NAME
       DGESVD - the singular value decomposition (SVD) of a real M-by-N matrix
       A, optionally computing the left and/or right singular vectors

SYNOPSIS
       SUBROUTINE DGESVD( JOBU, JOBVT, M, N, A, LDA,  S,  U,  LDU,  VT,  LDVT,
                          WORK, LWORK, INFO )

           CHARACTER      JOBU, JOBVT

           INTEGER        INFO, LDA, LDU, LDVT, LWORK, M, N

           DOUBLE         PRECISION  A(  LDA,  *  ),  S( * ), U( LDU, * ), VT(
                          LDVT, * ), WORK( * )

  Purpose
  =======

  DGESVD computes the singular value decomposition (SVD) of a real
  M-by-N matrix A, optionally computing the left and/or right singular
  vectors. The SVD is written

       A = U * SIGMA * transpose(V)

  where SIGMA is an M-by-N matrix which is zero except for its
  min(m,n) diagonal elements, U is an M-by-M orthogonal matrix, and
  V is an N-by-N orthogonal matrix.  The diagonal elements of SIGMA
  are the singular values of A; they are real and non-negative, and
  are returned in descending order.  The first min(m,n) columns of
  U and V are the left and right singular vectors of A.

  Note that the routine returns V**T, not V.

  Arguments
  =========

  JOBU    (input) CHARACTER*1
```

```
          Specifies options for computing all or part of the matrix U:
          = 'A':  all M columns of U are returned in array U:
          = 'S':  the first min(m,n) columns of U (the left singular
                  vectors) are returned in the array U;
          = 'O':  the first min(m,n) columns of U (the left singular
                  vectors) are overwritten on the array A;
          = 'N':  no columns of U (no left singular vectors) are
                  computed.

JOBVT     (input) CHARACTER*1
          Specifies options for computing all or part of the matrix
          V**T:
          = 'A':  all N rows of V**T are returned in the array VT;
          = 'S':  the first min(m,n) rows of V**T (the right singular
                  vectors) are returned in the array VT;
          = 'O':  the first min(m,n) rows of V**T (the right singular
                  vectors) are overwritten on the array A;
          = 'N':  no rows of V**T (no right singular vectors) are
                  computed.

          JOBVT and JOBU cannot both be 'O'.

M         (input) INTEGER
          The number of rows of the input matrix A.  M >= 0.

N         (input) INTEGER
          The number of columns of the input matrix A.  N >= 0.

A         (input/output) DOUBLE PRECISION array, dimension (LDA,N)
          On entry, the M-by-N matrix A.
          On exit,
          if JOBU = 'O',  A is overwritten with the first min(m,n)
                          columns of U (the left singular vectors,
                          stored columnwise);
          if JOBVT = 'O', A is overwritten with the first min(m,n)
                          rows of V**T (the right singular vectors,
                          stored rowwise);
          if JOBU .ne. 'O' and JOBVT .ne. 'O', the contents of A
                          are destroyed.

LDA       (input) INTEGER
          The leading dimension of the array A.  LDA >= max(1,M).

S         (output) DOUBLE PRECISION array, dimension (min(M,N))
          The singular values of A, sorted so that S(i) >= S(i+1).

U         (output) DOUBLE PRECISION array, dimension (LDU,UCOL)
          (LDU,M) if JOBU = 'A' or (LDU,min(M,N)) if JOBU = 'S'.
          If JOBU = 'A', U contains the M-by-M orthogonal matrix U;
          if JOBU = 'S', U contains the first min(m,n) columns of U
```

```
        (the left singular vectors, stored columnwise);
        if JOBU = 'N' or 'O', U is not referenced.

LDU     (input) INTEGER
        The leading dimension of the array U.  LDU >= 1; if
        JOBU = 'S' or 'A', LDU >= M.

VT      (output) DOUBLE PRECISION array, dimension (LDVT,N)
        If JOBVT = 'A', VT contains the N-by-N orthogonal matrix
        V**T;
        if JOBVT = 'S', VT contains the first min(m,n) rows of
        V**T (the right singular vectors, stored rowwise);
        if JOBVT = 'N' or 'O', VT is not referenced.

LDVT    (input) INTEGER
        The leading dimension of the array VT.  LDVT >= 1; if
        JOBVT = 'A', LDVT >= N; if JOBVT = 'S', LDVT >= min(M,N).

WORK    (workspace/output) DOUBLE PRECISION array, dimension (LWORK)
        On exit, if INFO = 0, WORK(1) returns the optimal LWORK;
        if INFO > 0, WORK(2:MIN(M,N)) contains the unconverged
        superdiagonal elements of an upper bidiagonal matrix B
        whose diagonal is in S (not necessarily sorted). B
        satisfies A = U * B * VT, so it has the same singular values
        as A, and singular vectors related by U and VT.

LWORK   (input) INTEGER
        The dimension of the array WORK. LWORK >= 1.
        LWORK >= MAX(3*MIN(M,N)+MAX(M,N),5*MIN(M,N)).
        For good performance, LWORK should generally be larger.

        If LWORK = -1, then a workspace query is assumed; the routine
        only calculates the optimal size of the WORK array, returns
        this value as the first entry of the WORK array, and no error
        message related to LWORK is issued by XERBLA.

INFO    (output) INTEGER
        = 0:  successful exit.
        < 0:  if INFO = -i, the i-th argument had an illegal value.
        > 0:  if DBDSQR did not converge, INFO specifies how many
              superdiagonals of an intermediate bidiagonal form B
              did not converge to zero. See the description of WORK
              above for details.

NAME
       DGESV - the solution to a real system of linear equations  A * X = B,

SYNOPSIS
       SUBROUTINE DGESV( N, NRHS, A, LDA, IPIV, B, LDB, INFO )

           INTEGER       INFO, LDA, LDB, N, NRHS

           INTEGER       IPIV( * )

           DOUBLE        PRECISION A( LDA, * ), B( LDB, * )

PURPOSE
       DGESV computes the solution to a real system of linear equations
          A  *  X  =  B, where A is an N-by-N matrix and X and B are N-by-NRHS
```

```
       matrices.

       The LU decomposition with partial pivoting and row interchanges is used
       to factor A as
          A = P * L * U,
       where  P  is a permutation matrix, L is unit lower triangular, and U is
       upper triangular.  The factored form of A is then  used  to  solve  the
       system of equations A * X = B.

ARGUMENTS
       N       (input) INTEGER
               The  number  of linear equations, i.e., the order of the matrix
               A.  N >= 0.

       NRHS    (input) INTEGER
               The number of right hand sides, i.e., the number of columns  of
               the matrix B.  NRHS >= 0.

       A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
               On  entry,  the N-by-N coefficient matrix A.  On exit, the fac-
               tors L and U from the factorization A = P*L*U; the unit  diago-
               nal elements of L are not stored.

       LDA     (input) INTEGER
               The leading dimension of the array A.  LDA >= max(1,N).

       IPIV    (output) INTEGER array, dimension (N)
               The  pivot  indices that define the permutation matrix P; row i
               of the matrix was interchanged with row IPIV(i).

       B       (input/output) DOUBLE PRECISION array, dimension (LDB,NRHS)
               On entry, the N-by-NRHS matrix of right hand side matrix B.  On
               exit, if INFO = 0, the N-by-NRHS solution matrix X.

       LDB     (input) INTEGER
               The leading dimension of the array B.  LDB >= max(1,N).

       INFO    (output) INTEGER
               = 0:  successful exit
               < 0:  if INFO = -i, the i-th argument had an illegal value
               >  0:   if INFO = i, U(i,i) is exactly zero.  The factorization
               has been completed, but the factor U is  exactly  singular,  so
               the solution could not be computed.

NAME
       DGETF2 - an LU factorization of a general m-by-n matrix A using partial
       pivoting with row interchanges

SYNOPSIS
       SUBROUTINE DGETF2( M, N, A, LDA, IPIV, INFO )

           INTEGER        INFO, LDA, M, N

           INTEGER        IPIV( * )

           DOUBLE         PRECISION A( LDA, * )
```

```
PURPOSE
       DGETF2 computes an LU factorization of a general m-by-n matrix A  using
       partial pivoting with row interchanges.

       The factorization has the form
          A = P * L * U
       where P is a permutation matrix, L is lower triangular with unit diago-
       nal elements (lower trapezoidal if m > n), and U  is  upper  triangular
       (upper trapezoidal if m < n).

       This is the right-looking Level 2 BLAS version of the algorithm.

ARGUMENTS
       M       (input) INTEGER
               The number of rows of the matrix A.  M >= 0.

       N       (input) INTEGER
               The number of columns of the matrix A.  N >= 0.

       A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
               On  entry, the m by n matrix to be factored.  On exit, the fac-
               tors L and U from the factorization A = P*L*U; the unit  diago-
               nal elements of L are not stored.

       LDA     (input) INTEGER
               The leading dimension of the array A.  LDA >= max(1,M).

       IPIV    (output) INTEGER array, dimension (min(M,N))
               The  pivot indices; for 1 <= i <= min(M,N), row i of the matrix
               was interchanged with row IPIV(i).

       INFO    (output) INTEGER
               = 0: successful exit
               < 0: if INFO = -k, the k-th argument had an illegal value
               > 0: if INFO = k, U(k,k) is exactly zero. The factorization has
               been completed, but the factor U is exactly singular, and divi-
               sion by zero will occur if it is used  to  solve  a  system  of
               equations.

NAME
       DGETRF - an LU factorization of a general M-by-N matrix A using partial
       pivoting with row interchanges

SYNOPSIS
       SUBROUTINE DGETRF( M, N, A, LDA, IPIV, INFO )

           INTEGER        INFO, LDA, M, N

           INTEGER        IPIV( * )

           DOUBLE         PRECISION A( LDA, * )

PURPOSE
       DGETRF computes an LU factorization of a general M-by-N matrix A  using
       partial pivoting with row interchanges.

       The factorization has the form
          A = P * L * U
       where P is a permutation matrix, L is lower triangular with unit diago-
       nal elements (lower trapezoidal if m > n), and U  is  upper  triangular
       (upper trapezoidal if m < n).

       This is the right-looking Level 3 BLAS version of the algorithm.

ARGUMENTS
       M       (input) INTEGER
               The number of rows of the matrix A.  M >= 0.
```

```
       N       (input) INTEGER
               The number of columns of the matrix A.  N >= 0.

       A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
               On  entry, the M-by-N matrix to be factored.  On exit, the fac-
               tors L and U from the factorization A = P*L*U; the unit  diago-
               nal elements of L are not stored.

       LDA     (input) INTEGER
               The leading dimension of the array A.  LDA >= max(1,M).

       IPIV    (output) INTEGER array, dimension (min(M,N))
               The  pivot indices; for 1 <= i <= min(M,N), row i of the matrix
               was interchanged with row IPIV(i).

       INFO    (output) INTEGER
               = 0:  successful exit
               < 0:  if INFO = -i, the i-th argument had an illegal value
               > 0:  if INFO = i, U(i,i) is exactly  zero.  The  factorization
               has  been  completed, but the factor U is exactly singular, and
               division by zero will occur if it is used to solve a system  of
               equations.
```

NAME
       DGETRS  -  a system of linear equations  A * X = B or A' * X = B with a
       general N-by-N matrix A using the LU factorization computed by DGETRF

SYNOPSIS
       SUBROUTINE DGETRS( TRANS, N, NRHS, A, LDA, IPIV, B, LDB, INFO )

           CHARACTER      TRANS

           INTEGER        INFO, LDA, LDB, N, NRHS

           INTEGER        IPIV( * )

           DOUBLE         PRECISION A( LDA, * ), B( LDB, * )

PURPOSE
       DGETRS solves a system of linear equations
          A * X = B  or  A' * X = B with a general N-by-N matrix A  using  the
       LU factorization computed by DGETRF.

ARGUMENTS
       TRANS   (input) CHARACTER*1
               Specifies the form of the system of equations:
               = 'N':  A * X = B  (No transpose)
               = 'T':  A'* X = B  (Transpose)
               = 'C':  A'* X = B  (Conjugate transpose = Transpose)

       N       (input) INTEGER
               The order of the matrix A.  N >= 0.

       NRHS    (input) INTEGER
               The  number of right hand sides, i.e., the number of columns of
               the matrix B.  NRHS >= 0.

       A       (input) DOUBLE PRECISION array, dimension (LDA,N)
               The factors L and U from the factorization A =  P*L*U  as  com-
               puted by DGETRF.

       LDA     (input) INTEGER
               The leading dimension of the array A.  LDA >= max(1,N).

       IPIV    (input) INTEGER array, dimension (N)
               The pivot indices from DGETRF; for 1<=i<=N, row i of the matrix
```

```
              was interchanged with row IPIV(i).

       B      (input/output) DOUBLE PRECISION array, dimension (LDB,NRHS)
              On entry, the right hand side matrix B.  On exit, the  solution
              matrix X.

       LDB    (input) INTEGER
              The leading dimension of the array B.  LDB >= max(1,N).

       INFO   (output) INTEGER
              = 0:  successful exit
              < 0:  if INFO = -i, the i-th argument had an illegal value
```

NAME
       DHSEQR - compute the eigenvalues of a Hessenberg matrix H  and, option-
       ally, the matrices T and Z from the Schur decomposition  H = Z T  Z**T,
       where T is an upper quasi-triangular matrix (the  Schur form), and Z is
       the orthogonal matrix of Schur vectors

       Optionally Z may be postmultiplied into an input orthogonal matrix Q,
       so that this routine can give the Schur factorization of a matrix A
       which has been reduced to the Hessenberg form H by the orthogonal
       matrix Q:  A = Q*H*Q**T = (QZ)*T*(QZ)**T.

SYNOPSIS
       SUBROUTINE DHSEQR( JOB, COMPZ, N, ILO, IHI, H, LDH,  WR,  WI,  Z,  LDZ,
                          WORK, LWORK, INFO )

           INTEGER        IHI, ILO, INFO, LDH, LDZ, LWORK, N

           CHARACTER      COMPZ, JOB

           DOUBLE         PRECISION  H( LDH, * ), WI( * ), WORK( * ), WR( * ),
                          Z( LDZ, * )

PURPOSE
          DHSEQR computes the eigenvalues of a Hessenberg matrix H
          and, optionally, the matrices T and Z from the Schur decomposition
          H = Z T Z**T, where T is an upper quasi-triangular matrix (the
          Schur form), and Z is the orthogonal matrix of Schur vectors.

          Optionally Z may be postmultiplied into an input orthogonal
          matrix Q so that this routine can give the Schur factorization
          of a matrix A which has been reduced to the Hessenberg form H
          by the orthogonal matrix Q:  A = Q*H*Q**T = (QZ)*T*(QZ)**T.

ARGUMENTS
  JOB     (input) CHARACTER*1
          = 'E':  compute eigenvalues only;
          = 'S':  compute eigenvalues and the Schur form T.
```

```
COMPZ   (input) CHARACTER*1
        = 'N':  no Schur vectors are computed;
        = 'I':  Z is initialized to the unit matrix and the matrix Z
                of Schur vectors of H is returned;
        = 'V':  Z must contain an orthogonal matrix Q on entry, and
                the product Q*Z is returned.

N       (input) INTEGER
        The order of the matrix H.  N >= 0.

ILO     (input) INTEGER
IHI     (input) INTEGER
        It is assumed that H is already upper triangular in rows
        and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally
        set by a previous call to DGEBAL, and then passed to SGEHRD
        when the matrix output by DGEBAL is reduced to Hessenberg
        form. Otherwise ILO and IHI should be set to 1 and N
        respectively.
        1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

H       (input/output) DOUBLE PRECISION array, dimension (LDH,N)
        On entry, the upper Hessenberg matrix H.
        On exit, if JOB = 'S', H contains the upper quasi-triangular
        matrix T from the Schur decomposition (the Schur form);
        2-by-2 diagonal blocks (corresponding to complex conjugate
        pairs of eigenvalues) are returned in standard form, with
        H(i,i) = H(i+1,i+1) and H(i+1,i)*H(i,i+1) < 0. If JOB = 'E',
        the contents of H are unspecified on exit.

LDH     (input) INTEGER
        The leading dimension of the array H. LDH >= max(1,N).

WR      (output) DOUBLE PRECISION array, dimension (N)
WI      (output) DOUBLE PRECISION array, dimension (N)
        The real and imaginary parts, respectively, of the computed
        eigenvalues. If two eigenvalues are computed as a complex
        conjugate pair, they are stored in consecutive elements of
        WR and WI, say the i-th and (i+1)th, with WI(i) > 0 and
        WI(i+1) < 0. If JOB = 'S', the eigenvalues are stored in the
        same order as on the diagonal of the Schur form returned in
        H, with WR(i) = H(i,i) and, if H(i:i+1,i:i+1) is a 2-by-2
        diagonal block, WI(i) = sqrt(H(i+1,i)*H(i,i+1)) and
        WI(i+1) = -WI(i).

Z       (input/output) DOUBLE PRECISION array, dimension (LDZ,N)
        If COMPZ = 'N': Z is not referenced.
        If COMPZ = 'I': on entry, Z need not be set, and on exit, Z
        contains the orthogonal matrix Z of the Schur vectors of H.
        If COMPZ = 'V': on entry Z must contain an N-by-N matrix Q,
        which is assumed to be equal to the unit matrix except for
```

```
          the submatrix Z(ILO:IHI,ILO:IHI); on exit Z contains Q*Z.
          Normally Q is the orthogonal matrix generated by DORGHR after
          the call to DGEHRD which formed the Hessenberg matrix H.

  LDZ     (input) INTEGER
          The leading dimension of the array Z.
          LDZ >= max(1,N) if COMPZ = 'I' or 'V'; LDZ >= 1 otherwise.

  WORK    (workspace/output) DOUBLE PRECISION array, dimension (LWORK)
          On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

  LWORK   (input) INTEGER
          The dimension of the array WORK.  LWORK >= max(1,N).

          If LWORK = -1, then a workspace query is assumed; the routine
          only calculates the optimal size of the WORK array, returns
          this value as the first entry of the WORK array, and no error
          message related to LWORK is issued by XERBLA.

  INFO    (output) INTEGER
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an illegal value
          > 0:  if INFO = i, DHSEQR failed to compute all of the
                eigenvalues in a total of 30*(IHI-ILO+1) iterations;
                elements 1:ilo-1 and i+1:n of WR and WI contain those
                eigenvalues which have been successfully computed.

     LOGICAL FUNCTION DISNAN( DIN )

     .. Scalar Arguments ..
     DOUBLE PRECISION   DIN
     ..

 Purpose:
 =============

 DISNAN returns .TRUE. if its argument is NaN, and .FALSE.
 otherwise.  To be replaced by the Fortran 2003 intrinsic in the
 future.

 Arguments:
 ==========

 [in] DIN
       DIN is DOUBLE PRECISION
       Input to test for NaN.

NAME
       DLABAD  - a input the values computed by DLAMCH for underflow and over-
       flow, and returns the square root of each of these values if the log of
       LARGE is sufficiently large

SYNOPSIS
       SUBROUTINE DLABAD( SMALL, LARGE )

           DOUBLE         PRECISION LARGE, SMALL

PURPOSE
       DLABAD  takes  as input the values computed by DLAMCH for underflow and
       overflow, and returns the square root of each of these  values  if  the
       log  of  LARGE  is  sufficiently large.  This subroutine is intended to
       identify machines with a large exponent range, such as the  Crays,  and
       redefine  the  underflow  and overflow limits to be the square roots of
       the values computed by  DLAMCH.   This  subroutine  is  needed  because
       DLAMCH does not compensate for poor arithmetic in the upper half of the
       exponent range, as is found on a Cray.

ARGUMENTS
       SMALL   (input/output) DOUBLE PRECISION
               On entry, the underflow threshold as computed  by  DLAMCH.   On
               exit, if LOG10(LARGE) is sufficiently large, the square root of
               SMALL, otherwise unchanged.

       LARGE   (input/output) DOUBLE PRECISION
               On entry, the overflow threshold as  computed  by  DLAMCH.   On
               exit, if LOG10(LARGE) is sufficiently large, the square root of
               LARGE, otherwise unchanged.

NAME
       DLABRD  - the first NB rows and columns of a real general m by n matrix
       A to upper or lower bidiagonal form by an orthogonal transformation  Q'
       * A * P, and returns the matrices X and Y which are needed to apply the
       transformation to the unreduced part of A

SYNOPSIS
       SUBROUTINE DLABRD( M, N, NB, A, LDA, D, E, TAUQ, TAUP, X, LDX, Y, LDY )

           INTEGER        LDA, LDX, LDY, M, N, NB

           DOUBLE         PRECISION  A(  LDA,  * ), D( * ), E( * ), TAUP( * ),
                          TAUQ( * ), X( LDX, * ), Y( LDY, * )

PURPOSE
       DLABRD reduces the first NB rows and columns of a real general m  by  n
       matrix A to upper or lower bidiagonal form by an orthogonal transforma-
       tion Q' * A * P, and returns the matrices X and Y which are  needed  to
       apply the transformation to the unreduced part of A.

       If  m  >=  n, A is reduced to upper bidiagonal form; if m < n, to lower
       bidiagonal form.

       This is an auxiliary routine called by DGEBRD

ARGUMENTS
```

M (input) INTEGER
The number of rows in the matrix A.

N (input) INTEGER
The number of columns in the matrix A.

NB (input) INTEGER
The number of leading rows and columns of A to be reduced.

A (input/output) DOUBLE PRECISION array, dimension (LDA,N)
On entry, the m by n general matrix to be reduced. On exit, the first NB rows and columns of the matrix are overwritten; the rest of the array is unchanged. If m >= n, elements on and below the diagonal in the first NB columns, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors; and elements above the diagonal in the first NB rows, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors. If m < n, elements below the diagonal in the first NB columns, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors, and elements on and above the diagonal in the first NB rows, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors. See Further Details. LDA (input) INTEGER The leading dimension of the array A. LDA >= max(1,M).

D (output) DOUBLE PRECISION array, dimension (NB)
The diagonal elements of the first NB rows and columns of the reduced matrix. D(i) = A(i,i).

E (output) DOUBLE PRECISION array, dimension (NB)
The off-diagonal elements of the first NB rows and columns of the reduced matrix.

TAUQ (output) DOUBLE PRECISION array dimension (NB)
The scalar factors of the elementary reflectors which represent the orthogonal matrix Q. See Further Details. TAUP (output) DOUBLE PRECISION array, dimension (NB) The scalar factors of the elementary reflectors which represent the orthogonal matrix P. See Further Details. X (output) DOUBLE PRECISION array, dimension (LDX,NB) The m-by-nb matrix X required to update the unreduced part of A.

LDX (input) INTEGER
The leading dimension of the array X. LDX >= M.

Y (output) DOUBLE PRECISION array, dimension (LDY,NB)
The n-by-nb matrix Y required to update the unreduced part of A.

```
       LDY     (input) INTEGER
               The leading dimension of the array Y. LDY >= N.

FURTHER DETAILS
       The  matrices Q and P are represented as products of elementary reflec-
       tors:

          Q = H(1) H(2) . . . H(nb)  and  P = G(1) G(2) . . . G(nb)

       Each H(i) and G(i) has the form:

          H(i) = I - tauq * v * v'  and G(i) = I - taup * u * u'

       where tauq and taup are real scalars, and v and u are real vectors.

       If m >= n, v(1:i-1) = 0, v(i) = 1, and v(i:m)  is  stored  on  exit  in
       A(i:m,i);  u(1:i)  =  0,  u(i+1) = 1, and u(i+1:n) is stored on exit in
       A(i,i+1:n); tauq is stored in TAUQ(i) and taup in TAUP(i).

       If m < n, v(1:i) = 0, v(i+1) = 1, and v(i+1:m) is  stored  on  exit  in
       A(i+2:m,i);  u(1:i-1)  =  0,  u(i) = 1, and u(i:n) is stored on exit in
       A(i,i+1:n); tauq is stored in TAUQ(i) and taup in TAUP(i).

       The elements of the vectors v and u together form the m-by-nb matrix  V
       and  the nb-by-n matrix U' which are needed, with X and Y, to apply the
       transformation to the unreduced part  of  the  matrix,  using  a  block
       update of the form:  A := A - V*Y' - X*U'.

       The  contents  of  A  on exit are illustrated by the following examples
       with nb = 2:

       m = 6 and n = 5 (m > n):          m = 5 and n = 6 (m < n):

         (  1   1   u1  u1  u1 )           (  1   u1  u1  u1  u1  u1 )
         (  v1  1   1   u2  u2 )           (  1   1   u2  u2  u2  u2 )
         (  v1  v2  a   a   a  )           (  v1  1   a   a   a   a  )
         (  v1  v2  a   a   a  )           (  v1  v2  a   a   a   a  )
         (  v1  v2  a   a   a  )           (  v1  v2  a   a   a   a  )
         (  v1  v2  a   a   a  )

NAME
       DLACON - the 1-norm of a square, real matrix A

SYNOPSIS
       SUBROUTINE DLACON( N, V, X, ISGN, EST, KASE )

           INTEGER        KASE, N

           DOUBLE         PRECISION EST

           INTEGER        ISGN( * )

           DOUBLE         PRECISION V( * ), X( * )
```

```
PURPOSE
       DLACON estimates the 1-norm of a square, real matrix A.  Reverse commu-
       nication is used for evaluating matrix-vector products.

ARGUMENTS
       N      (input) INTEGER
              The order of the matrix.  N >= 1.

       V      (workspace) DOUBLE PRECISION array, dimension (N)
              On the final return, V = A*W,  where  EST =  norm(V)/norm(W)  (W
              is not returned).

       X      (input/output) DOUBLE PRECISION array, dimension (N)
              On  an  intermediate  return,  X should be overwritten by A * X,
              if KASE=1, A' * X,  if KASE=2, and DLACON must be re-called with
              all the other parameters unchanged.

       ISGN   (workspace) INTEGER array, dimension (N)

       EST    (input/output) DOUBLE PRECISION
              On  entry  with  KASE  =  1  or  2  and  JUMP = 3, EST should be
              unchanged from the previous call to DLACON.  On exit, EST is  an
              estimate (a lower bound) for norm(A).

       KASE   (input/output) INTEGER
              On the initial call to DLACON, KASE should be 0.  On an interme-
              diate return, KASE will be 1 or 2, indicating whether  X  should
              be  overwritten  by  A * X  or A' * X.  On the final return from
              DLACON, KASE will again be 0.

FURTHER DETAILS
       Reference: N.J. Higham, "FORTRAN codes for estimating the one-norm of a
       real or complex matrix, with applications to condition estimation", ACM
       Trans. Math. Soft., vol. 14, no. 4, pp. 381-396, December 1988.

NAME
       DLACPY - all or part of a two-dimensional matrix A to another matrix B

SYNOPSIS
       SUBROUTINE DLACPY( UPLO, M, N, A, LDA, B, LDB )

           CHARACTER      UPLO

           INTEGER        LDA, LDB, M, N

           DOUBLE         PRECISION A( LDA, * ), B( LDB, * )
```

```
PURPOSE
       DLACPY  copies  all  or  part  of a two-dimensional matrix A to another
       matrix B.

ARGUMENTS
       UPLO    (input) CHARACTER*1
               Specifies the part of the matrix A to be copied to B.   =  'U':
               Upper triangular part
               = 'L':      Lower triangular part
               Otherwise:  All of the matrix A

       M       (input) INTEGER
               The number of rows of the matrix A.  M >= 0.

       N       (input) INTEGER
               The number of columns of the matrix A.  N >= 0.

       A       (input) DOUBLE PRECISION array, dimension (LDA,N)
               The m by n matrix A.  If UPLO = 'U', only the upper triangle or
               trapezoid is accessed; if UPLO = 'L', only the  lower  triangle
               or trapezoid is accessed.

       LDA     (input) INTEGER
               The leading dimension of the array A.  LDA >= max(1,M).

       B       (output) DOUBLE PRECISION array, dimension (LDB,N)
               On exit, B = A in the locations specified by UPLO.

       LDB     (input) INTEGER
               The leading dimension of the array B.  LDB >= max(1,M).
```

NAME
  DLADIV performs complex division in  real arithmetic

                        a + i*b
             p + i*q = ---------
                        c + i*d
```

```
  The algorithm is due to Robert L. Smith and can be found
  in D. Knuth, The art of Computer Programming, Vol.2, p.195

 Arguments
 =========

  A       (input) DOUBLE PRECISION
  B       (input) DOUBLE PRECISION
  C       (input) DOUBLE PRECISION
  D       (input) DOUBLE PRECISION
          The scalars a, b, c, and d in the above expression.

  P       (output) DOUBLE PRECISION
  Q       (output) DOUBLE PRECISION
          The scalars p and q in the above expression.
```

Man Page Details
========================================================================

 Purpose
 =======

  DLAED6 computes the positive or negative root (closest to the origin)
  of
                   z(1)        z(2)        z(3)
  f(x) =   rho + --------- + ---------- + ---------
                  d(1)-x      d(2)-x      d(3)-x

  It is assumed that

        if ORGATI = .true. the root is between d(2) and d(3);
        otherwise it is between d(1) and d(2)

  This routine will be called by DLAED4 when necessary. In most cases,
  the root sought is the smallest in magnitude, though it might not be
  in some extremely rare situations.

  Arguments
  =========

  KNITER       (input) INTEGER
               Refer to DLAED4 for its significance.

  ORGATI       (input) LOGICAL
               If ORGATI is true, the needed root is between d(2) and
               d(3); otherwise it is between d(1) and d(2).  See
               DLAED4 for further details.

  RHO          (input) DOUBLE PRECISION
               Refer to the equation f(x) above.
```

```
 D            (input) DOUBLE PRECISION array, dimension (3)
              D satisfies d(1) < d(2) < d(3).

 Z            (input) DOUBLE PRECISION array, dimension (3)
              Each of the elements in z must be positive.

 FINIT        (input) DOUBLE PRECISION
              The value of f at 0. It is more accurate than the one
              evaluated inside this routine (if someone wants to do
              so).

 TAU          (output) DOUBLE PRECISION
              The root of the equation f(x).

 INFO         (output) INTEGER
              = 0: successful exit
              > 0: if INFO = 1, failure to converge

Further Details
===============

NAME
       DLAEXC  -  adjacent  diagonal  blocks T11 and T22 of order 1 or 2 in an
       upper quasi-triangular matrix T by an orthogonal similarity transforma-
       tion

SYNOPSIS
       SUBROUTINE DLAEXC( WANTQ, N, T, LDT, Q, LDQ, J1, N1, N2, WORK, INFO )

           LOGICAL        WANTQ

           INTEGER        INFO, J1, LDQ, LDT, N, N1, N2

           DOUBLE         PRECISION Q( LDQ, * ), T( LDT, * ), WORK( * )

PURPOSE
       DLAEXC swaps adjacent diagonal blocks T11 and T22 of order 1 or 2 in an
       upper quasi-triangular matrix T by an orthogonal similarity transforma-
       tion.

       T must be in Schur canonical form, that is, block upper triangular with
       1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block  has  its
       diagonal  elemnts equal and its off-diagonal elements of opposite sign.

ARGUMENTS
       WANTQ   (input) LOGICAL
               = .TRUE. : accumulate the transformation in the matrix Q;
```

```
              = .FALSE.: do not accumulate the transformation.

       N      (input) INTEGER
              The order of the matrix T. N >= 0.

       T      (input/output) DOUBLE PRECISION array, dimension (LDT,N)
              On entry, the upper quasi-triangular matrix T, in Schur canoni-
              cal form.  On exit, the updated matrix T, again in Schur canon-
              ical form.

       LDT    (input)  INTEGER
              The leading dimension of the array T. LDT >= max(1,N).

       Q      (input/output) DOUBLE PRECISION array, dimension (LDQ,N)
              On entry, if WANTQ is .TRUE., the orthogonal matrix Q.  On
              exit,  if  WANTQ  is .TRUE., the updated matrix Q.  If WANTQ is
              .FALSE., Q is not referenced.

       LDQ    (input) INTEGER
              The leading dimension of the array Q.  LDQ >= 1; and  if  WANTQ
              is .TRUE., LDQ >= N.

       J1     (input) INTEGER
              The index of the first row of the first block T11.

       N1     (input) INTEGER
              The order of the first block T11. N1 = 0, 1 or 2.

       N2     (input) INTEGER
              The order of the second block T22. N2 = 0, 1 or 2.

       WORK   (workspace) DOUBLE PRECISION array, dimension (N)

       INFO   (output) INTEGER
              = 0: successful exit
              = 1: the transformed matrix T would be too far from Schur form;
              the blocks are not swapped and T and Q are unchanged.
```

NAME
       DLAHQR - An auxiliary routine called by DHSEQR to update the  eigenval-
       ues and Schur decomposition already computed  by  DHSEQR,  by   dealing
       with the Hessenberg submatrix in rows and columns ILO to IHI

SYNOPSIS
       SUBROUTINE DLAHQR( WANTT,  WANTZ,  N,  ILO,  IHI, H, LDH, WR, WI, ILOZ,
                          IHIZ, Z, LDZ, INFO )

           INTEGER        IHI, IHIZ, ILO, ILOZ, INFO, LDH, LDZ, N

           LOGICAL        WANTT, WANTZ

           DOUBLE         PRECISION H( LDH, * ), WI( * ), WR( * ), Z( LDZ, * )

 Purpose
 =======

  DLAHQR is an auxiliary routine called by DHSEQR to update the
  eigenvalues and Schur decomposition already computed by DHSEQR, by
  dealing with the Hessenberg submatrix in rows and columns ILO to IHI.

 Arguments
 =========

  WANTT   (input) LOGICAL
          = .TRUE. : the full Schur form T is required;
          = .FALSE.: only eigenvalues are required.

  WANTZ   (input) LOGICAL
          = .TRUE. : the matrix of Schur vectors Z is required;
          = .FALSE.: Schur vectors are not required.

  N       (input) INTEGER
          The order of the matrix H.  N >= 0.

  ILO     (input) INTEGER
  IHI     (input) INTEGER
          It is assumed that H is already upper quasi-triangular in
          rows and columns IHI+1:N, and that H(ILO,ILO-1) = 0 (unless
          ILO = 1). DLAHQR works primarily with the Hessenberg
          submatrix in rows and columns ILO to IHI, but applies
          transformations to all of H if WANTT is .TRUE..
          1 <= ILO <= max(1,IHI); IHI <= N.

  H       (input/output) DOUBLE PRECISION array, dimension (LDH,N)
          On entry, the upper Hessenberg matrix H.
```

```
        On exit, if WANTT is .TRUE., H is upper quasi-triangular in
        rows and columns ILO:IHI, with any 2-by-2 diagonal blocks in
        standard form. If WANTT is .FALSE., the contents of H are
        unspecified on exit.

LDH     (input) INTEGER
        The leading dimension of the array H. LDH >= max(1,N).

WR      (output) DOUBLE PRECISION array, dimension (N)
WI      (output) DOUBLE PRECISION array, dimension (N)
        The real and imaginary parts, respectively, of the computed
        eigenvalues ILO to IHI are stored in the corresponding
        elements of WR and WI. If two eigenvalues are computed as a
        complex conjugate pair, they are stored in consecutive
        elements of WR and WI, say the i-th and (i+1)th, with
        WI(i) > 0 and WI(i+1) < 0. If WANTT is .TRUE., the
        eigenvalues are stored in the same order as on the diagonal
        of the Schur form returned in H, with WR(i) = H(i,i), and, if
        H(i:i+1,i:i+1) is a 2-by-2 diagonal block,
        WI(i) = sqrt(H(i+1,i)*H(i,i+1)) and WI(i+1) = -WI(i).

ILOZ    (input) INTEGER
IHIZ    (input) INTEGER
        Specify the rows of Z to which transformations must be
        applied if WANTZ is .TRUE..
        1 <= ILOZ <= ILO; IHI <= IHIZ <= N.

Z       (input/output) DOUBLE PRECISION array, dimension (LDZ,N)
        If WANTZ is .TRUE., on entry Z must contain the current
        matrix Z of transformations accumulated by DHSEQR, and on
        exit Z has been updated; transformations are applied only to
        the submatrix Z(ILOZ:IHIZ,ILO:IHI).
        If WANTZ is .FALSE., Z is not referenced.

LDZ     (input) INTEGER
        The leading dimension of the array Z. LDZ >= max(1,N).

INFO    (output) INTEGER
        = 0: successful exit
        > 0: DLAHQR failed to compute all the eigenvalues ILO to IHI
             in a total of 30*(IHI-ILO+1) iterations; if INFO = i,
             elements i+1:ihi of WR and WI contain those eigenvalues
             which have been successfully computed.

NAME
       DLAHRD  -  the first NB columns of a real general n-by-(n-k+1) matrix A
       so that elements below the k-th subdiagonal are zero

SYNOPSIS
       SUBROUTINE DLAHRD( N, K, NB, A, LDA, TAU, T, LDT, Y, LDY )

           INTEGER        K, LDA, LDT, LDY, N, NB

           DOUBLE         PRECISION A( LDA, * ), T( LDT, NB ), TAU( NB  ),  Y(
                          LDY, NB )

PURPOSE
       DLAHRD  reduces  the  first  NB  columns of a real general n-by-(n-k+1)
       matrix A so that elements below the  k-th  subdiagonal  are  zero.  The
       reduction  is performed by an orthogonal similarity transformation Q' *
       A * Q. The routine returns the matrices V and T which determine Q as  a
       block reflector I - V*T*V', and also the matrix Y = A * V * T.

       This is an OBSOLETE auxiliary routine.
       This routine will be 'deprecated' in a  future release.
       Please use the new routine DLAHR2 instead.

ARGUMENTS
       N       (input) INTEGER
               The order of the matrix A.

       K       (input) INTEGER
               The offset for the reduction. Elements below the k-th subdiago-
               nal in the first NB columns are reduced to zero.

       NB      (input) INTEGER
               The number of columns to be reduced.

       A       (input/output) DOUBLE PRECISION array, dimension (LDA,N-K+1)
               On entry, the n-by-(n-k+1) general matrix A.  On exit, the ele-
               ments on and above the k-th subdiagonal in the first NB columns
               are overwritten with the corresponding elements of the  reduced
               matrix; the elements below the k-th subdiagonal, with the array
               TAU, represent the matrix Q as a product of elementary  reflec-
               tors.  The  other  columns  of  A  are  unchanged.  See Further
```

```
          Details.  LDA     (input) INTEGER The leading dimension of  the
          array A.  LDA >= max(1,N).

      TAU     (output) DOUBLE PRECISION array, dimension (NB)
          The  scalar  factors  of the elementary reflectors. See Further
          Details.

      T       (output) DOUBLE PRECISION array, dimension (LDT,NB)
          The upper triangular matrix T.

      LDT     (input) INTEGER
          The leading dimension of the array T.  LDT >= NB.

      Y       (output) DOUBLE PRECISION array, dimension (LDY,NB)
          The n-by-nb matrix Y.

      LDY     (input) INTEGER
          The leading dimension of the array Y. LDY >= N.

FURTHER DETAILS
      The matrix Q is represented as a product of nb elementary reflectors

         Q = H(1) H(2) . . . H(nb).

      Each H(i) has the form

         H(i) = I - tau * v * v'

      where tau is a real scalar, and v is a real vector with
      v(1:i+k-1)  =  0,  v(i+k)  =  1;  v(i+k+1:n)  is  stored  on  exit  in
      A(i+k+1:n,i), and tau in TAU(i).

      The  elements of the vectors v together form the (n-k+1)-by-nb matrix V
      which is needed, with T and Y, to apply the transformation to the unre-
      duced  part  of  the  matrix,  using  an  update of the form: A := (I -
      V*T*V') * (A - Y*V').

      The contents of A on exit are illustrated by the following example with
      n = 7, k = 3 and nb = 2:

         ( a   h   a   a   a )
         ( a   h   a   a   a )
         ( a   h   a   a   a )
         ( h   h   a   a   a )
         ( v1  h   a   a   a )
         ( v1  v2  a   a   a )
         ( v1  v2  a   a   a )

      where  a denotes an element of the original matrix A, h denotes a modi-
      fied element of the upper Hessenberg matrix H, and vi denotes  an  ele-
```

ment of the vector defining H(i).

