  Unchanged
           on exit.

     C     - COMPLEX*16       array of DIMENSION ( LDC, n ).
           Before entry  with  UPLO = 'U' or 'u',  the leading
           n by n upper triangular part of the array C must con-
           tain the upper triangular part  of the  hermitian
           matrix  and the strictly lower triangular part of C
           is not referenced.  On exit, the upper triangular
           part of the array  C is overwritten by the upper tri-
           angular part of the updated matrix.  Before entry
           with  UPLO = 'L' or 'l',  the leading  n by n lower
           triangular part of the array C must contain the lower
           triangular part  of the  hermitian matrix  and the
           strictly upper triangular part of C is not refer-
           enced.  On exit, the lower triangular part of the
```

```
            array  C is overwritten by the lower triangular part
            of the updated matrix.  Note that the imaginary parts

            of the diagonal elements need not be set,  they are
            assumed to be zero,  and on exit they are set to
            zero.

      LDC   - INTEGER.
            On entry, LDC specifies the first dimension of C as
            declared in  the  calling  (sub)  program.   LDC
            must  be  at  least max( 1, n ).  Unchanged on exit.

 NAME
      ZSYMM - perform one of the matrix-matrix operations   C :=
      alpha*A*B + beta*C,

 SYNOPSIS
      SUBROUTINE ZSYMM ( SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB,
                      BETA, C, LDC )

          CHARACTER*1  SIDE, UPLO

          INTEGER      M, N, LDA, LDB, LDC

          COMPLEX*16   ALPHA, BETA

          COMPLEX*16   A( LDA, * ), B( LDB, * ), C( LDC, * )

 PURPOSE
      ZSYMM  performs one of the matrix-matrix operations

      or

         C := alpha*B*A + beta*C,

      where  alpha and beta are scalars, A is a symmetric matrix
      and  B and C are m by n matrices.

 PARAMETERS
      SIDE   - CHARACTER*1.
             On entry,  SIDE  specifies whether  the  symmetric
             matrix  A appears on the  left or right  in the
             operation as follows:

             SIDE = 'L' or 'l'   C := alpha*A*B + beta*C,

             SIDE = 'R' or 'r'   C := alpha*B*A + beta*C,
```

```
            Unchanged on exit.

      UPLO  - CHARACTER*1.
            On  entry,  UPLO  specifies  whether  the  upper  or
            lower triangular  part  of  the  symmetric  matrix
            A  is  to  be referenced as follows:

            UPLO = 'U' or 'u'   Only the upper triangular part of
            the symmetric matrix is to be referenced.

            UPLO = 'L' or 'l'   Only the lower triangular part of
            the symmetric matrix is to be referenced.

            Unchanged on exit.

      M     - INTEGER.
            On entry,  M  specifies the number of rows of the
            matrix  C.  M  must be at least zero.  Unchanged on
            exit.

      N     - INTEGER.
            On entry, N specifies the number of columns of the
            matrix C.  N  must be at least zero.  Unchanged on
            exit.

      ALPHA - COMPLEX*16      .
            On entry, ALPHA specifies the scalar alpha.
            Unchanged on exit.

ka is
      A     -
             COMPLEX*16       array of DIMENSION ( LDA, ka ), where
            m  when  SIDE = 'L' or 'l'  and is n  otherwise.
            Before entry  with  SIDE = 'L' or 'l',  the  m by m
            part of the array  A  must contain the  symmetric
            matrix,  such that when  UPLO = 'U' or 'u', the lead-
            ing m by m upper triangular part of the array  A
            must contain the upper triangular part of the  sym-
            metric matrix and the  strictly  lower triangular
            part of  A  is not referenced,  and when  UPLO = 'L'
            or 'l', the leading  m by m  lower triangular part
            of the  array  A must  contain  the  lower triangular
            part  of the  symmetric matrix and the  strictly
            upper triangular part of  A  is not referenced.
            Before entry  with  SIDE = 'R' or 'r',  the  n by n
            part of the array  A  must contain the  symmetric
            matrix,  such that when  UPLO = 'U' or 'u', the lead-
            ing n by n upper triangular part of the array  A
            must contain the upper triangular part of the  sym-
```

```
*           metric matrix and the  strictly  lower triangular
*           part of  A  is not referenced,  and when  UPLO = 'L'
*           or 'l', the leading  n by n  lower triangular part
*           of the  array  A must  contain  the  lower triangular
*           part  of the  symmetric matrix and the  strictly
*           upper triangular part of  A  is not referenced.
*           Unchanged on exit.
*
*  LDA    - INTEGER.
*           On entry, LDA specifies the first dimension of A as
*           declared in the  calling (sub) program. When  SIDE =
*           'L' or 'l'  then LDA must be at least  max( 1, m ),
*           otherwise  LDA must be at least max( 1, n ).
*           Unchanged on exit.
*
*  B      - COMPLEX*16       array of DIMENSION ( LDB, n ).
*           Before entry, the leading  m by n part of the array
*           B  must contain the matrix B.  Unchanged on exit.
*
*  LDB    - INTEGER.
*           On entry, LDB specifies the first dimension of B as
*           declared in  the  calling  (sub)  program.   LDB
*           must  be  at  least max( 1, m ).  Unchanged on exit.
*
*  BETA   - COMPLEX*16      .
*           On entry,  BETA  specifies the scalar  beta.  When
*           BETA  is supplied as zero then C need not be set on
*           input.  Unchanged on exit.
*
*  C      - COMPLEX*16       array of DIMENSION ( LDC, n ).
*           Before entry, the leading  m by n  part of the array
*           C must contain the matrix  C,  except when  beta  is
*           zero, in which case C need not be set on entry.  On
*           exit, the array  C  is overwritten by the  m by n
*           updated matrix.
*
*  LDC    - INTEGER.
*           On entry, LDC specifies the first dimension of C as
*           declared in  the  calling  (sub)  program.   LDC
*           must  be  at  least max( 1, m ).  Unchanged on exit.

 NAME
      ZSYR2K - perform one of the symmetric rank 2k operations   C
      := alpha*A*B' + alpha*B*A' + beta*C,

 SYNOPSIS
      SUBROUTINE ZSYR2K( UPLO, TRANS, N, K, ALPHA, A, LDA, B, LDB,
                         BETA, C, LDC )

          CHARACTER*1    UPLO, TRANS

          INTEGER        N, K, LDA, LDB, LDC

          COMPLEX*16     ALPHA, BETA

          COMPLEX*16     A( LDA, * ), B( LDB, * ), C( LDC, * )

 PURPOSE
      ZSYR2K  performs one of the symmetric rank 2k operations

      or

         C := alpha*A'*B + alpha*B'*A + beta*C,

      where  alpha and beta  are scalars,  C is an  n by n sym-
      metric matrix and  A and B  are  n by k  matrices  in the
      first  case  and  k by n matrices in the second case.

 PARAMETERS
      UPLO   - CHARACTER*1.
               On  entry,   UPLO  specifies  whether  the  upper  or
               lower triangular  part  of the  array  C  is to be
               referenced  as follows:
```

```
             UPLO = 'U' or 'u'   Only the  upper triangular part
             of  C is to be referenced.

             UPLO = 'L' or 'l'   Only the  lower triangular part
             of  C is to be referenced.

             Unchanged on exit.

      TRANS  - CHARACTER*1.
             On entry,  TRANS  specifies the operation to be per-
             formed as follows:

             TRANS = 'N' or 'n'    C := alpha*A*B' + alpha*B*A' +
             beta*C.

             TRANS = 'T' or 't'    C := alpha*A'*B + alpha*B'*A +
             beta*C.

             Unchanged on exit.

      N      - INTEGER.
             On entry,  N specifies the order of the matrix C.  N
             must be at least zero.  Unchanged on exit.

      K      - INTEGER.
             On entry with  TRANS = 'N' or 'n',  K  specifies  the
             number of  columns  of the  matrices  A and B,  and
             on  entry  with TRANS = 'T' or 't',  K  specifies
             the number of rows of the matrices  A and B.  K must
             be at least zero.  Unchanged on exit.

      ALPHA  - COMPLEX*16      .
             On entry, ALPHA specifies the scalar alpha.
             Unchanged on exit.

ka is
      A      -
              COMPLEX*16       array of DIMENSION ( LDA, ka ), where
             k  when  TRANS = 'N' or 'n',  and is  n  otherwise.
             Before entry with  TRANS = 'N' or 'n',  the  leading
             n by k part of the array  A  must contain the matrix
             A,  otherwise the leading  k by n  part of the array
             A  must contain  the matrix A.  Unchanged on exit.

      LDA    - INTEGER.
             On entry, LDA specifies the first dimension of A as
             declared in  the  calling  (sub)  program.   When
             TRANS = 'N' or 'n' then  LDA must be at least  max(
             1, n ), otherwise  LDA must be at least  max( 1, k ).
             Unchanged on exit.
```

```
kb is
     B      -
             COMPLEX*16       array of DIMENSION ( LDB, kb ), where
            k  when  TRANS = 'N' or 'n',  and is  n  otherwise.
            Before entry with  TRANS = 'N' or 'n',  the  leading
            n by k part of the array  B  must contain the matrix
            B,  otherwise the leading  k by n  part of the array
            B  must contain  the matrix B.  Unchanged on exit.

     LDB    - INTEGER.
            On entry, LDB specifies the first dimension of B as
            declared in  the  calling  (sub)  program.   When
            TRANS = 'N' or 'n' then  LDB must be at least  max(
            1, n ), otherwise  LDB must be at least  max( 1, k ).
            Unchanged on exit.

     BETA   - COMPLEX*16      .
            On entry, BETA specifies the scalar beta.  Unchanged
            on exit.

     C      - COMPLEX*16       array of DIMENSION ( LDC, n ).
            Before entry  with  UPLO = 'U' or 'u',  the leading
            n by n upper triangular part of the array C must con-
            tain the upper triangular part  of the  symmetric
            matrix  and the strictly lower triangular part of C
            is not referenced.  On exit, the upper triangular
            part of the array  C is overwritten by the upper tri-
            angular part of the updated matrix.  Before entry
            with  UPLO = 'L' or 'l',  the leading  n by n lower
            triangular part of the array C must contain the lower
            triangular part  of the  symmetric matrix  and the
            strictly upper triangular part of C is not refer-
            enced.  On exit, the lower triangular part of the
            array  C is overwritten by the lower triangular part
            of the updated matrix.

     LDC    - INTEGER.
            On entry, LDC specifies the first dimension of C as
            declared in  the  calling  (sub)  program.   LDC
            must  be  at  least max( 1, n ).  Unchanged on exit.