      LOGICAL FUNCTION DLAISNAN( DIN1, DIN2 )

      .. Scalar Arguments ..
      DOUBLE PRECISION   DIN1, DIN2
      ..

 Purpose:
 =============

 This routine is not for general use.  It exists solely to avoid
 over-optimization in DISNAN.
```

```
DLAISNAN checks for NaNs by comparing its two arguments for
inequality.  NaN is the only floating-point value where NaN != NaN
returns .TRUE.  To check for NaNs, pass the same variable as both
arguments.

A compiler must assume that the two arguments are
not the same variable, and the test will not be optimized away.
Interprocedural or whole-program optimization may delete this
test.  The ISNAN functions will be replaced by the correct
Fortran 03 intrinsic once the intrinsic is widely available.

 Arguments:
 ==========

 [in] DIN1
        DIN1 is DOUBLE PRECISION

 [in] DIN2
        DIN2 is DOUBLE PRECISION
        Two numbers to compare for inequality.

NAME
       DLALN2  - a system of the form (ca A - w D ) X = s B or (ca A' - w D) X
       = s B with possible scaling ("s") and perturbation of A
```

```
SYNOPSIS
       SUBROUTINE DLALN2( LTRANS, NA, NW, SMIN, CA, A, LDA, D1,  D2,  B,  LDB,
                          WR, WI, X, LDX, SCALE, XNORM, INFO )

           LOGICAL        LTRANS

           INTEGER        INFO, LDA, LDB, LDX, NA, NW

           DOUBLE         PRECISION CA, D1, D2, SCALE, SMIN, WI, WR, XNORM

           DOUBLE         PRECISION A( LDA, * ), B( LDB, * ), X( LDX, * )

 Purpose
 =======

  DLALN2 solves a system of the form  (ca A - w D ) X = s B
  or (ca A' - w D) X = s B   with possible scaling ("s") and
  perturbation of A.  (A' means A-transpose.)

  A is an NA x NA real matrix, ca is a real scalar, D is an NA x NA
  real diagonal matrix, w is a real or complex value, and X and B are
  NA x 1 matrices -- real if w is real, complex if w is complex.  NA
  may be 1 or 2.

  If w is complex, X and B are represented as NA x 2 matrices,
  the first column of each being the real part and the second
  being the imaginary part.

  "s" is a scaling factor (.LE. 1), computed by DLALN2, which is
  so chosen that X can be computed without overflow.  X is further
  scaled if necessary to assure that norm(ca A - w D)*norm(X) is less
  than overflow.

  If both singular values of (ca A - w D) are less than SMIN,
  SMIN*identity will be used instead of (ca A - w D).  If only one
  singular value is less than SMIN, one element of (ca A - w D) will be
  perturbed enough to make the smallest singular value roughly SMIN.
  If both singular values are at least SMIN, (ca A - w D) will not be
  perturbed.  In any case, the perturbation will be at most some small
  multiple of max( SMIN, ulp*norm(ca A - w D) ).  The singular values
  are computed by infinity-norm approximations, and thus will only be
  correct to a factor of 2 or so.

  Note: all input quantities are assumed to be smaller than overflow
  by a reasonable factor.  (See BIGNUM.)

 Arguments
 ==========

  LTRANS  (input) LOGICAL
```

```
        =.TRUE.:  A-transpose will be used.
        =.FALSE.: A will be used (not transposed.)

NA      (input) INTEGER
        The size of the matrix A.  It may (only) be 1 or 2.

NW      (input) INTEGER
        1 if "w" is real, 2 if "w" is complex.  It may only be 1
        or 2.

SMIN    (input) DOUBLE PRECISION
        The desired lower bound on the singular values of A.  This
        should be a safe distance away from underflow or overflow,
        say, between (underflow/machine precision) and  (machine
        precision * overflow ).  (See BIGNUM and ULP.)

CA      (input) DOUBLE PRECISION
        The coefficient c, which A is multiplied by.

A       (input) DOUBLE PRECISION array, dimension (LDA,NA)
        The NA x NA matrix A.

LDA     (input) INTEGER
        The leading dimension of A.  It must be at least NA.

D1      (input) DOUBLE PRECISION
        The 1,1 element in the diagonal matrix D.

D2      (input) DOUBLE PRECISION
        The 2,2 element in the diagonal matrix D.  Not used if NW=1.

B       (input) DOUBLE PRECISION array, dimension (LDB,NW)
        The NA x NW matrix B (right-hand side).  If NW=2 ("w" is
        complex), column 1 contains the real part of B and column 2
        contains the imaginary part.

LDB     (input) INTEGER
        The leading dimension of B.  It must be at least NA.

WR      (input) DOUBLE PRECISION
        The real part of the scalar "w".

WI      (input) DOUBLE PRECISION
        The imaginary part of the scalar "w".  Not used if NW=1.

X       (output) DOUBLE PRECISION array, dimension (LDX,NW)
        The NA x NW matrix X (unknowns), as computed by DLALN2.
        If NW=2 ("w" is complex), on exit, column 1 will contain
        the real part of X and column 2 will contain the imaginary
        part.
```

```
  LDX     (input) INTEGER
          The leading dimension of X.  It must be at least NA.

  SCALE   (output) DOUBLE PRECISION
          The scale factor that B must be multiplied by to insure
          that overflow does not occur when computing X.  Thus,
          (ca A - w D) X  will be SCALE*B, not B (ignoring
          perturbations of A.)  It will be at most 1.

  XNORM   (output) DOUBLE PRECISION
          The infinity-norm of X, when X is regarded as an NA x NW
          real matrix.

  INFO    (output) INTEGER
          An error flag.  It will be set to zero if no error occurs,
          a negative number if an argument is in error, or a positive
          number if  ca A - w D  had to be perturbed.
          The possible values are:
          = 0: No error occurred, and (ca A - w D) did not have to be
                 perturbed.
          = 1: (ca A - w D) had to be perturbed to make its smallest
               (or only) singular value greater than SMIN.
          NOTE: In the interests of speed, this routine does not
                check the inputs for errors.

NAME
       DLAMCH - determine double precision machine parameters

SYNOPSIS
       DOUBLE PRECISION FUNCTION DLAMCH( CMACH )

           CHARACTER    CMACH

 Purpose
 =======
```

```
 DLAMCH determines double precision machine parameters.

Arguments
=========

 CMACH   (input) CHARACTER*1
         Specifies the value to be returned by DLAMCH:
         = 'E' or 'e',   DLAMCH := eps
         = 'S' or 's' ,  DLAMCH := sfmin
         = 'B' or 'b',   DLAMCH := base
         = 'P' or 'p',   DLAMCH := eps*base
         = 'N' or 'n',   DLAMCH := t
         = 'R' or 'r',   DLAMCH := rnd
         = 'M' or 'm',   DLAMCH := emin
         = 'U' or 'u',   DLAMCH := rmin
         = 'L' or 'l',   DLAMCH := emax
         = 'O' or 'o',   DLAMCH := rmax

         where

         eps   = relative machine precision
         sfmin = safe minimum, such that 1/sfmin does not overflow
         base  = base of the machine
         prec  = eps*base
         t     = number of (base) digits in the mantissa
         rnd   = 1.0 when rounding occurs in addition, 0.0 otherwise
         emin  = minimum exponent before (gradual) underflow
         rmin  = underflow threshold - base**(emin-1)
         emax  = largest exponent before overflow
         rmax  = overflow threshold  - (base**emax)*(1-eps)
```

  -- LAPACK auxiliary routine (version 1.1) --
     Univ. of Tennessee, Univ. of California Berkeley, NAG Ltd.,
     Courant Institute, Argonne National Lab, and Rice University
     October 31, 1992

     .. Scalar Arguments ..
<       LOGICAL            IEEE1, RND >
<       INTEGER            BETA, T >
     ..

  Purpose
  =======

  DLAMC1 determines the machine parameters given by BETA, T, RND, and
  IEEE1.

  Arguments
  =========

  BETA    (output) INTEGER
          The base of the machine.

  T       (output) INTEGER
          The number of ( BETA ) digits in the mantissa.

  RND     (output) LOGICAL
          Specifies whether proper rounding  ( RND = .TRUE. )  or
          chopping  ( RND = .FALSE. )  occurs in addition. This may not
          be a reliable guide to the way in which the machine performs
          its arithmetic.

  IEEE1   (output) LOGICAL
          Specifies whether rounding appears to be done in the IEEE
          'round to nearest' style.

  Further Details
  ===============

*
      IF( FIRST ) THEN
         FIRST = .FALSE.
         ONE = 1
*
*        LBETA,  LIEEE1,  LT and  LRND  are the  local values  of  BETA,
*        IEEE1, T and RND.
*
*        Throughout this routine  we use the function  DLAMC3  to ensure
*        that relevant values are  stored and not held in registers,  or
*        are not affected by optimizers.
*
*        Compute  a = 2.0**m  with the  smallest positive integer m such
```

```
*        that
*
*          fl( a + 1.0 ) = a.
*
         A = 1
         C = 1
*
*+       WHILE( C.EQ.ONE )LOOP
   10    CONTINUE
         IF( C.EQ.ONE ) THEN
            A = 2*A
            C = DLAMC3( A, ONE )
            C = DLAMC3( C, -A )
            GO TO 10
         END IF
*+       END WHILE
*
*        Now compute  b = 2.0**m  with the smallest positive integer m
*        such that
*
*          fl( a + b ) .gt. a.
*
         B = 1
         C = DLAMC3( A, B )
*
*+       WHILE( C.EQ.A )LOOP
   20    CONTINUE
         IF( C.EQ.A ) THEN
            B = 2*B

            GO TO 20
         END IF
*+       END WHILE
*
*        Now compute the base.  a and c  are neighbouring floating point
*        numbers  in the  interval  ( beta**t, beta**( t + 1 ) )  and so
*        their difference is beta. Adding 0.25 to c is to ensure that it
*        is truncated to beta and not ( beta - 1 ).
*
         QTR = ONE / 4
         SAVEC = C
         C = DLAMC3( C, -A )
         LBETA = C + QTR
*
*        Now determine whether rounding or chopping occurs,  by adding a
*        bit  less  than  beta/2  and a  bit  more  than  beta/2  to  a.
*
         B = LBETA
         F = DLAMC3( B / 2, -B / 100 )
         C = DLAMC3( F, A )
```

```
         IF( C.EQ.A ) THEN
            LRND = .TRUE.
         ELSE
            LRND = .FALSE.
         END IF
         F = DLAMC3( B / 2, B / 100 )
         C = DLAMC3( F, A )
         IF( ( LRND ) .AND. ( C.EQ.A ) )
     $      LRND = .FALSE.
*
*        Try and decide whether rounding is done in the  IEEE  'round to
*        nearest' style. B/2 is half a unit in the last place of the two
*        numbers A and SAVEC. Furthermore, A is even, i.e. has last  bit
*        zero, and SAVEC is odd. Thus adding B/2 to A should not  change
*        A, but adding B/2 to SAVEC should change SAVEC.
*
         T1 = DLAMC3( B / 2, A )
         T2 = DLAMC3( B / 2, SAVEC )
         LIEEE1 = ( T1.EQ.A ) .AND. ( T2.GT.SAVEC ) .AND. LRND
*
*        Now find  the  mantissa, t.  It should  be the  integer part of
*        log to the base beta of a,  however it is safer to determine  t
*        by powering.  So we find t as the smallest positive integer for
*        which
*
*           fl( beta**t + 1.0 ) = 1.0.
*

  -- LAPACK auxiliary routine (version 1.1) --
     Univ. of Tennessee, Univ. of California Berkeley, NAG Ltd.,
     Courant Institute, Argonne National Lab, and Rice University
     October 31, 1992

     .. Scalar Arguments ..
<       LOGICAL            RND >
<       INTEGER            BETA, EMAX, EMIN, T >
<       DOUBLE PRECISION   EPS, RMAX, RMIN >
     ..

  Purpose
  =======

  DLAMC2 determines the machine parameters specified in its argument
  list.

  Arguments
  =========

  BETA    (output) INTEGER
          The base of the machine.

  T       (output) INTEGER
          The number of ( BETA ) digits in the mantissa.

  RND     (output) LOGICAL
```

```
          Specifies whether proper rounding  ( RND = .TRUE. )  or
          chopping  ( RND = .FALSE. )  occurs in addition. This may not
          be a reliable guide to the way in which the machine performs
          its arithmetic.

  EPS     (output) DOUBLE PRECISION
          The smallest positive number such that

             fl( 1.0 - EPS ) .LT. 1.0,

          where fl denotes the computed value.

  EMIN    (output) INTEGER
          The minimum exponent before (gradual) underflow occurs.

  RMIN    (output) DOUBLE PRECISION
          The smallest normalized number for the machine, given by
          BASE**( EMIN - 1 ), where  BASE  is the floating point value
          of BETA.

  EMAX    (output) INTEGER
          The maximum exponent before overflow occurs.

  RMAX    (output) DOUBLE PRECISION
          The largest positive number for the machine, given by
          BASE**EMAX * ( 1 - EPS ), where  BASE  is the floating point
          value of BETA.

  Further Details
  ===============

  The computation of  EPS  is based on a routine PARANOIA by
  W. Kahan of the University of California at Berkeley.

  -- LAPACK auxiliary routine (version 1.1) --
     Univ. of Tennessee, Univ. of California Berkeley, NAG Ltd.,
     Courant Institute, Argonne National Lab, and Rice University
     October 31, 1992

     .. Scalar Arguments ..
<       DOUBLE PRECISION   A, B >
     ..

  Purpose
  =======

  DLAMC3  is intended to force  A  and  B  to be stored prior to doing
  the addition of  A  and  B ,  for use in situations where optimizers
  might hold one of these in a register.

  Arguments
  =========

  A, B    (input) DOUBLE PRECISION
          The values A and B.
```

     October 31, 1992

     .. Scalar Arguments ..
<       INTEGER            BASE, EMIN >
<       DOUBLE PRECISION   START >
     ..

  Purpose
  =======

  DLAMC4 is a service routine for DLAMC2.

  Arguments
  =========

  EMIN    (output) EMIN
          The minimum exponent before (gradual) underflow, computed by
          setting A = START and dividing by BASE until the previous A
          can not be recovered.

  START   (input) DOUBLE PRECISION
          The starting point for determining EMIN.

  BASE    (input) INTEGER
```

The base of the machine.

  -- LAPACK auxiliary routine (version 1.1) --
     Univ. of Tennessee, Univ. of California Berkeley, NAG Ltd.,
     Courant Institute, Argonne National Lab, and Rice University
     October 31, 1992

     .. Scalar Arguments ..
<       LOGICAL            IEEE >
<       INTEGER            BETA, EMAX, EMIN, P >
<       DOUBLE PRECISION   RMAX >
     ..

  Purpose
  =======

  DLAMC5 attempts to compute RMAX, the largest machine floating-point
  number, without overflow.  It assumes that EMAX + abs(EMIN) sum
  approximately to a power of 2.  It will fail on machines where this
  assumption does not hold, for example, the Cyber 205 (EMIN = -28625,
  EMAX = 28718).  It will also fail if the value supplied for EMIN is
  too large (i.e. too close to zero), probably with overflow.

  Arguments
  =========

  BETA    (input) INTEGER
```

```
          The base of floating-point arithmetic.

  P       (input) INTEGER
          The number of base BETA digits in the mantissa of a
          floating-point value.

  EMIN    (input) INTEGER
          The minimum exponent before (gradual) underflow.

  IEEE    (input) LOGICAL
          A logical flag specifying whether or not the arithmetic
          system is thought to comply with the IEEE standard.

  EMAX    (output) INTEGER
          The largest exponent before overflow

  RMAX    (output) DOUBLE PRECISION
          The largest machine floating-point number.
```

*     ..
*     .. Intrinsic Functions ..
      INTRINSIC          MOD
*     ..
*     .. Executable Statements ..
*
*     First compute LEXP and UEXP, two powers of 2 that bound
*     abs(EMIN). We then assume that EMAX + abs(EMIN) will sum
*     approximately to the bound that is closest to abs(EMIN).
*     (EMAX is the exponent of the required number RMAX).
*
      LEXP = 1
      EXBITS = 1
   10 CONTINUE
      TRY = LEXP*2
      IF( TRY.LE.( -EMIN ) ) THEN
         LEXP = TRY
         EXBITS = EXBITS + 1
         GO TO 10
      END IF
      IF( LEXP.EQ.-EMIN ) THEN
         UEXP = LEXP
      ELSE
         UEXP = TRY
         EXBITS = EXBITS + 1
      END IF
*
*     Now -LEXP is less than or equal to EMIN, and -UEXP is greater
*     than or equal to EMIN. EXBITS is the number of bits needed to
*     store the exponent.
*
      IF( ( UEXP+EMIN ).GT.( -LEXP-EMIN ) ) THEN
         EXPSUM = 2*LEXP
      ELSE
         EXPSUM = 2*UEXP
      END IF
*
*     EXPSUM is the exponent range, approximately equal to
*     EMAX - EMIN + 1 .
*
      EMAX = EXPSUM + EMIN - 1
      NBITS = 1 + EXBITS + P
*
*     NBITS is the total number of bits needed to store a
*     floating-point number.
*
      IF( ( MOD( NBITS, 2 ).EQ.1 ) .AND. ( BETA.EQ.2 ) ) THEN
```

```
*
*        Either there are an odd number of bits used to store a
*        floating-point number, which is unlikely, or some bits are
*        not used in the representation of numbers, which is possible,
*        (e.g. Cray machines) or the mantissa has an implicit bit,
*        (e.g. IEEE machines, Dec Vax machines), which is perhaps the
*        most likely. We have to assume the last alternative.
*        If this is true, then we need to reduce EMAX by one because
*        there must be some way of representing zero in an implicit-bit
*        system. On machines like Cray, we are reducing EMAX by one
*        unnecessarily.
*
         EMAX = EMAX - 1
      END IF
*
      IF( IEEE ) THEN
*
*        Assume we are on an IEEE machine which reserves one exponent
*        for infinity and NaN.
*
         EMAX = EMAX - 1
      END IF
*
*     Now create RMAX, the largest machine number, which should
*     be equal to (1.0 - BETA**(-P)) * BETA**EMAX .
*
*     First compute 1.0 - BETA**(-P), being careful that the
*     result is less than 1.0 .
*
      RECBAS = ONE / BETA
      Z = BETA - ONE
      Y = ZERO
      DO 20 I = 1, P
         Z = Z*RECBAS

NAME
       DLAMRG  -  create a permutation list which will merge the elements of A
       (which is composed of two independently sorted sets) into a single  set
       which is sorted in ascending order

SYNOPSIS
       SUBROUTINE DLAMRG( N1, N2, A, DTRD1, DTRD2, INDEX )

           INTEGER        DTRD1, DTRD2, N1, N2

           INTEGER        INDEX( * )

           DOUBLE         PRECISION A( * )

 Purpose
 =======

  DLAMRG will create a permutation list which will merge the elements
  of A (which is composed of two independently sorted sets) into a
  single set which is sorted in ascending order.

 Arguments
 =========

  N1     (input) INTEGER
  N2     (input) INTEGER
         These arguements contain the respective lengths of the two
         sorted lists to be merged.

  A      (input) DOUBLE PRECISION array, dimension (N1+N2)
         The first N1 elements of A contain a list of numbers which
         are sorted in either ascending or descending order.  Likewise
         for the final N2 elements.

  DTRD1  (input) INTEGER
  DTRD2  (input) INTEGER
         These are the strides to be taken through the array A.
```

```
        Allowable strides are 1 and -1.  They indicate whether a
        subset of A is sorted in ascending (DTRDx = 1) or descending
        (DTRDx = -1) order.

  INDX  (output) INTEGER array, dimension (N1+N2)
        On exit this array will contain a permutation such that
        if B( I ) = A( INDX( I ) ) for I=1,N1+N2, then B will be
        sorted in ascending order.
```

NAME
       DLANGE  -  the  value  of  the  one norm, or the Frobenius norm, or the
       infinity norm, or the element of  largest  absolute  value  of  a  real
       matrix A

SYNOPSIS
       DOUBLE PRECISION FUNCTION DLANGE( NORM, M, N, A, LDA, WORK )

           CHARACTER    NORM

           INTEGER      LDA, M, N

           DOUBLE       PRECISION A( LDA, * ), WORK( * )

PURPOSE
       DLANGE   returns  the value of the one norm,  or the Frobenius norm, or
       the  infinity norm,  or the  element of  largest absolute value   of  a
       real matrix A.
```

```
DESCRIPTION
       DLANGE returns the value

          DLANGE = ( max(abs(A(i,j))), NORM = 'M' or 'm'
                   (
                   ( norm1(A),         NORM = '1', 'O' or 'o'
                   (
                   ( normI(A),         NORM = 'I' or 'i'
                   (
                   ( normF(A),         NORM = 'F', 'f', 'E' or 'e'

       where  norm1  denotes the  one norm of a matrix (maximum column sum),
       normI  denotes the  infinity norm  of a matrix  (maximum row  sum)  and
       normF  denotes  the  Frobenius norm of a matrix (square root of sum of
       squares).  Note that  max(abs(A(i,j)))  is  not  a  consistent  matrix
       norm.

ARGUMENTS
       NORM    (input) CHARACTER*1
               Specifies  the  value  to  be  returned  in DLANGE as described
               above.

       M       (input) INTEGER
               The number of rows of the matrix A.  M  >=  0.  When  M  =  0,
               DLANGE is set to zero.

       N       (input) INTEGER
               The  number  of  columns of the matrix A.  N >= 0.  When N = 0,
               DLANGE is set to zero.

       A       (input) DOUBLE PRECISION array, dimension (LDA,N)
               The m by n matrix A.

       LDA     (input) INTEGER
               The leading dimension of the array A.  LDA >= max(M,1).

       WORK    (workspace) DOUBLE PRECISION array, dimension (MAX(1,LWORK)),
               where LWORK >= M when NORM = 'I'; otherwise, WORK is not refer-
               enced.

NAME
       DLANHS  -  the  value  of  the  one norm, or the Frobenius norm, or the
       infinity norm, or the element of largest absolute value of a Hessenberg
       matrix A

SYNOPSIS
       DOUBLE PRECISION FUNCTION DLANHS( NORM, N, A, LDA, WORK )

           CHARACTER    NORM

           INTEGER      LDA, N

           DOUBLE       PRECISION A( LDA, * ), WORK( * )

PURPOSE
       DLANHS   returns  the value of the one norm,  or the Frobenius norm, or
       the  infinity norm,  or the  element of  largest absolute value   of  a
       Hessenberg matrix A.
```

```
DESCRIPTION
       DLANHS returns the value

          DLANHS = ( max(abs(A(i,j))), NORM = 'M' or 'm'
                   (
                   ( norm1(A),         NORM = '1', 'O' or 'o'
                   (
                   ( normI(A),         NORM = 'I' or 'i'
                   (
                   ( normF(A),         NORM = 'F', 'f', 'E' or 'e'

       where  norm1  denotes the  one norm of a matrix (maximum column sum),
       normI  denotes the  infinity norm  of a matrix  (maximum row  sum)  and
       normF  denotes  the  Frobenius norm of a matrix (square root of sum of
       squares).  Note that  max(abs(A(i,j)))  is  not  a  consistent  matrix
       norm.

ARGUMENTS
       NORM    (input) CHARACTER*1
               Specifies  the  value  to  be  returned  in DLANHS as described
               above.

       N       (input) INTEGER
               The order of the matrix A.  N >= 0.  When N = 0, DLANHS is  set
               to zero.

       A       (input) DOUBLE PRECISION array, dimension (LDA,N)
               The  n  by n upper Hessenberg matrix A; the part of A below the
               first sub-diagonal is not referenced.

       LDA     (input) INTEGER
               The leading dimension of the array A.  LDA >= max(N,1).

       WORK    (workspace) DOUBLE PRECISION array, dimension (MAX(1,LWORK)),
               where LWORK >= N when NORM = 'I'; otherwise, WORK is not refer-
               enced.

NAME
       DLANST  -  the  value  of  the  one norm, or the Frobenius norm, or the
       infinity norm, or the element of largest absolute value of a real  sym-
       metric tridiagonal matrix A
```

```
SYNOPSIS
       DOUBLE PRECISION FUNCTION DLANST( NORM, N, D, E )

           CHARACTER    NORM

           INTEGER      N

           DOUBLE       PRECISION D( * ), E( * )

PURPOSE
       DLANST  returns  the value of the one norm,  or the Frobenius norm, or
       the  infinity norm,  or the  element of  largest absolute value  of  a
       real symmetric tridiagonal matrix A.

DESCRIPTION
       DLANST returns the value

          DLANST = ( max(abs(A(i,j))), NORM = 'M' or 'm'
                   (
                   ( norm1(A),         NORM = '1', 'O' or 'o'
                   (
                   ( normI(A),         NORM = 'I' or 'i'
                   (
                   ( normF(A),         NORM = 'F', 'f', 'E' or 'e'

       where  norm1  denotes the  one norm of a matrix (maximum column sum),
       normI  denotes the  infinity norm  of a matrix  (maximum row  sum)  and
       normF  denotes  the  Frobenius norm of a matrix (square root of sum of
       squares).  Note that  max(abs(A(i,j)))  is  not  a  consistent  matrix
       norm.

ARGUMENTS
       NORM    (input) CHARACTER*1
               Specifies  the  value  to  be  returned  in DLANST as described
               above.

       N       (input) INTEGER
               The order of the matrix A.  N >= 0.  When N = 0, DLANST is  set
               to zero.

       D       (input) DOUBLE PRECISION array, dimension (N)
               The diagonal elements of A.

       E       (input) DOUBLE PRECISION array, dimension (N-1)
               The (n-1) sub-diagonal or super-diagonal elements of A.
```

NAME
       DLANV2  -  the Schur factorization of a real 2-by-2 nonsymmetric matrix
       in standard form

SYNOPSIS
       SUBROUTINE DLANV2( A, B, C, D, RT1R, RT1I, RT2R, RT2I, CS, SN )

           DOUBLE         PRECISION A, B, C, CS, D, RT1I, RT1R, RT2I, RT2R, SN

 Purpose
 =======

  DLANV2 computes the Schur factorization of a real 2-by-2 nonsymmetric
  matrix in standard form:

       [ A  B ] = [ CS -SN ] [ AA  BB ] [ CS  SN ]
       [ C  D ]   [ SN  CS ] [ CC  DD ] [-SN  CS ]

  where either
  1) CC = 0 so that AA and DD are real eigenvalues of the matrix, or
  2) AA = DD and BB*CC < 0, so that AA + or - sqrt(BB*CC) are complex
  conjugate eigenvalues.

 Arguments
 =========

  A       (input/output) DOUBLE PRECISION
  B       (input/output) DOUBLE PRECISION
  C       (input/output) DOUBLE PRECISION
  D       (input/output) DOUBLE PRECISION
          On entry, the elements of the input matrix.
          On exit, they are overwritten by the elements of the
```

```
          standardised Schur form.

  RT1R    (output) DOUBLE PRECISION
  RT1I    (output) DOUBLE PRECISION
  RT2R    (output) DOUBLE PRECISION
  RT2I    (output) DOUBLE PRECISION
          The real and imaginary parts of the eigenvalues. If the
          eigenvalues are a complex conjugate pair, RT1I > 0.

  CS      (output) DOUBLE PRECISION
  SN      (output) DOUBLE PRECISION
          Parameters of the rotation matrix.

  Further Details
  ===============

  Modified by V. Sima, Research Institute for Informatics, Bucharest,
  Romania, to reduce the risk of cancellation errors,
  when computing real eigenvalues, and to ensure, if possible, that
  abs(RT1R) >= abs(RT2R).
```

      DOUBLE PRECISION FUNCTION DLAPY3( X, Y, Z )

      .. Scalar Arguments ..
      DOUBLE PRECISION   X, Y, Z
      ..

 Purpose:
 =============

 DLAPY3 returns sqrt(x**2+y**2+z**2), taking care not to cause
 unnecessary overflow.

 Arguments:
 ==========

 [in] X
          X is DOUBLE PRECISION

 [in] Y
          Y is DOUBLE PRECISION

 [in] Z
          Z is DOUBLE PRECISION
          X, Y and Z specify the values x, y and z.

NAME
       DLAQTR - the real quasi-triangular system   op(T)*p = scale*c, if LREAL
       = .TRUE

SYNOPSIS
       SUBROUTINE DLAQTR( LTRAN, LREAL, N, T, LDT, B, W, SCALE, X, WORK,  INFO
                          )

           LOGICAL         LREAL, LTRAN

           INTEGER         INFO, LDT, N

           DOUBLE          PRECISION SCALE, W

           DOUBLE          PRECISION B( * ), T( LDT, * ), WORK( * ), X( * )

 Purpose
 =======

  DLAQTR solves the real quasi-triangular system

               op(T)*p = scale*c,               if LREAL = .TRUE.

  or the complex quasi-triangular systems

             op(T + iB)*(p+iq) = scale*(c+id),  if LREAL = .FALSE.

  in real arithmetic, where T is upper quasi-triangular.
  If LREAL = .FALSE., then the first diagonal block of T must be
  1 by 1, B is the specially structured matrix

                 B = [ b(1) b(2) ... b(n) ]
                     [       w            ]
                     [           w        ]
                     [              .     ]
                     [                 w  ]

  op(A) = A or A', A' denotes the conjugate transpose of
  matrix A.

  On input, X = [ c ].  On output, X = [ p ].
                [ d ]                  [ q ]
```

```
 This subroutine is designed for the condition number estimation
 in routine DTRSNA.

Arguments
=========

 LTRAN   (input) LOGICAL
         On entry, LTRAN specifies the option of conjugate transpose:
            = .FALSE.,    op(T+i*B) = T+i*B,
            = .TRUE.,     op(T+i*B) = (T+i*B)'.

 LREAL   (input) LOGICAL
         On entry, LREAL specifies the input matrix structure:
            = .FALSE.,    the input is complex
            = .TRUE.,     the input is real

 N       (input) INTEGER
         On entry, N specifies the order of T+i*B. N >= 0.

 T       (input) DOUBLE PRECISION array, dimension (LDT,N)
         On entry, T contains a matrix in Schur canonical form.
         If LREAL = .FALSE., then the first diagonal block of T mu
         be 1 by 1.

 LDT     (input) INTEGER
         The leading dimension of the matrix T. LDT >= max(1,N).

 B       (input) DOUBLE PRECISION array, dimension (N)
         On entry, B contains the elements to form the matrix
         B as described above.
         If LREAL = .TRUE., B is not referenced.

 W       (input) DOUBLE PRECISION
         On entry, W is the diagonal element of the matrix B.
         If LREAL = .TRUE., W is not referenced.

 SCALE   (output) DOUBLE PRECISION
         On exit, SCALE is the scale factor.

 X       (input/output) DOUBLE PRECISION array, dimension (2*N)
         On entry, X contains the right hand side of the system.
         On exit, X is overwritten by the solution.

 WORK    (workspace) DOUBLE PRECISION array, dimension (N)

 INFO    (output) INTEGER
         On exit, INFO is set to
            0: successful exit.
              1: the some diagonal 1 by 1 block has been perturbed by
```

```
                a small number SMIN to keep nonsingularity.
             2: the some diagonal 2 by 2 block has been perturbed by
                a small number in DLALN2 to keep nonsingularity.
          NOTE: In the interests of speed, this routine does not
                check the inputs for errors.

NAME
       DLARFB  - a real block reflector H or its transpose H' to a real m by n
       matrix C, from either the left or the right

SYNOPSIS
       SUBROUTINE DLARFB( SIDE, TRANS, DIRECT, STOREV, M, N,  K,  V,  LDV,  T,
                          LDT, C, LDC, WORK, LDWORK )

           CHARACTER      DIRECT, SIDE, STOREV, TRANS

           INTEGER        K, LDC, LDT, LDV, LDWORK, M, N

           DOUBLE         PRECISION  C(  LDC,  *  ), T( LDT, * ), V( LDV, * ),
                          WORK( LDWORK, * )

 Purpose
 =======

  DLARFB applies a real block reflector H or its transpose H' to a
  real m by n matrix C, from either the left or the right.

 Arguments
 =========

  SIDE    (input) CHARACTER*1
          = 'L': apply H or H' from the Left
          = 'R': apply H or H' from the Right

  TRANS   (input) CHARACTER*1
```

```
          = 'N': apply H (No transpose)
          = 'T': apply H' (Transpose)

  DIRECT  (input) CHARACTER*1
          Indicates how H is formed from a product of elementary
          reflectors
          = 'F': H = H(1) H(2) . . . H(k) (Forward)
          = 'B': H = H(k) . . . H(2) H(1) (Backward)

  STOREV  (input) CHARACTER*1
          Indicates how the vectors which define the elementary
          reflectors are stored:
          = 'C': Columnwise
          = 'R': Rowwise

  M       (input) INTEGER
          The number of rows of the matrix C.

  N       (input) INTEGER
          The number of columns of the matrix C.

  K       (input) INTEGER
          The order of the matrix T (= the number of elementary
          reflectors whose product defines the block reflector).

  V       (input) DOUBLE PRECISION array, dimension
                                (LDV,K) if STOREV = 'C'
                                (LDV,M) if STOREV = 'R' and SIDE = 'L'
                                (LDV,N) if STOREV = 'R' and SIDE = 'R'
          The matrix V. See further details.

  LDV     (input) INTEGER
          The leading dimension of the array V.
          If STOREV = 'C' and SIDE = 'L', LDV >= max(1,M);
          if STOREV = 'C' and SIDE = 'R', LDV >= max(1,N);
          if STOREV = 'R', LDV >= K.

  T       (input) DOUBLE PRECISION array, dimension (LDT,K)
          The triangular k by k matrix T in the representation of the
          block reflector.

  LDT     (input) INTEGER
          The leading dimension of the array T. LDT >= K.

  C       (input/output) DOUBLE PRECISION array, dimension (LDC,N)
          On entry, the m by n matrix C.
          On exit, C is overwritten by H*C or H'*C or C*H or C*H'.

  LDC     (input) INTEGER
          The leading dimension of the array C. LDA >= max(1,M).
```

```
  WORK    (workspace) DOUBLE PRECISION array, dimension (LDWORK,K)

  LDWORK  (input) INTEGER
          The leading dimension of the array WORK.
          If SIDE = 'L', LDWORK >= max(1,N);
          if SIDE = 'R', LDWORK >= max(1,M).
```

NAME
       DLARFG  -  a  real elementary reflector H of order n, such that   H * (
       alpha ) = ( beta ), H' * H = I

SYNOPSIS
       SUBROUTINE DLARFG( N, ALPHA, X, INCX, TAU )

           INTEGER        INCX, N

           DOUBLE         PRECISION ALPHA, TAU

           DOUBLE         PRECISION X( * )

 Purpose
 =======

  DLARFG generates a real elementary reflector H of order n, such
  that

        H * ( alpha ) = ( beta ),   H' * H = I.
            (   x   )   (   0  )

  where alpha and beta are scalars, and x is an (n-1)-element real
  vector. H is represented in the form

        H = I - tau * ( 1 ) * ( 1 v' ) ,
                      ( v )

  where tau is a real scalar and v is a real (n-1)-element
  vector.

  If the elements of x are all zero, then tau = 0 and H is taken to be
  the unit matrix.
```

```
  Otherwise  1 <= tau <= 2.

 Arguments
 =========

  N       (input) INTEGER
          The order of the elementary reflector.

  ALPHA   (input/output) DOUBLE PRECISION
          On entry, the value alpha.
          On exit, it is overwritten with the value beta.

  X       (input/output) DOUBLE PRECISION array, dimension
                         (1+(N-2)*abs(INCX))
          On entry, the vector x.
          On exit, it is overwritten with the vector v.

  INCX    (input) INTEGER
          The increment between elements of X. INCX > 0.

  TAU     (output) DOUBLE PRECISION
          The value tau.
```

NAME
       DLARF  -  a real elementary reflector H to a real m by n matrix C, from
       either the left or the right

SYNOPSIS
       SUBROUTINE DLARF( SIDE, M, N, V, INCV, TAU, C, LDC, WORK )

           CHARACTER     SIDE

           INTEGER       INCV, LDC, M, N

           DOUBLE        PRECISION TAU

           DOUBLE        PRECISION C( LDC, * ), V( * ), WORK( * )

 Purpose
 =======

  DLARF applies a real elementary reflector H to a real m by n matrix
  C, from either the left or the right. H is represented in the form

        H = I - tau * v * v'

  where tau is a real scalar and v is a real vector.

  If tau = 0, then H is taken to be the unit matrix.

 Arguments
 =========

  SIDE    (input) CHARACTER*1
          = 'L': form  H * C
          = 'R': form  C * H

  M       (input) INTEGER
          The number of rows of the matrix C.

  N       (input) INTEGER
          The number of columns of the matrix C.
```

```
 V       (input) DOUBLE PRECISION array, dimension
                    (1 + (M-1)*abs(INCV)) if SIDE = 'L'
                  or (1 + (N-1)*abs(INCV)) if SIDE = 'R'
         The vector v in the representation of H. V is not used if
         TAU = 0.

 INCV    (input) INTEGER
         The increment between elements of v. INCV <> 0.

 TAU     (input) DOUBLE PRECISION
         The value tau in the representation of H.

 C       (input/output) DOUBLE PRECISION array, dimension (LDC,N)
         On entry, the m by n matrix C.
         On exit, C is overwritten by the matrix H * C if SIDE = 'L',
         or C * H if SIDE = 'R'.

 LDC     (input) INTEGER
         The leading dimension of the array C. LDC >= max(1,M).

 WORK    (workspace) DOUBLE PRECISION array, dimension
                        (N) if SIDE = 'L'
                      or (M) if SIDE = 'R'

NAME
       DLARFT  -  the triangular factor T of a real block reflector H of order
       n, which is defined as a product of k elementary reflectors

SYNOPSIS
       SUBROUTINE DLARFT( DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT )

           CHARACTER      DIRECT, STOREV

           INTEGER        K, LDT, LDV, N

           DOUBLE         PRECISION T( LDT, * ), TAU( * ), V( LDV, * )

 Purpose
 =======

  DLARFT forms the triangular factor T of a real block reflector H
  of order n, which is defined as a product of k elementary reflectors.

  If DIRECT = 'F', H = H(1) H(2) . . . H(k) and T is upper triangular;

  If DIRECT = 'B', H = H(k) . . . H(2) H(1) and T is lower triangular.

  If STOREV = 'C', the vector which defines the elementary reflector
  H(i) is stored in the i-th column of the array V, and

     H  =  I - V * T * V'

  If STOREV = 'R', the vector which defines the elementary reflector
  H(i) is stored in the i-th row of the array V, and

     H  =  I - V' * T * V

 Arguments
```

```
=========

 DIRECT  (input) CHARACTER*1
         Specifies the order in which the elementary reflectors are
         multiplied to form the block reflector:
         = 'F': H = H(1) H(2) . . . H(k) (Forward)
         = 'B': H = H(k) . . . H(2) H(1) (Backward)

 STOREV  (input) CHARACTER*1
         Specifies how the vectors which define the elementary
         reflectors are stored (see also Further Details):
         = 'C': columnwise
         = 'R': rowwise

 N       (input) INTEGER
         The order of the block reflector H. N >= 0.

 K       (input) INTEGER
         The order of the triangular factor T (= the number of
         elementary reflectors). K >= 1.

 V       (input/output) DOUBLE PRECISION array, dimension
                              (LDV,K) if STOREV = 'C'
                              (LDV,N) if STOREV = 'R'
         The matrix V. See further details.

 LDV     (input) INTEGER
         The leading dimension of the array V.
         If STOREV = 'C', LDV >= max(1,N); if STOREV = 'R', LDV >= K.

 TAU     (input) DOUBLE PRECISION array, dimension (K)
         TAU(i) must contain the scalar factor of the elementary
         reflector H(i).

 T       (output) DOUBLE PRECISION array, dimension (LDT,K)
         The k by k triangular factor T of the block reflector.
         If DIRECT = 'F', T is upper triangular; if DIRECT = 'B', T is
         lower triangular. The rest of the array is not used.

 LDT     (input) INTEGER
         The leading dimension of the array T. LDT >= K.

 Further Details
 ===============

 The shape of the matrix V and the storage of the vectors which define
 the H(i) is best illustrated by the following example with n = 5 and
 k = 3. The elements equal to 1 are not stored; the corresponding
 array elements are modified but restored on exit. The rest of the
 array is not used.
```

```
  DIRECT = 'F' and STOREV = 'C':         DIRECT = 'F' and STOREV = 'R':

               V = (  1       )                 V = (  1 v1 v1 v1 v1 )
                   ( v1  1    )                     (     1 v2 v2 v2 )
                   ( v1 v2  1 )                     (        1 v3 v3 )
                   ( v1 v2 v3 )
                   ( v1 v2 v3 )

  DIRECT = 'B' and STOREV = 'C':         DIRECT = 'B' and STOREV = 'R':

               V = ( v1 v2 v3 )                 V = ( v1 v1  1       )
                   ( v1 v2 v3 )                     ( v2 v2 v2  1    )
                   (  1 v2 v3 )                     ( v3 v3 v3 v3  1 )
                   (     1 v3 )
                   (        1 )

NAME
       DLARFX  - a real elementary reflector H to a real m by n matrix C, from
       either the left or the right

SYNOPSIS
       SUBROUTINE DLARFX( SIDE, M, N, V, TAU, C, LDC, WORK )

           CHARACTER      SIDE

           INTEGER        LDC, M, N

           DOUBLE         PRECISION TAU

           DOUBLE         PRECISION C( LDC, * ), V( * ), WORK( * )

 Purpose
 =======

  DLARFX applies a real elementary reflector H to a real m by n
  matrix C, from either the left or the right. H is represented in the
  form

        H = I - tau * v * v'

  where tau is a real scalar and v is a real vector.

  If tau = 0, then H is taken to be the unit matrix
```

```
 This version uses inline code if H has order < 11.

Arguments
=========

 SIDE    (input) CHARACTER*1
         = 'L': form  H * C
         = 'R': form  C * H

 M       (input) INTEGER
         The number of rows of the matrix C.

 N       (input) INTEGER
         The number of columns of the matrix C.

 V       (input) DOUBLE PRECISION array, dimension (M) if SIDE = 'L'
                                      or (N) if SIDE = 'R'
         The vector v in the representation of H.

 TAU     (input) DOUBLE PRECISION
         The value tau in the representation of H.

 C       (input/output) DOUBLE PRECISION array, dimension (LDC,N)
         On entry, the m by n matrix C.
         On exit, C is overwritten by the matrix H * C if SIDE = 'L',
         or C * H if SIDE = 'R'.

 LDC     (input) INTEGER
         The leading dimension of the array C. LDA >= (1,M).

 WORK    (workspace) DOUBLE PRECISION array, dimension
                     (N) if SIDE = 'L'
                     or (M) if SIDE = 'R'
         WORK is not referenced if H has order < 11.
```

NAME
       DLARTG - a plane rotation so that   [ CS SN ]

SYNOPSIS
       SUBROUTINE DLARTG( F, G, CS, SN, R )

           DOUBLE         PRECISION CS, F, G, R, SN

 Purpose
 =======

  DLARTG generate a plane rotation so that

     [  CS  SN  ]  .  [ F ]  =  [ R ]   where CS**2 + SN**2 = 1.
     [ -SN  CS  ]     [ G ]     [ 0 ]

  This is a slower, more accurate version of the BLAS1 routine DROTG,
  with the following other differences:
     F and G are unchanged on return.
     If G=0, then CS=1 and SN=0.
     If F=0 and (G .ne. 0), then CS=0 and SN=1 without doing any
        floating point operations (saves work in DBDSQR when
        there are zeros on the diagonal).

  If F exceeds G in magnitude, CS will be positive.

 Arguments
 =========

  F       (input) DOUBLE PRECISION
          The first component of vector to be rotated.

  G       (input) DOUBLE PRECISION
          The second component of vector to be rotated.
```

```
  CS      (output) DOUBLE PRECISION
          The cosine of the rotation.

  SN      (output) DOUBLE PRECISION
          The sine of the rotation.

  R       (output) DOUBLE PRECISION
          The nonzero component of the rotated vector.
```

NAME
       DLAS2 - the singular values of the 2-by-2 matrix  [ F G ]  [ 0 H ]

SYNOPSIS
       SUBROUTINE DLAS2( F, G, H, SSMIN, SSMAX )
```

```
          DOUBLE        PRECISION F, G, H, SSMAX, SSMIN

PURPOSE
       DLAS2  computes the singular values of the 2-by-2 matrix
          [  F   G  ]
          [  0   H  ].  On return, SSMIN is the smaller singular value and
       SSMAX is the larger singular value.

ARGUMENTS
       F       (input) DOUBLE PRECISION
               The (1,1) element of the 2-by-2 matrix.

       G       (input) DOUBLE PRECISION
               The (1,2) element of the 2-by-2 matrix.

       H       (input) DOUBLE PRECISION
               The (2,2) element of the 2-by-2 matrix.

       SSMIN   (output) DOUBLE PRECISION
               The smaller singular value.

       SSMAX   (output) DOUBLE PRECISION
               The larger singular value.

FURTHER DETAILS
       Barring over/underflow, all output quantities are correct to  within  a
       few  units  in  the  last  place (ulps), even in the absence of a guard
       digit in addition/subtraction.

       In IEEE arithmetic, the code works correctly if one matrix  element  is
       infinite.

       Overflow  will not occur unless the largest singular value itself over-
       flows, or is within a few ulps of overflow. (On machines  with  partial
       overflow,  like  the  Cray,  overflow may occur if the largest singular
       value is within a factor of 2 of overflow.)

       Underflow is harmless if underflow is gradual. Otherwise,  results  may
       correspond  to  a  matrix  modified  by  perturbations of size near the
       underflow threshold.

NAME
       DLASCL - the M by N real matrix A by the real scalar CTO/CFROM

SYNOPSIS
       SUBROUTINE DLASCL( TYPE, KL, KU, CFROM, CTO, M, N, A, LDA, INFO )

           CHARACTER      TYPE

           INTEGER        INFO, KL, KU, LDA, M, N

           DOUBLE         PRECISION CFROM, CTO

           DOUBLE         PRECISION A( LDA, * )

 Purpose
 =======

  DLASCL multiplies the M by N real matrix A by the real scalar
  CTO/CFROM.  This is done without over/underflow as long as the final
  result CTO*A(I,J)/CFROM does not over/underflow. TYPE specifies that
  A may be full, upper triangular, lower triangular, upper Hessenberg,
  or banded.

 Arguments
 =========

  TYPE    (input) CHARACTER*1
          TYPE indices the storage type of the input matrix.
          = 'G':  A is a full matrix.
          = 'L':  A is a lower triangular matrix.
          = 'U':  A is an upper triangular matrix.
```

```
          = 'H':  A is an upper Hessenberg matrix.
          = 'B':  A is a symmetric band matrix with lower bandwidth KL
                  and upper bandwidth KU and with the only the lower
                  half stored.
          = 'Q':  A is a symmetric band matrix with lower bandwidth KL
                  and upper bandwidth KU and with the only the upper
                  half stored.
          = 'Z':  A is a band matrix with lower bandwidth KL and upper
                  bandwidth KU.

  KL      (input) INTEGER
          The lower bandwidth of A.  Referenced only if TYPE = 'B',
          'Q' or 'Z'.

  KU      (input) INTEGER
          The upper bandwidth of A.  Referenced only if TYPE = 'B',
          'Q' or 'Z'.

  CFROM   (input) DOUBLE PRECISION
  CTO     (input) DOUBLE PRECISION
          The matrix A is multiplied by CTO/CFROM. A(I,J) is computed
          without over/underflow if the final result CTO*A(I,J)/CFROM
          can be represented without over/underflow.  CFROM must be
          nonzero.

  M       (input) INTEGER
          The number of rows of the matrix A.  M >= 0.

  N       (input) INTEGER
          The number of columns of the matrix A.  N >= 0.

  A       (input/output) DOUBLE PRECISION array, dimension (LDA,M)
          The matrix to be multiplied by CTO/CFROM.  See TYPE for the
          storage type.

  LDA     (input) INTEGER
          The leading dimension of the array A.  LDA >= max(1,M).

  INFO    (output) INTEGER
          0  - successful exit
          <0 - if INFO = -i, the i-th argument had an illegal value.

NAME
       DLASD0  -  divide  and  conquer  approach, DLASD0 computes the singular
       value decomposition (SVD) of a real upper bidiagonal  N-by-M  matrix  B
       with diagonal D and offdiagonal E, where M = N + SQRE

SYNOPSIS
       SUBROUTINE DLASD0( N,  SQRE,  D,  E,  U,  LDU, VT, LDVT, SMLSIZ, IWORK,
                          WORK, INFO )

           INTEGER        INFO, LDU, LDVT, N, SMLSIZ, SQRE

           INTEGER        IWORK( * )

           DOUBLE         PRECISION D( * ), E( * ), U( LDU, * ), VT(  LDVT,  *
                          ), WORK( * )

 Purpose
 =======

  Using a divide and conquer approach, DLASD0 computes the singular
  value decomposition (SVD) of a real upper bidiagonal N-by-M
  matrix B with diagonal D and offdiagonal E, where M = N + SQRE.
  The algorithm computes orthogonal matrices U and VT such that
  B = U * S * VT. The singular values S are overwritten on D.

  A related subroutine, DLASDA, computes only the singular values,
  and optionally, the singular vectors in compact form.

  Arguments
  =========

  N      (input) INTEGER
         On entry, the row dimension of the upper bidiagonal matrix.
         This is also the dimension of the main diagonal array D.

  SQRE   (input) INTEGER
         Specifies the column dimension of the bidiagonal matrix.
         = 0: The bidiagonal matrix has column dimension M = N;
         = 1: The bidiagonal matrix has column dimension M = N+1;

  D      (input/output) DOUBLE PRECISION array, dimension (N)
         On entry D contains the main diagonal of the bidiagonal
         matrix.
         On exit D, if INFO = 0, contains its singular values.
```

```
  E      (input) DOUBLE PRECISION array, dimension (M-1)
         Contains the subdiagonal entries of the bidiagonal matrix.
         On exit, E has been destroyed.

  U      (output) DOUBLE PRECISION array, dimension at least (LDQ, N)
         On exit, U contains the left singular vectors.

  LDU    (input) INTEGER
         On entry, leading dimension of U.

  VT     (output) DOUBLE PRECISION array, dimension at least (LDVT, M)
         On exit, VT' contains the right singular vectors.

  LDVT   (input) INTEGER
         On entry, leading dimension of VT.

  SMLSIZ (input) INTEGER
         On entry, maximum size of the subproblems at the
         bottom of the computation tree.

  IWORK  INTEGER work array.
         Dimension must be at least (8 * N)

  WORK   DOUBLE PRECISION work array.
         Dimension must be at least (3 * M**2 + 2 * M)

  INFO   (output) INTEGER
          = 0:  successful exit.
          < 0:  if INFO = -i, the i-th argument had an illegal value.
          > 0:  if INFO = 1, an singular value did not converge

  Further Details

NAME
       DLASD1 - the SVD of an upper bidiagonal N-by-M matrix B,

SYNOPSIS
       SUBROUTINE DLASD1( NL,  NR,  SQRE,  D,  ALPHA,  BETA, U, LDU, VT, LDVT,
                          IDXQ, IWORK, WORK, INFO )

           INTEGER        INFO, LDU, LDVT, NL, NR, SQRE

           DOUBLE         PRECISION ALPHA, BETA

           INTEGER        IDXQ( * ), IWORK( * )

           DOUBLE         PRECISION D( * ), U( LDU, * ), VT( LDVT, * ),  WORK(
                          * )

  Purpose
  =======

  DLASD1 computes the SVD of an upper bidiagonal N-by-M matrix B,
  where N = NL + NR + 1 and M = N + SQRE. DLASD1 is called from DLASD0.
```

```
A related subroutine DLASD7 handles the case in which the singular
values (and the singular vectors in factored form) are desired.

DLASD1 computes the SVD as follows:

              ( D1(in)  0    0     0 )
  B = U(in) * (   Z1'   a   Z2'    b ) * VT(in)
              (   0     0   D2(in) 0 )

    = U(out) * ( D(out) 0) * VT(out)

where Z' = (Z1' a Z2' b) = u' VT', and u is a vector of dimension M
with ALPHA and BETA in the NL+1 and NL+2 th entries and zeros
elsewhere; and the entry b is empty if SQRE = 0.

The left singular vectors of the original matrix are stored in U, and
the transpose of the right singular vectors are stored in VT, and the
singular values are in D.  The algorithm consists of three stages:

   The first stage consists of deflating the size of the problem
   when there are multiple singular values or when there are zeros in
   the Z vector.  For each such occurence the dimension of the
   secular equation problem is reduced by one.  This stage is
   performed by the routine DLASD2.

   The second stage consists of calculating the updated
   singular values. This is done by finding the square roots of the
   roots of the secular equation via the routine DLASD4 (as called
   by DLASD3). This routine also calculates the singular vectors of
   the current problem.

   The final stage consists of computing the updated singular vectors
   directly using the updated singular values.  The singular vectors
   for the current problem are multiplied with the singular vectors
   from the overall problem.

Arguments
=========

NL     (input) INTEGER
       The row dimension of the upper block.  NL >= 1.

NR     (input) INTEGER
       The row dimension of the lower block.  NR >= 1.

SQRE   (input) INTEGER
       = 0: the lower block is an NR-by-NR square matrix.
       = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

       The bidiagonal matrix has row dimension N = NL + NR + 1,
```

```
       and column dimension M = N + SQRE.

 D     (input/output) DOUBLE PRECISION array,
                      dimension (N = NL+NR+1).
       On entry D(1:NL,1:NL) contains the singular values of the
       upper block; and D(NL+2:N) contains the singular values of
       the lower block. On exit D(1:N) contains the singular values
       of the modified matrix.

 ALPHA (input) DOUBLE PRECISION
       Contains the diagonal element associated with the added row.

 BETA  (input) DOUBLE PRECISION
       Contains the off-diagonal element associated with the added
       row.

 U     (input/output) DOUBLE PRECISION array, dimension(LDU,N)
       On entry U(1:NL, 1:NL) contains the left singular vectors of
       the upper block; U(NL+2:N, NL+2:N) contains the left singular
       vectors of the lower block. On exit U contains the left
       singular vectors of the bidiagonal matrix.

 LDU   (input) INTEGER
       The leading dimension of the array U.  LDU >= max( 1, N ).

 VT    (input/output) DOUBLE PRECISION array, dimension(LDVT,M)
       where M = N + SQRE.
       On entry VT(1:NL+1, 1:NL+1)' contains the right singular
       vectors of the upper block; VT(NL+2:M, NL+2:M)' contains
       the right singular vectors of the lower block. On exit
       VT' contains the right singular vectors of the
       bidiagonal matrix.

 LDVT  (input) INTEGER
       The leading dimension of the array VT.  LDVT >= max( 1, M ).

 IDXQ  (output) INTEGER array, dimension(N)
       This contains the permutation which will reintegrate the
       subproblem just solved back into sorted order, i.e.
       D( IDXQ( I = 1, N ) ) will be in ascending order.

 IWORK (workspace) INTEGER array, dimension( 4 * N )

 WORK  (workspace) DOUBLE PRECISION array, dimension( 3*M**2 + 2*M )

 INFO  (output) INTEGER
        = 0:  successful exit.
        < 0:  if INFO = -i, the i-th argument had an illegal value.
        > 0:  if INFO = 1, an singular value did not converge
```

```

NAME
       DLASD2  - the two sets of singular values together into a single sorted
       set

SYNOPSIS
       SUBROUTINE DLASD2( NL, NR, SQRE, K, D, Z,  ALPHA,  BETA,  U,  LDU,  VT,
                          LDVT, DSIGMA, U2, LDU2, VT2, LDVT2, IDXP, IDX, IDXC,
                          IDXQ, COLTYP, INFO )

           INTEGER        INFO, K, LDU, LDU2, LDVT, LDVT2, NL, NR, SQRE

           DOUBLE         PRECISION ALPHA, BETA

           INTEGER        COLTYP( * ), IDX( * ), IDXC( * ), IDXP( * ), IDXQ( *
                          )

           DOUBLE         PRECISION  D(  *  ),  DSIGMA(  * ), U( LDU, * ), U2(
                          LDU2, * ), VT( LDVT, * ), VT2( LDVT2, * ), Z( * )

  Purpose
  =======

  DLASD2 merges the two sets of singular values together into a single
  sorted set.  Then it tries to deflate the size of the problem.
  There are two ways in which deflation can occur:  when two or more
  singular values are close together or if there is a tiny entry in the
  Z vector.  For each such occurrence the order of the related secular
  equation problem is reduced by one.

  DLASD2 is called from DLASD1.

  Arguments
  =========

  NL     (input) INTEGER
         The row dimension of the upper block.  NL >= 1.

  NR     (input) INTEGER
         The row dimension of the lower block.  NR >= 1.

  SQRE   (input) INTEGER
         = 0: the lower block is an NR-by-NR square matrix.
         = 1: the lower block is an NR-by-(NR+1) rectangular matrix.
```

```
       The bidiagonal matrix has N = NL + NR + 1 rows and
       M = N + SQRE >= N columns.

K      (output) INTEGER
       Contains the dimension of the non-deflated matrix,
       This is the order of the related secular equation. 1 <= K <=N.

D      (input/output) DOUBLE PRECISION array, dimension(N)
       On entry D contains the singular values of the two submatrices
       to be combined.  On exit D contains the trailing (N-K) updated
       singular values (those which were deflated) sorted into
       increasing order.

ALPHA  (input) DOUBLE PRECISION
       Contains the diagonal element associated with the added row.

BETA   (input) DOUBLE PRECISION
       Contains the off-diagonal element associated with the added
       row.

U      (input/output) DOUBLE PRECISION array, dimension(LDU,N)
       On entry U contains the left singular vectors of two
       submatrices in the two square blocks with corners at (1,1),
       (NL, NL), and (NL+2, NL+2), (N,N).
       On exit U contains the trailing (N-K) updated left singular
       vectors (those which were deflated) in its last N-K columns.

LDU    (input) INTEGER
       The leading dimension of the array U.  LDU >= N.

Z      (output) DOUBLE PRECISION array, dimension(N)
       On exit Z contains the updating row vector in the secular
       equation.

DSIGMA (output) DOUBLE PRECISION array, dimension (N)
       Contains a copy of the diagonal elements (K-1 singular values
       and one zero) in the secular equation.

U2     (output) DOUBLE PRECISION array, dimension(LDU2,N)
       Contains a copy of the first K-1 left singular vectors which
       will be used by DLASD3 in a matrix multiply (DGEMM) to solve
       for the new left singular vectors. U2 is arranged into four
       blocks. The first block contains a column with 1 at NL+1 and
       zero everywhere else; the second block contains non-zero
       entries only at and above NL; the third contains non-zero
       entries only below NL+1; and the fourth is dense.

LDU2   (input) INTEGER
       The leading dimension of the array U2.  LDU2 >= N.
```

```
VT     (input/output) DOUBLE PRECISION array, dimension(LDVT,M)
       On entry VT' contains the right singular vectors of two
       submatrices in the two square blocks with corners at (1,1),
       (NL+1, NL+1), and (NL+2, NL+2), (M,M).
       On exit VT' contains the trailing (N-K) updated right singular
       vectors (those which were deflated) in its last N-K columns.
       In case SQRE =1, the last row of VT spans the right null
       space.

LDVT   (input) INTEGER
       The leading dimension of the array VT.  LDVT >= M.

VT2    (output) DOUBLE PRECISION array, dimension(LDVT2,N)
       VT2' contains a copy of the first K right singular vectors
       which will be used by DLASD3 in a matrix multiply (DGEMM) to
       solve for the new right singular vectors. VT2 is arranged into
       three blocks. The first block contains a row that corresponds
       to the special 0 diagonal element in SIGMA; the second block
       contains non-zeros only at and before NL +1; the third block
       contains non-zeros only at and after  NL +2.

LDVT2  (input) INTEGER
       The leading dimension of the array VT2.  LDVT2 >= M.

IDXP   (workspace) INTEGER array, dimension(N)
       This will contain the permutation used to place deflated
       values of D at the end of the array. On output IDXP(2:K)
       points to the nondeflated D-values and IDXP(K+1:N)
       points to the deflated singular values.

IDX    (workspace) INTEGER array, dimension(N)
       This will contain the permutation used to sort the contents of
       D into ascending order.

IDXC   (output) INTEGER array, dimension(N)
       This will contain the permutation used to arrange the columns
       of the deflated U matrix into three groups:  the first group
       contains non-zero entries only at and above NL, the second
       contains non-zero entries only below NL+2, and the third is
       dense.

COLTYP (workspace/output) INTEGER array, dimension(N)
       As workspace, this will contain a label which will indicate
       which of the following types a column in the U2 matrix or a
       row in the VT2 matrix is:
       1 : non-zero in the upper half only
       2 : non-zero in the lower half only
       3 : dense
       4 : deflated
```

```
        On exit, it is an array of dimension 4, with COLTYP(I) being
        the dimension of the I-th type columns.

  IDXQ   (input) INTEGER array, dimension(N)
        This contains the permutation which separately sorts the two
        sub-problems in D into ascending order.  Note that entries in
        the first hlaf of this permutation must first be moved one
        position backward; and entries in the second half
        must first have NL+1 added to their values.

  INFO   (output) INTEGER
         = 0:  successful exit.
         < 0:  if INFO = -i, the i-th argument had an illegal value.

  Further Details
  ===============

*
*     There are 2 kinds of deflation -- first a value in the z-vector
*     is small, second two (or more) singular values are very close
*     together (their difference is small).
*
*     If the value in the z-vector is small, we simply permute the
*     array so that the corresponding singular value is moved to the
*     end.
*
*     If two values in the D-vector are close, we perform a two-sided
*     rotation designed to make one of the corresponding z-vector
*     entries zero, and then permute the array so that the deflated
*     singular value is moved to the end.
*
*     If there are multiple singular values then the problem deflates.
*     Here the number of equal singular values are found.  As each equal
*     singular value is found, an elementary reflector is computed to
*     rotate the corresponding singular subspace so that the
*     corresponding components of Z are zero in this new basis.

NAME
       DLASD3  - all the square roots of the roots of the secular equation, as
       defined by the values in D and Z

SYNOPSIS
       SUBROUTINE DLASD3( NL, NR, SQRE, K, D, Q,  LDQ,  DSIGMA,  U,  LDU,  U2,
                          LDU2, VT, LDVT, VT2, LDVT2, IDXC, CTOT, Z, INFO )

           INTEGER        INFO, K, LDQ, LDU, LDU2, LDVT, LDVT2, NL, NR, SQRE

           INTEGER        CTOT( * ), IDXC( * )

           DOUBLE         PRECISION  D( * ), DSIGMA( * ), Q( LDQ, * ), U( LDU,
                          * ), U2( LDU2, * ), VT( LDVT, * ), VT2( LDVT2, *  ),
                          Z( * )

  Purpose
  =======

  DLASD3 finds all the square roots of the roots of the secular
  equation, as defined by the values in D and Z.  It makes the
  appropriate calls to DLASD4 and then updates the singular
  vectors by matrix multiplication.

  This code makes very mild assumptions about floating point
  arithmetic. It will work on machines with a guard digit in
  add/subtract, or on those binary machines without guard digits
  which subtract like the Cray XMP, Cray YMP, Cray C 90, or Cray 2.
  It could conceivably fail on hexadecimal or decimal machines
  without guard digits, but we know of none.

  DLASD3 is called from DLASD1.

  Arguments
  =========

  NL     (input) INTEGER
```

```
        The row dimension of the upper block.  NL >= 1.

NR      (input) INTEGER
        The row dimension of the lower block.  NR >= 1.

SQRE    (input) INTEGER
        = 0: the lower block is an NR-by-NR square matrix.
        = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

        The bidiagonal matrix has N = NL + NR + 1 rows and
        M = N + SQRE >= N columns.

K       (input) INTEGER
        The size of the secular equation, 1 =< K = < N.

D       (output) DOUBLE PRECISION array, dimension(K)
        On exit the square roots of the roots of the secular equation,
        in ascending order.

Q       (workspace) DOUBLE PRECISION array,
                    dimension at least (LDQ,K).

LDQ     (input) INTEGER
        The leading dimension of the array Q.  LDQ >= K.

DSIGMA (input) DOUBLE PRECISION array, dimension(K)
        The first K elements of this array contain the old roots
        of the deflated updating problem.  These are the poles
        of the secular equation.

U       (input) DOUBLE PRECISION array, dimension (LDU, N)
        The last N - K columns of this matrix contain the deflated
        left singular vectors.

LDU     (input) INTEGER
        The leading dimension of the array U.  LDU >= N.

U2      (input) DOUBLE PRECISION array, dimension (LDU2, N)
        The first K columns of this matrix contain the non-deflated
        left singular vectors for the split problem.

LDU2    (input) INTEGER
        The leading dimension of the array U2.  LDU2 >= N.

VT      (input) DOUBLE PRECISION array, dimension (LDVT, M)
        The last M - K columns of VT' contain the deflated
        right singular vectors.

LDVT    (input) INTEGER
        The leading dimension of the array VT.  LDVT >= N.
```

```
VT2    (input) DOUBLE PRECISION array, dimension (LDVT2, N)
       The first K columns of VT2' contain the non-deflated
       right singular vectors for the split problem.

LDVT2  (input) INTEGER
       The leading dimension of the array VT2.  LDVT2 >= N.

IDXC   (input) INTEGER array, dimension ( N )
       The permutation used to arrange the columns of U (and rows of
       VT) into three groups:  the first group contains non-zero
       entries only at and above (or before) NL +1; the second
       contains non-zero entries only at and below (or after) NL+2;
       and the third is dense. The first column of U and the row of
       VT are treated separately, however.

       The rows of the singular vectors found by DLASD4
       must be likewise permuted before the matrix multiplies can
       take place.

CTOT   (input) INTEGER array, dimension ( 4 )
       A count of the total number of the various types of columns
       in U (or rows in VT), as described in IDXC. The fourth column
       type is any column which has been deflated.

Z      (input) DOUBLE PRECISION array, dimension (K)
       The first K elements of this array contain the components
       of the deflation-adjusted updating row vector.

INFO   (output) INTEGER
       = 0:  successful exit.
       < 0:  if INFO = -i, the i-th argument had an illegal value.
       > 0:  if INFO = 1, an singular value did not converge

*
*     Modify values DSIGMA(i) to make sure all DSIGMA(i)-DSIGMA(j) can
*     be computed with high relative accuracy (barring over/underflow).
*     This is a problem on machines without a guard digit in
*     add/subtract (Cray XMP, Cray YMP, Cray C 90 and Cray 2).
*     The following code replaces DSIGMA(I) by 2*DSIGMA(I)-DSIGMA(I),
*     which on any of these machines zeros out the bottommost
*     bit of DSIGMA(I) if it is 1; this makes the subsequent
*     subtractions DSIGMA(I)-DSIGMA(J) unproblematic when cancellation
*     occurs. On binary machines with a guard digit (almost all
*     machines) it does not change DSIGMA(I) at all. On hexadecimal
```

```
*     and decimal machines with a guard digit, it slightly
*     changes the bottommost bits of DSIGMA(I). It does not account
*     for hexadecimal or decimal machines without guard digits
*     (we know of none). We use a subroutine call to compute
*     2*DLAMBDA(I) to prevent optimizing compilers from eliminating
*     this code.

NAME
       DLASD4  -  compute  the square root of the I-th updated eigenvalue of a
       positive symmetric rank-one modification to a positive diagonal  matrix
       whose  entries are given as the squares of the corresponding entries in
       the array d, and that   0 <= D(i) < D(j) for i < j  and that RHO > 0

SYNOPSIS
       SUBROUTINE DLASD4( N, I, D, Z, DELTA, RHO, SIGMA, WORK, INFO )

           INTEGER        I, INFO, N

           DOUBLE         PRECISION RHO, SIGMA

           DOUBLE         PRECISION D( * ), DELTA( * ), WORK( * ), Z( * )

  Purpose
  =======

  This subroutine computes the square root of the I-th updated
  eigenvalue of a positive symmetric rank-one modification to
  a positive diagonal matrix whose entries are given as the squares
  of the corresponding entries in the array d, and that
```

```
       0 <= D(i) < D(j)  for  i < j

and that RHO > 0. This is arranged by the calling routine, and is
no loss in generality.  The rank-one modified system is thus

       diag( D ) * diag( D ) +  RHO *  Z * Z_transpose.

where we assume the Euclidean norm of Z is 1.

The method consists of approximating the rational functions in the
secular equation by simpler interpolating rational functions.

Arguments
=========

N      (input) INTEGER
       The length of all arrays.

I      (input) INTEGER
       The index of the eigenvalue to be computed.  1 <= I <= N.

D      (input) DOUBLE PRECISION array, dimension ( N )
       The original eigenvalues.  It is assumed that they are in
       order, 0 <= D(I) < D(J)  for I < J.

Z      (input) DOUBLE PRECISION array, dimension ( N )
       The components of the updating vector.

DELTA  (output) DOUBLE PRECISION array, dimension ( N )
       If N .ne. 1, DELTA contains (D(j) - sigma_I) in its  j-th
       component.  If N = 1, then DELTA(1) = 1.  The vector DELTA
       contains the information necessary to construct the
       (singular) eigenvectors.

RHO    (input) DOUBLE PRECISION
       The scalar in the symmetric updating formula.

SIGMA  (output) DOUBLE PRECISION
       The computed lambda_I, the I-th updated eigenvalue.

WORK   (workspace) DOUBLE PRECISION array, dimension ( N )
       If N .ne. 1, WORK contains (D(j) + sigma_I) in its  j-th
       component.  If N = 1, then WORK( 1 ) = 1.

INFO   (output) INTEGER
       = 0:  successful exit
       > 0:  if INFO = 1, the updating process failed.

Internal Parameters
```

```
  ==================

  Logical variable ORGATI (origin-at-i?) is used for distinguishing
  whether D(i) or D(i+1) is treated as the origin.

            ORGATI = .true.    origin at i
            ORGATI = .false.   origin at i+1

  Logical variable SWTCH3 (switch-for-3-poles?) is for noting
  if we are working with THREE poles!

  MAXIT is the maximum number of iterations allowed for each
  eigenvalue.

  Further Details
  ===============

  Based on contributions by
     Ren-Cang Li, Computer Science Division, University of California
     at Berkeley, USA

NAME
       DLASD5  -  compute the square root of the I-th eigenvalue of a positive
       symmetric rank-one modification of a 2-by-2 diagonal matrix   diag( D )
       *  diag(  D ) + RHO  The diagonal entries in the array D are assumed to
       satisfy   0 <= D(i) < D(j) for i < j

SYNOPSIS
       SUBROUTINE DLASD5( I, D, Z, DELTA, RHO, DSIGMA, WORK )

           INTEGER        I

           DOUBLE         PRECISION DSIGMA, RHO

           DOUBLE         PRECISION D( 2 ), DELTA( 2 ), WORK( 2 ), Z( 2 )

  Purpose
  =======

  This subroutine computes the square root of the I-th eigenvalue
  of a positive symmetric rank-one modification of a 2-by-2 diagonal
  matrix

             diag( D ) * diag( D ) +  RHO *  Z * transpose(Z) .

  The diagonal entries in the array D are assumed to satisfy

             0 <= D(i) < D(j)  for  i < j .

  We also assume RHO > 0 and that the Euclidean norm of the vector
  Z is one.

  Arguments
  =========

  I      (input) INTEGER
         The index of the eigenvalue to be computed.  I = 1 or I = 2.

  D      (input) DOUBLE PRECISION array, dimension ( 2 )
         The original eigenvalues.  We assume 0 <= D(1) < D(2).

  Z      (input) DOUBLE PRECISION array, dimension ( 2 )
         The components of the updating vector.

  DELTA  (output) DOUBLE PRECISION array, dimension ( 2 )
         Contains (D(j) - lambda_I) in its  j-th component.
         The vector DELTA contains the information necessary
         to construct the eigenvectors.
```

```
  RHO    (input) DOUBLE PRECISION
         The scalar in the symmetric updating formula.

  DSIGMA (output) DOUBLE PRECISION
         The computed lambda_I, the I-th updated eigenvalue.

  WORK   (workspace) DOUBLE PRECISION array, dimension ( 2 )
         WORK contains (D(j) + sigma_I) in its  j-th component.

  Further Details
  ===============

  Based on contributions by
     Ren-Cang Li, Computer Science Division, University of California
     at Berkeley, USA

NAME
       DLASD6  -  the  SVD of an updated upper bidiagonal matrix B obtained by
       merging two smaller ones by appending a row

SYNOPSIS
       SUBROUTINE DLASD6( ICOMPQ, NL, NR, SQRE, D, VF, VL, ALPHA, BETA,  IDXQ,
                          PERM, GIVPTR, GIVCOL, LDGCOL, GIVNUM, LDGNUM, POLES,
                          DIFL, DIFR, Z, K, C, S, WORK, IWORK, INFO )

           INTEGER        GIVPTR, ICOMPQ, INFO, K,  LDGCOL,  LDGNUM,  NL,  NR,
                          SQRE

           DOUBLE         PRECISION ALPHA, BETA, C, S

           INTEGER        GIVCOL(  LDGCOL, * ), IDXQ( * ), IWORK( * ), PERM( *
                          )

           DOUBLE         PRECISION D( * ), DIFL( *  ),  DIFR(  *  ),  GIVNUM(
                          LDGNUM,  *  ), POLES( LDGNUM, * ), VF( * ), VL( * ),
                          WORK( * ), Z( * )

  Purpose
```

```
=======

DLASD6 computes the SVD of an updated upper bidiagonal matrix B
obtained by merging two smaller ones by appending a row. This
routine is used only for the problem which requires all singular
values and optionally singular vector matrices in factored form.
B is an N-by-M matrix with N = NL + NR + 1 and M = N + SQRE.
A related subroutine, DLASD1, handles the case in which all singular
values and singular vectors of the bidiagonal matrix are desired.

DLASD6 computes the SVD as follows:

              ( D1(in)  0    0     0 )
  B = U(in) * (   Z1'   a   Z2'    b ) * VT(in)
              (   0     0   D2(in) 0 )

    = U(out) * ( D(out) 0) * VT(out)

where Z' = (Z1' a Z2' b) = u' VT', and u is a vector of dimension M
with ALPHA and BETA in the NL+1 and NL+2 th entries and zeros
elsewhere; and the entry b is empty if SQRE = 0.

The singular values of B can be computed using D1, D2, the first
components of all the right singular vectors of the lower block, and
the last components of all the right singular vectors of the upper
block. These components are stored and updated in VF and VL,
respectively, in DLASD6. Hence U and VT are not explicitly
referenced.

The singular values are stored in D. The algorithm consists of two
stages:

      The first stage consists of deflating the size of the problem
      when there are multiple singular values or if there is a zero
      in the Z vector. For each such occurence the dimension of the
      secular equation problem is reduced by one. This stage is
      performed by the routine DLASD7.

      The second stage consists of calculating the updated
      singular values. This is done by finding the roots of the
      secular equation via the routine DLASD4 (as called by DLASD8).
      This routine also updates VF and VL and computes the distances
      between the updated singular values and the old singular
      values.

DLASD6 is called from DLASDA.

Arguments
=========
```

```
ICOMPQ (input) INTEGER
       Specifies whether singular vectors are to be computed in
       factored form:
       = 0: Compute singular values only.
       = 1: Compute singular vectors in factored form as well.

NL     (input) INTEGER
       The row dimension of the upper block.  NL >= 1.

NR     (input) INTEGER
       The row dimension of the lower block.  NR >= 1.

SQRE   (input) INTEGER
       = 0: the lower block is an NR-by-NR square matrix.
       = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

       The bidiagonal matrix has row dimension N = NL + NR + 1,
       and column dimension M = N + SQRE.

D      (input/output) DOUBLE PRECISION array, dimension ( NL+NR+1 ).
       On entry D(1:NL,1:NL) contains the singular values of the
       upper block, and D(NL+2:N) contains the singular values
       of the lower block. On exit D(1:N) contains the singular
       values of the modified matrix.

VF     (input/output) DOUBLE PRECISION array, dimension ( M )
       On entry, VF(1:NL+1) contains the first components of all
       right singular vectors of the upper block; and VF(NL+2:M)
       contains the first components of all right singular vectors
       of the lower block. On exit, VF contains the first components
       of all right singular vectors of the bidiagonal matrix.

VL     (input/output) DOUBLE PRECISION array, dimension ( M )
       On entry, VL(1:NL+1) contains the  last components of all
       right singular vectors of the upper block; and VL(NL+2:M)
       contains the last components of all right singular vectors of
       the lower block. On exit, VL contains the last components of
       all right singular vectors of the bidiagonal matrix.

ALPHA  (input) DOUBLE PRECISION
       Contains the diagonal element associated with the added row.

BETA   (input) DOUBLE PRECISION
       Contains the off-diagonal element associated with the added
       row.

IDXQ   (output) INTEGER array, dimension ( N )
       This contains the permutation which will reintegrate the
       subproblem just solved back into sorted order, i.e.
       D( IDXQ( I = 1, N ) ) will be in ascending order.
```

```
PERM   (output) INTEGER array, dimension ( N )
       The permutations (from deflation and sorting) to be applied
       to each block. Not referenced if ICOMPQ = 0.

GIVPTR (output) INTEGER
       The number of Givens rotations which took place in this
       subproblem. Not referenced if ICOMPQ = 0.

GIVCOL (output) INTEGER array, dimension ( LDGCOL, 2 )
       Each pair of numbers indicates a pair of columns to take place
       in a Givens rotation. Not referenced if ICOMPQ = 0.

LDGCOL (input) INTEGER
       leading dimension of GIVCOL, must be at least N.

GIVNUM (output) DOUBLE PRECISION array, dimension ( LDGNUM, 2 )
       Each number indicates the C or S value to be used in the
       corresponding Givens rotation. Not referenced if ICOMPQ = 0.

LDGNUM (input) INTEGER
       The leading dimension of GIVNUM and POLES, must be at least N.

POLES  (output) DOUBLE PRECISION array, dimension ( LDGNUM, 2 )
       On exit, POLES(1,*) is an array containing the new singular
       values obtained from solving the secular equation, and
       POLES(2,*) is an array containing the poles in the secular
       equation. Not referenced if ICOMPQ = 0.

DIFL   (output) DOUBLE PRECISION array, dimension ( N )
       On exit, DIFL(I) is the distance between I-th updated
       (undeflated) singular value and the I-th (undeflated) old
       singular value.

DIFR   (output) DOUBLE PRECISION array,
                dimension ( LDGNUM, 2 ) if ICOMPQ = 1 and
                dimension ( N ) if ICOMPQ = 0.
       On exit, DIFR(I, 1) is the distance between I-th updated
       (undeflated) singular value and the I+1-th (undeflated) old
       singular value.

       If ICOMPQ = 1, DIFR(1:K,2) is an array containing the
       normalizing factors for the right singular vector matrix.

       See DLASD8 for details on DIFL and DIFR.

Z      (output) DOUBLE PRECISION array, dimension ( M )
       The first elements of this array contain the components
       of the deflation-adjusted updating row vector.
```

```
  K      (output) INTEGER
         Contains the dimension of the non-deflated matrix,
         This is the order of the related secular equation. 1 <= K <=N.

  C      (output) DOUBLE PRECISION
         C contains garbage if SQRE =0 and the C-value of a Givens
         rotation related to the right null space if SQRE = 1.

  S      (output) DOUBLE PRECISION
         S contains garbage if SQRE =0 and the S-value of a Givens
         rotation related to the right null space if SQRE = 1.

  WORK   (workspace) DOUBLE PRECISION array, dimension ( 4 * M )

  IWORK  (workspace) INTEGER array, dimension ( 3 * N )

  INFO   (output) INTEGER
          = 0:  successful exit.
          < 0:  if INFO = -i, the i-th argument had an illegal value.
          > 0:  if INFO = 1, an singular value did not converge

  Further Details
  ===============

NAME
       DLASD7  - the two sets of singular values together into a single sorted
       set

SYNOPSIS
       SUBROUTINE DLASD7( ICOMPQ, NL, NR, SQRE, K, D, Z, ZW, VF, VFW, VL, VLW,
                          ALPHA,  BETA, DSIGMA, IDX, IDXP, IDXQ, PERM, GIVPTR,
                          GIVCOL, LDGCOL, GIVNUM, LDGNUM, C, S, INFO )

           INTEGER        GIVPTR, ICOMPQ, INFO, K,  LDGCOL,  LDGNUM,  NL,  NR,
                          SQRE

           DOUBLE         PRECISION ALPHA, BETA, C, S

           INTEGER        GIVCOL( LDGCOL, * ), IDX( * ), IDXP( * ), IDXQ( * ),
                          PERM( * )

           DOUBLE         PRECISION D( * ), DSIGMA( * ), GIVNUM( LDGNUM, *  ),
                          VF(  * ), VFW( * ), VL( * ), VLW( * ), Z( * ), ZW( *
                          )

  Purpose
  =======

  DLASD7 merges the two sets of singular values together into a single
  sorted set. Then it tries to deflate the size of the problem. There
  are two ways in which deflation can occur:  when two or more singular
  values are close together or if there is a tiny entry in the Z
  vector. For each such occurrence the order of the related
  secular equation problem is reduced by one.

  DLASD7 is called from DLASD6.

  Arguments
  =========

  ICOMPQ  (input) INTEGER
          Specifies whether singular vectors are to be computed
          in compact form, as follows:
          = 0: Compute singular values only.
          = 1: Compute singular vectors of upper
               bidiagonal matrix in compact form.
```

```
NL     (input) INTEGER
       The row dimension of the upper block. NL >= 1.

NR     (input) INTEGER
       The row dimension of the lower block. NR >= 1.

SQRE   (input) INTEGER
       = 0: the lower block is an NR-by-NR square matrix.
       = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

       The bidiagonal matrix has
       N = NL + NR + 1 rows and
       M = N + SQRE >= N columns.

K      (output) INTEGER
       Contains the dimension of the non-deflated matrix, this is
       the order of the related secular equation. 1 <= K <=N.

D      (input/output) DOUBLE PRECISION array, dimension ( N )
       On entry D contains the singular values of the two submatrices
       to be combined. On exit D contains the trailing (N-K) updated
       singular values (those which were deflated) sorted into
       increasing order.

Z      (output) DOUBLE PRECISION array, dimension ( M )
       On exit Z contains the updating row vector in the secular
       equation.

ZW     (workspace) DOUBLE PRECISION array, dimension ( M )
       Workspace for Z.

VF     (input/output) DOUBLE PRECISION array, dimension ( M )
       On entry, VF(1:NL+1) contains the first components of all
       right singular vectors of the upper block; and VF(NL+2:M)
       contains the first components of all right singular vectors
       of the lower block. On exit, VF contains the first components
       of all right singular vectors of the bidiagonal matrix.

VFW    (workspace) DOUBLE PRECISION array, dimension ( M )
       Workspace for VF.

VL     (input/output) DOUBLE PRECISION array, dimension ( M )
       On entry, VL(1:NL+1) contains the  last components of all
       right singular vectors of the upper block; and VL(NL+2:M)
       contains the last components of all right singular vectors
       of the lower block. On exit, VL contains the last components
       of all right singular vectors of the bidiagonal matrix.

VLW    (workspace) DOUBLE PRECISION array, dimension ( M )
       Workspace for VL.
```

```
ALPHA  (input) DOUBLE PRECISION
       Contains the diagonal element associated with the added row.

BETA   (input) DOUBLE PRECISION
       Contains the off-diagonal element associated with the added
       row.

DSIGMA (output) DOUBLE PRECISION array, dimension ( N )
       Contains a copy of the diagonal elements (K-1 singular values
       and one zero) in the secular equation.

IDX    (workspace) INTEGER array, dimension ( N )
       This will contain the permutation used to sort the contents of
       D into ascending order.

IDXP   (workspace) INTEGER array, dimension ( N )
       This will contain the permutation used to place deflated
       values of D at the end of the array. On output IDXP(2:K)
       points to the nondeflated D-values and IDXP(K+1:N)
       points to the deflated singular values.

IDXQ   (input) INTEGER array, dimension ( N )
       This contains the permutation which separately sorts the two
       sub-problems in D into ascending order.  Note that entries in
       the first half of this permutation must first be moved one
       position backward; and entries in the second half
       must first have NL+1 added to their values.

PERM   (output) INTEGER array, dimension ( N )
       The permutations (from deflation and sorting) to be applied
       to each singular block. Not referenced if ICOMPQ = 0.

GIVPTR (output) INTEGER
       The number of Givens rotations which took place in this
       subproblem. Not referenced if ICOMPQ = 0.

GIVCOL (output) INTEGER array, dimension ( LDGCOL, 2 )
       Each pair of numbers indicates a pair of columns to take place
       in a Givens rotation. Not referenced if ICOMPQ = 0.

LDGCOL (input) INTEGER
       The leading dimension of GIVCOL, must be at least N.

GIVNUM (output) DOUBLE PRECISION array, dimension ( LDGNUM, 2 )
       Each number indicates the C or S value to be used in the
       corresponding Givens rotation. Not referenced if ICOMPQ = 0.

LDGNUM (input) INTEGER
       The leading dimension of GIVNUM, must be at least N.
```

```
  C      (output) DOUBLE PRECISION
         C contains garbage if SQRE =0 and the C-value of a Givens
         rotation related to the right null space if SQRE = 1.

  S      (output) DOUBLE PRECISION
         S contains garbage if SQRE =0 and the S-value of a Givens
         rotation related to the right null space if SQRE = 1.

  INFO   (output) INTEGER
         = 0:  successful exit.
         < 0:  if INFO = -i, the i-th argument had an illegal value.

  Further Details
  ===============

      TOL = EIGHT*EIGHT*EPS*MAX( ABS( D( N ) ), TOL )
*
*     There are 2 kinds of deflation -- first a value in the z-vector
*     is small, second two (or more) singular values are very close
*     together (their difference is small).
*
*     If the value in the z-vector is small, we simply permute the
*     array so that the corresponding singular value is moved to the
*     end.
*
*     If two values in the D-vector are close, we perform a two-sided
*     rotation designed to make one of the corresponding z-vector
*     entries zero, and then permute the array so that the deflated
*     singular value is moved to the end.
*
*     If there are multiple singular values then the problem deflates.
*     Here the number of equal singular values are found.  As each equal
*     singular value is found, an elementary reflector is computed to
*     rotate the corresponding singular subspace so that the
*     corresponding components of Z are zero in this new basis.

NAME
       DLASD8 - the square roots of the roots of the secular equation,

SYNOPSIS
       SUBROUTINE DLASD8( ICOMPQ, K, D, Z, VF, VL, DIFL, DIFR, LDDIFR, DSIGMA,
                          WORK, INFO )

           INTEGER        ICOMPQ, INFO, K, LDDIFR

           DOUBLE         PRECISION D( * ), DIFL( *  ),  DIFR(  LDDIFR,  *  ),
                          DSIGMA( * ), VF( * ), VL( * ), WORK( * ), Z( * )
```

```
Purpose
=======

DLASD8 finds the square roots of the roots of the secular equation,
as defined by the values in DSIGMA and Z. It makes the appropriate
calls to DLASD4, and stores, for each  element in D, the distance
to its two nearest poles (elements in DSIGMA). It also updates
the arrays VF and VL, the first and last components of all the
right singular vectors of the original bidiagonal matrix.

DLASD8 is called from DLASD6.

Arguments
=========

ICOMPQ  (input) INTEGER
        Specifies whether singular vectors are to be computed in
        factored form in the calling routine:
        = 0: Compute singular values only.
        = 1: Compute singular vectors in factored form as well.

K       (input) INTEGER
        The number of terms in the rational function to be solved
        by DLASD4.  K >= 1.

D       (output) DOUBLE PRECISION array, dimension ( K )
        On output, D contains the updated singular values.

Z       (input) DOUBLE PRECISION array, dimension ( K )
        The first K elements of this array contain the components
        of the deflation-adjusted updating row vector.

VF      (input/output) DOUBLE PRECISION array, dimension ( K )
        On entry, VF contains  information passed through DBEDE8.
        On exit, VF contains the first K components of the first
        components of all right singular vectors of the bidiagonal
        matrix.

VL      (input/output) DOUBLE PRECISION array, dimension ( K )
        On entry, VL contains  information passed through DBEDE8.
        On exit, VL contains the first K components of the last
        components of all right singular vectors of the bidiagonal
        matrix.

DIFL    (output) DOUBLE PRECISION array, dimension ( K )
        On exit, DIFL(I) = D(I) - DSIGMA(I).

DIFR    (output) DOUBLE PRECISION array,
                 dimension ( LDDIFR, 2 ) if ICOMPQ = 1 and
                 dimension ( K ) if ICOMPQ = 0.
```

```
          On exit, DIFR(I,1) = D(I) - DSIGMA(I+1), DIFR(K,1) is not
          defined and will not be referenced.

          If ICOMPQ = 1, DIFR(1:K,2) is an array containing the
          normalizing factors for the right singular vector matrix.

  LDDIFR  (input) INTEGER
          The leading dimension of DIFR, must be at least K.

  DSIGMA  (input) DOUBLE PRECISION array, dimension ( K )
          The first K elements of this array contain the old roots
          of the deflated updating problem.  These are the poles
          of the secular equation.

  WORK    (workspace) DOUBLE PRECISION array, dimension at least 3 * K

  INFO    (output) INTEGER
          = 0:  successful exit.
          < 0:  if INFO = -i, the i-th argument had an illegal value.
          > 0:  if INFO = 1, an singular value did not converge

  Further Details
  ===============

  Based on contributions by
     Ming Gu and Huan Ren, Computer Science Division, University of
     California at Berkeley, USA