 NAME
      ZSYRK - perform one of the symmetric rank k operations   C
      := alpha*A*A' + beta*C,

 SYNOPSIS
      SUBROUTINE ZSYRK ( UPLO, TRANS, N, K, ALPHA, A, LDA, BETA,
                      C, LDC )

          CHARACTER*1  UPLO, TRANS

          INTEGER      N, K, LDA, LDC

          COMPLEX*16   ALPHA, BETA

          COMPLEX*16   A( LDA, * ), C( LDC, * )

 PURPOSE
      ZSYRK  performs one of the symmetric rank k operations

      or

         C := alpha*A'*A + beta*C,

      where  alpha and beta  are scalars,  C is an  n by n sym-
      metric matrix and  A  is an  n by k  matrix in the first
      case and a  k by n  matrix in the second case.

 PARAMETERS
      UPLO   - CHARACTER*1.
               On  entry,  UPLO  specifies  whether  the  upper  or
               lower triangular  part  of the  array  C  is to be
               referenced  as follows:

               UPLO = 'U' or 'u'   Only the  upper triangular part
               of  C is to be referenced.
```

```
           UPLO = 'L' or 'l'   Only the  lower triangular part
           of  C is to be referenced.

           Unchanged on exit.

     TRANS  - CHARACTER*1.
           On entry,  TRANS  specifies the operation to be per-
           formed as follows:

           TRANS = 'N' or 'n'   C := alpha*A*A' + beta*C.

           TRANS = 'T' or 't'   C := alpha*A'*A + beta*C.

           Unchanged on exit.

     N     - INTEGER.
           On entry,  N specifies the order of the matrix C.  N
           must be at least zero.  Unchanged on exit.

     K     - INTEGER.
           On entry with  TRANS = 'N' or 'n',  K  specifies  the
           number of  columns   of  the   matrix   A,   and  on
           entry   with TRANS = 'T' or 't',  K  specifies  the
           number of rows of the matrix A.  K must be at least
           zero.  Unchanged on exit.

     ALPHA  - COMPLEX*16      .
           On entry, ALPHA specifies the scalar alpha.
           Unchanged on exit.

ka is
     A     -
            COMPLEX*16       array of DIMENSION ( LDA, ka ), where
           k  when  TRANS = 'N' or 'n',  and is  n  otherwise.
           Before entry with  TRANS = 'N' or 'n',  the  leading
           n by k part of the array  A  must contain the matrix
           A,  otherwise the leading  k by n  part of the array
           A  must contain  the matrix A.  Unchanged on exit.

     LDA    - INTEGER.
           On entry, LDA specifies the first dimension of A as
           declared in  the  calling  (sub)  program.   When
           TRANS = 'N' or 'n' then  LDA must be at least  max(
           1, n ), otherwise  LDA must be at least  max( 1, k ).
           Unchanged on exit.

     BETA   - COMPLEX*16      .
           On entry, BETA specifies the scalar beta.  Unchanged
           on exit.
```

```
      C      - COMPLEX*16       array of DIMENSION ( LDC, n ).
             Before entry  with  UPLO = 'U' or 'u',  the leading
             n by n upper triangular part of the array C must con-
             tain the upper triangular part  of the  symmetric
             matrix  and the strictly lower triangular part of C
             is not referenced.  On exit, the upper triangular
             part of the array  C is overwritten by the upper tri-
             angular part of the updated matrix.  Before entry
             with  UPLO = 'L' or 'l',  the leading  n by n lower
             triangular part of the array C must contain the lower
             triangular part  of the  symmetric matrix  and the
             strictly upper triangular part of C is not refer-
             enced.  On exit, the lower triangular part of the
             array  C is overwritten by the lower triangular part
             of the updated matrix.

      LDC    - INTEGER.

             On entry, LDC specifies the first dimension of C as
             declared in  the  calling  (sub)  program.   LDC
             must  be  at  least max( 1, n ).  Unchanged on exit.

 NAME
      ZTRMM - perform one of the matrix-matrix operations   B :=
      alpha*op( A )*B, or B := alpha*B*op( A )  where alpha is a
      scalar, B is an m by n matrix, A is a unit, or non-unit,
      upper or lower triangular matrix and op( A ) is one of   op(
      A ) = A or op( A ) = A' or op( A ) = conjg( A' )

 SYNOPSIS
      SUBROUTINE ZTRMM ( SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A,
                       LDA, B, LDB )

          CHARACTER*1  SIDE, UPLO, TRANSA, DIAG

          INTEGER      M, N, LDA, LDB

          COMPLEX*16   ALPHA

          COMPLEX*16   A( LDA, * ), B( LDB, * )

 PURPOSE
      ZTRMM  performs one of the matrix-matrix operations

 PARAMETERS
      SIDE   - CHARACTER*1.
             On entry,  SIDE specifies whether  op( A ) multiplies
             B from the left or right as follows:

             SIDE = 'L' or 'l'   B := alpha*op( A )*B.
```

```
       SIDE = 'R' or 'r'   B := alpha*B*op( A ).

       Unchanged on exit.

UPLO   - CHARACTER*1.
       On entry, UPLO specifies whether the matrix A is an
       upper or lower triangular matrix as follows:

       UPLO = 'U' or 'u'   A is an upper triangular matrix.

       UPLO = 'L' or 'l'   A is a lower triangular matrix.

       Unchanged on exit.

       TRANSA - CHARACTER*1.  On entry, TRANSA specifies the
       form of op( A ) to be used in the matrix multiplica-
       tion as follows:

       TRANSA = 'N' or 'n'   op( A ) = A.

       TRANSA = 'T' or 't'   op( A ) = A'.

       TRANSA = 'C' or 'c'   op( A ) = conjg( A' ).

       Unchanged on exit.

DIAG   - CHARACTER*1.
       On entry, DIAG specifies whether or not A is unit
       triangular as follows:

       DIAG = 'U' or 'u'   A is assumed to be unit triangu-
       lar.

       DIAG = 'N' or 'n'   A is not assumed to be unit tri-
       angular.

       Unchanged on exit.

M      - INTEGER.
       On entry, M specifies the number of rows of B. M must
       be at least zero.  Unchanged on exit.

N      - INTEGER.
       On entry, N specifies the number of columns of B.  N
       must be at least zero.  Unchanged on exit.

ALPHA  - COMPLEX*16      .
       On entry,  ALPHA specifies the scalar  alpha. When
       alpha is zero then  A is not referenced and  B need
```

```
            not be set before entry.  Unchanged on exit.

 is m
      A      -
             COMPLEX*16       array of DIMENSION ( LDA, k ), where k
             when  SIDE = 'L' or 'l'  and is  n  when  SIDE = 'R'
             or 'r'.  Before entry  with  UPLO = 'U' or 'u',  the
             leading  k by k upper triangular part of the array  A
             must contain the upper triangular matrix  and the
             strictly lower triangular part of A is not refer-
             enced.  Before entry  with  UPLO = 'L' or 'l',  the
             leading  k by k lower triangular part of the array  A
             must contain the lower triangular matrix  and the
             strictly upper triangular part of A is not refer-
             enced.  Note that when  DIAG = 'U' or 'u',  the diag-
             onal elements of A  are not referenced either,  but
             are assumed to be  unity.  Unchanged on exit.

      LDA    - INTEGER.
             On entry, LDA specifies the first dimension of A as
             declared in the calling (sub) program.  When  SIDE =
             'L' or 'l'  then LDA  must be at least  max( 1, m ),
             when  SIDE = 'R' or 'r' then LDA must be at least
             max( 1, n ).  Unchanged on exit.

      B      - COMPLEX*16       array of DIMENSION ( LDB, n ).
             Before entry,  the leading  m by n part of the array
             B must contain the matrix  B,  and  on exit  is
             overwritten  by the transformed matrix.

      LDB    - INTEGER.
             On entry, LDB specifies the first dimension of B as
             declared in  the  calling  (sub)  program.   LDB
             must  be  at  least max( 1, m ).  Unchanged on exit.

 NAME
      ZTRSM - solve one of the matrix equations   op( A )*X =
      alpha*B, or X*op( A ) = alpha*B,

 SYNOPSIS
      SUBROUTINE ZTRSM ( SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A,
                         LDA, B, LDB )

          CHARACTER*1  SIDE, UPLO, TRANSA, DIAG

          INTEGER      M, N, LDA, LDB

          COMPLEX*16   ALPHA

          COMPLEX*16   A( LDA, * ), B( LDB, * )

 PURPOSE
      ZTRSM  solves one of the matrix equations

      where alpha is a scalar, X and B are m by n matrices, A is a
      unit, or non-unit,  upper or lower triangular matrix  and
      op( A )  is one  of

         op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg(
      A' ).

      The matrix X is overwritten on B.

 PARAMETERS
      SIDE   - CHARACTER*1.
               On entry, SIDE specifies whether op( A ) appears on
               the left or right of X as follows:

               SIDE = 'L' or 'l'   op( A )*X = alpha*B.

               SIDE = 'R' or 'r'   X*op( A ) = alpha*B.

               Unchanged on exit.

      UPLO   - CHARACTER*1.
               On entry, UPLO specifies whether the matrix A is an
               upper or lower triangular matrix as follows:

               UPLO = 'U' or 'u'   A is an upper triangular matrix.

               UPLO = 'L' or 'l'   A is a lower triangular matrix.
```

```
            Unchanged on exit.

            TRANSA - CHARACTER*1.  On entry, TRANSA specifies the
            form of op( A ) to be used in the matrix

            multiplication as follows:

            TRANSA = 'N' or 'n'   op( A ) = A.

            TRANSA = 'T' or 't'   op( A ) = A'.

            TRANSA = 'C' or 'c'   op( A ) = conjg( A' ).

            Unchanged on exit.

      DIAG  - CHARACTER*1.
            On entry, DIAG specifies whether or not A is unit
            triangular as follows:

            DIAG = 'U' or 'u'   A is assumed to be unit triangu-
            lar.

            DIAG = 'N' or 'n'   A is not assumed to be unit tri-
            angular.

            Unchanged on exit.

      M     - INTEGER.
            On entry, M specifies the number of rows of B. M must
            be at least zero.  Unchanged on exit.

      N     - INTEGER.
            On entry, N specifies the number of columns of B.  N
            must be at least zero.  Unchanged on exit.

      ALPHA - COMPLEX*16      .
            On entry,  ALPHA specifies the scalar  alpha. When
            alpha is zero then  A is not referenced and  B need
            not be set before entry.  Unchanged on exit.

is m
      A     -
             COMPLEX*16       array of DIMENSION ( LDA, k ), where k
            when  SIDE = 'L' or 'l'  and is  n  when  SIDE = 'R'
            or 'r'.  Before entry  with  UPLO = 'U' or 'u',  the
            leading  k by k upper triangular part of the array  A
            must contain the upper triangular matrix  and the
            strictly lower triangular part of A is not refer-
            enced.  Before entry  with  UPLO = 'L' or 'l',  the
            leading  k by k lower triangular part of the array  A
```

```
           must contain the lower triangular matrix  and the
           strictly upper triangular part of A is not refer-
           enced.  Note that when  DIAG = 'U' or 'u',  the diag-
           onal elements of A  are not referenced either,  but
           are assumed to be  unity.  Unchanged on exit.

     LDA   - INTEGER.

           On entry, LDA specifies the first dimension of A as
           declared in the calling (sub) program.  When  SIDE =
           'L' or 'l'  then LDA  must be at least  max( 1, m ),
           when  SIDE = 'R' or 'r' then LDA must be at least
           max( 1, n ).  Unchanged on exit.

     B     - COMPLEX*16       array of DIMENSION ( LDB, n ).
           Before entry,  the leading  m by n part of the array
           B must contain  the  right-hand  side  matrix  B,
           and  on exit  is overwritten by the solution matrix
           X.

     LDB   - INTEGER.
           On entry, LDB specifies the first dimension of B as
           declared in  the  calling  (sub)  program.   LDB
           must  be  at  least max( 1, m ).  Unchanged on exit.

NAME
       DBDSDC - the singular value decomposition (SVD) of a real N-by-N (upper
       or lower) bidiagonal matrix B
```

```
SYNOPSIS
       SUBROUTINE DBDSDC( UPLO, COMPQ, N, D, E, U, LDU, VT, LDVT, Q, IQ, WORK,
                          IWORK, INFO )

           CHARACTER      COMPQ, UPLO

           INTEGER        INFO, LDU, LDVT, N

           INTEGER        IQ( * ), IWORK( * )

           DOUBLE         PRECISION  D(  * ), E( * ), Q( * ), U( LDU, * ), VT(
                          LDVT, * ), WORK( * )

PURPOSE
       DBDSDC computes the singular value decomposition (SVD) of a real N-by-N
       (upper  or  lower) bidiagonal matrix B:  B = U * S * VT, using a divide
       and conquer method, where S is  a  diagonal  matrix  with  non-negative
       diagonal elements (the singular values of B), and U and VT are orthogo-
       nal matrices of left and right singular vectors,  respectively.  DBDSDC
       can  be  used  to compute all singular values, and optionally, singular
       vectors or singular vectors in compact form.

       This code makes very mild assumptions about floating point  arithmetic.
       It  will  work  on  machines  with a guard digit in add/subtract, or on
       those binary machines without guard digits which subtract like the Cray
       X-MP,  Cray  Y-MP,  Cray C-90, or Cray-2.  It could conceivably fail on
       hexadecimal or decimal machines without guard digits, but  we  know  of
       none.  See DLASD3 for details.

       The  code  currently  calls DLASDQ if singular values only are desired.
       However, it can be slightly modified to compute singular  values  using
       the divide and conquer method.

ARGUMENTS
       UPLO    (input) CHARACTER*1
               = 'U':  B is upper bidiagonal.
               = 'L':  B is lower bidiagonal.

       COMPQ   (input) CHARACTER*1
               Specifies  whether  singular vectors are to be computed as fol-
               lows:
               = 'N':  Compute singular values only;
               = 'P':  Compute singular values and compute singular vectors in
               compact form; = 'I':  Compute singular values and singular vec-
               tors.

       N       (input) INTEGER
               The order of the matrix B.  N >= 0.
```

D (input/output) DOUBLE PRECISION array, dimension (N)
On entry, the n diagonal elements of the bidiagonal matrix B. On exit, if INFO=0, the singular values of B.

E (input/output) DOUBLE PRECISION array, dimension (N-1)
On entry, the elements of E contain the offdiagonal elements of the bidiagonal matrix whose SVD is desired. On exit, E has been destroyed.

U (output) DOUBLE PRECISION array, dimension (LDU,N)
If COMPQ = 'I', then: On exit, if INFO = 0, U contains the left singular vectors of the bidiagonal matrix. For other values of COMPQ, U is not referenced.

LDU (input) INTEGER
The leading dimension of the array U. LDU >= 1. If singular vectors are desired, then LDU >= max(1, N).

VT (output) DOUBLE PRECISION array, dimension (LDVT,N)
If COMPQ = 'I', then: On exit, if INFO = 0, VT' contains the right singular vectors of the bidiagonal matrix. For other values of COMPQ, VT is not referenced.

LDVT (input) INTEGER
The leading dimension of the array VT. LDVT >= 1. If singular vectors are desired, then LDVT >= max(1, N).

Q (output) DOUBLE PRECISION array, dimension (LDQ)
If COMPQ = 'P', then: On exit, if INFO = 0, Q and IQ contain the left and right singular vectors in a compact form, requiring O(N log N) space instead of 2*N**2. In particular, Q contains all the DOUBLE PRECISION data in LDQ >= N*(11 + 2*SMLSIZ + 8*INT(LOG_2(N/(SMLSIZ+1)))) words of memory, where SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25). For other values of COMPQ, Q is not referenced.

IQ (output) INTEGER array, dimension (LDIQ)
If COMPQ = 'P', then: On exit, if INFO = 0, Q and IQ contain the left and right singular vectors in a compact form, requiring O(N log N) space instead of 2*N**2. In particular, IQ contains all INTEGER data in LDIQ >= N*(3 + 3*INT(LOG_2(N/(SMLSIZ+1)))) words of memory, where SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25). For other values of COMPQ, IQ is not referenced.

WORK (workspace) DOUBLE PRECISION array, dimension (MAX(1,LWORK))
If COMPQ = 'N' then LWORK >= (4 * N). If COMPQ = 'P' then LWORK >= (6 * N). If COMPQ = 'I' then LWORK >= (3 * N**2 + 4 *

```
              N).

       IWORK   (workspace) INTEGER array, dimension (8*N)

       INFO    (output) INTEGER
               = 0:  successful exit.
               < 0:  if INFO = -i, the i-th argument had an illegal value.
               >  0:   The algorithm failed to compute an singular value.  The
               update process of divide and conquer failed.