```

```
*
*     Modify values DSIGMA(i) to make sure all DSIGMA(i)-DSIGMA(j) can
*     be computed with high relative accuracy (barring over/underflow).
*     This is a problem on machines without a guard digit in
*     add/subtract (Cray XMP, Cray YMP, Cray C 90 and Cray 2).
*     The following code replaces DSIGMA(I) by 2*DSIGMA(I)-DSIGMA(I),
*     which on any of these machines zeros out the bottommost
*     bit of DSIGMA(I) if it is 1; this makes the subsequent
*     subtractions DSIGMA(I)-DSIGMA(J) unproblematic when cancellation
*     occurs. On binary machines with a guard digit (almost all
*     machines) it does not change DSIGMA(I) at all. On hexadecimal
*     and decimal machines with a guard digit, it slightly
*     changes the bottommost bits of DSIGMA(I). It does not account
*     for hexadecimal or decimal machines without guard digits
*     (we know of none). We use a subroutine call to compute
*     2*DLAMBDA(I) to prevent optimizing compilers from eliminating
*     this code.

NAME
       DLASDA  -  divide  and  conquer  approach, DLASDA computes the singular
       value decomposition (SVD) of a real upper bidiagonal  N-by-M  matrix  B
       with diagonal D and offdiagonal E, where M = N + SQRE

SYNOPSIS
       SUBROUTINE DLASDA( ICOMPQ,  SMLSIZ, N, SQRE, D, E, U, LDU, VT, K, DIFL,
                          DIFR,  Z,  POLES,  GIVPTR,  GIVCOL,  LDGCOL,   PERM,
                          GIVNUM, C, S, WORK, IWORK, INFO )

           INTEGER        ICOMPQ, INFO, LDGCOL, LDU, N, SMLSIZ, SQRE
```

```
          INTEGER        GIVCOL(  LDGCOL,  * ), GIVPTR( * ), IWORK( * ), K( *
                         ), PERM( LDGCOL, * )

          DOUBLE         PRECISION C( * ), D( * ), DIFL( LDU, * ), DIFR( LDU,
                         * ), E( * ), GIVNUM( LDU, * ), POLES( LDU, * ), S( *
                         ), U( LDU, * ), VT( LDU, * ), WORK( * ), Z( LDU, * )

  Purpose
  =======

  Using a divide and conquer approach, DLASDA computes the singular
  value decomposition (SVD) of a real upper bidiagonal N-by-M matrix
  B with diagonal D and offdiagonal E, where M = N + SQRE. The
  algorithm computes the singular values in the SVD B = U * S * VT.
  The orthogonal matrices U and VT are optionally computed in
  compact form.

  A related subroutine, DLASD0, computes the singular values and
  the singular vectors in explicit form.

  Arguments
  =========

  ICOMPQ (input) INTEGER
         Specifies whether singular vectors are to be computed
         in compact form, as follows
         = 0: Compute singular values only.
         = 1: Compute singular vectors of upper bidiagonal
              matrix in compact form.

  SMLSIZ (input) INTEGER
         The maximum size of the subproblems at the bottom of the
         computation tree.

  N      (input) INTEGER
         The row dimension of the upper bidiagonal matrix. This is
         also the dimension of the main diagonal array D.

  SQRE   (input) INTEGER
         Specifies the column dimension of the bidiagonal matrix.
         = 0: The bidiagonal matrix has column dimension M = N;
         = 1: The bidiagonal matrix has column dimension M = N + 1.

  D      (input/output) DOUBLE PRECISION array, dimension ( N )
         On entry D contains the main diagonal of the bidiagonal
         matrix. On exit D, if INFO = 0, contains its singular values.

  E      (input) DOUBLE PRECISION array, dimension ( M-1 )
         Contains the subdiagonal entries of the bidiagonal matrix.
```

```
        On exit, E has been destroyed.

U       (output) DOUBLE PRECISION array,
        dimension ( LDU, SMLSIZ ) if ICOMPQ = 1, and not referenced
        if ICOMPQ = 0. If ICOMPQ = 1, on exit, U contains the left
        singular vector matrices of all subproblems at the bottom
        level.

LDU     (input) INTEGER, LDU = > N.
        The leading dimension of arrays U, VT, DIFL, DIFR, POLES,
        GIVNUM, and Z.

VT      (output) DOUBLE PRECISION array,
        dimension ( LDU, SMLSIZ+1 ) if ICOMPQ = 1, and not referenced
        if ICOMPQ = 0. If ICOMPQ = 1, on exit, VT' contains the right
        singular vector matrices of all subproblems at the bottom
        level.

K       (output) INTEGER array,
        dimension ( N ) if ICOMPQ = 1 and dimension 1 if ICOMPQ = 0.
        If ICOMPQ = 1, on exit, K(I) is the dimension of the I-th
        secular equation on the computation tree.

DIFL    (output) DOUBLE PRECISION array, dimension ( LDU, NLVL ),
        where NLVL = floor(log_2 (N/SMLSIZ))).

DIFR    (output) DOUBLE PRECISION array,
                 dimension ( LDU, 2 * NLVL ) if ICOMPQ = 1 and
                 dimension ( N ) if ICOMPQ = 0.
        If ICOMPQ = 1, on exit, DIFL(1:N, I) and DIFR(1:N, 2 * I - 1)
        record distances between singular values on the I-th
        level and singular values on the (I -1)-th level, and
        DIFR(1:N, 2 * I ) contains the normalizing factors for
        the right singular vector matrix. See DLASD8 for details.

Z       (output) DOUBLE PRECISION array,
                 dimension ( LDU, NLVL ) if ICOMPQ = 1 and
                 dimension ( N ) if ICOMPQ = 0.
        The first K elements of Z(1, I) contain the components of
        the deflation-adjusted updating row vector for subproblems
        on the I-th level.

POLES   (output) DOUBLE PRECISION array,
        dimension ( LDU, 2 * NLVL ) if ICOMPQ = 1, and not referenced
        if ICOMPQ = 0. If ICOMPQ = 1, on exit, POLES(1, 2*I - 1) and
        POLES(1, 2*I) contain  the new and old singular values
        involved in the secular equations on the I-th level.

GIVPTR (output) INTEGER array,
        dimension ( N ) if ICOMPQ = 1, and not referenced if
```

```
       ICOMPQ = 0. If ICOMPQ = 1, on exit, GIVPTR( I ) records
       the number of Givens rotations performed on the I-th
       problem on the computation tree.

GIVCOL (output) INTEGER array,
       dimension ( LDGCOL, 2 * NLVL ) if ICOMPQ = 1, and not
       referenced if ICOMPQ = 0. If ICOMPQ = 1, on exit, for each I,
       GIVCOL(1, 2 *I - 1) and GIVCOL(1, 2 *I) record the locations
       of Givens rotations performed on the I-th level on the
       computation tree.

LDGCOL (input) INTEGER, LDGCOL = > N.
       The leading dimension of arrays GIVCOL and PERM.

PERM   (output) INTEGER array,
       dimension ( LDGCOL, NLVL ) if ICOMPQ = 1, and not referenced
       if ICOMPQ = 0. If ICOMPQ = 1, on exit, PERM(1, I) records
       permutations done on the I-th level of the computation tree.

GIVNUM (output) DOUBLE PRECISION array,
       dimension ( LDU,  2 * NLVL ) if ICOMPQ = 1, and not
       referenced if ICOMPQ = 0. If ICOMPQ = 1, on exit, for each I,
       GIVNUM(1, 2 *I - 1) and GIVNUM(1, 2 *I) record the C- and S-
       values of Givens rotations performed on the I-th level on
       the computation tree.

C      (output) DOUBLE PRECISION array,
       dimension ( N ) if ICOMPQ = 1, and dimension 1 if ICOMPQ = 0.
       If ICOMPQ = 1 and the I-th subproblem is not square, on exit,
       C( I ) contains the C-value of a Givens rotation related to
       the right null space of the I-th subproblem.

S      (output) DOUBLE PRECISION array, dimension ( N ) if
       ICOMPQ = 1, and dimension 1 if ICOMPQ = 0. If ICOMPQ = 1
       and the I-th subproblem is not square, on exit, S( I )
       contains the S-value of a Givens rotation related to
       the right null space of the I-th subproblem.

WORK   (workspace) DOUBLE PRECISION array, dimension
       (6 * N + (SMLSIZ + 1)*(SMLSIZ + 1)).

IWORK  (workspace) INTEGER array.
       Dimension must be at least (7 * N).

INFO   (output) INTEGER
        = 0:  successful exit.
        < 0:  if INFO = -i, the i-th argument had an illegal value.
        > 0:  if INFO = 1, an singular value did not converge

Further Details

NAME
       DLASDQ  -  the  singular  value decomposition (SVD) of a real (upper or
       lower) bidiagonal matrix with diagonal D and offdiagonal E,  accumulat-
       ing the transformations if desired

SYNOPSIS
       SUBROUTINE DLASDQ( UPLO,  SQRE,  N,  NCVT, NRU, NCC, D, E, VT, LDVT, U,
                          LDU, C, LDC, WORK, INFO )

           CHARACTER      UPLO

           INTEGER        INFO, LDC, LDU, LDVT, N, NCC, NCVT, NRU, SQRE

           DOUBLE         PRECISION C( LDC, * ), D( * ), E( * ), U( LDU, *  ),
                          VT( LDVT, * ), WORK( * )

  Purpose
  =======

  DLASDQ computes the singular value decomposition (SVD) of a real
  (upper or lower) bidiagonal matrix with diagonal D and offdiagonal
  E, accumulating the transformations if desired. Letting B denote
  the input bidiagonal matrix, the algorithm computes orthogonal
  matrices Q and P such that B = Q * S * P' (P' denotes the transpose
  of P). The singular values S are overwritten on D.

  The input matrix U  is changed to U  * Q  if desired.
  The input matrix VT is changed to P' * VT if desired.
  The input matrix C  is changed to Q' * C  if desired.

  See "Computing  Small Singular Values of Bidiagonal Matrices With
  Guaranteed High Relative Accuracy," by J. Demmel and W. Kahan,
  LAPACK Working Note #3, for a detailed description of the algorithm.

  Arguments
  =========
```

```
UPLO  (input) CHARACTER*1
      On entry, UPLO specifies whether the input bidiagonal matrix
      is upper or lower bidiagonal, and wether it is square are
      not.
         UPLO = 'U' or 'u'   B is upper bidiagonal.
         UPLO = 'L' or 'l'   B is lower bidiagonal.

SQRE  (input) INTEGER
      = 0: then the input matrix is N-by-N.
      = 1: then the input matrix is N-by-(N+1) if UPLU = 'U' and
           (N+1)-by-N if UPLU = 'L'.

      The bidiagonal matrix has
      N = NL + NR + 1 rows and
      M = N + SQRE >= N columns.

N     (input) INTEGER
      On entry, N specifies the number of rows and columns
      in the matrix. N must be at least 0.

NCVT  (input) INTEGER
      On entry, NCVT specifies the number of columns of
      the matrix VT. NCVT must be at least 0.

NRU   (input) INTEGER
      On entry, NRU specifies the number of rows of
      the matrix U. NRU must be at least 0.

NCC   (input) INTEGER
      On entry, NCC specifies the number of columns of
      the matrix C. NCC must be at least 0.

D     (input/output) DOUBLE PRECISION array, dimension (N)
      On entry, D contains the diagonal entries of the
      bidiagonal matrix whose SVD is desired. On normal exit,
      D contains the singular values in ascending order.

E     (input/output) DOUBLE PRECISION array.
      dimension is (N-1) if SQRE = 0 and N if SQRE = 1.
      On entry, the entries of E contain the offdiagonal entries
      of the bidiagonal matrix whose SVD is desired. On normal
      exit, E will contain 0. If the algorithm does not converge,
      D and E will contain the diagonal and superdiagonal entries
      of a bidiagonal matrix orthogonally equivalent to the one
      given as input.

VT    (input/output) DOUBLE PRECISION array, dimension (LDVT, NCVT)
      On entry, contains a matrix which on exit has been
      premultiplied by P', dimension N-by-NCVT if SQRE = 0
      and (N+1)-by-NCVT if SQRE = 1 (not referenced if NCVT=0).
```

```
LDVT  (input) INTEGER
      On entry, LDVT specifies the leading dimension of VT as
      declared in the calling (sub) program. LDVT must be at
      least 1. If NCVT is nonzero LDVT must also be at least N.

U     (input/output) DOUBLE PRECISION array, dimension (LDU, N)
      On entry, contains a  matrix which on exit has been
      postmultiplied by Q, dimension NRU-by-N if SQRE = 0
      and NRU-by-(N+1) if SQRE = 1 (not referenced if NRU=0).

LDU   (input) INTEGER
      On entry, LDU  specifies the leading dimension of U as
      declared in the calling (sub) program. LDU must be at
      least max( 1, NRU ) .

C     (input/output) DOUBLE PRECISION array, dimension (LDC, NCC)
      On entry, contains an N-by-NCC matrix which on exit
      has been premultiplied by Q'  dimension N-by-NCC if SQRE = 0
      and (N+1)-by-NCC if SQRE = 1 (not referenced if NCC=0).

LDC   (input) INTEGER
      On entry, LDC  specifies the leading dimension of C as
      declared in the calling (sub) program. LDC must be at
      least 1. If NCC is nonzero, LDC must also be at least N.

WORK  (workspace) DOUBLE PRECISION array, dimension (4*N)
      Workspace. Only referenced if one of NCVT, NRU, or NCC is
      nonzero, and if N is at least 2.

INFO  (output) INTEGER
      On exit, a value of 0 indicates a successful exit.
      If INFO < 0, argument number -INFO is illegal.
      If INFO > 0, the algorithm did not converge, and INFO
      specifies how many superdiagonals did not converge.

NAME
       DLASDT - a tree of subproblems for bidiagonal divide and conquer

SYNOPSIS
       SUBROUTINE DLASDT( N, LVL, ND, INODE, NDIML, NDIMR, MSUB )

           INTEGER        LVL, MSUB, N, ND

           INTEGER        INODE( * ), NDIML( * ), NDIMR( * )

  Purpose
  =======

  DLASDT creates a tree of subproblems for bidiagonal divide and
  conquer.

  Arguments
  =========

   N      (input) INTEGER
          On entry, the number of diagonal elements of the
          bidiagonal matrix.

   LVL    (output) INTEGER
          On exit, the number of levels on the computation tree.

   ND     (output) INTEGER
          On exit, the number of nodes on the tree.

   INODE  (output) INTEGER array, dimension ( N )
          On exit, centers of subproblems.

   NDIML  (output) INTEGER array, dimension ( N )
          On exit, row dimensions of left children.
```

```
   NDIMR  (output) INTEGER array, dimension ( N )
          On exit, row dimensions of right children.

   MSUB   (input) INTEGER.
          On entry, the maximum row dimension each subproblem at the
          bottom of the tree can be of.

  Further Details
  ===============

  Based on contributions by
     Ming Gu and Huan Ren, Computer Science Division, University of
     California at Berkeley, USA

NAME
       DLASET  -  an  m-by-n matrix A to BETA on the diagonal and ALPHA on the
       offdiagonals

SYNOPSIS
       SUBROUTINE DLASET( UPLO, M, N, ALPHA, BETA, A, LDA )

           CHARACTER      UPLO

           INTEGER        LDA, M, N

           DOUBLE         PRECISION ALPHA, BETA

           DOUBLE         PRECISION A( LDA, * )

  Purpose
  =======
```

```
  DLASET initializes an m-by-n matrix A to BETA on the diagonal and
  ALPHA on the offdiagonals.

  Arguments
  =========

  UPLO    (input) CHARACTER*1
          Specifies the part of the matrix A to be set.
          = 'U':      Upper triangular part is set; the strictly lower
                      triangular part of A is not changed.
          = 'L':      Lower triangular part is set; the strictly upper
                      triangular part of A is not changed.
          Otherwise:  All of the matrix A is set.

  M       (input) INTEGER
          The number of rows of the matrix A.  M >= 0.

  N       (input) INTEGER
          The number of columns of the matrix A.  N >= 0.

  ALPHA   (input) DOUBLE PRECISION
          The constant to which the offdiagonal elements are to be set.

  BETA    (input) DOUBLE PRECISION
          The constant to which the diagonal elements are to be set.

  A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
          On exit, the leading m-by-n submatrix of A is set as follows:

          if UPLO = 'U', A(i,j) = ALPHA, 1<=i<=j-1, 1<=j<=n,
          if UPLO = 'L', A(i,j) = ALPHA, j+1<=i<=m, 1<=j<=n,
          otherwise,     A(i,j) = ALPHA, 1<=i<=m, 1<=j<=n, i.ne.j,

          and, for all UPLO, A(i,i) = BETA, 1<=i<=min(m,n).

  LDA     (input) INTEGER
          The leading dimension of the array A.  LDA >= max(1,M).
```

NAME
       DLASQ1  -  the  singular values of a real N-by-N bidiagonal matrix with
       diagonal D and off-diagonal E

SYNOPSIS
       SUBROUTINE DLASQ1( N, D, E, WORK, INFO )

           INTEGER        INFO, N

           DOUBLE         PRECISION D( * ), E( * ), WORK( * )

  Purpose
  =======

  DLASQ1 computes the singular values of a real N-by-N bidiagonal
  matrix with diagonal D and off-diagonal E. The singular values
  are computed to high relative accuracy, in the absence of
  denormalization, underflow and overflow. The algorithm was first
  presented in

  "Accurate singular values and differential qd algorithms" by K. V.
  Fernando and B. N. Parlett, Numer. Math., Vol-67, No. 2, pp. 191-230,
  1994,

  and the present implementation is described in "An implementation of
  the dqds Algorithm (Positive Case)", LAPACK Working Note.

  Arguments
```

```
  =========

  N     (input) INTEGER
        The number of rows and columns in the matrix. N >= 0.

  D     (input/output) DOUBLE PRECISION array, dimension (N)
        On entry, D contains the diagonal elements of the
        bidiagonal matrix whose SVD is desired. On normal exit,
        D contains the singular values in decreasing order.

  E     (input/output) DOUBLE PRECISION array, dimension (N)
        On entry, elements E(1:N-1) contain the off-diagonal elements
        of the bidiagonal matrix whose SVD is desired.
        On exit, E is overwritten.

  WORK  (workspace) DOUBLE PRECISION array, dimension (4*N)

  INFO  (output) INTEGER
        = 0: successful exit
        < 0: if INFO = -i, the i-th argument had an illegal value
        > 0: the algorithm failed
             = 1, a split was marked by a positive value in E
             = 2, current block of Z not diagonalized after 30*N
                  iterations (in inner while loop)
             = 3, termination criterion of outer while loop not met
                  (program created more than N unreduced blocks)
```

NAME
       DLASQ2  - all the eigenvalues of the symmetric positive definite tridi-
       agonal matrix associated with the qd array Z to high relative  accuracy
       are  computed to high relative accuracy, in the absence of denormaliza-
       tion, underflow and overflow

SYNOPSIS
       SUBROUTINE DLASQ2( N, Z, INFO )

           INTEGER        INFO, N
```

```
         DOUBLE         PRECISION Z( * )

Purpose
=======

DLASQ2 computes all the eigenvalues of the symmetric positive
definite tridiagonal matrix associated with the qd array Z to high
relative accuracy are computed to high relative accuracy, in the
absence of denormalization, underflow and overflow.

To see the relation of Z to the tridiagonal matrix, let L be a
unit lower bidiagonal matrix with subdiagonals Z(2,4,6,,..) and
let U be an upper bidiagonal matrix with 1's above and diagonal
Z(1,3,5,,..). The tridiagonal is L*U or, if you prefer, the
symmetric tridiagonal to which it is similar.

Note : DLASQ2 defines a logical variable, IEEE, which is true
on machines which follow ieee-754 floating-point standard in their
handling of infinities and NaNs, and false otherwise. This variable
is passed to DLASQ3.

Arguments
=========

N     (input) INTEGER
      The number of rows and columns in the matrix. N >= 0.

Z     (workspace) DOUBLE PRECISION array, dimension ( 4*N )
      On entry Z holds the qd array. On exit, entries 1 to N hold
      the eigenvalues in decreasing order, Z( 2*N+1 ) holds the
      trace, and Z( 2*N+2 ) holds the sum of the eigenvalues. If
      N > 2, then Z( 2*N+3 ) holds the iteration count, Z( 2*N+4 )
      holds NDIVS/NIN^2, and Z( 2*N+5 ) holds the percentage of
      shifts that failed.

INFO  (output) INTEGER
      = 0: successful exit
      < 0: if the i-th argument is a scalar and had an illegal
           value, then INFO = -i, if the i-th argument is an
           array and the j-entry had an illegal value, then
           INFO = -(i*100+j)
      > 0: the algorithm failed
            = 1, a split was marked by a positive value in E
            = 2, current block of Z not diagonalized after 30*N
                 iterations (in inner while loop)
            = 3, termination criterion of outer while loop not met
                 (program created more than N unreduced blocks)

Further Details
```

```
*  ===============
*  Local Variables: I0:N0 defines a current unreduced segment of Z.
*  The shifts are accumulated in SIGMA. Iteration count is in ITER.
*  Ping-pong is controlled by PP (alternates between 0 and 1).
```

NAME
       DLASQ3 - for deflation, computes a shift (TAU) and calls dqds

SYNOPSIS
       SUBROUTINE DLASQ3( I0,  N0,  Z,  PP,  DMIN,  SIGMA, DESIG, QMAX, NFAIL,
                          ITER, NDIV, IEEE )

           LOGICAL        IEEE

           INTEGER        I0, ITER, N0, NDIV, NFAIL, PP

           DOUBLE         PRECISION DESIG, DMIN, QMAX, SIGMA

           DOUBLE         PRECISION Z( * )

  Purpose
  =======

  DLASQ3 checks for deflation, computes a shift (TAU) and calls dqds.
  In case of failure it changes shifts, and tries again until output
  is positive.

  Arguments
  =========

  I0     (input) INTEGER
         First index.

  N0     (input) INTEGER
         Last index.

  Z      (input) DOUBLE PRECISION array, dimension ( 4*N )
         Z holds the qd array.

  PP     (input) INTEGER
         PP=0 for ping, PP=1 for pong.

  DMIN   (output) DOUBLE PRECISION
         Minimum value of d.

  SIGMA  (output) DOUBLE PRECISION
         Sum of shifts used in current segment.

  DESIG  (input/output) DOUBLE PRECISION
         Lower order part of SIGMA
```

```
  QMAX   (input) DOUBLE PRECISION
         Maximum value of q.

  NFAIL  (output) INTEGER
         Number of times shift was too big.

  ITER   (output) INTEGER
         Number of iterations.

  NDIV   (output) INTEGER
         Number of divisions.

  TTYPE  (output) INTEGER
         Shift type.