 Further Details
 ===============

  Based on contributions by
     Ming Gu and Huan Ren, Computer Science Division, University of
     California at Berkeley, USA
```

The input arguments are:

- uplo - simple-array character (1)
- compq - (simple-array character (1)
- n - fixnum
- d - array doublefloat
- e - array doublefloat
- u - array doublefloat
- ldu - fixnum
- vt - doublefloat
- ldvt - fixnum
- q - array doublefloat
- iq - array fixnum
- work - array doublefloat
- iwork - array fixnum
- info - fixnum

The return values are:

- uplo - nil
- compq - nil
- n - nil
- d - nil
- e - nil
- u - nil
- ldu - nil
- vt - nil
- ldvt - nil
- q - nil
- iq - nil
- work - nil
- iwork - nil
- info - info

NAME
       DBDSQR  -  the  singular  values and, optionally, the right and/or left
       singular vectors from the singular value decomposition (SVD) of a  real
       N-by-N  (upper  or  lower) bidiagonal matrix B using the implicit zero-
       shift QR algorithm

SYNOPSIS
       SUBROUTINE DBDSQR( UPLO, N, NCVT, NRU, NCC, D, E, VT, LDVT, U, LDU,  C,
                          LDC, WORK, INFO )

           CHARACTER      UPLO

           INTEGER        INFO, LDC, LDU, LDVT, N, NCC, NCVT, NRU

           DOUBLE         PRECISION  C( LDC, * ), D( * ), E( * ), U( LDU, * ),
                          VT( LDVT, * ), WORK( * )

PURPOSE
       DBDSQR computes the singular values and, optionally, the  right  and/or
       left  singular vectors from the singular value decomposition (SVD) of a
       real N-by-N (upper or lower) bidiagonal matrix  B  using  the  implicit
       zero-shift QR algorithm.  The SVD of B has the form
```

```
   B = Q * S * P**T

where  S  is the diagonal matrix of singular values, Q is an orthogonal
matrix of left singular vectors, and P is an orthogonal matrix of right
singular vectors.  If left singular vectors are requested, this subrou-
tine actually returns U*Q instead of Q, and, if right singular  vectors
are  requested,  this  subroutine  returns P**T*VT instead of P**T, for
given real input matrices U and VT.  When U and VT are  the  orthogonal
matrices  that  reduce  a  general  matrix  A  to bidiagonal form:  A =
U*B*VT, as computed by DGEBRD, then

   A = (U*Q) * S * (P**T*VT)

is the SVD of A.  Optionally, the subroutine may  also  compute  Q**T*C
for a given real input matrix C.

See "Computing  Small Singular Values of Bidiagonal Matrices With Guar-
anteed High Relative Accuracy," by J. Demmel and W. Kahan, LAPACK Work-
ing  Note  #3  (or  SIAM  J.  Sci. Statist. Comput. vol. 11, no. 5, pp.
873-912, Sept 1990) and
"Accurate singular values and differential qd algorithms," by  B.  Par-
lett  and  V.  Fernando, Technical Report CPAM-554, Mathematics Depart-
ment, University of California at Berkeley, July 1992  for  a  detailed
description of the algorithm.

ARGUMENTS
       UPLO    (input) CHARACTER*1
               = 'U':  B is upper bidiagonal;
               = 'L':  B is lower bidiagonal.

       N       (input) INTEGER
               The order of the matrix B.  N >= 0.

       NCVT    (input) INTEGER
               The number of columns of the matrix VT. NCVT >= 0.

       NRU     (input) INTEGER
               The number of rows of the matrix U. NRU >= 0.

       NCC     (input) INTEGER
               The number of columns of the matrix C. NCC >= 0.

       D       (input/output) DOUBLE PRECISION array, dimension (N)
               On  entry,  the n diagonal elements of the bidiagonal matrix B.
               On exit, if INFO=0, the singular  values  of  B  in  decreasing
               order.

       E       (input/output) DOUBLE PRECISION array, dimension (N-1)
```

```
              On entry, the N-1 offdiagonal elements of the bidiagonal matrix
              B.  On exit, if INFO = 0, E is destroyed; if INFO > 0, D and  E
              will contain the diagonal and superdiagonal elements of a bidi-
              agonal matrix orthogonally  equivalent  to  the  one  given  as
              input.

       VT     (input/output) DOUBLE PRECISION array, dimension (LDVT, NCVT)
              On  entry,  an N-by-NCVT matrix VT.  On exit, VT is overwritten
              by P**T * VT.  Not referenced if NCVT = 0.

       LDVT   (input) INTEGER
              The leading dimension of the array VT.   LDVT  >=  max(1,N)  if
              NCVT > 0; LDVT >= 1 if NCVT = 0.

       U      (input/output) DOUBLE PRECISION array, dimension (LDU, N)
              On entry, an NRU-by-N matrix U.  On exit, U is overwritten by U
              * Q.  Not referenced if NRU = 0.

       LDU    (input) INTEGER
              The leading dimension of the array U.  LDU >= max(1,NRU).

       C      (input/output) DOUBLE PRECISION array, dimension (LDC, NCC)
              On entry, an N-by-NCC matrix C.  On exit, C is  overwritten  by
              Q**T * C.  Not referenced if NCC = 0.

       LDC    (input) INTEGER
              The leading dimension of the array C.  LDC >= max(1,N) if NCC >
              0; LDC >=1 if NCC = 0.

       WORK   (workspace) DOUBLE PRECISION array, dimension (2*N)
              if NCVT = NRU = NCC = 0, (max(1, 4*N)) otherwise

       INFO   (output) INTEGER
              = 0:  successful exit
              < 0:  If INFO = -i, the i-th argument had an illegal value
              > 0:  the algorithm did not converge; D and E contain the  ele-
              ments  of  a bidiagonal matrix which is orthogonally similar to
              the input matrix B;  if INFO = i, i elements of E have not con-
              verged to zero.

PARAMETERS
       TOLMUL  DOUBLE PRECISION, default = max(10,min(100,EPS**(-1/8)))
              TOLMUL  controls  the convergence criterion of the QR loop.  If
              it is positive, TOLMUL*EPS is the desired relative precision in
              the  computed  singular  values.   If  it is negative, abs(TOL-
              MUL*EPS*sigma_max) is the desired absolute accuracy in the com-
              puted  singular  values  (corresponds  to  relative  accuracy
              abs(TOLMUL*EPS) in the  largest  singular  value.   abs(TOLMUL)
              should  be  between 1 and 1/EPS, and preferably between 10 (for
              fast convergence) and .1/EPS (for there to be some accuracy  in
```

```
              the  results).  Default is to lose at either one eighth or 2 of
              the available decimal digits in each  computed  singular  value
              (whichever is smaller).

       MAXITR  INTEGER, default = 6
              MAXITR  controls  the maximum number of passes of the algorithm
              through its inner loop. The algorithms stops (and so  fails  to
              converge)  if  the  number  of  passes  through  the inner loop
              exceeds MAXITR*N**2.

NAME
       DDISNA  -  the  reciprocal  condition numbers for the eigenvectors of a
       real symmetric or complex Hermitian matrix or for  the  left  or  right
       singular vectors of a general m-by-n matrix

SYNOPSIS
       SUBROUTINE DDISNA( JOB, M, N, D, SEP, INFO )

           CHARACTER      JOB

           INTEGER        INFO, M, N

           DOUBLE         PRECISION D( * ), SEP( * )

PURPOSE
       DDISNA  computes  the reciprocal condition numbers for the eigenvectors
       of a real symmetric or complex Hermitian matrix  or  for  the  left  or
       right  singular vectors of a general m-by-n matrix. The reciprocal con-
       dition number is the 'gap' between the corresponding eigenvalue or sin-
       gular value and the nearest other one.

       The  bound on the error, measured by angle in radians, in the I-th com-
       puted vector is given by

              DLAMCH( 'E' ) * ( ANORM / SEP( I ) )

       where ANORM = 2-norm(A) = max( abs( D(j) ) ).  SEP(I) is not allowed to
       be  smaller  than DLAMCH( 'E' )*ANORM in order to limit the size of the
       error bound.

       DDISNA may also be used to compute error bounds for eigenvectors of the
       generalized symmetric definite eigenproblem.

ARGUMENTS
       JOB     (input) CHARACTER*1
               Specifies  for  which  problem the reciprocal condition numbers
               should be computed:
               = 'E':  the eigenvectors of a symmetric/Hermitian matrix;
               = 'L':  the left singular vectors of a general matrix;
               = 'R':  the right singular vectors of a general matrix.

       M       (input) INTEGER
               The number of rows of the matrix. M >= 0.

       N       (input) INTEGER
```

```
              If JOB = 'L' or 'R', the number of columns of  the  matrix,  in
              which case N >= 0. Ignored if JOB = 'E'.

       D      (input) DOUBLE PRECISION array, dimension (M) if JOB = 'E'
              dimension  (min(M,N))  if  JOB = 'L' or 'R' The eigenvalues (if
              JOB = 'E') or singular values (if JOB =  'L'  or  'R')  of  the
              matrix,  in  either increasing or decreasing order. If singular
              values, they must be non-negative.

       SEP    (output) DOUBLE PRECISION array, dimension (M) if JOB = 'E'
              dimension (min(M,N)) if JOB = 'L' or 'R' The reciprocal  condi-
              tion numbers of the vectors.

       INFO   (output) INTEGER
              = 0:  successful exit.
              < 0:  if INFO = -i, the i-th argument had an illegal value.
```

NAME
       DGEBAK  -  the  right  or left eigenvectors of a real general matrix by
       backward transformation on the computed eigenvectors  of  the  balanced
       matrix output by DGEBAL

SYNOPSIS
       SUBROUTINE DGEBAK( JOB, SIDE, N, ILO, IHI, SCALE, M, V, LDV, INFO )

           CHARACTER      JOB, SIDE

           INTEGER        IHI, ILO, INFO, LDV, M, N
```

```
          DOUBLE         PRECISION SCALE( * ), V( LDV, * )

PURPOSE
      DGEBAK forms the right or left eigenvectors of a real general matrix by
      backward transformation on the computed eigenvectors  of  the  balanced
      matrix output by DGEBAL.

ARGUMENTS
      JOB     (input) CHARACTER*1
              Specifies  the type of backward transformation required: = 'N',
              do nothing, return immediately; = 'P', do backward  transforma-
              tion  for  permutation  only; = 'S', do backward transformation
              for scaling only; = 'B', do backward transformations  for  both
              permutation  and scaling.  JOB must be the same as the argument
              JOB supplied to DGEBAL.

      SIDE    (input) CHARACTER*1
              = 'R':  V contains right eigenvectors;
              = 'L':  V contains left eigenvectors.

      N       (input) INTEGER
              The number of rows of the matrix V.  N >= 0.

      ILO     (input) INTEGER
              IHI     (input) INTEGER The integers ILO and IHI determined  by
              DGEBAL.   1  <=  ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if
              N=0.

      SCALE   (input) DOUBLE PRECISION array, dimension (N)
              Details of the permutation and scaling factors, as returned  by
              DGEBAL.

      M       (input) INTEGER
              The number of columns of the matrix V.  M >= 0.

      V       (input/output) DOUBLE PRECISION array, dimension (LDV,M)
              On entry, the matrix of right or left eigenvectors to be trans-
              formed, as returned by DHSEIN or DTREVC.  On exit, V  is  over-
              written by the transformed eigenvectors.

      LDV     (input) INTEGER
              The leading dimension of the array V. LDV >= max(1,N).

      INFO    (output) INTEGER
              = 0:  successful exit
              < 0:  if INFO = -i, the i-th argument had an illegal value.
```

NAME
       DGEBAL - a general real matrix A

SYNOPSIS
       SUBROUTINE DGEBAL( JOB, N, A, LDA, ILO, IHI, SCALE, INFO )

           CHARACTER      JOB

           INTEGER        IHI, ILO, INFO, LDA, N

           DOUBLE         PRECISION A( LDA, * ), SCALE( * )

PURPOSE
       DGEBAL balances a general real matrix A.  This involves, first, permut-
       ing A by a similarity transformation  to  isolate  eigenvalues  in  the
       first 1 to ILO-1 and last IHI+1 to N elements on the diagonal; and sec-
       ond, applying a diagonal similarity transformation to rows and  columns
       ILO  to  IHI to make the rows and columns as close in norm as possible.
       Both steps are optional.

       Balancing may reduce the 1-norm of the matrix, and improve the accuracy
       of the computed eigenvalues and/or eigenvectors.

ARGUMENTS
       JOB     (input) CHARACTER*1
               Specifies the operations to be performed on A:
               =  'N':  none:  simply set ILO = 1, IHI = N, SCALE(I) = 1.0 for
               i = 1,...,N; = 'P':  permute only;
               = 'S':  scale only;
               = 'B':  both permute and scale.

       N       (input) INTEGER
               The order of the matrix A.  N >= 0.

       A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
               On entry, the input matrix A.  On exit,  A  is  overwritten  by
               the  balanced  matrix.  If JOB = 'N', A is not referenced.  See
               Further Details.  LDA     (input) INTEGER The leading dimension
               of the array A.  LDA >= max(1,N).

       ILO     (output) INTEGER
```

```
            IHI      (output)  INTEGER ILO and IHI are set to integers such
            that on exit A(i,j) = 0 if i > j and j =  1,...,ILO-1  or  I  =
            IHI+1,...,N.  If JOB = 'N' or 'S', ILO = 1 and IHI = N.

      SCALE   (output) DOUBLE PRECISION array, dimension (N)
            Details  of  the permutations and scaling factors applied to A.
            If P(j) is the index of the row and  column  interchanged  with
            row  and column j and D(j) is the scaling factor applied to row
            and column j, then SCALE(j) = P(j)    for  j  =  1,...,ILO-1  =
            D(j)    for j = ILO,...,IHI = P(j)    for j = IHI+1,...,N.  The
            order in which the interchanges are made is N to IHI+1, then  1
            to ILO-1.

      INFO    (output) INTEGER
            = 0:  successful exit.
            < 0:  if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS
      The  permutations  consist of row and column interchanges which put the
      matrix in the form

                 ( T1   X   Y  )
         P A P = (  0   B   Z  )
                 (  0   0   T2 )

      where T1 and T2 are upper triangular  matrices  whose  eigenvalues  lie
      along  the  diagonal.  The column indices ILO and IHI mark the starting
      and ending columns of the submatrix B. Balancing consists of applying a
      diagonal  similarity  transformation inv(D) * B * D to make the 1-norms
      of each row of B and its corresponding column nearly equal.  The output
      matrix is

         ( T1     X*D          Y    )
         (  0  inv(D)*B*D  inv(D)*Z ).
         (  0      0           T2   )

      Information  about  the  permutations  P  and  the diagonal matrix D is
      returned in the vector SCALE.

      This subroutine is based on the EISPACK routine BALANC.

NAME

DGEBD2 - a real general m by n matrix A to upper or lower bidiagonal form B by an orthogonal transformation

SYNOPSIS

```
SUBROUTINE DGEBD2( M, N, A, LDA, D, E, TAUQ, TAUP, WORK, INFO )

    INTEGER        INFO, LDA, M, N

    DOUBLE         PRECISION A( LDA, * ), D( * ), E( * ),  TAUP(  *  ),
                   TAUQ( * ), WORK( * )
```

PURPOSE

DGEBD2 reduces a real general m by n matrix A to upper or lower bidiagonal form B by an orthogonal transformation: Q' * A * P = B.

If m >= n, B is upper bidiagonal; if m < n, B is lower bidiagonal.

ARGUMENTS

M (input) INTEGER
The number of rows in the matrix A. M >= 0.

N (input) INTEGER
The number of columns in the matrix A. N >= 0.

A (input/output) DOUBLE PRECISION array, dimension (LDA,N)
On entry, the m by n general matrix to be reduced. On exit, if m >= n, the diagonal and the first superdiagonal are overwritten with the upper bidiagonal matrix B; the elements below the diagonal, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors; if m < n, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B; the elements below the first subdiagonal, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors. See Further Details. LDA (input) INTEGER The leading dimension of the array A. LDA >= max(1,M).

D (output) DOUBLE PRECISION array, dimension (min(M,N))
The diagonal elements of the bidiagonal matrix B: D(i) = A(i,i).

E (output) DOUBLE PRECISION array, dimension (min(M,N)-1)
The off-diagonal elements of the bidiagonal matrix B: if m >=

```
          n, E(i) = A(i,i+1) for i =  1,2,...,n-1;  if  m  <  n,  E(i)  =
          A(i+1,i) for i = 1,2,...,m-1.

      TAUQ    (output) DOUBLE PRECISION array dimension (min(M,N))
              The scalar factors of the elementary reflectors which represent
              the orthogonal matrix Q. See Further Details.  TAUP    (output)
              DOUBLE PRECISION array, dimension (min(M,N)) The scalar factors
              of the elementary reflectors  which  represent  the  orthogonal
              matrix P. See Further Details.  WORK    (workspace) DOUBLE PRE-
              CISION array, dimension (max(M,N))

      INFO    (output) INTEGER
              = 0: successful exit.
              < 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS
      The matrices Q and P are represented as products of elementary  reflec-
      tors:

      If m >= n,

         Q = H(1) H(2) . . . H(n)  and  P = G(1) G(2) . . . G(n-1)

      Each H(i) and G(i) has the form:

         H(i) = I - tauq * v * v'  and G(i) = I - taup * u * u'

      where  tauq  and  taup  are real scalars, and v and u are real vectors;
      v(1:i-1) = 0, v(i) = 1, and v(i+1:m) is stored on exit  in  A(i+1:m,i);
      u(1:i)  =  0, u(i+1) = 1, and u(i+2:n) is stored on exit in A(i,i+2:n);
      tauq is stored in TAUQ(i) and taup in TAUP(i).

      If m < n,

         Q = H(1) H(2) . . . H(m-1)  and  P = G(1) G(2) . . . G(m)

      Each H(i) and G(i) has the form:

         H(i) = I - tauq * v * v'  and G(i) = I - taup * u * u'

      where tauq and taup are real scalars, and v and  u  are  real  vectors;
      v(1:i)  =  0, v(i+1) = 1, and v(i+2:m) is stored on exit in A(i+2:m,i);
      u(1:i-1) = 0, u(i) = 1, and u(i+1:n) is stored on exit  in  A(i,i+1:n);
      tauq is stored in TAUQ(i) and taup in TAUP(i).

      The contents of A on exit are illustrated by the following examples:

      m = 6 and n = 5 (m > n):          m = 5 and n = 6 (m < n):

        (  d   e   u1  u1  u1 )           (  d   u1  u1  u1  u1  u1 )
```

```
  (  v1  d   e   u2  u2 )          (  e   d   u2  u2  u2  u2 )
  (  v1  v2  d   e   u3 )          (  v1  e   d   u3  u3  u3 )
  (  v1  v2  v3  d   e  )          (  v1  v2  e   d   u4  u4 )
  (  v1  v2  v3  v4  d  )          (  v1  v2  v3  e   d   u5 )
  (  v1  v2  v3  v4  v5 )
```

where d and e denote diagonal and off-diagonal elements of B, vi denotes an element of the vector defining H(i), and ui an element of the vector defining G(i).

NAME
       DGEBRD  -  a  general real M-by-N matrix A to upper or lower bidiagonal
       form B by an orthogonal transformation

SYNOPSIS
       SUBROUTINE DGEBRD( M, N, A, LDA, D, E, TAUQ, TAUP, WORK, LWORK, INFO )

           INTEGER        INFO, LDA, LWORK, M, N

           DOUBLE         PRECISION A( LDA, * ), D( * ), E( * ),  TAUP(  *  ),
                          TAUQ( * ), WORK( * )

PURPOSE
       DGEBRD reduces a general real M-by-N matrix A to upper or lower bidiag-
       onal form B by an orthogonal transformation: Q**T * A * P = B.

       If m >= n, B is upper bidiagonal; if m < n, B is lower bidiagonal.

ARGUMENTS
       M       (input) INTEGER
               The number of rows in the matrix A.  M >= 0.

       N       (input) INTEGER
               The number of columns in the matrix A.  N >= 0.

       A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
               On entry, the M-by-N general matrix to be reduced.  On exit, if
               m  >= n, the diagonal and the first superdiagonal are overwrit-
               ten with the upper bidiagonal matrix B; the elements below  the
               diagonal,  with the array TAUQ, represent the orthogonal matrix
               Q as a product of elementary reflectors, and the elements above
               the  first  superdiagonal,  with  the array TAUP, represent the
               orthogonal matrix P as a product of elementary reflectors; if m
               <  n,  the  diagonal  and the first subdiagonal are overwritten
               with the lower bidiagonal matrix  B;  the  elements  below  the
               first  subdiagonal, with the array TAUQ, represent the orthogo-
               nal matrix Q as a product of  elementary  reflectors,  and  the
               elements above the diagonal, with the array TAUP, represent the
               orthogonal matrix P as a product of elementary reflectors.  See
               Further Details.  LDA     (input) INTEGER The leading dimension
               of the array A.  LDA >= max(1,M).

       D       (output) DOUBLE PRECISION array, dimension (min(M,N))
               The diagonal elements  of  the  bidiagonal  matrix  B:  D(i)  =
               A(i,i).
```

```
       E       (output) DOUBLE PRECISION array, dimension (min(M,N)-1)
               The  off-diagonal  elements of the bidiagonal matrix B: if m >=
               n, E(i) = A(i,i+1) for i =  1,2,...,n-1;  if  m  <  n,  E(i)  =
               A(i+1,i) for i = 1,2,...,m-1.

       TAUQ    (output) DOUBLE PRECISION array dimension (min(M,N))
               The scalar factors of the elementary reflectors which represent
               the orthogonal matrix Q. See Further Details.  TAUP    (output)
               DOUBLE PRECISION array, dimension (min(M,N)) The scalar factors
               of the elementary reflectors  which  represent  the  orthogonal
               matrix P. See Further Details.  WORK    (workspace/output) DOU-
               BLE PRECISION array, dimension (MAX(1,LWORK)) On exit, if  INFO
               = 0, WORK(1) returns the optimal LWORK.

       LWORK   (input) INTEGER
               The  length of the array WORK.  LWORK >= max(1,M,N).  For opti-
               mum performance LWORK >= (M+N)*NB,  where  NB  is  the  optimal
               blocksize.

               If  LWORK  = -1, then a workspace query is assumed; the routine
               only calculates the optimal size of  the  WORK  array,  returns
               this  value  as the first entry of the WORK array, and no error
               message related to LWORK is issued by XERBLA.

       INFO    (output) INTEGER
               = 0:  successful exit
               < 0:  if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS
       The matrices Q and P are represented as products of elementary  reflec-
       tors:

       If m >= n,

          Q = H(1) H(2) . . . H(n)  and  P = G(1) G(2) . . . G(n-1)

       Each H(i) and G(i) has the form:

          H(i) = I - tauq * v * v'  and G(i) = I - taup * u * u'

       where  tauq  and  taup  are real scalars, and v and u are real vectors;
       v(1:i-1) = 0, v(i) = 1, and v(i+1:m) is stored on exit  in  A(i+1:m,i);
       u(1:i)  =  0, u(i+1) = 1, and u(i+2:n) is stored on exit in A(i,i+2:n);
       tauq is stored in TAUQ(i) and taup in TAUP(i).

       If m < n,

          Q = H(1) H(2) . . . H(m-1)  and  P = G(1) G(2) . . . G(m)

       Each H(i) and G(i) has the form:
```

```
   H(i) = I - tauq * v * v'  and G(i) = I - taup * u * u'

  where tauq and taup are real scalars, and v and  u  are  real  vectors;
  v(1:i)  =  0, v(i+1) = 1, and v(i+2:m) is stored on exit in A(i+2:m,i);
  u(1:i-1) = 0, u(i) = 1, and u(i+1:n) is stored on exit  in  A(i,i+1:n);
  tauq is stored in TAUQ(i) and taup in TAUP(i).

  The contents of A on exit are illustrated by the following examples:

  m = 6 and n = 5 (m > n):          m = 5 and n = 6 (m < n):

    (  d   e   u1  u1  u1 )           (  d   u1  u1  u1  u1  u1 )
    (  v1  d   e   u2  u2 )           (  e   d   u2  u2  u2  u2 )
    (  v1  v2  d   e   u3 )           (  v1  e   d   u3  u3  u3 )
    (  v1  v2  v3  d   e  )           (  v1  v2  e   d   u4  u4 )
    (  v1  v2  v3  v4  d  )           (  v1  v2  v3  e   d   u5 )
    (  v1  v2  v3  v4  v5 )

  where  d  and  e  denote  diagonal  and  off-diagonal elements of B, vi
  denotes an element of the vector defining H(i), and ui  an  element  of
  the vector defining G(i).
```

NAME
       DGEEV  - for an N-by-N real nonsymmetric matrix A, the eigenvalues and,
```

```
       optionally, the left and/or right eigenvectors

SYNOPSIS
       SUBROUTINE DGEEV( JOBVL, JOBVR, N, A, LDA, WR, WI, VL, LDVL, VR,  LDVR,
                         WORK, LWORK, INFO )

           CHARACTER     JOBVL, JOBVR

           INTEGER       INFO, LDA, LDVL, LDVR, LWORK, N

           DOUBLE        PRECISION  A( LDA, * ), VL( LDVL, * ), VR( LDVR, * ),
                         WI( * ), WORK( * ), WR( * )

PURPOSE
       DGEEV computes for an N-by-N real nonsymmetric matrix A, the  eigenval-
       ues and, optionally, the left and/or right eigenvectors.