  IEEE   (input) LOGICAL
         Flag for IEEE or non IEEE arithmetic (passed to DLASQ5).
```

NAME
       DLASQ4  -  an approximation TAU to the smallest eigenvalue using values
       of d from the previous transform

SYNOPSIS
       SUBROUTINE DLASQ4( I0, N0, Z, PP, NOIN, DMIN, DMIN1,  DMIN2,  DN,  DN1,
                          DN2, TAU, TTYPE )

           INTEGER        I0, N0, NOIN, PP, TTYPE

           DOUBLE         PRECISION DMIN, DMIN1, DMIN2, DN, DN1, DN2, TAU

           DOUBLE         PRECISION Z( * )

  Purpose
  =======

  DLASQ4 computes an approximation TAU to the smallest eigenvalue
  using values of d from the previous transform.

  I0    (input) INTEGER
        First index.

  N0    (input) INTEGER
        Last index.

  Z     (input) DOUBLE PRECISION array, dimension ( 4*N )
        Z holds the qd array.

  PP    (input) INTEGER
        PP=0 for ping, PP=1 for pong.

  NOIN  (input) INTEGER
        The value of N0 at start of EIGTEST.

  DMIN  (input) DOUBLE PRECISION
        Minimum value of d.
```

```
  DMIN1 (input) DOUBLE PRECISION
        Minimum value of d, excluding D( NO ).

  DMIN2 (input) DOUBLE PRECISION
        Minimum value of d, excluding D( NO ) and D( NO-1 ).

  DN    (input) DOUBLE PRECISION
        d(N)

  DN1   (input) DOUBLE PRECISION
        d(N-1)

  DN2   (input) DOUBLE PRECISION
        d(N-2)

  TAU   (output) DOUBLE PRECISION
        This is the shift.

  TTYPE (output) INTEGER
        Shift type.

NAME
       DLASQ5  -  one  dqds  transform in ping-pong form, one version for IEEE
       machines another for non IEEE machines

SYNOPSIS
       SUBROUTINE DLASQ5( I0, N0, Z, PP, TAU, DMIN, DMIN1,  DMIN2,  DN,  DNM1,
                          DNM2, IEEE )

           LOGICAL        IEEE

           INTEGER        I0, N0, PP

           DOUBLE         PRECISION DMIN, DMIN1, DMIN2, DN, DNM1, DNM2, TAU

           DOUBLE         PRECISION Z( * )

  Purpose
  =======

  DLASQ5 computes one dqds transform in ping-pong form, one
  version for IEEE machines another for non IEEE machines.

  Arguments
  =========

  I0    (input) INTEGER
        First index.

  N0    (input) INTEGER
```

```
       Last index.

  Z     (input) DOUBLE PRECISION array, dimension ( 4*N )
       Z holds the qd array. EMIN is stored in Z(4*N0) to avoid
       an extra argument.

  PP    (input) INTEGER
       PP=0 for ping, PP=1 for pong.

  TAU   (input) DOUBLE PRECISION
       This is the shift.

  DMIN  (output) DOUBLE PRECISION
       Minimum value of d.

  DMIN1 (output) DOUBLE PRECISION
       Minimum value of d, excluding D( N0 ).

  DMIN2 (output) DOUBLE PRECISION
       Minimum value of d, excluding D( N0 ) and D( N0-1 ).

  DN    (output) DOUBLE PRECISION
       d(N0), the last value of d.

  DNM1  (output) DOUBLE PRECISION
       d(N0-1).

  DNM2  (output) DOUBLE PRECISION
       d(N0-2).

  IEEE  (input) LOGICAL
       Flag for IEEE or non IEEE arithmetic.
```

NAME
       DLASQ6  -  one  dqd  (shift equal to zero) transform in ping-pong form,
       with protection against underflow and overflow

SYNOPSIS
       SUBROUTINE DLASQ6( I0, N0, Z, PP, DMIN, DMIN1, DMIN2, DN, DNM1, DNM2 )

           INTEGER        I0, N0, PP

           DOUBLE         PRECISION DMIN, DMIN1, DMIN2, DN, DNM1, DNM2

           DOUBLE         PRECISION Z( * )

  Purpose
  =======
```

```
  DLASQ6 computes one dqd (shift equal to zero) transform in
  ping-pong form, with protection against underflow and overflow.

  Arguments
  =========

  I0    (input) INTEGER
        First index.

  N0    (input) INTEGER
        Last index.

  Z     (input) DOUBLE PRECISION array, dimension ( 4*N )
        Z holds the qd array. EMIN is stored in Z(4*N0) to avoid
        an extra argument.

  PP    (input) INTEGER
        PP=0 for ping, PP=1 for pong.

  DMIN  (output) DOUBLE PRECISION
        Minimum value of d.

  DMIN1 (output) DOUBLE PRECISION
        Minimum value of d, excluding D( N0 ).

  DMIN2 (output) DOUBLE PRECISION
        Minimum value of d, excluding D( N0 ) and D( N0-1 ).

  DN    (output) DOUBLE PRECISION
        d(N0), the last value of d.

  DNM1  (output) DOUBLE PRECISION
        d(N0-1).

  DNM2  (output) DOUBLE PRECISION
        d(N0-2).

NAME
       DLASR - a sequence of plane rotations to a real matrix A,

SYNOPSIS
```

```
      SUBROUTINE DLASR( SIDE, PIVOT, DIRECT, M, N, C, S, A, LDA )

          CHARACTER     DIRECT, PIVOT, SIDE

          INTEGER       LDA, M, N

          DOUBLE        PRECISION A( LDA, * ), C( * ), S( * )

  Purpose
  =======

  DLASR   performs the transformation

     A := P*A,   when SIDE = 'L' or 'l'  (  Left-hand side )

     A := A*P',  when SIDE = 'R' or 'r'  ( Right-hand side )

  where A is an m by n real matrix and P is an orthogonal matrix,
  consisting of a sequence of plane rotations determined by the
  parameters PIVOT and DIRECT as follows ( z = m when SIDE = 'L' or 'l'
  and z = n when SIDE = 'R' or 'r' ):

  When  DIRECT = 'F' or 'f'  ( Forward sequence ) then

     P = P( z - 1 )*...*P( 2 )*P( 1 ),

  and when DIRECT = 'B' or 'b'  ( Backward sequence ) then

     P = P( 1 )*P( 2 )*...*P( z - 1 ),

  where  P( k ) is a plane rotation matrix for the following planes:

     when  PIVOT = 'V' or 'v'  ( Variable pivot ),
        the plane ( k, k + 1 )

     when  PIVOT = 'T' or 't'  ( Top pivot ),
        the plane ( 1, k + 1 )

     when  PIVOT = 'B' or 'b'  ( Bottom pivot ),
        the plane ( k, z )

  c( k ) and s( k )  must contain the  cosine and sine that define the
  matrix  P( k ).  The two by two plane rotation part of the matrix
  P( k ), R( k ), is assumed to be of the form

     R( k ) = (  c( k )  s( k ) ).
              ( -s( k )  c( k ) )

  This version vectorises across rows of the array A when SIDE = 'L'.
```

```
Arguments
=========

SIDE    (input) CHARACTER*1
        Specifies whether the plane rotation matrix P is applied to
        A on the left or the right.
        = 'L':  Left, compute A := P*A
        = 'R':  Right, compute A:= A*P'

DIRECT  (input) CHARACTER*1
        Specifies whether P is a forward or backward sequence of
        plane rotations.
        = 'F':  Forward, P = P( z - 1 )*...*P( 2 )*P( 1 )
        = 'B':  Backward, P = P( 1 )*P( 2 )*...*P( z - 1 )

PIVOT   (input) CHARACTER*1
        Specifies the plane for which P(k) is a plane rotation
        matrix.
        = 'V':  Variable pivot, the plane (k,k+1)
        = 'T':  Top pivot, the plane (1,k+1)
        = 'B':  Bottom pivot, the plane (k,z)

M       (input) INTEGER
        The number of rows of the matrix A.  If m <= 1, an immediate
        return is effected.

N       (input) INTEGER
        The number of columns of the matrix A.  If n <= 1, an
        immediate return is effected.

C, S    (input) DOUBLE PRECISION arrays, dimension
                (M-1) if SIDE = 'L'
                (N-1) if SIDE = 'R'
        c(k) and s(k) contain the cosine and sine that define the
        matrix P(k).  The two by two plane rotation part of the
        matrix P(k), R(k), is assumed to be of the form
        R( k ) = (  c( k )  s( k ) ).
                 ( -s( k )  c( k ) )

A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
        The m by n matrix A.  On exit, A is overwritten by P*A if
        SIDE = 'R' or by A*P' if SIDE = 'L'.

LDA     (input) INTEGER
        The leading dimension of the array A.  LDA >= max(1,M).

NAME
       DLASRT - number in D in increasing order (if ID = 'I') or in decreasing
       order (if ID = 'D' )

SYNOPSIS
       SUBROUTINE DLASRT( ID, N, D, INFO )

           CHARACTER      ID

           INTEGER        INFO, N

           DOUBLE         PRECISION D( * )

  Purpose
  =======
```

```
  Sort the numbers in D in increasing order (if ID = 'I') or
  in decreasing order (if ID = 'D' ).

  Use Quick Sort, reverting to Insertion sort on arrays of
  size <= 20. Dimension of STACK limits N to about 2**32.

  Arguments
  =========

  ID      (input) CHARACTER*1
          = 'I': sort D in increasing order;
          = 'D': sort D in decreasing order.

  N       (input) INTEGER
          The length of the array D.

  D       (input/output) DOUBLE PRECISION array, dimension (N)
          On entry, the array to be sorted.
          On exit, D has been sorted into increasing order
          (D(1) <= ... <= D(N) ) or into decreasing order
          (D(1) >= ... >= D(N) ), depending on ID.

  INFO    (output) INTEGER
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an illegal value
```

NAME
       DLASSQ  -  the  values  scl and smsq such that   ( scl**2 )*smsq = x( 1
       )**2 +...+ x( n )**2 + ( scale**2 )*sumsq,

SYNOPSIS
       SUBROUTINE DLASSQ( N, X, INCX, SCALE, SUMSQ )

           INTEGER        INCX, N

           DOUBLE         PRECISION SCALE, SUMSQ

           DOUBLE         PRECISION X( * )

  Purpose
  =======

  DLASSQ  returns the values  scl  and  smsq  such that

     ( scl**2 )*smsq = x( 1 )**2 +...+ x( n )**2 + ( scale**2 )*sumsq,

  where  x( i ) = X( 1 + ( i - 1 )*INCX ). The value of  sumsq  is
  assumed to be non-negative and  scl  returns the value

     scl = max( scale, abs( x( i ) ) ).

  scale and sumsq must be supplied in SCALE and SUMSQ and
  scl and smsq are overwritten on SCALE and SUMSQ respectively.

  The routine makes only one pass through the vector x.

  Arguments
  =========

  N       (input) INTEGER
          The number of elements to be used from the vector X.

  X       (input) DOUBLE PRECISION array, dimension (N)
          The vector for which a scaled sum of squares is computed.
             x( i )  = X( 1 + ( i - 1 )*INCX ), 1 <= i <= n.

  INCX    (input) INTEGER
          The increment between successive values of the vector X.
          INCX > 0.

  SCALE   (input/output) DOUBLE PRECISION
          On entry, the value  scale  in the equation above.
          On exit, SCALE is overwritten with  scl , the scaling factor
```

```
          for the sum of squares.

  SUMSQ   (input/output) DOUBLE PRECISION
          On entry, the value  sumsq  in the equation above.
          On exit, SUMSQ is overwritten with  smsq , the basic sum of
          squares from which  scl  has been factored out.
```

NAME
       DLASV2 - the singular value decomposition of a 2-by-2 triangular matrix
       [ F G ]  [ 0 H ]

SYNOPSIS
       SUBROUTINE DLASV2( F, G, H, SSMIN, SSMAX, SNR, CSR, SNL, CSL )

           DOUBLE         PRECISION CSL, CSR, F, G, H, SNL, SNR, SSMAX, SSMIN

  Purpose
  =======

  DLASV2 computes the singular value decomposition of a 2-by-2
  triangular matrix
     [  F   G  ]
```

```
   [  0   H  ].
On return, abs(SSMAX) is the larger singular value, abs(SSMIN) is the
smaller singular value, and (CSL,SNL) and (CSR,SNR) are the left and
right singular vectors for abs(SSMAX), giving the decomposition

   [ CSL  SNL ] [  F   G  ] [ CSR -SNR ]  =  [ SSMAX   0   ]
   [-SNL  CSL ] [  0   H  ] [ SNR  CSR ]     [  0    SSMIN ].

Arguments
=========

F       (input) DOUBLE PRECISION
        The (1,1) element of the 2-by-2 matrix.

G       (input) DOUBLE PRECISION
        The (1,2) element of the 2-by-2 matrix.

H       (input) DOUBLE PRECISION
        The (2,2) element of the 2-by-2 matrix.

SSMIN   (output) DOUBLE PRECISION
        abs(SSMIN) is the smaller singular value.

SSMAX   (output) DOUBLE PRECISION
        abs(SSMAX) is the larger singular value.

SNL     (output) DOUBLE PRECISION
CSL     (output) DOUBLE PRECISION
        The vector (CSL, SNL) is a unit left singular vector for the
        singular value abs(SSMAX).

SNR     (output) DOUBLE PRECISION
CSR     (output) DOUBLE PRECISION
        The vector (CSR, SNR) is a unit right singular vector for the
        singular value abs(SSMAX).

Further Details
===============

Any input parameter may be aliased with any output parameter.

Barring over/underflow and assuming a guard digit in subtraction, all
output quantities are correct to within a few units in the last
place (ulps).

In IEEE arithmetic, the code works correctly if one matrix element is
infinite.

Overflow will not occur unless the largest singular value itself
overflows or is within a few ulps of overflow. (On machines with
```

```
  partial overflow, like the Cray, overflow may occur if the largest
  singular value is within a factor of 2 of overflow.)

  Underflow is harmless if underflow is gradual. Otherwise, results
  may correspond to a matrix modified by perturbations of size near
  the underflow threshold.
```

NAME
       DLASWP - a series of row interchanges on the matrix A

SYNOPSIS
       SUBROUTINE DLASWP( N, A, LDA, K1, K2, IPIV, INCX )

           INTEGER        INCX, K1, K2, LDA, N

           INTEGER        IPIV( * )

           DOUBLE         PRECISION A( LDA, * )

  Purpose
  =======

  DLASWP performs a series of row interchanges on the matrix A.
  One row interchange is initiated for each of rows K1 through K2 of A.

  Arguments
  =========

  N       (input) INTEGER
          The number of columns of the matrix A.

  A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
          On entry, the matrix of column dimension N to which the row
          interchanges will be applied.
          On exit, the permuted matrix.

  LDA     (input) INTEGER
          The leading dimension of the array A.
```

```
  K1      (input) INTEGER
          The first element of IPIV for which a row interchange will
          be done.

  K2      (input) INTEGER
          The last element of IPIV for which a row interchange will
          be done.

  IPIV    (input) INTEGER array, dimension (M*abs(INCX))
          The vector of pivot indices.  Only the elements in positions
          K1 through K2 of IPIV are accessed.
          IPIV(K) = L implies rows K and L are to be interchanged.

  INCX    (input) INTEGER
          The increment between successive values of IPIV.  If IPIV
          is negative, the pivots are applied in reverse order.

  Further Details
  ===============

NAME
       DLASY2  -  for  the N1 by N2 matrix X, 1 <= N1,N2 <= 2, in   op(TL)*X +
       ISGN*X*op(TR) = SCALE*B,
```

```
SYNOPSIS
      SUBROUTINE DLASY2( LTRANL, LTRANR, ISGN, N1, N2, TL, LDTL, TR, LDTR, B,
                         LDB, SCALE, X, LDX, XNORM, INFO )

          LOGICAL        LTRANL, LTRANR

          INTEGER        INFO, ISGN, LDB, LDTL, LDTR, LDX, N1, N2

          DOUBLE         PRECISION SCALE, XNORM

          DOUBLE         PRECISION B( LDB, * ), TL( LDTL, * ), TR( LDTR, * ),
                         X( LDX, * )

  Purpose
  =======

  DLASY2 solves for the N1 by N2 matrix X, 1 <= N1,N2 <= 2, in

         op(TL)*X + ISGN*X*op(TR) = SCALE*B,

  where TL is N1 by N1, TR is N2 by N2, B is N1 by N2, and ISGN = 1 or
  -1.  op(T) = T or T', where T' denotes the transpose of T.

  Arguments
  =========

  LTRANL  (input) LOGICAL
          On entry, LTRANL specifies the op(TL):
             = .FALSE., op(TL) = TL,
             = .TRUE., op(TL) = TL'.

  LTRANR  (input) LOGICAL
          On entry, LTRANR specifies the op(TR):
            = .FALSE., op(TR) = TR,
            = .TRUE., op(TR) = TR'.

  ISGN    (input) INTEGER
          On entry, ISGN specifies the sign of the equation
          as described before. ISGN may only be 1 or -1.

  N1      (input) INTEGER
          On entry, N1 specifies the order of matrix TL.
          N1 may only be 0, 1 or 2.

  N2      (input) INTEGER
          On entry, N2 specifies the order of matrix TR.
          N2 may only be 0, 1 or 2.

  TL      (input) DOUBLE PRECISION array, dimension (LDTL,2)
```

```
          On entry, TL contains an N1 by N1 matrix.

  LDTL    (input) INTEGER
          The leading dimension of the matrix TL. LDTL >= max(1,N1).

  TR      (input) DOUBLE PRECISION array, dimension (LDTR,2)
          On entry, TR contains an N2 by N2 matrix.

  LDTR    (input) INTEGER
          The leading dimension of the matrix TR. LDTR >= max(1,N2).

  B       (input) DOUBLE PRECISION array, dimension (LDB,2)
          On entry, the N1 by N2 matrix B contains the right-hand
          side of the equation.

  LDB     (input) INTEGER
          The leading dimension of the matrix B. LDB >= max(1,N1).

  SCALE   (output) DOUBLE PRECISION
          On exit, SCALE contains the scale factor. SCALE is chosen
          less than or equal to 1 to prevent the solution overflowing.

  X       (output) DOUBLE PRECISION array, dimension (LDX,2)
          On exit, X contains the N1 by N2 solution.

  LDX     (input) INTEGER
          The leading dimension of the matrix X. LDX >= max(1,N1).

  XNORM   (output) DOUBLE PRECISION
          On exit, XNORM is the infinity-norm of the solution.

  INFO    (output) INTEGER
          On exit, INFO is set to
             0: successful exit.
             1: TL and TR have too close eigenvalues, so TL or
                TR is perturbed to get a nonsingular equation.
          NOTE: In the interests of speed, this routine does not
                check the inputs for errors.
```

NAME
       DORG2R - an m by n real matrix Q with orthonormal columns,

SYNOPSIS
       SUBROUTINE DORG2R( M, N, K, A, LDA, TAU, WORK, INFO )

           INTEGER         INFO, K, LDA, M, N

           DOUBLE          PRECISION A( LDA, * ), TAU( * ), WORK( * )

  Purpose
  =======

  DORG2R generates an m by n real matrix Q with orthonormal columns,
  which is defined as the first n columns of a product of k elementary
  reflectors of order m

        Q  =  H(1) H(2) . . . H(k)

  as returned by DGEQRF.

  Arguments
```

```
  =========

  M       (input) INTEGER
          The number of rows of the matrix Q. M >= 0.

  N       (input) INTEGER
          The number of columns of the matrix Q. M >= N >= 0.

  K       (input) INTEGER
          The number of elementary reflectors whose product defines the
          matrix Q. N >= K >= 0.

  A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
          On entry, the i-th column must contain the vector which
          defines the elementary reflector H(i), for i = 1,2,...,k, as
          returned by DGEQRF in the first k columns of its array
          argument A.
          On exit, the m-by-n matrix Q.

  LDA     (input) INTEGER
          The first dimension of the array A. LDA >= max(1,M).

  TAU     (input) DOUBLE PRECISION array, dimension (K)
          TAU(i) must contain the scalar factor of the elementary
          reflector H(i), as returned by DGEQRF.

  WORK    (workspace) DOUBLE PRECISION array, dimension (N)

  INFO    (output) INTEGER
          = 0: successful exit
          < 0: if INFO = -i, the i-th argument has an illegal value
```

NAME
       DORGBR  -  one  of the real orthogonal matrices Q or P**T determined by
       DGEBRD when reducing a real matrix A to bidiagonal form

SYNOPSIS
       SUBROUTINE DORGBR( VECT, M, N, K, A, LDA, TAU, WORK, LWORK, INFO )

           CHARACTER      VECT

           INTEGER        INFO, K, LDA, LWORK, M, N

           DOUBLE         PRECISION A( LDA, * ), TAU( * ), WORK( * )
```

```
Purpose
=======

DORGBR generates one of the real orthogonal matrices Q or P**T
determined by DGEBRD when reducing a real matrix A to bidiagonal
form: A = Q * B * P**T.  Q and P**T are defined as products of
elementary reflectors H(i) or G(i) respectively.

If VECT = 'Q', A is assumed to have been an M-by-K matrix, and Q
is of order M:
if m >= k, Q = H(1) H(2) . . . H(k) and DORGBR returns the first n
columns of Q, where m >= n >= k;
if m < k, Q = H(1) H(2) . . . H(m-1) and DORGBR returns Q as an
M-by-M matrix.

If VECT = 'P', A is assumed to have been a K-by-N matrix, and P**T
is of order N:
if k < n, P**T = G(k) . . . G(2) G(1) and DORGBR returns the first m
rows of P**T, where n >= m >= k;
if k >= n, P**T = G(n-1) . . . G(2) G(1) and DORGBR returns P**T as
an N-by-N matrix.

Arguments
=========

VECT    (input) CHARACTER*1
        Specifies whether the matrix Q or the matrix P**T is
        required, as defined in the transformation applied by DGEBRD:
        = 'Q':  generate Q;
        = 'P':  generate P**T.

M       (input) INTEGER
        The number of rows of the matrix Q or P**T to be returned.
        M >= 0.

N       (input) INTEGER
        The number of columns of the matrix Q or P**T to be returned.
        N >= 0.
        If VECT = 'Q', M >= N >= min(M,K);
        if VECT = 'P', N >= M >= min(N,K).

K       (input) INTEGER
        If VECT = 'Q', the number of columns in the original M-by-K
        matrix reduced by DGEBRD.
        If VECT = 'P', the number of rows in the original K-by-N
        matrix reduced by DGEBRD.
        K >= 0.

A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
```

```
          On entry, the vectors which define the elementary reflectors,
          as returned by DGEBRD.
          On exit, the M-by-N matrix Q or P**T.

  LDA     (input) INTEGER
          The leading dimension of the array A. LDA >= max(1,M).

  TAU     (input) DOUBLE PRECISION array, dimension
                                (min(M,K)) if VECT = 'Q'
                                (min(N,K)) if VECT = 'P'
          TAU(i) must contain the scalar factor of the elementary
          reflector H(i) or G(i), which determines Q or P**T, as
          returned by DGEBRD in its array argument TAUQ or TAUP.

  WORK    (workspace/output) DOUBLE PRECISION array, dimension (LWORK)
          On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

  LWORK   (input) INTEGER
          The dimension of the array WORK. LWORK >= max(1,min(M,N)).
          For optimum performance LWORK >= min(M,N)*NB, where NB
          is the optimal blocksize.

          If LWORK = -1, then a workspace query is assumed; the routine
          only calculates the optimal size of the WORK array, returns
          this value as the first entry of the WORK array, and no error
          message related to LWORK is issued by XERBLA.

  INFO    (output) INTEGER
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an illegal value
```

NAME
       DORGHR  - a real orthogonal matrix Q which is defined as the product of
       IHI-ILO elementary reflectors of order N, as returned by DGEHRD

SYNOPSIS
       SUBROUTINE DORGHR( N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO )

           INTEGER        IHI, ILO, INFO, LDA, LWORK, N

           DOUBLE         PRECISION A( LDA, * ), TAU( * ), WORK( * )

  Purpose
  =======

  DORGHR generates a real orthogonal matrix Q which is defined as the
  product of IHI-ILO elementary reflectors of order N, as returned by
  DGEHRD:

  Q = H(ilo) H(ilo+1) . . . H(ihi-1).

  Arguments
  =========
```

```
  N       (input) INTEGER
          The order of the matrix Q. N >= 0.

  ILO     (input) INTEGER
  IHI     (input) INTEGER
          ILO and IHI must have the same values as in the previous call
          of DGEHRD. Q is equal to the unit matrix except in the
          submatrix Q(ilo+1:ihi,ilo+1:ihi).
          1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

  A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
          On entry, the vectors which define the elementary reflectors,
          as returned by DGEHRD.
          On exit, the N-by-N orthogonal matrix Q.

  LDA     (input) INTEGER
          The leading dimension of the array A. LDA >= max(1,N).

  TAU     (input) DOUBLE PRECISION array, dimension (N-1)
          TAU(i) must contain the scalar factor of the elementary
          reflector H(i), as returned by DGEHRD.

  WORK    (workspace/output) DOUBLE PRECISION array, dimension (LWORK)
          On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

  LWORK   (input) INTEGER
          The dimension of the array WORK. LWORK >= IHI-ILO.
          For optimum performance LWORK >= (IHI-ILO)*NB, where NB is
          the optimal blocksize.

          If LWORK = -1, then a workspace query is assumed; the routine
          only calculates the optimal size of the WORK array, returns
          this value as the first entry of the WORK array, and no error
          message related to LWORK is issued by XERBLA.

  INFO    (output) INTEGER
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an illegal value
```

NAME
       DORGL2 - an m by n real matrix Q with orthonormal rows,

SYNOPSIS
       SUBROUTINE DORGL2( M, N, K, A, LDA, TAU, WORK, INFO )

           INTEGER        INFO, K, LDA, M, N

           DOUBLE         PRECISION A( LDA, * ), TAU( * ), WORK( * )

  Purpose
  =======

  DORGL2 generates an m by n real matrix Q with orthonormal rows,
  which is defined as the first m rows of a product of k elementary
  reflectors of order n

        Q  =  H(k) . . . H(2) H(1)

  as returned by DGELQF.

  Arguments
  =========

  M       (input) INTEGER
          The number of rows of the matrix Q. M >= 0.

  N       (input) INTEGER
          The number of columns of the matrix Q. N >= M.

  K       (input) INTEGER
          The number of elementary reflectors whose product defines the
          matrix Q. M >= K >= 0.

  A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
```

```
          On entry, the i-th row must contain the vector which defines
          the elementary reflector H(i), for i = 1,2,...,k, as returned
          by DGELQF in the first k rows of its array argument A.
          On exit, the m-by-n matrix Q.

  LDA     (input) INTEGER
          The first dimension of the array A. LDA >= max(1,M).

  TAU     (input) DOUBLE PRECISION array, dimension (K)
          TAU(i) must contain the scalar factor of the elementary
          reflector H(i), as returned by DGELQF.

  WORK    (workspace) DOUBLE PRECISION array, dimension (M)

  INFO    (output) INTEGER
          = 0: successful exit
          < 0: if INFO = -i, the i-th argument has an illegal value
```

NAME
       DORGLQ - an M-by-N real matrix Q with orthonormal rows,

SYNOPSIS
       SUBROUTINE DORGLQ( M, N, K, A, LDA, TAU, WORK, LWORK, INFO )

           INTEGER        INFO, K, LDA, LWORK, M, N
```

```
          DOUBLE         PRECISION A( LDA, * ), TAU( * ), WORK( * )

  Purpose
  =======

  DORGLQ generates an M-by-N real matrix Q with orthonormal rows,
  which is defined as the first M rows of a product of K elementary
  reflectors of order N

        Q  =  H(k) . . . H(2) H(1)

  as returned by DGELQF.

  Arguments
  =========

  M       (input) INTEGER
          The number of rows of the matrix Q. M >= 0.

  N       (input) INTEGER
          The number of columns of the matrix Q. N >= M.

  K       (input) INTEGER
          The number of elementary reflectors whose product defines the
          matrix Q. M >= K >= 0.

  A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
          On entry, the i-th row must contain the vector which defines
          the elementary reflector H(i), for i = 1,2,...,k, as returned
          by DGELQF in the first k rows of its array argument A.
          On exit, the M-by-N matrix Q.

  LDA     (input) INTEGER
          The first dimension of the array A. LDA >= max(1,M).

  TAU     (input) DOUBLE PRECISION array, dimension (K)
          TAU(i) must contain the scalar factor of the elementary
          reflector H(i), as returned by DGELQF.

  WORK    (workspace/output) DOUBLE PRECISION array, dimension (LWORK)
          On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

  LWORK   (input) INTEGER
          The dimension of the array WORK. LWORK >= max(1,M).
          For optimum performance LWORK >= M*NB, where NB is
          the optimal blocksize.

          If LWORK = -1, then a workspace query is assumed; the routine
          only calculates the optimal size of the WORK array, returns
          this value as the first entry of the WORK array, and no error
```

```
          message related to LWORK is issued by XERBLA.

  INFO    (output) INTEGER
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument has an illegal value
```

NAME
       DORGQR - an M-by-N real matrix Q with orthonormal columns,

SYNOPSIS
       SUBROUTINE DORGQR( M, N, K, A, LDA, TAU, WORK, LWORK, INFO )

           INTEGER        INFO, K, LDA, LWORK, M, N

           DOUBLE         PRECISION A( LDA, * ), TAU( * ), WORK( * )

  Purpose
  =======

  DORGQR generates an M-by-N real matrix Q with orthonormal columns,
  which is defined as the first N columns of a product of K elementary
  reflectors of order M

        Q  =  H(1) H(2) . . . H(k)

  as returned by DGEQRF.

  Arguments
  =========

  M       (input) INTEGER
          The number of rows of the matrix Q. M >= 0.
```

```
  N       (input) INTEGER
          The number of columns of the matrix Q. M >= N >= 0.

  K       (input) INTEGER
          The number of elementary reflectors whose product defines the
          matrix Q. N >= K >= 0.

  A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
          On entry, the i-th column must contain the vector which
          defines the elementary reflector H(i), for i = 1,2,...,k, as
          returned by DGEQRF in the first k columns of its array
          argument A.
          On exit, the M-by-N matrix Q.

  LDA     (input) INTEGER
          The first dimension of the array A. LDA >= max(1,M).

  TAU     (input) DOUBLE PRECISION array, dimension (K)
          TAU(i) must contain the scalar factor of the elementary
          reflector H(i), as returned by DGEQRF.

  WORK    (workspace/output) DOUBLE PRECISION array, dimension (LWORK)
          On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

  LWORK   (input) INTEGER
          The dimension of the array WORK. LWORK >= max(1,N).
          For optimum performance LWORK >= N*NB, where NB is the
          optimal blocksize.

          If LWORK = -1, then a workspace query is assumed; the routine
          only calculates the optimal size of the WORK array, returns
          this value as the first entry of the WORK array, and no error
          message related to LWORK is issued by XERBLA.

  INFO    (output) INTEGER
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument has an illegal value
```

NAME
       DORM2R  -  the  general real m by n matrix C with   Q * C if SIDE = 'L'
       and TRANS = 'N', or   Q'* C if SIDE = 'L' and TRANS = 'T', or   C  *  Q
       if  SIDE  =  'R' and TRANS = 'N', or   C * Q' if SIDE = 'R' and TRANS =
       'T',

SYNOPSIS
       SUBROUTINE DORM2R( SIDE, TRANS, M, N, K, A, LDA,  TAU,  C,  LDC,  WORK,
                          INFO )

           CHARACTER      SIDE, TRANS

           INTEGER        INFO, K, LDA, LDC, M, N

           DOUBLE         PRECISION  A( LDA, * ), C( LDC, * ), TAU( * ), WORK(
                          * )

  Purpose
  =======

  DORM2R overwrites the general real m by n matrix C with

        Q * C  if SIDE = 'L' and TRANS = 'N', or

        Q'* C  if SIDE = 'L' and TRANS = 'T', or

        C * Q  if SIDE = 'R' and TRANS = 'N', or

        C * Q' if SIDE = 'R' and TRANS = 'T',

  where Q is a real orthogonal matrix defined as the product of k
  elementary reflectors

        Q = H(1) H(2) . . . H(k)

  as returned by DGEQRF. Q is of order m if SIDE = 'L' and of order n
  if SIDE = 'R'.

  Arguments
  =========

  SIDE    (input) CHARACTER*1
          = 'L': apply Q or Q' from the Left
          = 'R': apply Q or Q' from the Right

  TRANS   (input) CHARACTER*1
```

```
        = 'N': apply Q  (No transpose)
        = 'T': apply Q' (Transpose)

M       (input) INTEGER
        The number of rows of the matrix C. M >= 0.

N       (input) INTEGER
        The number of columns of the matrix C. N >= 0.

K       (input) INTEGER
        The number of elementary reflectors whose product defines
        the matrix Q.
        If SIDE = 'L', M >= K >= 0;
        if SIDE = 'R', N >= K >= 0.

A       (input) DOUBLE PRECISION array, dimension (LDA,K)
        The i-th column must contain the vector which defines the
        elementary reflector H(i), for i = 1,2,...,k, as returned by
        DGEQRF in the first k columns of its array argument A.
        A is modified by the routine but restored on exit.

LDA     (input) INTEGER
        The leading dimension of the array A.
        If SIDE = 'L', LDA >= max(1,M);
        if SIDE = 'R', LDA >= max(1,N).

TAU     (input) DOUBLE PRECISION array, dimension (K)
        TAU(i) must contain the scalar factor of the elementary
        reflector H(i), as returned by DGEQRF.

C       (input/output) DOUBLE PRECISION array, dimension (LDC,N)
        On entry, the m by n matrix C.
        On exit, C is overwritten by Q*C or Q'*C or C*Q' or C*Q.

LDC     (input) INTEGER
        The leading dimension of the array C. LDC >= max(1,M).

WORK    (workspace) DOUBLE PRECISION array, dimension
                                (N) if SIDE = 'L',
                                (M) if SIDE = 'R'

INFO    (output) INTEGER
        = 0: successful exit
        < 0: if INFO = -i, the i-th argument had an illegal value
```

NAME
       DORMBR - = 'Q', DORMBR overwrites the general real M-by-N matrix C with
       SIDE = 'L' SIDE = 'R' TRANS = 'N'

SYNOPSIS
       SUBROUTINE DORMBR( VECT, SIDE, TRANS, M, N, K, A,  LDA,  TAU,  C,  LDC,
                          WORK, LWORK, INFO )

           CHARACTER      SIDE, TRANS, VECT

           INTEGER        INFO, K, LDA, LDC, LWORK, M, N

           DOUBLE         PRECISION  A( LDA, * ), C( LDC, * ), TAU( * ), WORK(
                          * )

  Purpose
  =======

  If VECT = 'Q', DORMBR overwrites the general real M-by-N matrix C
  with
                  SIDE = 'L'     SIDE = 'R'
  TRANS = 'N':      Q * C          C * Q
  TRANS = 'T':      Q**T * C       C * Q**T

  If VECT = 'P', DORMBR overwrites the general real M-by-N matrix C
  with
                  SIDE = 'L'     SIDE = 'R'
  TRANS = 'N':      P * C          C * P
  TRANS = 'T':      P**T * C       C * P**T

  Here Q and P**T are the orthogonal matrices determined by DGEBRD when
  reducing a real matrix A to bidiagonal form: A = Q * B * P**T. Q and
  P**T are defined as products of elementary reflectors H(i) and G(i)
  respectively.

  Let nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Thus nq is the
  order of the orthogonal matrix Q or P**T that is applied.

  If VECT = 'Q', A is assumed to have been an NQ-by-K matrix:
  if nq >= k, Q = H(1) H(2) . . . H(k);
  if nq < k, Q = H(1) H(2) . . . H(nq-1).

  If VECT = 'P', A is assumed to have been a K-by-NQ matrix:
  if k < nq, P = G(1) G(2) . . . G(k);
  if k >= nq, P = G(1) G(2) . . . G(nq-1).

  Arguments
  =========
```

```
VECT    (input) CHARACTER*1
        = 'Q': apply Q or Q**T;
        = 'P': apply P or P**T.

SIDE    (input) CHARACTER*1
        = 'L': apply Q, Q**T, P or P**T from the Left;
        = 'R': apply Q, Q**T, P or P**T from the Right.

TRANS   (input) CHARACTER*1
        = 'N':  No transpose, apply Q  or P;
        = 'T':  Transpose, apply Q**T or P**T.

M       (input) INTEGER
        The number of rows of the matrix C. M >= 0.

N       (input) INTEGER
        The number of columns of the matrix C. N >= 0.

K       (input) INTEGER
        If VECT = 'Q', the number of columns in the original
        matrix reduced by DGEBRD.
        If VECT = 'P', the number of rows in the original
        matrix reduced by DGEBRD.
        K >= 0.

A       (input) DOUBLE PRECISION array, dimension
                              (LDA,min(nq,K)) if VECT = 'Q'
                              (LDA,nq)        if VECT = 'P'
        The vectors which define the elementary reflectors H(i) and
        G(i), whose products determine the matrices Q and P, as
        returned by DGEBRD.

LDA     (input) INTEGER
        The leading dimension of the array A.
        If VECT = 'Q', LDA >= max(1,nq);
        if VECT = 'P', LDA >= max(1,min(nq,K)).

TAU     (input) DOUBLE PRECISION array, dimension (min(nq,K))
        TAU(i) must contain the scalar factor of the elementary
        reflector H(i) or G(i) which determines Q or P, as returned
        by DGEBRD in the array argument TAUQ or TAUP.

C       (input/output) DOUBLE PRECISION array, dimension (LDC,N)
        On entry, the M-by-N matrix C.
        On exit, C is overwritten by Q*C or Q**T*C or C*Q**T or C*Q
        or P*C or P**T*C or C*P or C*P**T.

LDC     (input) INTEGER
        The leading dimension of the array C. LDC >= max(1,M).
```

```
  WORK    (workspace/output) DOUBLE PRECISION array, dimension (LWORK)
          On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

  LWORK   (input) INTEGER
          The dimension of the array WORK.
          If SIDE = 'L', LWORK >= max(1,N);
          if SIDE = 'R', LWORK >= max(1,M).
          For optimum performance LWORK >= N*NB if SIDE = 'L', and
          LWORK >= M*NB if SIDE = 'R', where NB is the optimal
          blocksize.

          If LWORK = -1, then a workspace query is assumed; the routine
          only calculates the optimal size of the WORK array, returns
          this value as the first entry of the WORK array, and no error
          message related to LWORK is issued by XERBLA.

  INFO    (output) INTEGER
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an illegal value
```

NAME
       DORML2  -  the  general real m by n matrix C with   Q * C if SIDE = 'L'
       and TRANS = 'N', or   Q'* C if SIDE = 'L' and TRANS = 'T', or   C  *  Q
       if  SIDE  =  'R' and TRANS = 'N', or   C * Q' if SIDE = 'R' and TRANS =
       'T',

SYNOPSIS
       SUBROUTINE DORML2( SIDE, TRANS, M, N, K, A, LDA,  TAU,  C,  LDC,  WORK,
                          INFO )

           CHARACTER      SIDE, TRANS

           INTEGER        INFO, K, LDA, LDC, M, N

           DOUBLE         PRECISION  A( LDA, * ), C( LDC, * ), TAU( * ), WORK(
                          * )

  Purpose
  =======

  DORML2 overwrites the general real m by n matrix C with

        Q * C  if SIDE = 'L' and TRANS = 'N', or

        Q'* C  if SIDE = 'L' and TRANS = 'T', or
```

```
      C * Q  if SIDE = 'R' and TRANS = 'N', or

      C * Q' if SIDE = 'R' and TRANS = 'T',

where Q is a real orthogonal matrix defined as the product of k
elementary reflectors

      Q = H(k) . . . H(2) H(1)

as returned by DGELQF. Q is of order m if SIDE = 'L' and of order n
if SIDE = 'R'.

Arguments
=========

SIDE    (input) CHARACTER*1
        = 'L': apply Q or Q' from the Left
        = 'R': apply Q or Q' from the Right

TRANS   (input) CHARACTER*1
        = 'N': apply Q  (No transpose)
        = 'T': apply Q' (Transpose)

M       (input) INTEGER
        The number of rows of the matrix C. M >= 0.

N       (input) INTEGER
        The number of columns of the matrix C. N >= 0.