       The right eigenvector v(j) of A satisfies
                        A * v(j) = lambda(j) * v(j)
       where lambda(j) is its eigenvalue.
       The left eigenvector u(j) of A satisfies
                     u(j)**H * A = lambda(j) * u(j)**H
       where u(j)**H denotes the conjugate transpose of u(j).

       The  computed  eigenvectors are normalized to have Euclidean norm equal
       to 1 and largest component real.

ARGUMENTS
       JOBVL   (input) CHARACTER*1
               = 'N': left eigenvectors of A are not computed;
               = 'V': left eigenvectors of A are computed.

       JOBVR   (input) CHARACTER*1
               = 'N': right eigenvectors of A are not computed;
               = 'V': right eigenvectors of A are computed.

       N       (input) INTEGER
               The order of the matrix A. N >= 0.

       A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
               On entry, the N-by-N matrix A.  On exit, A has  been  overwrit-
               ten.

       LDA     (input) INTEGER
               The leading dimension of the array A.  LDA >= max(1,N).

       WR      (output) DOUBLE PRECISION array, dimension (N)
               WI       (output)  DOUBLE PRECISION array, dimension (N) WR and
               WI contain the real and imaginary parts, respectively,  of  the
```

```
          computed  eigenvalues.  Complex conjugate pairs of eigenvalues
          appear consecutively with the eigenvalue  having  the  positive
          imaginary part first.

VL        (output) DOUBLE PRECISION array, dimension (LDVL,N)
          If JOBVL = 'V', the left eigenvectors u(j) are stored one after
          another in the columns of VL, in the same order as their eigen-
          values.  If  JOBVL  =  'N', VL is not referenced.  If the j-th
          eigenvalue is real, then u(j) = VL(:,j), the j-th column of VL.
          If  the  j-th and (j+1)-st eigenvalues form a complex conjugate
          pair, then u(j) = VL(:,j) + i*VL(:,j+1) and
          u(j+1) = VL(:,j) - i*VL(:,j+1).

LDVL      (input) INTEGER
          The leading dimension of the array VL.  LDVL >= 1; if  JOBVL  =
          'V', LDVL >= N.

VR        (output) DOUBLE PRECISION array, dimension (LDVR,N)
          If  JOBVR  =  'V',  the  right eigenvectors v(j) are stored one
          after another in the columns of VR, in the same order as  their
          eigenvalues.  If JOBVR = 'N', VR is not referenced.  If the j-
          th eigenvalue is real, then v(j) = VR(:,j), the j-th column  of
          VR.  If the j-th and (j+1)-st eigenvalues form a complex conju-
          gate pair, then v(j) = VR(:,j) + i*VR(:,j+1) and
          v(j+1) = VR(:,j) - i*VR(:,j+1).

LDVR      (input) INTEGER
          The leading dimension of the array VR.  LDVR >= 1; if  JOBVR  =
          'V', LDVR >= N.

WORK        (workspace/output)  DOUBLE  PRECISION  array,  dimension
(MAX(1,LWORK))
          On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK     (input) INTEGER
          The  dimension  of the array WORK.  LWORK >= max(1,3*N), and if
          JOBVL = 'V' or JOBVR = 'V', LWORK >=  4*N.  For  good  perfor-
          mance, LWORK must generally be larger.

          If  LWORK  = -1, then a workspace query is assumed; the routine
          only calculates the optimal size of  the  WORK  array,  returns
          this  value  as the first entry of the WORK array, and no error
          message related to LWORK is issued by XERBLA.

INFO      (output) INTEGER
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an illegal value.
          > 0:  if INFO = i, the QR algorithm failed to compute  all  the
          eigenvalues,  and  no eigenvectors have been computed; elements
          i+1:N of WR and WI contain eigenvalues which have converged.
```

NAME
       DGEEVX - for an N-by-N real nonsymmetric matrix A, the eigenvalues and,
       optionally, the left and/or right eigenvectors

SYNOPSIS
       SUBROUTINE DGEEVX( BALANC, JOBVL, JOBVR, SENSE, N, A, LDA, WR, WI,  VL,
                          LDVL,  VR,  LDVR,  ILO,  IHI,  SCALE, ABNRM, RCONDE,
                          RCONDV, WORK, LWORK, IWORK, INFO )

           CHARACTER      BALANC, JOBVL, JOBVR, SENSE
```

```
INTEGER        IHI, ILO, INFO, LDA, LDVL, LDVR, LWORK, N

DOUBLE         PRECISION ABNRM

INTEGER        IWORK( * )

DOUBLE         PRECISION A( LDA, * ), RCONDE( * ), RCONDV( * ),
               SCALE( * ), VL( LDVL, * ), VR( LDVR, * ), WI( * ),
               WORK( * ), WR( * )
```

PURPOSE

DGEEVX computes for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, SCALE, and ABNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right
eigenvectors (RCONDV).

The right eigenvector v(j) of A satisfies

```
A * v(j) = lambda(j) * v(j)
```

where lambda(j) is its eigenvalue.
The left eigenvector u(j) of A satisfies

```
u(j)**H * A = lambda(j) * u(j)**H
```

where u(j)**H denotes the conjugate transpose of u(j).

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Balancing a matrix means permuting the rows and columns to make it more nearly upper triangular, and applying a diagonal similarity transformation D * A * D**(-1), where D is a diagonal matrix, to make its rows and columns closer in norm and the condition numbers of its eigenvalues and eigenvectors smaller. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers (in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see section 4.10.2 of the LAPACK Users' Guide.

ARGUMENTS

BALANC (input) CHARACTER*1
Indicates how the input matrix should be diagonally scaled and/or permuted to improve the conditioning of its eigenvalues.
= 'N': Do not diagonally scale or permute;
= 'P': Perform permutations to make the matrix more nearly upper triangular. Do not diagonally scale; = 'S': Diagonally scale the matrix, i.e. replace A by D*A*D**(-1), where D is a diagonal matrix chosen to make the rows and columns of A more

```
          equal in norm. Do not permute; = 'B': Both diagonally scale and
          permute A.

          Computed reciprocal condition numbers will be  for  the  matrix
          after  balancing  and/or  permuting.  Permuting does not change
          condition numbers (in exact arithmetic), but balancing does.

     JOBVL   (input) CHARACTER*1
          = 'N': left eigenvectors of A are not computed;
          = 'V': left eigenvectors of A are computed.  If SENSE = 'E'  or
          'B', JOBVL must = 'V'.

     JOBVR   (input) CHARACTER*1
          = 'N': right eigenvectors of A are not computed;
          = 'V': right eigenvectors of A are computed.  If SENSE = 'E' or
          'B', JOBVR must = 'V'.

     SENSE   (input) CHARACTER*1
          Determines which reciprocal condition numbers are computed.   =
          'N': None are computed;
          = 'E': Computed for eigenvalues only;
          = 'V': Computed for right eigenvectors only;
          = 'B': Computed for eigenvalues and right eigenvectors.

          If  SENSE  =  'E' or 'B', both left and right eigenvectors must
          also be computed (JOBVL = 'V' and JOBVR = 'V').

     N       (input) INTEGER
          The order of the matrix A. N >= 0.

     A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
          On entry, the N-by-N matrix A.  On exit, A has  been  overwrit-
          ten.   If JOBVL = 'V' or JOBVR = 'V', A contains the real Schur
          form of the balanced version of the input matrix A.

     LDA     (input) INTEGER
          The leading dimension of the array A.  LDA >= max(1,N).

     WR      (output) DOUBLE PRECISION array, dimension (N)
          WI      (output) DOUBLE PRECISION array, dimension (N)  WR  and
          WI  contain  the real and imaginary parts, respectively, of the
          computed eigenvalues.  Complex conjugate pairs  of  eigenvalues
          will  appear consecutively with the eigenvalue having the posi-
          tive imaginary part first.

     VL      (output) DOUBLE PRECISION array, dimension (LDVL,N)
          If JOBVL = 'V', the left eigenvectors u(j) are stored one after
          another in the columns of VL, in the same order as their eigen-
          values.  If JOBVL = 'N', VL is not  referenced.   If  the  j-th
          eigenvalue is real, then u(j) = VL(:,j), the j-th column of VL.
```

If the j-th and (j+1)-st eigenvalues form a complex conjugate pair, then u(j) = VL(:,j) + i*VL(:,j+1) and u(j+1) = VL(:,j) - i*VL(:,j+1).

LDVL (input) INTEGER
The leading dimension of the array VL. LDVL >= 1; if JOBVL = 'V', LDVL >= N.

VR (output) DOUBLE PRECISION array, dimension (LDVR,N)
If JOBVR = 'V', the right eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. If JOBVR = 'N', VR is not referenced. If the j-th eigenvalue is real, then v(j) = VR(:,j), the j-th column of VR. If the j-th and (j+1)-st eigenvalues form a complex conjugate pair, then v(j) = VR(:,j) + i*VR(:,j+1) and v(j+1) = VR(:,j) - i*VR(:,j+1).

LDVR (input) INTEGER
The leading dimension of the array VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

ILO (output) INTEGER
IHI (output) INTEGER ILO and IHI are integer values determined when A was balanced. The balanced A(i,j) = 0 if I > J and J = 1,...,ILO-1 or I = IHI+1,...,N.

SCALE (output) DOUBLE PRECISION array, dimension (N)
Details of the permutations and scaling factors applied when balancing A. If P(j) is the index of the row and column interchanged with row and column j, and D(j) is the scaling factor applied to row and column j, then SCALE(J) = P(J), for J = 1,...,ILO-1 = D(J), for J = ILO,...,IHI = P(J) for J = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

ABNRM (output) DOUBLE PRECISION
The one-norm of the balanced matrix (the maximum of the sum of absolute values of elements of any column).