K       (input) INTEGER
        The number of elementary reflectors whose product defines
        the matrix Q.
        If SIDE = 'L', M >= K >= 0;
        if SIDE = 'R', N >= K >= 0.

A       (input) DOUBLE PRECISION array, dimension
                             (LDA,M) if SIDE = 'L',
                             (LDA,N) if SIDE = 'R'
        The i-th row must contain the vector which defines the
        elementary reflector H(i), for i = 1,2,...,k, as returned by
        DGELQF in the first k rows of its array argument A.
        A is modified by the routine but restored on exit.

LDA     (input) INTEGER
        The leading dimension of the array A. LDA >= max(1,K).

TAU     (input) DOUBLE PRECISION array, dimension (K)
        TAU(i) must contain the scalar factor of the elementary
        reflector H(i), as returned by DGELQF.
```

```
  C       (input/output) DOUBLE PRECISION array, dimension (LDC,N)
          On entry, the m by n matrix C.
          On exit, C is overwritten by Q*C or Q'*C or C*Q' or C*Q.

  LDC     (input) INTEGER
          The leading dimension of the array C. LDC >= max(1,M).

  WORK    (workspace) DOUBLE PRECISION array, dimension
                                  (N) if SIDE = 'L',
                                  (M) if SIDE = 'R'

  INFO    (output) INTEGER
          = 0: successful exit
          < 0: if INFO = -i, the i-th argument had an illegal value
```

NAME
       DORMLQ  - the general real M-by-N matrix C with   SIDE = 'L' SIDE = 'R'
       TRANS = 'N'

SYNOPSIS
       SUBROUTINE DORMLQ( SIDE, TRANS, M, N, K, A, LDA,  TAU,  C,  LDC,  WORK,
                          LWORK, INFO )

           CHARACTER      SIDE, TRANS

           INTEGER        INFO, K, LDA, LDC, LWORK, M, N

           DOUBLE         PRECISION  A( LDA, * ), C( LDC, * ), TAU( * ), WORK(
                          * )

  Purpose
  =======

  DORMLQ overwrites the general real M-by-N matrix C with

                  SIDE = 'L'     SIDE = 'R'
  TRANS = 'N':      Q * C          C * Q
  TRANS = 'T':      Q**T * C       C * Q**T

  where Q is a real orthogonal matrix defined as the product of k
  elementary reflectors
```

```
      Q = H(k) . . . H(2) H(1)

as returned by DGELQF. Q is of order M if SIDE = 'L' and of order N
if SIDE = 'R'.

Arguments
=========

SIDE    (input) CHARACTER*1
        = 'L': apply Q or Q**T from the Left;
        = 'R': apply Q or Q**T from the Right.

TRANS   (input) CHARACTER*1
        = 'N':  No transpose, apply Q;
        = 'T':  Transpose, apply Q**T.

M       (input) INTEGER
        The number of rows of the matrix C. M >= 0.

N       (input) INTEGER
        The number of columns of the matrix C. N >= 0.

K       (input) INTEGER
        The number of elementary reflectors whose product defines
        the matrix Q.
        If SIDE = 'L', M >= K >= 0;
        if SIDE = 'R', N >= K >= 0.

A       (input) DOUBLE PRECISION array, dimension
                             (LDA,M) if SIDE = 'L',
                             (LDA,N) if SIDE = 'R'
        The i-th row must contain the vector which defines the
        elementary reflector H(i), for i = 1,2,...,k, as returned by
        DGELQF in the first k rows of its array argument A.
        A is modified by the routine but restored on exit.

LDA     (input) INTEGER
        The leading dimension of the array A. LDA >= max(1,K).

TAU     (input) DOUBLE PRECISION array, dimension (K)
        TAU(i) must contain the scalar factor of the elementary
        reflector H(i), as returned by DGELQF.

C       (input/output) DOUBLE PRECISION array, dimension (LDC,N)
        On entry, the M-by-N matrix C.
        On exit, C is overwritten by Q*C or Q**T*C or C*Q**T or C*Q.

LDC     (input) INTEGER
        The leading dimension of the array C. LDC >= max(1,M).
```

```
  WORK    (workspace/output) DOUBLE PRECISION array, dimension (LWORK)
          On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

  LWORK   (input) INTEGER
          The dimension of the array WORK.
          If SIDE = 'L', LWORK >= max(1,N);
          if SIDE = 'R', LWORK >= max(1,M).
          For optimum performance LWORK >= N*NB if SIDE = 'L', and
          LWORK >= M*NB if SIDE = 'R', where NB is the optimal
          blocksize.

          If LWORK = -1, then a workspace query is assumed; the routine
          only calculates the optimal size of the WORK array, returns
          this value as the first entry of the WORK array, and no error
          message related to LWORK is issued by XERBLA.

  INFO    (output) INTEGER
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an illegal value
```

NAME
       DORMQR  - the general real M-by-N matrix C with   SIDE = 'L' SIDE = 'R'
       TRANS = 'N'

SYNOPSIS
       SUBROUTINE DORMQR( SIDE, TRANS, M, N, K, A, LDA,  TAU,  C,  LDC,  WORK,
                          LWORK, INFO )

           CHARACTER      SIDE, TRANS

           INTEGER        INFO, K, LDA, LDC, LWORK, M, N

           DOUBLE         PRECISION  A( LDA, * ), C( LDC, * ), TAU( * ), WORK(
                          * )

  Purpose
  =======

  DORMQR overwrites the general real M-by-N matrix C with

                  SIDE = 'L'     SIDE = 'R'
  TRANS = 'N':      Q * C          C * Q
  TRANS = 'T':      Q**T * C       C * Q**T

  where Q is a real orthogonal matrix defined as the product of k
  elementary reflectors

        Q = H(1) H(2) . . . H(k)

  as returned by DGEQRF. Q is of order M if SIDE = 'L' and of order N
  if SIDE = 'R'.

  Arguments
  =========

  SIDE    (input) CHARACTER*1
          = 'L': apply Q or Q**T from the Left;
```

```
        = 'R': apply Q or Q**T from the Right.

TRANS   (input) CHARACTER*1
        = 'N':  No transpose, apply Q;
        = 'T':  Transpose, apply Q**T.

M       (input) INTEGER
        The number of rows of the matrix C. M >= 0.

N       (input) INTEGER
        The number of columns of the matrix C. N >= 0.

K       (input) INTEGER
        The number of elementary reflectors whose product defines
        the matrix Q.
        If SIDE = 'L', M >= K >= 0;
        if SIDE = 'R', N >= K >= 0.

A       (input) DOUBLE PRECISION array, dimension (LDA,K)
        The i-th column must contain the vector which defines the
        elementary reflector H(i), for i = 1,2,...,k, as returned by
        DGEQRF in the first k columns of its array argument A.
        A is modified by the routine but restored on exit.

LDA     (input) INTEGER
        The leading dimension of the array A.
        If SIDE = 'L', LDA >= max(1,M);
        if SIDE = 'R', LDA >= max(1,N).

TAU     (input) DOUBLE PRECISION array, dimension (K)
        TAU(i) must contain the scalar factor of the elementary
        reflector H(i), as returned by DGEQRF.

C       (input/output) DOUBLE PRECISION array, dimension (LDC,N)
        On entry, the M-by-N matrix C.
        On exit, C is overwritten by Q*C or Q**T*C or C*Q**T or C*Q.

LDC     (input) INTEGER
        The leading dimension of the array C. LDC >= max(1,M).

WORK    (workspace/output) DOUBLE PRECISION array, dimension (LWORK)
        On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK   (input) INTEGER
        The dimension of the array WORK.
        If SIDE = 'L', LWORK >= max(1,N);
        if SIDE = 'R', LWORK >= max(1,M).
        For optimum performance LWORK >= N*NB if SIDE = 'L', and
        LWORK >= M*NB if SIDE = 'R', where NB is the optimal
        blocksize.
```

```
          If LWORK = -1, then a workspace query is assumed; the routine
          only calculates the optimal size of the WORK array, returns
          this value as the first entry of the WORK array, and no error
          message related to LWORK is issued by XERBLA.

  INFO    (output) INTEGER
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an illegal value
```

NAME
       DTREVC  -  some  or all of the right and/or left eigenvectors of a real
       upper quasi-triangular matrix T

SYNOPSIS
       SUBROUTINE DTREVC( SIDE, HOWMNY, SELECT, N, T, LDT, VL, LDVL, VR, LDVR,
                          MM, M, WORK, INFO )

           CHARACTER      HOWMNY, SIDE

           INTEGER        INFO, LDT, LDVL, LDVR, M, MM, N
```

```
          LOGICAL        SELECT( * )

          DOUBLE         PRECISION T( LDT, * ), VL( LDVL, * ), VR( LDVR, * ),
                         WORK( * )

  Purpose
  =======

  DTREVC computes some or all of the right and/or left eigenvectors of
  a real upper quasi-triangular matrix T.

  The right eigenvector x and the left eigenvector y of T corresponding
  to an eigenvalue w are defined by:

               T*x = w*x,     y'*T = w*y'

  where y' denotes the conjugate transpose of the vector y.

  If all eigenvectors are requested, the routine may either return the
  matrices X and/or Y of right or left eigenvectors of T, or the
  products Q*X and/or Q*Y, where Q is an input orthogonal
  matrix. If T was obtained from the real-Schur factorization of an
  original matrix A = Q*T*Q', then Q*X and Q*Y are the matrices of
  right or left eigenvectors of A.

  T must be in Schur canonical form (as returned by DHSEQR), that is,
  block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each
  2-by-2 diagonal block has its diagonal elements equal and its
  off-diagonal elements of opposite sign.  Corresponding to each 2-by-2
  diagonal block is a complex conjugate pair of eigenvalues and
  eigenvectors; only one eigenvector of the pair is computed, namely
  the one corresponding to the eigenvalue with positive imaginary part.

  Arguments
  =========

  SIDE    (input) CHARACTER*1
          = 'R':  compute right eigenvectors only;
          = 'L':  compute left eigenvectors only;
          = 'B':  compute both right and left eigenvectors.

  HOWMNY  (input) CHARACTER*1
          = 'A':  compute all right and/or left eigenvectors;
          = 'B':  compute all right and/or left eigenvectors,
                  and backtransform them using the input matrices
                  supplied in VR and/or VL;
          = 'S':  compute selected right and/or left eigenvectors,
                  specified by the logical array SELECT.

  SELECT  (input/output) LOGICAL array, dimension (N)
```

```
          If HOWMNY = 'S', SELECT specifies the eigenvectors to be
          computed.
          If HOWMNY = 'A' or 'B', SELECT is not referenced.
          To select the real eigenvector corresponding to a real
          eigenvalue w(j), SELECT(j) must be set to .TRUE..  To select
          the complex eigenvector corresponding to a complex conjugate
          pair w(j) and w(j+1), either SELECT(j) or SELECT(j+1) must be
          set to .TRUE.; then on exit SELECT(j) is .TRUE. and
          SELECT(j+1) is .FALSE..

  N       (input) INTEGER
          The order of the matrix T. N >= 0.

  T       (input) DOUBLE PRECISION array, dimension (LDT,N)
          The upper quasi-triangular matrix T in Schur canonical form.

  LDT     (input) INTEGER
          The leading dimension of the array T. LDT >= max(1,N).

  VL      (input/output) DOUBLE PRECISION array, dimension (LDVL,MM)
          On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must
          contain an N-by-N matrix Q (usually the orthogonal matrix Q
          of Schur vectors returned by DHSEQR).
          On exit, if SIDE = 'L' or 'B', VL contains:
          if HOWMNY = 'A', the matrix Y of left eigenvectors of T;
                           VL has the same quasi-lower triangular form
                           as T'. If T(i,i) is a real eigenvalue, then
                           the i-th column VL(i) of VL  is its
                           corresponding eigenvector. If T(i:i+1,i:i+1)
                           is a 2-by-2 block whose eigenvalues are
                           complex-conjugate eigenvalues of T, then
                           VL(i)+sqrt(-1)*VL(i+1) is the complex
                           eigenvector corresponding to the eigenvalue
                           with positive real part.
          if HOWMNY = 'B', the matrix Q*Y;
          if HOWMNY = 'S', the left eigenvectors of T specified by
                           SELECT, stored consecutively in the columns
                           of VL, in the same order as their
                           eigenvalues.
          A complex eigenvector corresponding to a complex eigenvalue
          is stored in two consecutive columns, the first holding the
          real part, and the second the imaginary part.
          If SIDE = 'R', VL is not referenced.

  LDVL    (input) INTEGER
          The leading dimension of the array VL.  LDVL >= max(1,N) if
          SIDE = 'L' or 'B'; LDVL >= 1 otherwise.

  VR      (input/output) DOUBLE PRECISION array, dimension (LDVR,MM)
          On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must
```

```
          contain an N-by-N matrix Q (usually the orthogonal matrix Q
          of Schur vectors returned by DHSEQR).
          On exit, if SIDE = 'R' or 'B', VR contains:
          if HOWMNY = 'A', the matrix X of right eigenvectors of T;
                           VR has the same quasi-upper triangular form
                           as T. If T(i,i) is a real eigenvalue, then
                           the i-th column VR(i) of VR  is its
                           corresponding eigenvector. If T(i:i+1,i:i+1)
                           is a 2-by-2 block whose eigenvalues are
                           complex-conjugate eigenvalues of T, then
                           VR(i)+sqrt(-1)*VR(i+1) is the complex
                           eigenvector corresponding to the eigenvalue
                           with positive real part.
          if HOWMNY = 'B', the matrix Q*X;
          if HOWMNY = 'S', the right eigenvectors of T specified by
                           SELECT, stored consecutively in the columns
                           of VR, in the same order as their
                           eigenvalues.
          A complex eigenvector corresponding to a complex eigenvalue
          is stored in two consecutive columns, the first holding the
          real part and the second the imaginary part.
          If SIDE = 'L', VR is not referenced.

LDVR      (input) INTEGER
          The leading dimension of the array VR.  LDVR >= max(1,N) if
          SIDE = 'R' or 'B'; LDVR >= 1 otherwise.

MM        (input) INTEGER
          The number of columns in the arrays VL and/or VR. MM >= M.

M         (output) INTEGER
          The number of columns in the arrays VL and/or VR actually
          used to store the eigenvectors.
          If HOWMNY = 'A' or 'B', M is set to N.
          Each selected real eigenvector occupies one column and each
          selected complex eigenvector occupies two columns.

WORK      (workspace) DOUBLE PRECISION array, dimension (3*N)

INFO      (output) INTEGER
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an illegal value

Further Details
===============

The algorithm used in this program is basically backward (forward)
substitution, with scaling to make the the code robust against
possible overflow.
```

```
  Each eigenvector is normalized so that the element of largest
  magnitude has magnitude 1; here the magnitude of a complex number
  (x,y) is taken to be |x| + |y|.

NAME
       DTREXC - the real Schur factorization of a real matrix A = Q*T*Q**T, so
       that the diagonal block of T with row index IFST is moved to row ILST

SYNOPSIS
       SUBROUTINE DTREXC( COMPQ, N, T, LDT, Q, LDQ, IFST, ILST, WORK, INFO )

           CHARACTER      COMPQ

           INTEGER        IFST, ILST, INFO, LDQ, LDT, N

           DOUBLE         PRECISION Q( LDQ, * ), T( LDT, * ), WORK( * )

  Purpose
  =======

  DTREXC reorders the real Schur factorization of a real matrix
  A = Q*T*Q**T, so that the diagonal block of T with row index IFST is
  moved to row ILST.

  The real Schur form T is reordered by an orthogonal similarity
  transformation Z**T*T*Z, and optionally the matrix Q of Schur vectors
  is updated by postmultiplying it with Z.

  T must be in Schur canonical form (as returned by DHSEQR), that is,
  block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each
  2-by-2 diagonal block has its diagonal elements equal and its
  off-diagonal elements of opposite sign.

  Arguments
  =========

  COMPQ   (input) CHARACTER*1
          = 'V':  update the matrix Q of Schur vectors;
          = 'N':  do not update Q.

  N       (input) INTEGER
          The order of the matrix T. N >= 0.

  T       (input/output) DOUBLE PRECISION array, dimension (LDT,N)
          On entry, the upper quasi-triangular matrix T, in Schur
          Schur canonical form.
          On exit, the reordered upper quasi-triangular matrix, again
          in Schur canonical form.

  LDT     (input) INTEGER
          The leading dimension of the array T. LDT >= max(1,N).

  Q       (input/output) DOUBLE PRECISION array, dimension (LDQ,N)
```

```
          On entry, if COMPQ = 'V', the matrix Q of Schur vectors.
          On exit, if COMPQ = 'V', Q has been postmultiplied by the
          orthogonal transformation matrix Z which reorders T.
          If COMPQ = 'N', Q is not referenced.

  LDQ     (input) INTEGER
          The leading dimension of the array Q.  LDQ >= max(1,N).

  IFST    (input/output) INTEGER
  ILST    (input/output) INTEGER
          Specify the reordering of the diagonal blocks of T.
          The block with row index IFST is moved to row ILST, by a
          sequence of transpositions between adjacent blocks.
          On exit, if IFST pointed on entry to the second row of a
          2-by-2 block, it is changed to point to the first row; ILST
          always points to the first row of the block in its final
          position (which may differ from its input value by +1 or -1).
          1 <= IFST <= N; 1 <= ILST <= N.

  WORK    (workspace) DOUBLE PRECISION array, dimension (N)

  INFO    (output) INTEGER
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an illegal value
          = 1:  two adjacent blocks were too close to swap (the problem
                is very ill-conditioned); T may have been partially
                reordered, and ILST points to the first row of the
                current position of the block being moved.
```

NAME
       DTRSNA  - reciprocal condition numbers for specified eigenvalues and/or
       right eigenvectors of a real upper quasi-triangular matrix T (or of any
       matrix Q*T*Q**T with Q orthogonal)

SYNOPSIS
       SUBROUTINE DTRSNA( JOB,  HOWMNY, SELECT, N, T, LDT, VL, LDVL, VR, LDVR,
                          S, SEP, MM, M, WORK, LDWORK, IWORK, INFO )

           CHARACTER      HOWMNY, JOB

           INTEGER        INFO, LDT, LDVL, LDVR, LDWORK, M, MM, N

           LOGICAL        SELECT( * )

           INTEGER        IWORK( * )

           DOUBLE         PRECISION S( * ), SEP( * ), T( LDT, * ), VL( LDVL, *
```

```
                        ), VR( LDVR, * ), WORK( LDWORK, * )

Purpose
=======

DTRSNA estimates reciprocal condition numbers for specified
eigenvalues and/or right eigenvectors of a real upper
quasi-triangular matrix T (or of any matrix Q*T*Q**T with Q
orthogonal).

T must be in Schur canonical form (as returned by DHSEQR), that is,
block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each
2-by-2 diagonal block has its diagonal elements equal and its
off-diagonal elements of opposite sign.

Arguments
=========

JOB     (input) CHARACTER*1
        Specifies whether condition numbers are required for
        eigenvalues (S) or eigenvectors (SEP):
        = 'E': for eigenvalues only (S);
        = 'V': for eigenvectors only (SEP);
        = 'B': for both eigenvalues and eigenvectors (S and SEP).

HOWMNY  (input) CHARACTER*1
        = 'A': compute condition numbers for all eigenpairs;
        = 'S': compute condition numbers for selected eigenpairs
               specified by the array SELECT.

SELECT  (input) LOGICAL array, dimension (N)
        If HOWMNY = 'S', SELECT specifies the eigenpairs for which
        condition numbers are required. To select condition numbers
        for the eigenpair corresponding to a real eigenvalue w(j),
        SELECT(j) must be set to .TRUE.. To select condition numbers
        corresponding to a complex conjugate pair of eigenvalues w(j)
        and w(j+1), either SELECT(j) or SELECT(j+1) or both, must be
        set to .TRUE..
        If HOWMNY = 'A', SELECT is not referenced.

N       (input) INTEGER
        The order of the matrix T. N >= 0.

T       (input) DOUBLE PRECISION array, dimension (LDT,N)
        The upper quasi-triangular matrix T, in Schur canonical form.

LDT     (input) INTEGER
        The leading dimension of the array T. LDT >= max(1,N).

VL      (input) DOUBLE PRECISION array, dimension (LDVL,M)
```

```
        If JOB = 'E' or 'B', VL must contain left eigenvectors of T
        (or of any Q*T*Q**T with Q orthogonal), corresponding to the
        eigenpairs specified by HOWMNY and SELECT. The eigenvectors
        must be stored in consecutive columns of VL, as returned by
        DHSEIN or DTREVC.
        If JOB = 'V', VL is not referenced.

LDVL    (input) INTEGER
        The leading dimension of the array VL.
        LDVL >= 1; and if JOB = 'E' or 'B', LDVL >= N.

VR      (input) DOUBLE PRECISION array, dimension (LDVR,M)
        If JOB = 'E' or 'B', VR must contain right eigenvectors of T
        (or of any Q*T*Q**T with Q orthogonal), corresponding to the
        eigenpairs specified by HOWMNY and SELECT. The eigenvectors
        must be stored in consecutive columns of VR, as returned by
        DHSEIN or DTREVC.
        If JOB = 'V', VR is not referenced.

LDVR    (input) INTEGER
        The leading dimension of the array VR.
        LDVR >= 1; and if JOB = 'E' or 'B', LDVR >= N.

S       (output) DOUBLE PRECISION array, dimension (MM)
        If JOB = 'E' or 'B', the reciprocal condition numbers of the
        selected eigenvalues, stored in consecutive elements of the
        array. For a complex conjugate pair of eigenvalues two
        consecutive elements of S are set to the same value. Thus
        S(j), SEP(j), and the j-th columns of VL and VR all
        correspond to the same eigenpair (but not in general the
        j-th eigenpair, unless all eigenpairs are selected).
        If JOB = 'V', S is not referenced.

SEP     (output) DOUBLE PRECISION array, dimension (MM)
        If JOB = 'V' or 'B', the estimated reciprocal condition
        numbers of the selected eigenvectors, stored in consecutive
        elements of the array. For a complex eigenvector two
        consecutive elements of SEP are set to the same value. If
        the eigenvalues cannot be reordered to compute SEP(j), SEP(j)
        is set to 0; this can only occur when the true value would be
        very small anyway.
        If JOB = 'E', SEP is not referenced.

MM      (input) INTEGER
        The number of elements in the arrays S (if JOB = 'E' or 'B')
         and/or SEP (if JOB = 'V' or 'B'). MM >= M.

M       (output) INTEGER
        The number of elements of the arrays S and/or SEP actually
        used to store the estimated condition numbers.
```

```
        If HOWMNY = 'A', M is set to N.

WORK    (workspace) DOUBLE PRECISION array, dimension (LDWORK,N+1)
        If JOB = 'E', WORK is not referenced.

LDWORK  (input) INTEGER
        The leading dimension of the array WORK.
        LDWORK >= 1; and if JOB = 'V' or 'B', LDWORK >= N.

IWORK   (workspace) INTEGER array, dimension (N)
        If JOB = 'E', IWORK is not referenced.

INFO    (output) INTEGER
        = 0: successful exit
        < 0: if INFO = -i, the i-th argument had an illegal value

Further Details
===============

The reciprocal of the condition number of an eigenvalue lambda is
defined as

        S(lambda) = |v'*u| / (norm(u)*norm(v))

where u and v are the right and left eigenvectors of T corresponding
to lambda; v' denotes the conjugate-transpose of v, and norm(u)
denotes the Euclidean norm. These reciprocal condition numbers always
lie between zero (very badly conditioned) and one (very well
conditioned). If n = 1, S(lambda) is defined to be 1.

An approximate error bound for a computed eigenvalue W(i) is given by

                    EPS * norm(T) / S(i)

where EPS is the machine precision.

The reciprocal of the condition number of the right eigenvector u
corresponding to lambda is defined as follows. Suppose

            T = ( lambda  c  )
                (   0    T22 )

Then the reciprocal condition number is

        SEP( lambda, T22 ) = sigma-min( T22 - lambda*I )

where sigma-min denotes the smallest singular value. We approximate
the smallest singular value by the reciprocal of an estimate of the
one-norm of the inverse of T22 - lambda*I. If n = 1, SEP(1) is
defined to be abs(T(1,1)).
```

```
  An approximate error bound for a computed right eigenvector VR(i)
  is given by

                     EPS * norm(T) / SEP(i)
```

       NaN arithmetic is safe (i.e

SYNOPSIS
       INTEGER FUNCTION IEEECK( ISPEC, ZERO, ONE )

           INTEGER      ISPEC

           REAL         ONE, ZERO

  Purpose
  =======

  IEEECK is called from the ILAENV to verify that Infinity and
  possibly NaN arithmetic is safe (i.e. will not trap).

  Arguments
  =========

  ISPEC   (input) INTEGER
          Specifies whether to test just for inifinity arithmetic
          or whether to test for infinity and NaN arithmetic.
          = 0: Verify infinity arithmetic only.
          = 1: Verify infinity and NaN arithmetic.

  ZERO    (input) REAL
          Must contain the value 0.0
          This is passed to prevent the compiler from optimizing
          away this code.

  ONE     (input) REAL
          Must contain the value 1.0
          This is passed to prevent the compiler from optimizing
          away this code.

  RETURN VALUE:  INTEGER
          = 0:  Arithmetic failed to produce the correct answers
          = 1:  Arithmetic produced the correct answers
```

NAME
       ILAENV  -  called  from the LAPACK routines to choose problem-dependent
       parameters for the local environment

SYNOPSIS
       INTEGER FUNCTION ILAENV( ISPEC, NAME, OPTS, N1, N2, N3, N4 )

           CHARACTER*(  * ) NAME, OPTS

           INTEGER      ISPEC, N1, N2, N3, N4

  Purpose
  =======
```

```
ILAENV is called from the LAPACK routines to choose problem-dependent
parameters for the local environment.  See ISPEC for a description of
the parameters.

This version provides a set of parameters which should give good,
but not optimal, performance on many of the currently available
computers.  Users are encouraged to modify this subroutine to set
the tuning parameters for their particular machine using the option
and problem size information in the arguments.

This routine will not function correctly if it is converted to all
lower case.  Converting it to all upper case is allowed.

Arguments
=========

ISPEC   (input) INTEGER
        Specifies the parameter to be returned as the value of
        ILAENV.
        = 1: the optimal blocksize; if this value is 1, an unblocked
             algorithm will give the best performance.
        = 2: the minimum block size for which the block routine
             should be used; if the usable block size is less than
             this value, an unblocked routine should be used.
        = 3: the crossover point (in a block routine, for N less
             than this value, an unblocked routine should be used)
        = 4: the number of shifts, used in the nonsymmetric
             eigenvalue routines
        = 5: the minimum column dimension for blocking to be used;
             rectangular blocks must have dimension at least k by m,
             where k is given by ILAENV(2,...) and m by ILAENV(5,...)
        = 6: the crossover point for the SVD (when reducing an m by n
             matrix to bidiagonal form, if max(m,n)/min(m,n) exceeds
             this value, a QR factorization is used first to reduce
             the matrix to a triangular form.)
        = 7: the number of processors
        = 8: the crossover point for the multishift QR and QZ methods
             for nonsymmetric eigenvalue problems.
        = 9: maximum size of the subproblems at the bottom of the
             computation tree in the divide-and-conquer algorithm
             (used by xGELSD and xGESDD)
        =10: ieee NaN arithmetic can be trusted not to trap
        =11: infinity arithmetic can be trusted not to trap

NAME    (input) CHARACTER*(*)
        The name of the calling subroutine, in either upper case or
        lower case.

OPTS    (input) CHARACTER*(*)
        The character options to the subroutine NAME, concatenated
```

```
          into a single character string.  For example, UPLO = 'U',
          TRANS = 'T', and DIAG = 'N' for a triangular routine would
          be specified as OPTS = 'UTN'.

  N1      (input) INTEGER
  N2      (input) INTEGER
  N3      (input) INTEGER
  N4      (input) INTEGER
          Problem dimensions for the subroutine NAME; these may not all
          be required.

 (ILAENV) (output) INTEGER
          >= 0: the value of the parameter specified by ISPEC
          < 0:  if ILAENV = -k, the k-th argument had an illegal value.

  Further Details
  ===============

  The following conventions have been used when calling ILAENV from the
  LAPACK routines:
  1)  OPTS is a concatenation of all of the character options to
      subroutine NAME, in the same order that they appear in the
      argument list for NAME, even if they are not used in determining
      the value of the parameter specified by ISPEC.
  2)  The problem dimensions N1, N2, N3, N4 are specified in the order
      that they appear in the argument list for NAME.  N1 is used
      first, N2 second, and so on, and unused problem dimensions are
      passed a value of -1.
  3)  The parameter value returned by ILAENV is checked for validity in
      the calling subroutine.  For example, ILAENV is used to retrieve
      the optimal blocksize for STRTRI as follows:

      NB = ILAENV( 1, 'STRTRI', UPLO // DIAG, N, -1, -1, -1 )
      IF( NB.LE.1 ) NB = MAX( 1, N )
```

       INTEGER FUNCTION ILAZLC( M, N, A, LDA )

       .. Scalar Arguments ..
       INTEGER            M, N, LDA
       ..
       .. Array Arguments ..
       COMPLEX*16         A( LDA, * )
       ..
```

```
 Purpose:
 =============

   ILAZLC scans A for its last non-zero column.

 Arguments:
 ==========

  [in] M
          M is INTEGER
          The number of rows of the matrix A.

  [in] N
          N is INTEGER
          The number of columns of the matrix A.

  [in] A
          A is COMPLEX*16 array, dimension (LDA,N)
          The m by n matrix A.

  [in] LDA
          LDA is INTEGER
          The leading dimension of the array A. LDA >= max(1,M).

  Definition:
  ===========

       SUBROUTINE ZGEBAK( JOB, SIDE, N, ILO, IHI, SCALE, M, V, LDV,
                          INFO )

       .. Scalar Arguments ..
       CHARACTER          JOB, SIDE
       INTEGER            IHI, ILO, INFO, LDV, M, N
       ..
       .. Array Arguments ..
       DOUBLE PRECISION   SCALE( * )
       COMPLEX*16         V( LDV, * )
       ..

  Purpose:
  =============
```

```
 ZGEBAK forms the right or left eigenvectors of a complex general
 matrix by backward transformation on the computed eigenvectors of the
 balanced matrix output by ZGEBAL.

Arguments:
==========

[in] JOB

        JOB is CHARACTER*1
        Specifies the type of backward transformation required:
        = 'N', do nothing, return immediately;
        = 'P', do backward transformation for permutation only;
        = 'S', do backward transformation for scaling only;
        = 'B', do backward transformations for both permutation and
               scaling.
        JOB must be the same as the argument JOB supplied to ZGEBAL.

[in] SIDE

        SIDE is CHARACTER*1
        = 'R':  V contains right eigenvectors;
        = 'L':  V contains left eigenvectors.

[in] N

        N is INTEGER
        The number of rows of the matrix V.  N >= 0.

[in] ILO

        ILO is INTEGER

[in] IHI

        IHI is INTEGER
        The integers ILO and IHI determined by ZGEBAL.
        1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

[in] SCALE

        SCALE is DOUBLE PRECISION array, dimension (N)
        Details of the permutation and scaling factors, as returned
        by ZGEBAL.

[in] M

        M is INTEGER
```

```
          The number of columns of the matrix V.  M >= 0.

  [in,out] V

          V is COMPLEX*16 array, dimension (LDV,M)
          On entry, the matrix of right or left eigenvectors to be
          transformed, as returned by ZHSEIN or ZTREVC.
          On exit, V is overwritten by the transformed eigenvectors.

  [in] LDV

          LDV is INTEGER
          The leading dimension of the array V. LDV >= max(1,N).

  [out] INFO

          INFO is INTEGER
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an illegal value.

       SUBROUTINE ZGEBAL( JOB, N, A, LDA, ILO, IHI, SCALE, INFO )

       .. Scalar Arguments ..
       CHARACTER          JOB
       INTEGER            IHI, ILO, INFO, LDA, N
       ..
       .. Array Arguments ..
       DOUBLE PRECISION   SCALE( * )
       COMPLEX*16         A( LDA, * )
```

```
      ..

 Purpose:
 =============

  ZGEBAL balances a general complex matrix A.  This involves, first,
  permuting A by a similarity transformation to isolate eigenvalues
  in the first 1 to ILO-1 and last IHI+1 to N elements on the
  diagonal; and second, applying a diagonal similarity transformation
  to rows and columns ILO to IHI to make the rows and columns as
  close in norm as possible.  Both steps are optional.

  Balancing may reduce the 1-norm of the matrix, and improve the
  accuracy of the computed eigenvalues and/or eigenvectors.

 Arguments:
 ==========

   [in] JOB

          JOB is CHARACTER*1
          Specifies the operations to be performed on A:
          = 'N':  none:  simply set ILO = 1, IHI = N, SCALE(I) = 1.0
                  for i = 1,...,N;
          = 'P':  permute only;
          = 'S':  scale only;
          = 'B':  both permute and scale.

   [in] N

          N is INTEGER
          The order of the matrix A.  N >= 0.

   [in,out] A

          A is COMPLEX*16 array, dimension (LDA,N)
          On entry, the input matrix A.
          On exit,  A is overwritten by the balanced matrix.
          If JOB = 'N', A is not referenced.
          See Further Details.

   [in] LDA

          LDA is INTEGER
          The leading dimension of the array A.  LDA >= max(1,N).

   [out] ILO

   [out] IHI
```

```
          ILO and IHI are set to INTEGER such that on exit
          A(i,j) = 0 if i > j and j = 1,...,ILO-1 or I = IHI+1,...,N.
          If JOB = 'N' or 'S', ILO = 1 and IHI = N.

  [out] SCALE

          SCALE is DOUBLE PRECISION array, dimension (N)
          Details of the permutations and scaling factors applied to
          A.  If P(j) is the index of the row and column interchanged
          with row and column j and D(j) is the scaling factor
          applied to row and column j, then
          SCALE(j) = P(j)    for j = 1,...,ILO-1
                   = D(j)    for j = ILO,...,IHI
                   = P(j)    for j = IHI+1,...,N.
          The order in which the interchanges are made is N to IHI+1,
          then 1 to ILO-1.

  [out] INFO

          INFO is INTEGER
          = 0:  successful exit.
          < 0:  if INFO = -i, the i-th argument had an illegal value.

November 2011

Further Details:
====================

 The permutations consist of row and column interchanges which put
 the matrix in the form

            ( T1   X   Y  )
    P A P = (  0   B   Z  )
            (  0   0   T2 )

 where T1 and T2 are upper triangular matrices whose eigenvalues lie
 along the diagonal.  The column indices ILO and IHI mark the starting
 and ending columns of the submatrix B. Balancing consists of applying
 a diagonal similarity transformation inv(D) * B * D to make the
 1-norms of each row of B and its corresponding column nearly equal.
```

```
  The output matrix is

     ( T1     X*D          Y    )
     (  0  inv(D)*B*D  inv(D)*Z ).
     (  0      0           T2   )

  Information about the permutations P and the diagonal matrix D is
  returned in the vector SCALE.

  This subroutine is based on the EISPACK routine CBAL.

  Modified by Tzu-Yi Chen, Computer Science Division, University of
    California at Berkeley, USA

ZGEEV computes the eigenvalues and, optionally, the left and/or right
eigenvectors for GE matrices

 Online html documentation available at
            http://www.netlib.org/lapack/explore-html/

 Definition:
 ===========

       SUBROUTINE ZGEEV( JOBVL, JOBVR, N, A, LDA, W, VL, LDVL, VR, LDVR,
```

```
                     WORK, LWORK, RWORK, INFO )

      .. Scalar Arguments ..
      CHARACTER          JOBVL, JOBVR
      INTEGER            INFO, LDA, LDVL, LDVR, LWORK, N
      ..
      .. Array Arguments ..
      DOUBLE PRECISION   RWORK( * )
      COMPLEX*16         A( LDA, * ), VL( LDVL, * ), VR( LDVR, * ),
     $                   W( * ), WORK( * )
      ..

Purpose:
=============

 ZGEEV computes for an N-by-N complex nonsymmetric matrix A, the
 eigenvalues and, optionally, the left and/or right eigenvectors.

 The right eigenvector v(j) of A satisfies
                  A * v(j) = lambda(j) * v(j)
  where lambda(j) is its eigenvalue.
 The left eigenvector u(j) of A satisfies
             u(j)**H * A = lambda(j) * u(j)**H
  where u(j)**H denotes the conjugate transpose of u(j).

The computed eigenvectors are normalized to have Euclidean norm
equal to 1 and largest component real.

Arguments:
==========

 [in] JOBVL

         JOBVL is CHARACTER*1
         = 'N': left eigenvectors of A are not computed;
         = 'V': left eigenvectors of are computed.

 [in] JOBVR

         JOBVR is CHARACTER*1
         = 'N': right eigenvectors of A are not computed;
         = 'V': right eigenvectors of A are computed.

 [in] N

         N is INTEGER
         The order of the matrix A. N >= 0.

 [in,out] A
```

```
          A is COMPLEX*16 array, dimension (LDA,N)
          On entry, the N-by-N matrix A.
          On exit, A has been overwritten.

  [in] LDA

          LDA is INTEGER
          The leading dimension of the array A.  LDA >= max(1,N).

  [out] W

          W is COMPLEX*16 array, dimension (N)
          W contains the computed eigenvalues.

  [out] VL

          VL is COMPLEX*16 array, dimension (LDVL,N)
          If JOBVL = 'V', the left eigenvectors u(j) are stored one
          after another in the columns of VL, in the same order
          as their eigenvalues.
          If JOBVL = 'N', VL is not referenced.
          u(j) = VL(:,j), the j-th column of VL.

  [in] LDVL

          LDVL is INTEGER
          The leading dimension of the array VL.  LDVL >= 1; if
          JOBVL = 'V', LDVL >= N.

  [out] VR

          VR is COMPLEX*16 array, dimension (LDVR,N)
          If JOBVR = 'V', the right eigenvectors v(j) are stored one
          after another in the columns of VR, in the same order
          as their eigenvalues.
          If JOBVR = 'N', VR is not referenced.
          v(j) = VR(:,j), the j-th column of VR.

  [in] LDVR

          LDVR is INTEGER
          The leading dimension of the array VR.  LDVR >= 1; if
          JOBVR = 'V', LDVR >= N.

  [out] WORK

          WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
          On exit, if INFO = 0, WORK(1) returns the optimal LWORK.
```

```
  [in] LWORK

          LWORK is INTEGER
          The dimension of the array WORK.  LWORK >= max(1,2*N).
          For good performance, LWORK must generally be larger.

          If LWORK = -1, then a workspace query is assumed; the routine
          only calculates the optimal size of the WORK array, returns
          this value as the first entry of the WORK array, and no error
          message related to LWORK is issued by XERBLA.

  [out] RWORK

          RWORK is DOUBLE PRECISION array, dimension (2*N)

  [out] INFO

          INFO is INTEGER
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an illegal value.
          > 0:  if INFO = i, the QR algorithm failed to compute all the
                eigenvalues, and no eigenvectors have been computed;
                elements and i+1:N of W contain eigenvalues which have
                converged.

Definition:
===========

      SUBROUTINE ZGEHD2( N, ILO, IHI, A, LDA, TAU, WORK, INFO )

      .. Scalar Arguments ..
      INTEGER            IHI, ILO, INFO, LDA, N
      ..
      .. Array Arguments ..
      COMPLEX*16         A( LDA, * ), TAU( * ), WORK( * )
      ..

Purpose:
=============

 ZGEHD2 reduces a complex general matrix A to upper Hessenberg form H
 by a unitary similarity transformation:  Q**H * A * Q = H .

Arguments:
==========

 [in] N

        N is INTEGER
        The order of the matrix A.  N >= 0.

 [in] ILO

        ILO is INTEGER

 [in] IHI

        IHI is INTEGER

        It is assumed that A is already upper triangular in rows
        and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally
        set by a previous call to ZGEBAL; otherwise they should be
        set to 1 and N respectively. See Further Details.
        1 <= ILO <= IHI <= max(1,N).

 [in,out] A

        A is COMPLEX*16 array, dimension (LDA,N)
        On entry, the n by n general matrix to be reduced.
        On exit, the upper triangle and the first subdiagonal of A
        are overwritten with the upper Hessenberg matrix H, and the
        elements below the first subdiagonal, with the array TAU,
        represent the unitary matrix Q as a product of elementary
```

```
          reflectors. See Further Details.

  [in] LDA

          LDA is INTEGER
          The leading dimension of the array A.  LDA >= max(1,N).

  [out] TAU

          TAU is COMPLEX*16 array, dimension (N-1)
          The scalar factors of the elementary reflectors (see Further
          Details).

  [out] WORK

          WORK is COMPLEX*16 array, dimension (N)

  [out] INFO

          INFO is INTEGER
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an illegal value.

Authors:

November 2011

Further Details:
====================

 The matrix Q is represented as a product of (ihi-ilo) elementary
 reflectors

    Q = H(ilo) H(ilo+1) . . . H(ihi-1).

 Each H(i) has the form

    H(i) = I - tau * v * v**H

 where tau is a complex scalar, and v is a complex vector with
 v(1:i) = 0, v(i+1) = 1 and v(ihi+1:n) = 0; v(i+2:ihi) is stored on
 exit in A(i+2:ihi,i), and tau in TAU(i).

 The contents of A are illustrated by the following example, with
```

```
  n = 7, ilo = 2 and ihi = 6:

  on entry,                       on exit,

  ( a   a   a   a   a   a   a )   (  a   a   h   h   h   h   a )
  (     a   a   a   a   a   a )   (      a   h   h   h   h   a )
  (     a   a   a   a   a   a )   (      h   h   h   h   h   h )
  (     a   a   a   a   a   a )   (      v2  h   h   h   h   h )
  (     a   a   a   a   a   a )   (      v2  v3  h   h   h   h )
  (     a   a   a   a   a   a )   (      v2  v3  v4  h   h   h )
  (                     a   )   (                      a   )

  where a denotes an element of the original matrix A, h denotes a
  modified element of the upper Hessenberg matrix H, and vi denotes an
  element of the vector defining H(i).

 Online html documentation available at
           http://www.netlib.org/lapack/explore-html/

 Definition:
 ===========

       SUBROUTINE ZGEHRD( N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO )

       .. Scalar Arguments ..
       INTEGER            IHI, ILO, INFO, LDA, LWORK, N
       ..
       .. Array Arguments ..
       COMPLEX*16         A( LDA, * ), TAU( * ), WORK( * )
       ..

 Purpose:
 =============

  ZGEHRD reduces a complex general matrix A to upper Hessenberg form H by
  an unitary similarity transformation:  Q**H * A * Q = H .
```

```
 Arguments:
 ==========

  [in] N

          N is INTEGER
          The order of the matrix A.  N >= 0.

  [in] ILO

          ILO is INTEGER

  [in] IHI

          IHI is INTEGER

          It is assumed that A is already upper triangular in rows
          and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally
          set by a previous call to ZGEBAL; otherwise they should be
          set to 1 and N respectively. See Further Details.
          1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

  [in,out] A

          A is COMPLEX*16 array, dimension (LDA,N)
          On entry, the N-by-N general matrix to be reduced.
          On exit, the upper triangle and the first subdiagonal of A
          are overwritten with the upper Hessenberg matrix H, and the
          elements below the first subdiagonal, with the array TAU,
          represent the unitary matrix Q as a product of elementary
          reflectors. See Further Details.

  [in] LDA

          LDA is INTEGER
          The leading dimension of the array A.  LDA >= max(1,N).

  [out] TAU

          TAU is COMPLEX*16 array, dimension (N-1)
          The scalar factors of the elementary reflectors (see Further
          Details). Elements 1:ILO-1 and IHI:N-1 of TAU are set to
          zero.

  [out] WORK

          WORK is COMPLEX*16 array, dimension (LWORK)
          On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

  [in] LWORK
```

```
          LWORK is INTEGER
          The length of the array WORK.  LWORK >= max(1,N).
          For optimum performance LWORK >= N*NB, where NB is the
          optimal blocksize.

          If LWORK = -1, then a workspace query is assumed; the routine
          only calculates the optimal size of the WORK array, returns
          this value as the first entry of the WORK array, and no error
          message related to LWORK is issued by XERBLA.

 [out] INFO

          INFO is INTEGER
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an illegal value.

Further Details:
=====================

 The matrix Q is represented as a product of (ihi-ilo) elementary
 reflectors

    Q = H(ilo) H(ilo+1) . . . H(ihi-1).

 Each H(i) has the form

    H(i) = I - tau * v * v**H

 where tau is a complex scalar, and v is a complex vector with
 v(1:i) = 0, v(i+1) = 1 and v(ihi+1:n) = 0; v(i+2:ihi) is stored on
 exit in A(i+2:ihi,i), and tau in TAU(i).

 The contents of A are illustrated by the following example, with
 n = 7, ilo = 2 and ihi = 6:

 on entry,                        on exit,

 ( a   a   a   a   a   a   a )    ( a   a   h   h   h   h   a )
 (     a   a   a   a   a   a )    (     a   h   h   h   h   a )
```

```
(     a   a   a   a   a   a )    (      h   h   h   h   h   h )
(     a   a   a   a   a   a )    (      v2  h   h   h   h   h )
(     a   a   a   a   a   a )    (      v2  v3  h   h   h   h )
(     a   a   a   a   a   a )    (      v2  v3  v4  h   h   h )
(                     a )    (                      a )
```

where a denotes an element of the original matrix A, h denotes a modified element of the upper Hessenberg matrix H, and vi denotes an element of the vector defining H(i).

This file is a slight modification of LAPACK-3.0's DGEHRD subroutine incorporating improvements proposed by Quintana-Orti and Van de Geijn (2006). (See DLAHR2.)

       SUBROUTINE ZHSEQR( JOB, COMPZ, N, ILO, IHI, H, LDH, W, Z, LDZ,
                          WORK, LWORK, INFO )

       .. Scalar Arguments ..
       INTEGER            IHI, ILO, INFO, LDH, LDZ, LWORK, N
       CHARACTER          COMPZ, JOB
       ..
       .. Array Arguments ..
       COMPLEX*16         H( LDH, * ), W( * ), WORK( * ), Z( LDZ, * )
       ..

 Purpose:
 =============

    ZHSEQR computes the eigenvalues of a Hessenberg matrix H
    and, optionally, the matrices T and Z from the Schur decomposition
    H = Z T Z**H, where T is an upper triangular matrix (the
    Schur form), and Z is the unitary matrix of Schur vectors.

    Optionally Z may be postmultiplied into an input unitary
    matrix Q so that this routine can give the Schur factorization
    of a matrix A which has been reduced to the Hessenberg form H
    by the unitary matrix Q:  A = Q*H*Q**H = (QZ)*H*(QZ)**H.

 Arguments:
 ==========

  [in] JOB

          JOB is CHARACTER*1
           = 'E':  compute eigenvalues only;
           = 'S':  compute eigenvalues and the Schur form T.

  [in] COMPZ

          COMPZ is CHARACTER*1
           = 'N':  no Schur vectors are computed;
```

```
          = 'I':  Z is initialized to the unit matrix and the matrix Z
                  of Schur vectors of H is returned;
          = 'V':  Z must contain an unitary matrix Q on entry, and
                  the product Q*Z is returned.

[in] N

        N is INTEGER
         The order of the matrix H.  N .GE. 0.

[in] ILO

        ILO is INTEGER

[in] IHI

        IHI is INTEGER

         It is assumed that H is already upper triangular in rows
         and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally
         set by a previous call to ZGEBAL, and then passed to ZGEHRD
         when the matrix output by ZGEBAL is reduced to Hessenberg
         form. Otherwise ILO and IHI should be set to 1 and N
         respectively.  If N.GT.0, then 1.LE.ILO.LE.IHI.LE.N.
         If N = 0, then ILO = 1 and IHI = 0.

[in,out] H

        H is COMPLEX*16 array, dimension (LDH,N)
         On entry, the upper Hessenberg matrix H.
         On exit, if INFO = 0 and JOB = 'S', H contains the upper
         triangular matrix T from the Schur decomposition (the
         Schur form). If INFO = 0 and JOB = 'E', the contents of
         H are unspecified on exit.  (The output value of H when
         INFO.GT.0 is given under the description of INFO below.)

         Unlike earlier versions of ZHSEQR, this subroutine may
         explicitly H(i,j) = 0 for i.GT.j and j = 1, 2, ... ILO-1
         or j = IHI+1, IHI+2, ... N.

[in] LDH

        LDH is INTEGER
         The leading dimension of the array H. LDH .GE. max(1,N).

[out] W

        W is COMPLEX*16 array, dimension (N)
         The computed eigenvalues. If JOB = 'S', the eigenvalues are
         stored in the same order as on the diagonal of the Schur
```

```
          form returned in H, with W(i) = H(i,i).

[in,out] Z

         Z is COMPLEX*16 array, dimension (LDZ,N)
          If COMPZ = 'N', Z is not referenced.
          If COMPZ = 'I', on entry Z need not be set and on exit,
          if INFO = 0, Z contains the unitary matrix Z of the Schur
          vectors of H.  If COMPZ = 'V', on entry Z must contain an
          N-by-N matrix Q, which is assumed to be equal to the unit
          matrix except for the submatrix Z(ILO:IHI,ILO:IHI). On exit,
          if INFO = 0, Z contains Q*Z.
          Normally Q is the unitary matrix generated by ZUNGHR
          after the call to ZGEHRD which formed the Hessenberg matrix
          H. (The output value of Z when INFO.GT.0 is given under
          the description of INFO below.)

[in] LDZ

         LDZ is INTEGER
          The leading dimension of the array Z.  if COMPZ = 'I' or
          COMPZ = 'V', then LDZ.GE.MAX(1,N).  Otherwize, LDZ.GE.1.

[out] WORK

         WORK is COMPLEX*16 array, dimension (LWORK)
          On exit, if INFO = 0, WORK(1) returns an estimate of
          the optimal value for LWORK.

[in] LWORK

         LWORK is INTEGER
          The dimension of the array WORK.  LWORK .GE. max(1,N)
          is sufficient and delivers very good and sometimes
          optimal performance.  However, LWORK as large as 11*N
          may be required for optimal performance.  A workspace
          query is recommended to determine the optimal workspace
          size.

          If LWORK = -1, then ZHSEQR does a workspace query.
          In this case, ZHSEQR checks the input parameters and
          estimates the optimal workspace size for the given
          values of N, ILO and IHI.  The estimate is returned
          in WORK(1).  No error message related to LWORK is
          issued by XERBLA.  Neither H nor Z are accessed.

[out] INFO

         INFO is INTEGER
            =  0:  successful exit
```

```
          .LT. 0:  if INFO = -i, the i-th argument had an illegal
                   value
          .GT. 0:  if INFO = i, ZHSEQR failed to compute all of
               the eigenvalues.  Elements 1:ilo-1 and i+1:n of WR
               and WI contain those eigenvalues which have been
               successfully computed.  (Failures are rare.)

               If INFO .GT. 0 and JOB = 'E', then on exit, the
               remaining unconverged eigenvalues are the eigen-
               values of the upper Hessenberg matrix rows and
               columns ILO through INFO of the final, output
               value of H.

               If INFO .GT. 0 and JOB   = 'S', then on exit

          (*)  (initial value of H)*U  = U*(final value of H)

               where U is a unitary matrix.  The final
               value of  H is upper Hessenberg and triangular in
               rows and columns INFO+1 through IHI.

               If INFO .GT. 0 and COMPZ = 'V', then on exit

                 (final value of Z)  =  (initial value of Z)*U

               where U is the unitary matrix in (*) (regard-
               less of the value of JOB.)

               If INFO .GT. 0 and COMPZ = 'I', then on exit
                     (final value of Z)  = U
               where U is the unitary matrix in (*) (regard-
               less of the value of JOB.)

               If INFO .GT. 0 and COMPZ = 'N', then Z is not
               accessed.

Further Details:
=====================

Default values supplied by
ILAENV(ISPEC,'ZHSEQR',JOB(:1)//COMPZ(:1),N,ILO,IHI,LWORK).
It is suggested that these defaults be adjusted in order
to attain best performance in each particular
computational environment.

ISPEC=12: The ZLAHQR vs ZLAQR0 crossover point.
Default: 75. (Must be at least 11.)

ISPEC=13: Recommended deflation window size.
This depends on ILO, IHI and NS. NS is the
number of simultaneous shifts returned
by ILAENV(ISPEC=15). (See ISPEC=15 below.)
The default for (IHI-ILO+1).LE.500 is NS.
The default for (IHI-ILO+1).GT.500 is 3*NS/2.

ISPEC=14: Nibble crossover point. (See IPARMQ for
details.) Default: 14% of deflation window
size.

ISPEC=15: Number of simultaneous shifts in a multishift
QR iteration.

If IHI-ILO+1 is ...

greater than or equal to ...	...but less than	... the default is
1	30	NS = 2(+)
30	60	NS = 4(+)
60	150	NS = 10(+)
150	590	NS = **
590	3000	NS = 64
3000	6000	NS = 128
6000	infinity	NS = 256

(+) By default some or all matrices of this order
are passed to the implicit double shift routine
ZLAHQR and this parameter is ignored. See
ISPEC=12 above and comments in IPARMQ for
details.