RCONDE (output) DOUBLE PRECISION array, dimension (N)
RCONDE(j) is the reciprocal condition number of the j-th eigenvalue.

RCONDV (output) DOUBLE PRECISION array, dimension (N)
RCONDV(j) is the reciprocal condition number of the j-th right eigenvector.

WORK (workspace/output) DOUBLE PRECISION array, dimension (MAX(1,LWORK))
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

```
       LWORK   (input) INTEGER
               The dimension of the array WORK.   If SENSE = 'N' or 'E', LWORK
               >= max(1,2*N), and if JOBVL = 'V' or JOBVR = 'V', LWORK >= 3*N.
               If SENSE = 'V' or 'B', LWORK >= N*(N+6).  For good performance,
               LWORK must generally be larger.

               If LWORK = -1, then a workspace query is assumed;  the  routine
               only  calculates  the  optimal  size of the WORK array, returns
               this value as the first entry of the WORK array, and  no  error
               message related to LWORK is issued by XERBLA.

       IWORK   (workspace) INTEGER array, dimension (2*N-2)
               If SENSE = 'N' or 'E', not referenced.

       INFO    (output) INTEGER
               = 0:  successful exit
               < 0:  if INFO = -i, the i-th argument had an illegal value.
               >  0:   if INFO = i, the QR algorithm failed to compute all the
               eigenvalues, and no eigenvectors or condition numbers have been
               computed;  elements  1:ILO-1  and  i+1:N  of  WR and WI contain
               eigenvalues which have converged.
```

NAME
       DGEHD2  -  a  real  general  matrix  A to upper Hessenberg form H by an
       orthogonal similarity transformation

SYNOPSIS
       SUBROUTINE DGEHD2( N, ILO, IHI, A, LDA, TAU, WORK, INFO )

           INTEGER        IHI, ILO, INFO, LDA, N

           DOUBLE         PRECISION A( LDA, * ), TAU( * ), WORK( * )

PURPOSE
       DGEHD2 reduces a real general matrix A to upper Hessenberg form H by an
       orthogonal similarity transformation:  Q' * A * Q = H .

ARGUMENTS
       N       (input) INTEGER
               The order of the matrix A.  N >= 0.

       ILO     (input) INTEGER
               IHI      (input)  INTEGER It is assumed that A is already upper
               triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI
               are  normally  set by a previous call to DGEBAL; otherwise they
               should be set to 1 and N respectively. See Further Details.

       A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
               On entry, the n by n general matrix to be  reduced.   On  exit,
```

```
          the upper triangle and the first subdiagonal of A are overwrit-
          ten with the upper Hessenberg matrix H, and the elements  below
          the  first  subdiagonal,  with  the  array  TAU,  represent the
          orthogonal matrix Q as a product of elementary reflectors.  See
          Further Details.  LDA     (input) INTEGER The leading dimension
          of the array A.  LDA >= max(1,N).

      TAU     (output) DOUBLE PRECISION array, dimension (N-1)
          The scalar factors of the elementary  reflectors  (see  Further
          Details).

      WORK    (workspace) DOUBLE PRECISION array, dimension (N)

      INFO    (output) INTEGER
          = 0:  successful exit.
          < 0:  if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS
      The  matrix  Q  is  represented  as  a  product of (ihi-ilo) elementary
      reflectors

         Q = H(ilo) H(ilo+1) . . . H(ihi-1).

      Each H(i) has the form

         H(i) = I - tau * v * v'

      where tau is a real scalar, and v is a real vector with
      v(1:i) = 0, v(i+1) = 1 and v(ihi+1:n) = 0; v(i+2:ihi) is stored on exit
      in A(i+2:ihi,i), and tau in TAU(i).

      The contents of A are illustrated by the following example, with n = 7,
      ilo = 2 and ihi = 6:

      on entry,                         on exit,

      ( a   a   a   a   a   a   a )     (  a   a   h   h   h   h   a )
      (     a   a   a   a   a   a )     (      a   h   h   h   h   a )
      (     a   a   a   a   a   a )     (      h   h   h   h   h   h )
      (     a   a   a   a   a   a )     (      v2  h   h   h   h   h )
      (     a   a   a   a   a   a )     (      v2  v3  h   h   h   h )
      (     a   a   a   a   a   a )     (      v2  v3  v4  h   h   h )
      (                     a   )     (                      a   )

      where a denotes an element of the original matrix A, h denotes a  modi-
      fied  element  of the upper Hessenberg matrix H, and vi denotes an ele-
      ment of the vector defining H(i).

NAME
       DGEHRD  -  Reduce a real general matrix A to upper Hessenberg form H by
       an orthogonal similarity transformation

SYNOPSIS
       SUBROUTINE DGEHRD( N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO )

           INTEGER        IHI, ILO, INFO, LDA, LWORK, N

           DOUBLE         PRECISION A( LDA, * ), TAU( * ), WORK( * )

PURPOSE
       DGEHRD reduces a real general matrix A to upper Hessenberg form H by an
       orthogonal similarity transformation:  Q' * A * Q = H .

ARGUMENTS
       N       (input) INTEGER
               The order of the matrix A.  N >= 0.

       ILO     (input) INTEGER
               IHI      (input)  INTEGER It is assumed that A is already upper
               triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI
               are  normally  set by a previous call to DGEBAL; otherwise they
               should be set to 1 and N respectively. See Further Details.

       A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
               On entry, the N-by-N general matrix to be  reduced.   On  exit,
               the upper triangle and the first subdiagonal of A are overwrit-
               ten with the upper Hessenberg matrix H, and the elements  below
               the  first  subdiagonal,  with  the  array  TAU,  represent the
               orthogonal matrix Q as a product of elementary reflectors.  See
               Further Details.  LDA     (input) INTEGER The leading dimension
               of the array A.  LDA >= max(1,N).

       TAU     (output) DOUBLE PRECISION array, dimension (N-1)
               The scalar factors of the elementary  reflectors  (see  Further
               Details).  Elements 1:ILO-1 and IHI:N-1 of TAU are set to zero.

       WORK    (workspace/output) DOUBLE PRECISION array, dimension (LWORK)
               On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

       LWORK   (input) INTEGER
               The length of the array WORK.  LWORK >= max(1,N).  For  optimum
               performance LWORK >= N*NB, where NB is the optimal blocksize.
```

```
            If  LWORK  = -1, then a workspace query is assumed; the routine
            only calculates the optimal size of  the  WORK  array,  returns
            this  value  as the first entry of the WORK array, and no error
            message related to LWORK is issued by XERBLA.

      INFO  (output) INTEGER
            = 0:  successful exit
            < 0:  if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS
      The matrix Q is  represented  as  a  product  of  (ihi-ilo)  elementary
      reflectors

         Q = H(ilo) H(ilo+1) . . . H(ihi-1).

      Each H(i) has the form

         H(i) = I - tau * v * v'

      where tau is a real scalar, and v is a real vector with
      v(1:i) = 0, v(i+1) = 1 and v(ihi+1:n) = 0; v(i+2:ihi) is stored on exit
      in A(i+2:ihi,i), and tau in TAU(i).

      The contents of A are illustrated by the following example, with n = 7,
      ilo = 2 and ihi = 6:

      on entry,                        on exit,

      ( a   a   a   a   a   a   a )    (  a   a   h   h   h   h   a )
      (     a   a   a   a   a   a )    (      a   h   h   h   h   a )
      (     a   a   a   a   a   a )    (      h   h   h   h   h   h )
      (     a   a   a   a   a   a )    (      v2  h   h   h   h   h )
      (     a   a   a   a   a   a )    (      v2  v3  h   h   h   h )
      (     a   a   a   a   a   a )    (      v2  v3  v4  h   h   h )
      (                     a   )    (                      a   )

      where  a denotes an element of the original matrix A, h denotes a modi-
      fied element of the upper Hessenberg matrix H, and vi denotes  an  ele-
      ment of the vector defining H(i).

      See Quintana-Orti and Van  de  Geijn (2005).

NAME
       DGELQ2 - an LQ factorization of a real m by n matrix A

SYNOPSIS
       SUBROUTINE DGELQ2( M, N, A, LDA, TAU, WORK, INFO )

           INTEGER        INFO, LDA, M, N

           DOUBLE         PRECISION A( LDA, * ), TAU( * ), WORK( * )

PURPOSE
       DGELQ2  computes an LQ factorization of a real m by n matrix A: A = L *
       Q.

ARGUMENTS
       M       (input) INTEGER
               The number of rows of the matrix A.  M >= 0.
```

```
       N       (input) INTEGER
               The number of columns of the matrix A.  N >= 0.

       A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
               On entry, the m by n matrix A.  On exit, the  elements  on  and
               below the diagonal of the array contain the m by min(m,n) lower
               trapezoidal matrix L (L is lower triangular if  m  <=  n);  the
               elements  above the diagonal, with the array TAU, represent the
               orthogonal matrix Q as a product of elementary reflectors  (see
               Further  Details).   LDA     (input) INTEGER The leading dimen-
               sion of the array A.  LDA >= max(1,M).

       TAU     (output) DOUBLE PRECISION array, dimension (min(M,N))
               The scalar factors of the elementary  reflectors  (see  Further
               Details).

       WORK    (workspace) DOUBLE PRECISION array, dimension (M)

       INFO    (output) INTEGER
               = 0: successful exit
               < 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS
       The matrix Q is represented as a product of elementary reflectors

          Q = H(k) . . . H(2) H(1), where k = min(m,n).

       Each H(i) has the form

          H(i) = I - tau * v * v'

       where tau is a real scalar, and v is a real vector with
       v(1:i-1)  =  0  and v(i) = 1; v(i+1:n) is stored on exit in A(i,i+1:n),
       and tau in TAU(i).

NAME
       DGELQF - an LQ factorization of a real M-by-N matrix A

SYNOPSIS
       SUBROUTINE DGELQF( M, N, A, LDA, TAU, WORK, LWORK, INFO )

           INTEGER        INFO, LDA, LWORK, M, N

           DOUBLE         PRECISION A( LDA, * ), TAU( * ), WORK( * )

PURPOSE
       DGELQF  computes an LQ factorization of a real M-by-N matrix A: A = L *
       Q.

ARGUMENTS
       M       (input) INTEGER
               The number of rows of the matrix A.  M >= 0.

       N       (input) INTEGER
               The number of columns of the matrix A.  N >= 0.

       A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
               On entry, the M-by-N matrix A.  On exit, the  elements  on  and
               below the diagonal of the array contain the m-by-min(m,n) lower
               trapezoidal matrix L (L is lower triangular if  m  <=  n);  the
               elements  above the diagonal, with the array TAU, represent the
               orthogonal matrix Q as a product of elementary reflectors  (see
               Further  Details).   LDA     (input) INTEGER The leading dimen-
```

```
              sion of the array A.  LDA >= max(1,M).

       TAU     (output) DOUBLE PRECISION array, dimension (min(M,N))
              The scalar factors of the elementary  reflectors  (see  Further
              Details).

       WORK       (workspace/output)  DOUBLE  PRECISION  array,  dimension
       (MAX(1,LWORK))
              On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

       LWORK   (input) INTEGER
              The dimension of the array WORK.  LWORK >= max(1,M).  For opti-
              mum performance LWORK >= M*NB, where NB is the  optimal  block-
              size.

              If  LWORK  = -1, then a workspace query is assumed; the routine
              only calculates the optimal size of  the  WORK  array,  returns
              this  value  as the first entry of the WORK array, and no error
              message related to LWORK is issued by XERBLA.

       INFO    (output) INTEGER
              = 0:  successful exit
              < 0:  if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS
       The matrix Q is represented as a product of elementary reflectors

          Q = H(k) . . . H(2) H(1), where k = min(m,n).

       Each H(i) has the form

          H(i) = I - tau * v * v'

       where tau is a real scalar, and v is a real vector with
       v(1:i-1) = 0 and v(i) = 1; v(i+1:n) is stored on  exit  in  A(i,i+1:n),
       and tau in TAU(i).

NAME
       DGEQR2 - a QR factorization of a real m by n matrix A

SYNOPSIS
       SUBROUTINE DGEQR2( M, N, A, LDA, TAU, WORK, INFO )

           INTEGER        INFO, LDA, M, N

           DOUBLE         PRECISION A( LDA, * ), TAU( * ), WORK( * )

PURPOSE
       DGEQR2  computes  a QR factorization of a real m by n matrix A: A = Q *
       R.

ARGUMENTS
       M       (input) INTEGER
               The number of rows of the matrix A.  M >= 0.

       N       (input) INTEGER
               The number of columns of the matrix A.  N >= 0.
```

```
       A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
               On entry, the m by n matrix A.  On exit, the  elements  on  and
               above the diagonal of the array contain the min(m,n) by n upper
               trapezoidal matrix R (R is upper triangular if  m  >=  n);  the
               elements  below the diagonal, with the array TAU, represent the
               orthogonal matrix Q as a product of elementary reflectors  (see
               Further  Details).   LDA     (input) INTEGER The leading dimen-
               sion of the array A.  LDA >= max(1,M).

       TAU     (output) DOUBLE PRECISION array, dimension (min(M,N))
               The scalar factors of the elementary  reflectors  (see  Further
               Details).

       WORK    (workspace) DOUBLE PRECISION array, dimension (N)

       INFO    (output) INTEGER
               = 0: successful exit
               < 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS
       The matrix Q is represented as a product of elementary reflectors

          Q = H(1) H(2) . . . H(k), where k = min(m,n).

       Each H(i) has the form

          H(i) = I - tau * v * v'

       where tau is a real scalar, and v is a real vector with
       v(1:i-1)  =  0  and v(i) = 1; v(i+1:m) is stored on exit in A(i+1:m,i),
       and tau in TAU(i).

NAME
       DGEQRF - a QR factorization of a real M-by-N matrix A

SYNOPSIS
       SUBROUTINE DGEQRF( M, N, A, LDA, TAU, WORK, LWORK, INFO )

           INTEGER        INFO, LDA, LWORK, M, N

           DOUBLE         PRECISION A( LDA, * ), TAU( * ), WORK( * )

PURPOSE
       DGEQRF  computes  a QR factorization of a real M-by-N matrix A: A = Q *
       R.

ARGUMENTS
       M       (input) INTEGER
               The number of rows of the matrix A.  M >= 0.

       N       (input) INTEGER
               The number of columns of the matrix A.  N >= 0.

       A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
               On entry, the M-by-N matrix A.  On exit, the  elements  on  and
               above the diagonal of the array contain the min(M,N)-by-N upper
               trapezoidal matrix R (R is upper triangular if  m  >=  n);  the
               elements  below the diagonal, with the array TAU, represent the
               orthogonal matrix Q as a product of min(m,n) elementary reflec-
               tors (see Further Details).

       LDA     (input) INTEGER
               The leading dimension of the array A.  LDA >= max(1,M).

       TAU     (output) DOUBLE PRECISION array, dimension (min(M,N))
               The  scalar  factors  of the elementary reflectors (see Further
               Details).
```

```
       WORK      (workspace/output)  DOUBLE  PRECISION  array,  dimension
       (MAX(1,LWORK))
              On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

       LWORK   (input) INTEGER
              The dimension of the array WORK.  LWORK >= max(1,N).  For opti-
              mum  performance  LWORK >= N*NB, where NB is the optimal block-
              size.

              If LWORK = -1, then a workspace query is assumed;  the  routine
              only  calculates  the  optimal  size of the WORK array, returns
              this value as the first entry of the WORK array, and  no  error
              message related to LWORK is issued by XERBLA.

       INFO    (output) INTEGER
              = 0:  successful exit
              < 0:  if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS
       The matrix Q is represented as a product of elementary reflectors

          Q = H(1) H(2) . . . H(k), where k = min(m,n).

       Each H(i) has the form

          H(i) = I - tau * v * v'

       where tau is a real scalar, and v is a real vector with
       v(1:i-1)  =  0  and v(i) = 1; v(i+1:m) is stored on exit in A(i+1:m,i),
       and tau in TAU(i).

NAME
       DGESDD - the singular value decomposition (SVD) of a real M-by-N matrix
       A, optionally computing the left and right singular vectors

SYNOPSIS
       SUBROUTINE DGESDD( JOBZ, M, N, A, LDA,  S,  U,  LDU,  VT,  LDVT,  WORK,
                          LWORK, IWORK, INFO )

           CHARACTER      JOBZ

           INTEGER        INFO, LDA, LDU, LDVT, LWORK, M, N

           INTEGER        IWORK( * )

           DOUBLE         PRECISION  A(  LDA,  *  ),  S( * ), U( LDU, * ), VT(
                          LDVT, * ), WORK( * )

PURPOSE
       DGESDD computes the singular value decomposition (SVD) of a real M-by-N
       matrix A, optionally computing the left and right singular vectors.  If
       singular vectors are desired, it uses a divide-and-conquer algorithm.

       The SVD is written

            A = U * SIGMA * transpose(V)
```

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M orthogonal matrix, and V is an N-by-N orthogonal matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns VT = V**T, not V.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input) CHARACTER*1
Specifies options for computing all or part of the matrix U: = 'A': all M columns of U and all N rows of V**T are returned in the arrays U and VT; = 'S': the first min(M,N) columns of U and the first min(M,N) rows of V**T are returned in the arrays U and VT; = 'O': If M >= N, the first N columns of U are overwritten on the array A and all rows of V**T are returned in the array VT; otherwise, all columns of U are returned in the array U and the first M rows of V**T are overwritten in the array A; = 'N': no columns of U or rows of V**T are computed.

M (input) INTEGER
The number of rows of the input matrix A. M >= 0.

N (input) INTEGER
The number of columns of the input matrix A. N >= 0.

A (input/output) DOUBLE PRECISION array, dimension (LDA,N)
On entry, the M-by-N matrix A. On exit, if JOBZ = 'O', A is overwritten with the first N columns of U (the left singular vectors, stored columnwise) if M >= N; A is overwritten with the first M rows of V**T (the right singular vectors, stored rowwise) otherwise. if JOBZ .ne. 'O', the contents of A are destroyed.

LDA (input) INTEGER
The leading dimension of the array A. LDA >= max(1,M).

S (output) DOUBLE PRECISION array, dimension (min(M,N))
The singular values of A, sorted so that S(i) >= S(i+1).

```
      U       (output) DOUBLE PRECISION array, dimension (LDU,UCOL)
              UCOL = M if JOBZ = 'A' or JOBZ = 'O' and M < N; UCOL = min(M,N)
              if  JOBZ  = 'S'.  If JOBZ = 'A' or JOBZ = 'O' and M < N, U con-
              tains the M-by-M orthogonal matrix U; if JOBZ = 'S', U contains
              the  first  min(M,N)  columns  of U (the left singular vectors,
              stored columnwise); if JOBZ = 'O' and M >= N, or JOBZ = 'N',  U
              is not referenced.

      LDU     (input) INTEGER
              The  leading dimension of the array U.  LDU >= 1; if JOBZ = 'S'
              or 'A' or JOBZ = 'O' and M < N, LDU >= M.

      VT      (output) DOUBLE PRECISION array, dimension (LDVT,N)
              If JOBZ = 'A' or JOBZ = 'O' and M >= N, VT contains the  N-by-N
              orthogonal  matrix  V**T;  if JOBZ = 'S', VT contains the first
              min(M,N) rows of V**T (the right singular vectors, stored  row-
              wise); if JOBZ = 'O' and M < N, or JOBZ = 'N', VT is not refer-
              enced.

      LDVT    (input) INTEGER
              The leading dimension of the array VT.  LDVT >= 1;  if  JOBZ  =
              'A' or JOBZ = 'O' and M >= N, LDVT >= N; if JOBZ = 'S', LDVT >=
              min(M,N).

      WORK      (workspace/output)   DOUBLE   PRECISION   array,    dimension
      (MAX(1,LWORK))
              On exit, if INFO = 0, WORK(1) returns the optimal LWORK;

      LWORK   (input) INTEGER
              The dimension of the array WORK. LWORK >= 1.  If  JOBZ  =  'N',
              LWORK >= 3*min(M,N) + max(max(M,N),7*min(M,N)).  If JOBZ = 'O',
              LWORK            >=            3*min(M,N)*min(M,N)            +
              max(max(M,N),5*min(M,N)*min(M,N)+4*min(M,N)).  If JOBZ = 'S' or
              'A'        LWORK        >=        3*min(M,N)*min(M,N)         +
              max(max(M,N),4*min(M,N)*min(M,N)+4*min(M,N)).  For good perfor-
              mance, LWORK should generally be larger.  If  LWORK  =  -1  but
              other  input  arguments  are legal, WORK(1) returns the optimal
              LWORK.

      IWORK   (workspace) INTEGER array, dimension (8*min(M,N))

      INFO    (output) INTEGER
              = 0:  successful exit.
              < 0:  if INFO = -i, the i-th argument had an illegal value.
              > 0:  DBDSDC did not converge, updating process failed.