(**) The asterisks (**) indicate an ad-hoc
function of N increasing from 10 to 64.

```
           ISPEC=16: Select structured matrix multiply.
                     If the number of simultaneous shifts (specified
                     by ISPEC=15) is less than 14, then the default
                     for ISPEC=16 is 0.  Otherwise the default for
                     ISPEC=16 is 2.

       SUBROUTINE ZLACGV( N, X, INCX )

       .. Scalar Arguments ..
       INTEGER            INCX, N
       ..
       .. Array Arguments ..
       COMPLEX*16         X( * )
       ..

 Purpose:
 =============

 ZLACGV conjugates a complex vector of length N.

 Arguments:
 ==========

  [in] N

          N is INTEGER
          The length of the vector X.  N >= 0.

  [in,out] X

          X is COMPLEX*16 array, dimension
                        (1+(N-1)*abs(INCX))
          On entry, the vector of length N to be conjugated.
          On exit, X is overwritten with conjg(X).

  [in] INCX

          INCX is INTEGER
```

```
          The spacing between successive elements of X.

 Definition:
 ===========

       SUBROUTINE ZLACPY( UPLO, M, N, A, LDA, B, LDB )

       .. Scalar Arguments ..
       CHARACTER          UPLO
       INTEGER            LDA, LDB, M, N
       ..
       .. Array Arguments ..
       COMPLEX*16         A( LDA, * ), B( LDB, * )
       ..
```

```
Purpose:
=============

 ZLACPY copies all or part of a two-dimensional matrix A to another
 matrix B.

Arguments:
==========

 [in] UPLO

         UPLO is CHARACTER*1
         Specifies the part of the matrix A to be copied to B.
         = 'U':      Upper triangular part
         = 'L':      Lower triangular part
         Otherwise:  All of the matrix A

 [in] M

         M is INTEGER
         The number of rows of the matrix A.  M >= 0.

 [in] N

         N is INTEGER
         The number of columns of the matrix A.  N >= 0.

 [in] A

         A is COMPLEX*16 array, dimension (LDA,N)
         The m by n matrix A.  If UPLO = 'U', only the upper trapezium
         is accessed; if UPLO = 'L', only the lower trapezium is
         accessed.

 [in] LDA

         LDA is INTEGER
         The leading dimension of the array A.  LDA >= max(1,M).

 [out] B

         B is COMPLEX*16 array, dimension (LDB,N)
         On exit, B = A in the locations specified by UPLO.

 [in] LDB

         LDB is INTEGER
         The leading dimension of the array B.  LDB >= max(1,M).

       COMPLEX*16     FUNCTION ZLADIV( X, Y )

       .. Scalar Arguments ..
       COMPLEX*16         X, Y
       ..

 Purpose:
 =============

  ZLADIV := X / Y, where X and Y are complex.  The computation of X / Y
  will not overflow on an intermediary step unless the results
  overflows.

 Arguments:
 ==========

  [in] X

          X is COMPLEX*16
```

```
 [in] Y

         Y is COMPLEX*16
         The complex scalars X and Y.

       SUBROUTINE ZLAHQR( WANTT, WANTZ, N, ILO, IHI, H, LDH, W, ILOZ,
                          IHIZ, Z, LDZ, INFO )

       .. Scalar Arguments ..
       INTEGER            IHI, IHIZ, ILO, ILOZ, INFO, LDH, LDZ, N
       LOGICAL            WANTT, WANTZ
       ..
       .. Array Arguments ..
       COMPLEX*16         H( LDH, * ), W( * ), Z( LDZ, * )
       ..

 Purpose:
 =============

    ZLAHQR is an auxiliary routine called by CHSEQR to update the
    eigenvalues and Schur decomposition already computed by CHSEQR, by
    dealing with the Hessenberg submatrix in rows and columns ILO to
    IHI.

 Arguments:
 ==========

  [in] WANTT

          WANTT is LOGICAL
          = .TRUE. : the full Schur form T is required;
          = .FALSE.: only eigenvalues are required.

  [in] WANTZ

          WANTZ is LOGICAL
          = .TRUE. : the matrix of Schur vectors Z is required;
          = .FALSE.: Schur vectors are not required.
```

```
[in] N

        N is INTEGER
        The order of the matrix H.  N >= 0.

[in] ILO

        ILO is INTEGER

[in] IHI

        IHI is INTEGER
        It is assumed that H is already upper triangular in rows and
        columns IHI+1:N, and that H(ILO,ILO-1) = 0 (unless ILO = 1).
        ZLAHQR works primarily with the Hessenberg submatrix in rows
        and columns ILO to IHI, but applies transformations to all of
        H if WANTT is .TRUE..
        1 <= ILO <= max(1,IHI); IHI <= N.

[in,out] H

        H is COMPLEX*16 array, dimension (LDH,N)
        On entry, the upper Hessenberg matrix H.
        On exit, if INFO is zero and if WANTT is .TRUE., then H
        is upper triangular in rows and columns ILO:IHI.  If INFO
        is zero and if WANTT is .FALSE., then the contents of H
        are unspecified on exit.  The output state of H in case
        INF is positive is below under the description of INFO.

[in] LDH

        LDH is INTEGER
        The leading dimension of the array H. LDH >= max(1,N).

[out] W

        W is COMPLEX*16 array, dimension (N)
        The computed eigenvalues ILO to IHI are stored in the
        corresponding elements of W. If WANTT is .TRUE., the
        eigenvalues are stored in the same order as on the diagonal
        of the Schur form returned in H, with W(i) = H(i,i).

[in] ILOZ

        ILOZ is INTEGER

[in] IHIZ

        IHIZ is INTEGER
        Specify the rows of Z to which transformations must be
```

```
          applied if WANTZ is .TRUE..
          1 <= ILOZ <= ILO; IHI <= IHIZ <= N.

  [in,out] Z

          Z is COMPLEX*16 array, dimension (LDZ,N)
          If WANTZ is .TRUE., on entry Z must contain the current
          matrix Z of transformations accumulated by CHSEQR, and on
          exit Z has been updated; transformations are applied only to
          the submatrix Z(ILOZ:IHIZ,ILO:IHI).
          If WANTZ is .FALSE., Z is not referenced.

  [in] LDZ

          LDZ is INTEGER
          The leading dimension of the array Z. LDZ >= max(1,N).

  [out] INFO

          INFO is INTEGER
           =   0: successful exit
          .GT. 0: if INFO = i, ZLAHQR failed to compute all the
                  eigenvalues ILO to IHI in a total of 30 iterations
                  per eigenvalue; elements i+1:ihi of W contain
                  those eigenvalues which have been successfully
                  computed.

                  If INFO .GT. 0 and WANTT is .FALSE., then on exit,
                  the remaining unconverged eigenvalues are the
                  eigenvalues of the upper Hessenberg matrix
                  rows and columns ILO thorugh INFO of the final,
                  output value of H.

                  If INFO .GT. 0 and WANTT is .TRUE., then on exit
          (*)       (initial value of H)*U  = U*(final value of H)
                  where U is an orthognal matrix.    The final
                  value of H is upper Hessenberg and triangular in
                  rows and columns INFO+1 through IHI.

                  If INFO .GT. 0 and WANTZ is .TRUE., then on exit
                      (final value of Z)  = (initial value of Z)*U
                  where U is the orthogonal matrix in (*)
                  (regardless of the value of WANTT.)

==================

    02-96 Based on modifications by
    David Day, Sandia National Laboratory, USA

    12-04 Further modifications by
    Ralph Byers, University of Kansas, USA
    This is a modified version of ZLAHQR from LAPACK version 3.0.
    It is (1) more robust against overflow and underflow and
    (2) adopts the more conservative Ahues & Tisseur stopping
    criterion (LAWN 122, 1997).

 Definition:
 ===========

       SUBROUTINE ZLAHR2( N, K, NB, A, LDA, TAU, T, LDT, Y, LDY )

       .. Scalar Arguments ..
       INTEGER            K, LDA, LDT, LDY, N, NB
       ..
       .. Array Arguments ..
       COMPLEX*16         A( LDA, * ), T( LDT, NB ), TAU( NB ),
      $                   Y( LDY, NB )
       ..

 Purpose:
 =============

  ZLAHR2 reduces the first NB columns of A complex general n-BY-(n-k+1)
  matrix A so that elements below the k-th subdiagonal are zero. The
  reduction is performed by an unitary similarity transformation
  Q**H * A * Q. The routine returns the matrices V and T which determine
  Q as a block reflector I - V*T*V**H, and also the matrix Y = A * V * T.

  This is an auxiliary routine called by ZGEHRD.

 Arguments:
 ==========

  [in] N
```

```
          N is INTEGER
          The order of the matrix A.

  [in] K

          K is INTEGER
          The offset for the reduction. Elements below the k-th
          subdiagonal in the first NB columns are reduced to zero.
          K < N.

  [in] NB

          NB is INTEGER
          The number of columns to be reduced.

  [in,out] A

          A is COMPLEX*16 array, dimension (LDA,N-K+1)
          On entry, the n-by-(n-k+1) general matrix A.
          On exit, the elements on and above the k-th subdiagonal in
          the first NB columns are overwritten with the corresponding
          elements of the reduced matrix; the elements below the k-th
          subdiagonal, with the array TAU, represent the matrix Q as a
          product of elementary reflectors. The other columns of A are
          unchanged. See Further Details.

  [in] LDA

          LDA is INTEGER
          The leading dimension of the array A.  LDA >= max(1,N).

  [out] TAU

          TAU is COMPLEX*16 array, dimension (NB)
          The scalar factors of the elementary reflectors. See Further
          Details.

  [out] T

          T is COMPLEX*16 array, dimension (LDT,NB)
          The upper triangular matrix T.

  [in] LDT

          LDT is INTEGER
          The leading dimension of the array T.  LDT >= NB.

  [out] Y
```

```
          Y is COMPLEX*16 array, dimension (LDY,NB)
          The n-by-nb matrix Y.

  [in] LDY

          LDY is INTEGER
          The leading dimension of the array Y. LDY >= N.

Further Details:
====================

 The matrix Q is represented as a product of nb elementary reflectors

    Q = H(1) H(2) . . . H(nb).

 Each H(i) has the form

    H(i) = I - tau * v * v**H

 where tau is a complex scalar, and v is a complex vector with
 v(1:i+k-1) = 0, v(i+k) = 1; v(i+k+1:n) is stored on exit in
 A(i+k+1:n,i), and tau in TAU(i).

 The elements of the vectors v together form the (n-k+1)-by-nb matrix
 V which is needed, with T and Y, to apply the transformation to the
 unreduced part of the matrix, using an update of the form:
 A := (I - V*T*V**H) * (A - Y*V**H).

 The contents of A on exit are illustrated by the following example
 with n = 7, k = 3 and nb = 2:

    ( a   a   a   a   a )
    ( a   a   a   a   a )
    ( a   a   a   a   a )
    ( h   h   a   a   a )
    ( v1  h   a   a   a )
    ( v1  v2  a   a   a )
    ( v1  v2  a   a   a )

 where a denotes an element of the original matrix A, h denotes a
```

```
  modified element of the upper Hessenberg matrix H, and vi denotes an
  element of the vector defining H(i).

  This subroutine is a slight modification of LAPACK-3.0's DLAHRD
  incorporating improvements proposed by Quintana-Orti and Van de
  Gejin. Note that the entries of A(1:K,2:NB) differ from those
  returned by the original LAPACK-3.0's DLAHRD routine. (This
  subroutine is not backward compatible with LAPACK-3.0's DLAHRD.)

            http://www.netlib.org/lapack/explore-html/

 Definition:
 ===========

       DOUBLE PRECISION FUNCTION ZLANGE( NORM, M, N, A, LDA, WORK )

      .. Scalar Arguments ..
       CHARACTER          NORM
       INTEGER            LDA, M, N
       ..
       .. Array Arguments ..
       DOUBLE PRECISION   WORK( * )
       COMPLEX*16         A( LDA, * )
       ..

 Purpose:
 =============

 ZLANGE  returns the value of the one norm,  or the Frobenius norm, or
```

```
the  infinity norm,  or the  element of  largest absolute value  of a
complex matrix A.

   ZLANGE = ( max(abs(A(i,j))), NORM = 'M' or 'm'
            (
            ( norm1(A),         NORM = '1', 'O' or 'o'
            (
            ( normI(A),         NORM = 'I' or 'i'
            (
            ( normF(A),         NORM = 'F', 'f', 'E' or 'e'

where  norm1  denotes the  one norm of a matrix (maximum column sum),
normI  denotes the  infinity norm  of a matrix  (maximum row sum) and
normF  denotes the  Frobenius norm of a matrix (square root of sum of
squares).  Note that  max(abs(A(i,j)))  is not a consistent matrix norm.

Arguments:
==========

 [in] NORM

         NORM is CHARACTER*1
         Specifies the value to be returned in ZLANGE as described
         above.

 [in] M

         M is INTEGER
         The number of rows of the matrix A.  M >= 0.  When M = 0,
         ZLANGE is set to zero.

 [in] N

         N is INTEGER
         The number of columns of the matrix A.  N >= 0.  When N = 0,
         ZLANGE is set to zero.

 [in] A

         A is COMPLEX*16 array, dimension (LDA,N)
         The m by n matrix A.

 [in] LDA

         LDA is INTEGER
         The leading dimension of the array A.  LDA >= max(M,1).

 [out] WORK
```

```
          WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK)),
          where LWORK >= M when NORM = 'I'; otherwise, WORK is not
          referenced.

 Definition:
 ===========

       SUBROUTINE ZLAQR0( WANTT, WANTZ, N, ILO, IHI, H, LDH, W, ILOZ,
                          IHIZ, Z, LDZ, WORK, LWORK, INFO )

       .. Scalar Arguments ..
       INTEGER            IHI, IHIZ, ILO, ILOZ, INFO, LDH, LDZ, LWORK, N
       LOGICAL            WANTT, WANTZ
       ..
       .. Array Arguments ..
       COMPLEX*16         H( LDH, * ), W( * ), WORK( * ), Z( LDZ, * )
       ..

 Purpose:
 =============

    ZLAQR0 computes the eigenvalues of a Hessenberg matrix H
    and, optionally, the matrices T and Z from the Schur decomposition
    H = Z T Z**H, where T is an upper triangular matrix (the
    Schur form), and Z is the unitary matrix of Schur vectors.

    Optionally Z may be postmultiplied into an input unitary
    matrix Q so that this routine can give the Schur factorization
    of a matrix A which has been reduced to the Hessenberg form H
    by the unitary matrix Q:  A = Q*H*Q**H = (QZ)*H*(QZ)**H.

 Arguments:
 ==========

  [in] WANTT

          WANTT is LOGICAL
          = .TRUE. : the full Schur form T is required;
          = .FALSE.: only eigenvalues are required.

  [in] WANTZ
```

```
          WANTZ is LOGICAL
          = .TRUE. : the matrix of Schur vectors Z is required;
          = .FALSE.: Schur vectors are not required.

[in] N

          N is INTEGER
           The order of the matrix H.  N .GE. 0.

[in] ILO

          ILO is INTEGER

[in] IHI

          IHI is INTEGER

           It is assumed that H is already upper triangular in rows
           and columns 1:ILO-1 and IHI+1:N and, if ILO.GT.1,
           H(ILO,ILO-1) is zero. ILO and IHI are normally set by a
           previous call to ZGEBAL, and then passed to ZGEHRD when the
           matrix output by ZGEBAL is reduced to Hessenberg form.
           Otherwise, ILO and IHI should be set to 1 and N,
           respectively.  If N.GT.0, then 1.LE.ILO.LE.IHI.LE.N.
           If N = 0, then ILO = 1 and IHI = 0.

[in,out] H

          H is COMPLEX*16 array, dimension (LDH,N)
           On entry, the upper Hessenberg matrix H.
           On exit, if INFO = 0 and WANTT is .TRUE., then H
           contains the upper triangular matrix T from the Schur
           decomposition (the Schur form). If INFO = 0 and WANT is
           .FALSE., then the contents of H are unspecified on exit.
           (The output value of H when INFO.GT.0 is given under the
           description of INFO below.)

           This subroutine may explicitly set H(i,j) = 0 for i.GT.j and
           j = 1, 2, ... ILO-1 or j = IHI+1, IHI+2, ... N.

[in] LDH

          LDH is INTEGER
           The leading dimension of the array H. LDH .GE. max(1,N).

[out] W

          W is COMPLEX*16 array, dimension (N)
           The computed eigenvalues of H(ILO:IHI,ILO:IHI) are stored
           in W(ILO:IHI). If WANTT is .TRUE., then the eigenvalues are
```

```
          stored in the same order as on the diagonal of the Schur
          form returned in H, with W(i) = H(i,i).

  [in] ILOZ

         ILOZ is INTEGER

  [in] IHIZ

         IHIZ is INTEGER
          Specify the rows of Z to which transformations must be
          applied if WANTZ is .TRUE..
          1 .LE. ILOZ .LE. ILO; IHI .LE. IHIZ .LE. N.

  [in,out] Z

         Z is COMPLEX*16 array, dimension (LDZ,IHI)
          If WANTZ is .FALSE., then Z is not referenced.
          If WANTZ is .TRUE., then Z(ILO:IHI,ILOZ:IHIZ) is
          replaced by Z(ILO:IHI,ILOZ:IHIZ)*U where U is the
          orthogonal Schur factor of H(ILO:IHI,ILO:IHI).
          (The output value of Z when INFO.GT.0 is given under
          the description of INFO below.)

  [in] LDZ

         LDZ is INTEGER
          The leading dimension of the array Z.  if WANTZ is .TRUE.
          then LDZ.GE.MAX(1,IHIZ).  Otherwize, LDZ.GE.1.

  [out] WORK

         WORK is COMPLEX*16 array, dimension LWORK
          On exit, if LWORK = -1, WORK(1) returns an estimate of
          the optimal value for LWORK.

  [in] LWORK

         LWORK is INTEGER
          The dimension of the array WORK.  LWORK .GE. max(1,N)
          is sufficient, but LWORK typically as large as 6*N may
          be required for optimal performance.  A workspace query
          to determine the optimal workspace size is recommended.

          If LWORK = -1, then ZLAQR0 does a workspace query.
          In this case, ZLAQR0 checks the input parameters and
          estimates the optimal workspace size for the given
          values of N, ILO and IHI.  The estimate is returned
          in WORK(1).  No error message related to LWORK is
          issued by XERBLA.  Neither H nor Z are accessed.
```

```
 [out] INFO

          INFO is INTEGER
             =  0:  successful exit
           .GT. 0:  if INFO = i, ZLAQR0 failed to compute all of
                the eigenvalues.  Elements 1:ilo-1 and i+1:n of WR
                and WI contain those eigenvalues which have been
                successfully computed.  (Failures are rare.)

                If INFO .GT. 0 and WANT is .FALSE., then on exit,
                the remaining unconverged eigenvalues are the eigen-
                values of the upper Hessenberg matrix rows and
                columns ILO through INFO of the final, output
                value of H.

                If INFO .GT. 0 and WANTT is .TRUE., then on exit

           (*)  (initial value of H)*U  = U*(final value of H)

                where U is a unitary matrix.  The final
                value of  H is upper Hessenberg and triangular in
                rows and columns INFO+1 through IHI.

                If INFO .GT. 0 and WANTZ is .TRUE., then on exit

                  (final value of Z(ILO:IHI,ILOZ:IHIZ)
                   =  (initial value of Z(ILO:IHI,ILOZ:IHIZ)*U

                where U is the unitary matrix in (*) (regard-
                less of the value of WANTT.)

                If INFO .GT. 0 and WANTZ is .FALSE., then Z is not
                accessed.

 Online html documentation available at
            http://www.netlib.org/lapack/explore-html/

 Definition:
 ===========

       SUBROUTINE ZLAQR1( N, H, LDH, S1, S2, V )

       .. Scalar Arguments ..
       COMPLEX*16         S1, S2
       INTEGER            LDH, N
       ..
       .. Array Arguments ..
       COMPLEX*16         H( LDH, * ), V( * )
       ..

 Purpose:
 =============

      Given a 2-by-2 or 3-by-3 matrix H, ZLAQR1 sets v to a
      scalar multiple of the first column of the product

      (*)  K = (H - s1*I)*(H - s2*I)

      scaling to avoid overflows and most underflows.

      This is useful for starting double implicit shift bulges
```

```
     in the QR algorithm.

 Arguments:
 ==========

  [in] N

          N is integer
              Order of the matrix H. N must be either 2 or 3.

  [in] H

          H is COMPLEX*16 array of dimension (LDH,N)
              The 2-by-2 or 3-by-3 matrix H in (*).

  [in] LDH

          LDH is integer
              The leading dimension of H as declared in
              the calling procedure.  LDH.GE.N

  [in] S1

          S1 is COMPLEX*16

  [in] S2

          S2 is COMPLEX*16

          S1 and S2 are the shifts defining K in (*) above.

  [out] V

          V is COMPLEX*16 array of dimension N
              A scalar multiple of the first column of the
              matrix K in (*).

      $                   LDZ, LWORK, N, ND, NH, NS, NV, NW
       LOGICAL            WANTT, WANTZ
       ..
       .. Array Arguments ..
       COMPLEX*16         H( LDH, * ), SH( * ), T( LDT, * ), V( LDV, * ),
      $                   WORK( * ), WV( LDWV, * ), Z( LDZ, * )
       ..

 Purpose:
 =============

    ZLAQR2 is identical to ZLAQR3 except that it avoids
    recursion by calling ZLAHQR instead of ZLAQR4.

    Aggressive early deflation:

    ZLAQR2 accepts as input an upper Hessenberg matrix
    H and performs an unitary similarity transformation
    designed to detect and deflate fully converged eigenvalues from
    a trailing principal submatrix.  On output H has been over-
    written by a new Hessenberg matrix that is a perturbation of
    an unitary similarity transformation of H.  It is to be
    hoped that the final version of H has many zero subdiagonal
    entries.
```

```
 Arguments:
 ==========

  [in] WANTT

          WANTT is LOGICAL
          If .TRUE., then the Hessenberg matrix H is fully updated
          so that the triangular Schur factor may be
          computed (in cooperation with the calling subroutine).
          If .FALSE., then only enough of H is updated to preserve
          the eigenvalues.

  [in] WANTZ

          WANTZ is LOGICAL
          If .TRUE., then the unitary matrix Z is updated so
          so that the unitary Schur factor may be computed
          (in cooperation with the calling subroutine).
          If .FALSE., then Z is not referenced.

  [in] N

          N is INTEGER
          The order of the matrix H and (if WANTZ is .TRUE.) the
          order of the unitary matrix Z.

  [in] KTOP

          KTOP is INTEGER
          It is assumed that either KTOP = 1 or H(KTOP,KTOP-1)=0.
          KBOT and KTOP together determine an isolated block
          along the diagonal of the Hessenberg matrix.

  [in] KBOT

          KBOT is INTEGER
          It is assumed without a check that either
          KBOT = N or H(KBOT+1,KBOT)=0.  KBOT and KTOP together
          determine an isolated block along the diagonal of the
          Hessenberg matrix.

  [in] NW

          NW is INTEGER
          Deflation window size.  1 .LE. NW .LE. (KBOT-KTOP+1).

  [in,out] H

          H is COMPLEX*16 array, dimension (LDH,N)
          On input the initial N-by-N section of H stores the
```

```
          Hessenberg matrix undergoing aggressive early deflation.
          On output H has been transformed by a unitary
          similarity transformation, perturbed, and the returned
          to Hessenberg form that (it is to be hoped) has some
          zero subdiagonal entries.

  [in] LDH

          LDH is integer
          Leading dimension of H just as declared in the calling
          subroutine.  N .LE. LDH

  [in] ILOZ

          ILOZ is INTEGER

  [in] IHIZ

          IHIZ is INTEGER
          Specify the rows of Z to which transformations must be
          applied if WANTZ is .TRUE.. 1 .LE. ILOZ .LE. IHIZ .LE. N.

  [in,out] Z

          Z is COMPLEX*16 array, dimension (LDZ,N)
          IF WANTZ is .TRUE., then on output, the unitary
          similarity transformation mentioned above has been
          accumulated into Z(ILOZ:IHIZ,ILO:IHI) from the right.
          If WANTZ is .FALSE., then Z is unreferenced.

  [in] LDZ

          LDZ is integer
          The leading dimension of Z just as declared in the
          calling subroutine.  1 .LE. LDZ.

  [out] NS

          NS is integer
          The number of unconverged (ie approximate) eigenvalues
          returned in SR and SI that may be used as shifts by the
          calling subroutine.

  [out] ND

          ND is integer
          The number of converged eigenvalues uncovered by this
          subroutine.

  [out] SH
```

```
          SH is COMPLEX*16 array, dimension KBOT
          On output, approximate eigenvalues that may
          be used for shifts are stored in SH(KBOT-ND-NS+1)
          through SR(KBOT-ND).  Converged eigenvalues are
          stored in SH(KBOT-ND+1) through SH(KBOT).

  [out] V

          V is COMPLEX*16 array, dimension (LDV,NW)
          An NW-by-NW work array.

  [in] LDV

          LDV is integer scalar
          The leading dimension of V just as declared in the
          calling subroutine.  NW .LE. LDV

  [in] NH

          NH is integer scalar
          The number of columns of T.  NH.GE.NW.

  [out] T

          T is COMPLEX*16 array, dimension (LDT,NW)

  [in] LDT

          LDT is integer
          The leading dimension of T just as declared in the
          calling subroutine.  NW .LE. LDT

  [in] NV

          NV is integer
          The number of rows of work array WV available for
          workspace.  NV.GE.NW.

  [out] WV

          WV is COMPLEX*16 array, dimension (LDWV,NW)

  [in] LDWV

          LDWV is integer
          The leading dimension of W just as declared in the
          calling subroutine.  NW .LE. LDV

  [out] WORK
```

```
          WORK is COMPLEX*16 array, dimension LWORK.
          On exit, WORK(1) is set to an estimate of the optimal value
          of LWORK for the given values of N, NW, KTOP and KBOT.

  [in] LWORK

          LWORK is integer
          The dimension of the work array WORK.  LWORK = 2*NW
          suffices, but greater efficiency may result from larger
          values of LWORK.

          If LWORK = -1, then a workspace query is assumed; ZLAQR2
          only estimates the optimal workspace size for the given
          values of N, NW, KTOP and KBOT.  The estimate is returned
          in WORK(1).  No error message related to LWORK is issued
          by XERBLA.  Neither H nor Z are accessed.

       SUBROUTINE ZLAQR3( WANTT, WANTZ, N, KTOP, KBOT, NW, H, LDH, ILOZ,
                          IHIZ, Z, LDZ, NS, ND, SH, V, LDV, NH, T, LDT,
                          NV, WV, LDWV, WORK, LWORK )

       .. Scalar Arguments ..
       INTEGER            IHIZ, ILOZ, KBOT, KTOP, LDH, LDT, LDV, LDWV,
      $                   LDZ, LWORK, N, ND, NH, NS, NV, NW
       LOGICAL            WANTT, WANTZ
       ..
       .. Array Arguments ..
       COMPLEX*16         H( LDH, * ), SH( * ), T( LDT, * ), V( LDV, * ),
      $                   WORK( * ), WV( LDWV, * ), Z( LDZ, * )
       ..

 Purpose:
 =============

    Aggressive early deflation:
```

```
    ZLAQR3 accepts as input an upper Hessenberg matrix
    H and performs an unitary similarity transformation
    designed to detect and deflate fully converged eigenvalues from
    a trailing principal submatrix.  On output H has been over-
    written by a new Hessenberg matrix that is a perturbation of
    an unitary similarity transformation of H.  It is to be
    hoped that the final version of H has many zero subdiagonal
    entries.

Arguments:
==========

 [in] WANTT

         WANTT is LOGICAL
         If .TRUE., then the Hessenberg matrix H is fully updated
         so that the triangular Schur factor may be
         computed (in cooperation with the calling subroutine).
         If .FALSE., then only enough of H is updated to preserve
         the eigenvalues.

 [in] WANTZ

         WANTZ is LOGICAL
         If .TRUE., then the unitary matrix Z is updated so
         so that the unitary Schur factor may be computed
         (in cooperation with the calling subroutine).
         If .FALSE., then Z is not referenced.

 [in] N

         N is INTEGER
         The order of the matrix H and (if WANTZ is .TRUE.) the
         order of the unitary matrix Z.

 [in] KTOP

         KTOP is INTEGER
         It is assumed that either KTOP = 1 or H(KTOP,KTOP-1)=0.
         KBOT and KTOP together determine an isolated block
         along the diagonal of the Hessenberg matrix.

 [in] KBOT

         KBOT is INTEGER
         It is assumed without a check that either
         KBOT = N or H(KBOT+1,KBOT)=0.  KBOT and KTOP together
         determine an isolated block along the diagonal of the
         Hessenberg matrix.
```

```
[in] NW

        NW is INTEGER
        Deflation window size.  1 .LE. NW .LE. (KBOT-KTOP+1).

[in,out] H

        H is COMPLEX*16 array, dimension (LDH,N)
        On input the initial N-by-N section of H stores the
        Hessenberg matrix undergoing aggressive early deflation.
        On output H has been transformed by a unitary
        similarity transformation, perturbed, and the returned
        to Hessenberg form that (it is to be hoped) has some
        zero subdiagonal entries.

[in] LDH

        LDH is integer
        Leading dimension of H just as declared in the calling
        subroutine.  N .LE. LDH

[in] ILOZ

        ILOZ is INTEGER

[in] IHIZ

        IHIZ is INTEGER
        Specify the rows of Z to which transformations must be
        applied if WANTZ is .TRUE.. 1 .LE. ILOZ .LE. IHIZ .LE. N.

[in,out] Z

        Z is COMPLEX*16 array, dimension (LDZ,N)
        IF WANTZ is .TRUE., then on output, the unitary
        similarity transformation mentioned above has been
        accumulated into Z(ILOZ:IHIZ,ILO:IHI) from the right.
        If WANTZ is .FALSE., then Z is unreferenced.

[in] LDZ

        LDZ is integer
        The leading dimension of Z just as declared in the
        calling subroutine.  1 .LE. LDZ.

[out] NS

        NS is integer
        The number of unconverged (ie approximate) eigenvalues
```

```
          returned in SR and SI that may be used as shifts by the
          calling subroutine.

  [out] ND

          ND is integer
          The number of converged eigenvalues uncovered by this
          subroutine.

  [out] SH

          SH is COMPLEX*16 array, dimension KBOT
          On output, approximate eigenvalues that may
          be used for shifts are stored in SH(KBOT-ND-NS+1)
          through SR(KBOT-ND).  Converged eigenvalues are
          stored in SH(KBOT-ND+1) through SH(KBOT).

  [out] V

          V is COMPLEX*16 array, dimension (LDV,NW)
          An NW-by-NW work array.

  [in] LDV

          LDV is integer scalar
          The leading dimension of V just as declared in the
          calling subroutine.  NW .LE. LDV

  [in] NH

          NH is integer scalar
          The number of columns of T.  NH.GE.NW.

  [out] T

          T is COMPLEX*16 array, dimension (LDT,NW)

  [in] LDT

          LDT is integer
          The leading dimension of T just as declared in the
          calling subroutine.  NW .LE. LDT

  [in] NV

          NV is integer
          The number of rows of work array WV available for
          workspace.  NV.GE.NW.

  [out] WV
```

```
          WV is COMPLEX*16 array, dimension (LDWV,NW)

  [in] LDWV

          LDWV is integer
          The leading dimension of W just as declared in the
          calling subroutine.  NW .LE. LDV

  [out] WORK

          WORK is COMPLEX*16 array, dimension LWORK.
          On exit, WORK(1) is set to an estimate of the optimal value
          of LWORK for the given values of N, NW, KTOP and KBOT.

  [in] LWORK

          LWORK is integer
          The dimension of the work array WORK.  LWORK = 2*NW
          suffices, but greater efficiency may result from larger
          values of LWORK.

          If LWORK = -1, then a workspace query is assumed; ZLAQR3
          only estimates the optimal workspace size for the given
          values of N, NW, KTOP and KBOT.  The estimate is returned
          in WORK(1).  No error message related to LWORK is issued
          by XERBLA.  Neither H nor Z are accessed.

       SUBROUTINE ZLAQR4( WANTT, WANTZ, N, ILO, IHI, H, LDH, W, ILOZ,
```

```
                        IHIZ, Z, LDZ, WORK, LWORK, INFO )

      .. Scalar Arguments ..
      INTEGER            IHI, IHIZ, ILO, ILOZ, INFO, LDH, LDZ, LWORK, N
      LOGICAL            WANTT, WANTZ
      ..
      .. Array Arguments ..
      COMPLEX*16         H( LDH, * ), W( * ), WORK( * ), Z( LDZ, * )
      ..

Purpose:
=============

   ZLAQR4 implements one level of recursion for ZLAQR0.
   It is a complete implementation of the small bulge multi-shift
   QR algorithm.  It may be called by ZLAQR0 and, for large enough
   deflation window size, it may be called by ZLAQR3.  This
   subroutine is identical to ZLAQR0 except that it calls ZLAQR2
   instead of ZLAQR3.

   ZLAQR4 computes the eigenvalues of a Hessenberg matrix H
   and, optionally, the matrices T and Z from the Schur decomposition
   H = Z T Z**H, where T is an upper triangular matrix (the
   Schur form), and Z is the unitary matrix of Schur vectors.

   Optionally Z may be postmultiplied into an input unitary
   matrix Q so that this routine can give the Schur factorization
   of a matrix A which has been reduced to the Hessenberg form H
   by the unitary matrix Q:  A = Q*H*Q**H = (QZ)*H*(QZ)**H.

Arguments:
==========

 [in] WANTT

         WANTT is LOGICAL
         = .TRUE. : the full Schur form T is required;
         = .FALSE.: only eigenvalues are required.

 [in] WANTZ

         WANTZ is LOGICAL
         = .TRUE. : the matrix of Schur vectors Z is required;
         = .FALSE.: Schur vectors are not required.

 [in] N

         N is INTEGER
          The order of the matrix H.  N .GE. 0.
```

```
[in] ILO

        ILO is INTEGER

[in] IHI

        IHI is INTEGER
         It is assumed that H is already upper triangular in rows
         and columns 1:ILO-1 and IHI+1:N and, if ILO.GT.1,
         H(ILO,ILO-1) is zero. ILO and IHI are normally set by a
         previous call to ZGEBAL, and then passed to ZGEHRD when the
         matrix output by ZGEBAL is reduced to Hessenberg form.
         Otherwise, ILO and IHI should be set to 1 and N,
         respectively.  If N.GT.0, then 1.LE.ILO.LE.IHI.LE.N.
         If N = 0, then ILO = 1 and IHI = 0.

[in,out] H

        H is COMPLEX*16 array, dimension (LDH,N)
         On entry, the upper Hessenberg matrix H.
         On exit, if INFO = 0 and WANTT is .TRUE., then H
         contains the upper triangular matrix T from the Schur
         decomposition (the Schur form). If INFO = 0 and WANT is
         .FALSE., then the contents of H are unspecified on exit.
         (The output value of H when INFO.GT.0 is given under the
         description of INFO below.)

         This subroutine may explicitly set H(i,j) = 0 for i.GT.j and
         j = 1, 2, ... ILO-1 or j = IHI+1, IHI+2, ... N.

[in] LDH

        LDH is INTEGER
         The leading dimension of the array H. LDH .GE. max(1,N).

[out] W

        W is COMPLEX*16 array, dimension (N)
         The computed eigenvalues of H(ILO:IHI,ILO:IHI) are stored
         in W(ILO:IHI). If WANTT is .TRUE., then the eigenvalues are
         stored in the same order as on the diagonal of the Schur
         form returned in H, with W(i) = H(i,i).

[in] ILOZ

        ILOZ is INTEGER

[in] IHIZ
```

```
          IHIZ is INTEGER
           Specify the rows of Z to which transformations must be
           applied if WANTZ is .TRUE..
           1 .LE. ILOZ .LE. ILO; IHI .LE. IHIZ .LE. N.

  [in,out] Z

          Z is COMPLEX*16 array, dimension (LDZ,IHI)
           If WANTZ is .FALSE., then Z is not referenced.
           If WANTZ is .TRUE., then Z(ILO:IHI,ILOZ:IHIZ) is
           replaced by Z(ILO:IHI,ILOZ:IHIZ)*U where U is the
           orthogonal Schur factor of H(ILO:IHI,ILO:IHI).
           (The output value of Z when INFO.GT.0 is given under
           the description of INFO below.)

  [in] LDZ

          LDZ is INTEGER
           The leading dimension of the array Z.  if WANTZ is .TRUE.
           then LDZ.GE.MAX(1,IHIZ).  Otherwize, LDZ.GE.1.

  [out] WORK

          WORK is COMPLEX*16 array, dimension LWORK
           On exit, if LWORK = -1, WORK(1) returns an estimate of
           the optimal value for LWORK.

  [in] LWORK

          LWORK is INTEGER
           The dimension of the array WORK.  LWORK .GE. max(1,N)
           is sufficient, but LWORK typically as large as 6*N may
           be required for optimal performance.  A workspace query
           to determine the optimal workspace size is recommended.

           If LWORK = -1, then ZLAQR4 does a workspace query.
           In this case, ZLAQR4 checks the input parameters and
           estimates the optimal workspace size for the given
           values of N, ILO and IHI.  The estimate is returned
           in WORK(1).  No error message related to LWORK is
           issued by XERBLA.  Neither H nor Z are accessed.

  [out] INFO

          INFO is INTEGER
             =  0:  successful exit
            .GT. 0:  if INFO = i, ZLAQR4 failed to compute all of
                 the eigenvalues.  Elements 1:ilo-1 and i+1:n of WR
                 and WI contain those eigenvalues which have been
                 successfully computed.  (Failures are rare.)
```

```
               If INFO .GT. 0 and WANT is .FALSE., then on exit,
               the remaining unconverged eigenvalues are the eigen-
               values of the upper Hessenberg matrix rows and
               columns ILO through INFO of the final, output
               value of H.

               If INFO .GT. 0 and WANTT is .TRUE., then on exit

          (*)  (initial value of H)*U  = U*(final value of H)

               where U is a unitary matrix.  The final
               value of  H is upper Hessenberg and triangular in
               rows and columns INFO+1 through IHI.

               If INFO .GT. 0 and WANTZ is .TRUE., then on exit

                 (final value of Z(ILO:IHI,ILOZ:IHIZ)
                  =  (initial value of Z(ILO:IHI,ILOZ:IHIZ)*U

               where U is the unitary matrix in (*) (regard-
               less of the value of WANTT.)

               If INFO .GT. 0 and WANTZ is .FALSE., then Z is not
               accessed.

       SUBROUTINE ZLAQR5( WANTT, WANTZ, KACC22, N, KTOP, KBOT, NSHFTS, S,
                          H, LDH, ILOZ, IHIZ, Z, LDZ, V, LDV, U, LDU, NV,
                          WV, LDWV, NH, WH, LDWH )

       .. Scalar Arguments ..
       INTEGER            IHIZ, ILOZ, KACC22, KBOT, KTOP, LDH, LDU, LDV,
      $                   LDWH, LDWV, LDZ, N, NH, NSHFTS, NV
       LOGICAL            WANTT, WANTZ
       ..
       .. Array Arguments ..
       COMPLEX*16         H( LDH, * ), S( * ), U( LDU, * ), V( LDV, * ),
      $                   WH( LDWH, * ), WV( LDWV, * ), Z( LDZ, * )
       ..

 Purpose:
 =============

    ZLAQR5, called by ZLAQR0, performs a
    single small-bulge multi-shift QR sweep.

 Arguments:
 ==========
```

```
[in] WANTT

        WANTT is logical scalar
           WANTT = .true. if the triangular Schur factor
           is being computed.  WANTT is set to .false. otherwise.

[in] WANTZ

        WANTZ is logical scalar
           WANTZ = .true. if the unitary Schur factor is being
           computed.  WANTZ is set to .false. otherwise.

[in] KACC22

        KACC22 is integer with value 0, 1, or 2.
           Specifies the computation mode of far-from-diagonal
           orthogonal updates.
      = 0: ZLAQR5 does not accumulate reflections and does not
           use matrix-matrix multiply to update far-from-diagonal
           matrix entries.
      = 1: ZLAQR5 accumulates reflections and uses matrix-matrix
           multiply to update the far-from-diagonal matrix entries.
      = 2: ZLAQR5 accumulates reflections, uses matrix-matrix
           multiply to update the far-from-diagonal matrix entries,
           and takes advantage of 2-by-2 block structure during
           matrix multiplies.

[in] N

        N is integer scalar
           N is the order of the Hessenberg matrix H upon which this
           subroutine operates.

[in] KTOP

        KTOP is integer scalar

[in] KBOT

        KBOT is integer scalar
           These are the first and last rows and columns of an
           isolated diagonal block upon which the QR sweep is to be
           applied. It is assumed without a check that
                     either KTOP = 1  or   H(KTOP,KTOP-1) = 0
           and
                     either KBOT = N  or   H(KBOT+1,KBOT) = 0.

[in] NSHFTS

        NSHFTS is integer scalar
```

```
            NSHFTS gives the number of simultaneous shifts.  NSHFTS
            must be positive and even.

  [in,out] S

          S is COMPLEX*16 array of size (NSHFTS)
            S contains the shifts of origin that define the multi-
            shift QR sweep.  On output S may be reordered.

  [in,out] H

          H is COMPLEX*16 array of size (LDH,N)
            On input H contains a Hessenberg matrix.  On output a
            multi-shift QR sweep with shifts SR(J)+i*SI(J) is applied
            to the isolated diagonal block in rows and columns KTOP
            through KBOT.

  [in] LDH

          LDH is integer scalar
            LDH is the leading dimension of H just as declared in the
            calling procedure.  LDH.GE.MAX(1,N).

  [in] ILOZ

          ILOZ is INTEGER

  [in] IHIZ

          IHIZ is INTEGER
            Specify the rows of Z to which transformations must be
            applied if WANTZ is .TRUE.. 1 .LE. ILOZ .LE. IHIZ .LE. N

  [in,out] Z

          Z is COMPLEX*16 array of size (LDZ,IHI)
            If WANTZ = .TRUE., then the QR Sweep unitary
            similarity transformation is accumulated into
            Z(ILOZ:IHIZ,ILO:IHI) from the right.
            If WANTZ = .FALSE., then Z is unreferenced.

  [in] LDZ

          LDZ is integer scalar
            LDA is the leading dimension of Z just as declared in
            the calling procedure. LDZ.GE.N.

  [out] V

          V is COMPLEX*16 array of size (LDV,NSHFTS/2)
```

```
[in] LDV

        LDV is integer scalar
           LDV is the leading dimension of V as declared in the
           calling procedure.  LDV.GE.3.

[out] U

        U is COMPLEX*16 array of size
           (LDU,3*NSHFTS-3)

[in] LDU

        LDU is integer scalar
           LDU is the leading dimension of U just as declared in the
           in the calling subroutine.  LDU.GE.3*NSHFTS-3.

[in] NH

        NH is integer scalar
           NH is the number of columns in array WH available for
           workspace. NH.GE.1.

[out] WH

        WH is COMPLEX*16 array of size (LDWH,NH)

[in] LDWH

        LDWH is integer scalar
           Leading dimension of WH just as declared in the
           calling procedure.  LDWH.GE.3*NSHFTS-3.

[in] NV

        NV is integer scalar
           NV is the number of rows in WV agailable for workspace.
           NV.GE.1.

[out] WV

        WV is COMPLEX*16 array of size
           (LDWV,3*NSHFTS-3)

[in] LDWV

        LDWV is integer scalar
           LDWV is the leading dimension of WV as declared in the
           in the calling subroutine.  LDWV.GE.NV.

 Definition:
 ===========

       SUBROUTINE ZLARFB( SIDE, TRANS, DIRECT, STOREV, M, N, K, V, LDV,
                          T, LDT, C, LDC, WORK, LDWORK )

       .. Scalar Arguments ..
       CHARACTER          DIRECT, SIDE, STOREV, TRANS
       INTEGER            K, LDC, LDT, LDV, LDWORK, M, N
       ..
       .. Array Arguments ..
       COMPLEX*16         C( LDC, * ), T( LDT, * ), V( LDV, * ),
      $                   WORK( LDWORK, * )
       ..

 Purpose:
 =============

 ZLARFB applies a complex block reflector H or its transpose H**H to a
 complex M-by-N matrix C, from either the left or the right.

 Arguments:
 ==========

  [in] SIDE

          SIDE is CHARACTER*1
          = 'L': apply H or H**H from the Left
```

```
          = 'R': apply H or H**H from the Right

  [in] TRANS

          TRANS is CHARACTER*1
          = 'N': apply H (No transpose)
          = 'C': apply H**H (Conjugate transpose)

  [in] DIRECT

          DIRECT is CHARACTER*1
          Indicates how H is formed from a product of elementary
          reflectors
          = 'F': H = H(1) H(2) . . . H(k) (Forward)
          = 'B': H = H(k) . . . H(2) H(1) (Backward)

  [in] STOREV

          STOREV is CHARACTER*1
          Indicates how the vectors which define the elementary
          reflectors are stored:
          = 'C': Columnwise
          = 'R': Rowwise

  [in] M

          M is INTEGER
          The number of rows of the matrix C.

  [in] N

          N is INTEGER
          The number of columns of the matrix C.

  [in] K

          K is INTEGER
          The order of the matrix T (= the number of elementary
          reflectors whose product defines the block reflector).

  [in] V

          V is COMPLEX*16 array, dimension
                                (LDV,K) if STOREV = 'C'
                                (LDV,M) if STOREV = 'R' and SIDE = 'L'
                                (LDV,N) if STOREV = 'R' and SIDE = 'R'
          See Further Details.

  [in] LDV
```

```
          LDV is INTEGER
          The leading dimension of the array V.
          If STOREV = 'C' and SIDE = 'L', LDV >= max(1,M);
          if STOREV = 'C' and SIDE = 'R', LDV >= max(1,N);
          if STOREV = 'R', LDV >= K.

  [in] T

          T is COMPLEX*16 array, dimension (LDT,K)
          The triangular K-by-K matrix T in the representation of the
          block reflector.

  [in] LDT

          LDT is INTEGER
          The leading dimension of the array T. LDT >= K.

  [in,out] C

          C is COMPLEX*16 array, dimension (LDC,N)
          On entry, the M-by-N matrix C.
          On exit, C is overwritten by H*C or H**H*C or C*H or C*H**H.

  [in] LDC

          LDC is INTEGER
          The leading dimension of the array C. LDC >= max(1,M).

  [out] WORK

          WORK is COMPLEX*16 array, dimension (LDWORK,K)

  [in] LDWORK

          LDWORK is INTEGER
          The leading dimension of the array WORK.
          If SIDE = 'L', LDWORK >= max(1,N);
          if SIDE = 'R', LDWORK >= max(1,M).

Further Details:
```

```
====================

 The shape of the matrix V and the storage of the vectors which define
 the H(i) is best illustrated by the following example with n = 5 and
 k = 3. The elements equal to 1 are not stored; the corresponding
 array elements are modified but restored on exit. The rest of the
 array is not used.

 DIRECT = 'F' and STOREV = 'C':         DIRECT = 'F' and STOREV = 'R':

              V = (  1       )                 V = (  1 v1 v1 v1 v1 )
                  ( v1  1    )                     (     1 v2 v2 v2 )
                  ( v1 v2  1 )                     (        1 v3 v3 )
                  ( v1 v2 v3 )
                  ( v1 v2 v3 )

 DIRECT = 'B' and STOREV = 'C':         DIRECT = 'B' and STOREV = 'R':

              V = ( v1 v2 v3 )                 V = ( v1 v1  1       )
                  ( v1 v2 v3 )                     ( v2 v2 v2  1    )
                  (  1 v2 v3 )                     ( v3 v3 v3 v3  1 )
                  (     1 v3 )
                  (        1 )

 Online html documentation available at
           http://www.netlib.org/lapack/explore-html/

 Definition:
 ===========
```

```
      SUBROUTINE ZLARF( SIDE, M, N, V, INCV, TAU, C, LDC, WORK )

      .. Scalar Arguments ..
      CHARACTER          SIDE
      INTEGER            INCV, LDC, M, N
      COMPLEX*16         TAU
      ..
      .. Array Arguments ..
      COMPLEX*16         C( LDC, * ), V( * ), WORK( * )
      ..

Purpose:
=============

ZLARF applies a complex elementary reflector H to a complex M-by-N
matrix C, from either the left or the right. H is represented in the
form

      H = I - tau * v * v**H

where tau is a complex scalar and v is a complex vector.

If tau = 0, then H is taken to be the unit matrix.

To apply H**H, supply conjg(tau) instead
tau.

Arguments:
==========

 [in] SIDE

        SIDE is CHARACTER*1
        = 'L': form  H * C
        = 'R': form  C * H

 [in] M

        M is INTEGER
        The number of rows of the matrix C.

 [in] N

        N is INTEGER
        The number of columns of the matrix C.

 [in] V
```

```
          V is COMPLEX*16 array, dimension
                     (1 + (M-1)*abs(INCV)) if SIDE = 'L'
                  or (1 + (N-1)*abs(INCV)) if SIDE = 'R'
          The vector v in the representation of H. V is not used if
          TAU = 0.

  [in] INCV

          INCV is INTEGER
          The increment between elements of v. INCV <> 0.

  [in] TAU

          TAU is COMPLEX*16
          The value tau in the representation of H.

  [in,out] C

          C is COMPLEX*16 array, dimension (LDC,N)
          On entry, the M-by-N matrix C.
          On exit, C is overwritten by the matrix H * C if SIDE = 'L',
          or C * H if SIDE = 'R'.

  [in] LDC

          LDC is INTEGER
          The leading dimension of the array C. LDC >= max(1,M).

  [out] WORK

          WORK is COMPLEX*16 array, dimension
                         (N) if SIDE = 'L'
                      or (M) if SIDE = 'R'

 Online html documentation available at
            http://www.netlib.org/lapack/explore-html/

 Definition:
 ===========

       SUBROUTINE ZLARFG( N, ALPHA, X, INCX, TAU )

       .. Scalar Arguments ..
       INTEGER            INCX, N
       COMPLEX*16         ALPHA, TAU
       ..
       .. Array Arguments ..
       COMPLEX*16         X( * )
       ..

 Purpose:
 =============

 ZLARFG generates a complex elementary reflector H of order n, such
```

```
that

      H**H * ( alpha ) = ( beta ),   H**H * H = I.
             (   x   )   (   0  )

where alpha and beta are scalars, with beta real, and x is an
(n-1)-element complex vector. H is represented in the form

      H = I - tau * ( 1 ) * ( 1 v**H ) ,
                    ( v )

where tau is a complex scalar and v is a complex (n-1)-element
vector. Note that H is not hermitian.

If the elements of x are all zero and alpha is real, then tau = 0
and H is taken to be the unit matrix.

Otherwise  1 <= real(tau) <= 2  and  abs(tau-1) <= 1 .

Arguments:
==========

 [in] N

         N is INTEGER
         The order of the elementary reflector.

 [in,out] ALPHA

         ALPHA is COMPLEX*16
         On entry, the value alpha.
         On exit, it is overwritten with the value beta.

 [in,out] X

         X is COMPLEX*16 array, dimension
                       (1+(N-2)*abs(INCX))
         On entry, the vector x.
         On exit, it is overwritten with the vector v.

 [in] INCX

         INCX is INTEGER
         The increment between elements of X. INCX > 0.

 [out] TAU

         TAU is COMPLEX*16
         The value tau.

 Online html documentation available at
            http://www.netlib.org/lapack/explore-html/

 Definition:
 ===========

       SUBROUTINE ZLARFT( DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT )

       .. Scalar Arguments ..
       CHARACTER          DIRECT, STOREV
       INTEGER            K, LDT, LDV, N
       ..
       .. Array Arguments ..
       COMPLEX*16         T( LDT, * ), TAU( * ), V( LDV, * )
       ..

 Purpose:
 =============

 ZLARFT forms the triangular factor T of a complex block reflector H
 of order n, which is defined as a product of k elementary reflectors.

 If DIRECT = 'F', H = H(1) H(2) . . . H(k) and T is upper triangular;

 If DIRECT = 'B', H = H(k) . . . H(2) H(1) and T is lower triangular.

 If STOREV = 'C', the vector which defines the elementary reflector
 H(i) is stored in the i-th column of the array V, and

    H  =  I - V * T * V**H

 If STOREV = 'R', the vector which defines the elementary reflector
 H(i) is stored in the i-th row of the array V, and

    H  =  I - V**H * T * V
```

```
 Arguments:
 ==========

  [in] DIRECT

          DIRECT is CHARACTER*1
          Specifies the order in which the elementary reflectors are
          multiplied to form the block reflector:
          = 'F': H = H(1) H(2) . . . H(k) (Forward)
          = 'B': H = H(k) . . . H(2) H(1) (Backward)

  [in] STOREV

          STOREV is CHARACTER*1
          Specifies how the vectors which define the elementary
          reflectors are stored (see also Further Details):
          = 'C': columnwise
          = 'R': rowwise

  [in] N

          N is INTEGER
          The order of the block reflector H. N >= 0.

  [in] K

          K is INTEGER
          The order of the triangular factor T (= the number of
          elementary reflectors). K >= 1.

  [in,out] V

          V is COMPLEX*16 array, dimension
                               (LDV,K) if STOREV = 'C'
                               (LDV,N) if STOREV = 'R'
          The matrix V. See further details.

  [in] LDV

          LDV is INTEGER
          The leading dimension of the array V.
          If STOREV = 'C', LDV >= max(1,N); if STOREV = 'R', LDV >= K.

  [in] TAU

          TAU is COMPLEX*16 array, dimension (K)
          TAU(i) must contain the scalar factor of the elementary
          reflector H(i).

  [out] T
```

```
          T is COMPLEX*16 array, dimension (LDT,K)
          The k by k triangular factor T of the block reflector.
          If DIRECT = 'F', T is upper triangular; if DIRECT = 'B', T is
          lower triangular. The rest of the array is not used.

 [in] LDT

          LDT is INTEGER
          The leading dimension of the array T. LDT >= K.

Further Details:
====================

 The shape of the matrix V and the storage of the vectors which define
 the H(i) is best illustrated by the following example with n = 5 and
 k = 3. The elements equal to 1 are not stored; the corresponding
 array elements are modified but restored on exit. The rest of the
 array is not used.

 DIRECT = 'F' and STOREV = 'C':         DIRECT = 'F' and STOREV = 'R':

              V = (  1       )                 V = (  1 v1 v1 v1 v1 )
                  ( v1  1    )                     (     1 v2 v2 v2 )
                  ( v1 v2  1 )                     (        1 v3 v3 )
                  ( v1 v2 v3 )
                  ( v1 v2 v3 )

 DIRECT = 'B' and STOREV = 'C':         DIRECT = 'B' and STOREV = 'R':

              V = ( v1 v2 v3 )                 V = ( v1 v1  1       )
                  ( v1 v2 v3 )                     ( v2 v2 v2  1    )
                  (  1 v2 v3 )                     ( v3 v3 v3 v3  1 )
                  (     1 v3 )
                  (        1 )
```

Man Page Details
===============================================================

 Online html documentation available at
           http://www.netlib.org/lapack/explore-html/

 Definition:
 ===========

       SUBROUTINE ZLARTG( F, G, CS, SN, R )

       .. Scalar Arguments ..
       DOUBLE PRECISION   CS
       COMPLEX*16         F, G, R, SN
       ..

 Purpose:
 =============

 ZLARTG generates a plane rotation so that

    [  CS  SN  ]     [ F ]     [ R ]
    [  __      ]  .  [   ]  =  [   ]   where CS**2 + |SN|**2 = 1.
    [ -SN  CS  ]     [ G ]     [ 0 ]

 This is a faster version of the BLAS1 routine ZROTG, except for
 the following differences:
    F and G are unchanged on return.
    If G=0, then CS=1 and SN=0.
    If F=0, then CS=0 and SN is chosen so that R is real.

 Arguments:
 ==========

  [in] F

          F is COMPLEX*16
          The first component of vector to be rotated.

  [in] G

          G is COMPLEX*16
          The second component of vector to be rotated.

  [out] CS
```

```
          CS is DOUBLE PRECISION
          The cosine of the rotation.

  [out] SN

          SN is COMPLEX*16
          The sine of the rotation.

  [out] R

          R is COMPLEX*16
          The nonzero component of the rotated vector.

 Online html documentation available at
            http://www.netlib.org/lapack/explore-html/

 Definition:
 ===========

       SUBROUTINE ZLASCL( TYPE, KL, KU, CFROM, CTO, M, N, A, LDA, INFO )

       .. Scalar Arguments ..
       CHARACTER          TYPE
       INTEGER            INFO, KL, KU, LDA, M, N
       DOUBLE PRECISION   CFROM, CTO
       ..
       .. Array Arguments ..
       COMPLEX*16         A( LDA, * )
       ..
```

```
Purpose:
=============

ZLASCL multiplies the M by N complex matrix A by the real scalar
CTO/CFROM.  This is done without over/underflow as long as the final
result CTO*A(I,J)/CFROM does not over/underflow. TYPE specifies that
A may be full, upper triangular, lower triangular, upper Hessenberg,
or banded.

Arguments:
==========

 [in] TYPE

        TYPE is CHARACTER*1
        TYPE indices the storage type of the input matrix.
        = 'G':  A is a full matrix.
        = 'L':  A is a lower triangular matrix.
        = 'U':  A is an upper triangular matrix.
        = 'H':  A is an upper Hessenberg matrix.
        = 'B':  A is a symmetric band matrix with lower bandwidth KL
                and upper bandwidth KU and with the only the lower
                half stored.
        = 'Q':  A is a symmetric band matrix with lower bandwidth KL
                and upper bandwidth KU and with the only the upper
                half stored.
        = 'Z':  A is a band matrix with lower bandwidth KL and upper
                bandwidth KU. See ZGBTRF for storage details.

 [in] KL

        KL is INTEGER
        The lower bandwidth of A.  Referenced only if TYPE = 'B',
        'Q' or 'Z'.

 [in] KU

        KU is INTEGER
        The upper bandwidth of A.  Referenced only if TYPE = 'B',
        'Q' or 'Z'.

 [in] CFROM

        CFROM is DOUBLE PRECISION

 [in] CTO

        CTO is DOUBLE PRECISION

        The matrix A is multiplied by CTO/CFROM. A(I,J) is computed
```

```
          without over/underflow if the final result CTO*A(I,J)/CFROM
          can be represented without over/underflow.  CFROM must be
          nonzero.

  [in] M

          M is INTEGER
          The number of rows of the matrix A.  M >= 0.

  [in] N

          N is INTEGER
          The number of columns of the matrix A.  N >= 0.

  [in,out] A

          A is COMPLEX*16 array, dimension (LDA,N)
          The matrix to be multiplied by CTO/CFROM.  See TYPE for the
          storage type.

  [in] LDA

          LDA is INTEGER
          The leading dimension of the array A.  LDA >= max(1,M).

  [out] INFO

          INFO is INTEGER
          0  - successful exit
          <0 - if INFO = -i, the i-th argument had an illegal value.

 Definition:
 ===========

       SUBROUTINE ZLASET( UPLO, M, N, ALPHA, BETA, A, LDA )

       .. Scalar Arguments ..
       CHARACTER          UPLO
       INTEGER            LDA, M, N
       COMPLEX*16         ALPHA, BETA
       ..
       .. Array Arguments ..
       COMPLEX*16         A( LDA, * )
```

```
      ..

Purpose:
=============

ZLASET initializes a 2-D array A to BETA on the diagonal and
ALPHA on the offdiagonals.

Arguments:
==========

 [in] UPLO

         UPLO is CHARACTER*1
         Specifies the part of the matrix A to be set.
         = 'U':      Upper triangular part is set. The lower triangle
                     is unchanged.
         = 'L':      Lower triangular part is set. The upper triangle
                     is unchanged.
         Otherwise:  All of the matrix A is set.

 [in] M

         M is INTEGER
         On entry, M specifies the number of rows of A.

 [in] N

         N is INTEGER
         On entry, N specifies the number of columns of A.

 [in] ALPHA

         ALPHA is COMPLEX*16
         All the offdiagonal array elements are set to ALPHA.

 [in] BETA

         BETA is COMPLEX*16
         All the diagonal array elements are set to BETA.

 [in,out] A

         A is COMPLEX*16 array, dimension (LDA,N)
         On entry, the m by n matrix A.
         On exit, A(i,j) = ALPHA, 1 <= i <= m, 1 <= j <= n, i.ne.j;
                  A(i,i) = BETA , 1 <= i <= min(m,n)

 [in] LDA
```

```
          LDA is INTEGER
          The leading dimension of the array A.  LDA >= max(1,M).

 Online html documentation available at
            http://www.netlib.org/lapack/explore-html/

 Definition:
 ===========

       SUBROUTINE ZLASSQ( N, X, INCX, SCALE, SUMSQ )

       .. Scalar Arguments ..
       INTEGER            INCX, N
       DOUBLE PRECISION   SCALE, SUMSQ
       ..
       .. Array Arguments ..
       COMPLEX*16         X( * )
       ..

 Purpose:
 =============

 ZLASSQ returns the values scl and ssq such that

    ( scl**2 )*ssq = x( 1 )**2 +...+ x( n )**2 + ( scale**2 )*sumsq,

 where x( i ) = abs( X( 1 + ( i - 1 )*INCX ) ). The value of sumsq is
 assumed to be at least unity and the value of ssq will then satisfy
```

```
   1.0 .le. ssq .le. ( sumsq + 2*n ).

scale is assumed to be non-negative and scl returns the value

   scl = max( scale, abs( real( x( i ) ) ), abs( aimag( x( i ) ) ) ),
          i

scale and sumsq must be supplied in SCALE and SUMSQ respectively.
SCALE and SUMSQ are overwritten by scl and ssq respectively.

The routine makes only one pass through the vector X.

Arguments:
==========

 [in] N

         N is INTEGER
         The number of elements to be used from the vector X.

 [in] X

         X is COMPLEX*16 array, dimension (N)
         The vector x as described above.
            x( i )  = X( 1 + ( i - 1 )*INCX ), 1 <= i <= n.

 [in] INCX

         INCX is INTEGER
         The increment between successive values of the vector X.
         INCX > 0.

 [in,out] SCALE

         SCALE is DOUBLE PRECISION
         On entry, the value  scale  in the equation above.
         On exit, SCALE is overwritten with the value  scl .

 [in,out] SUMSQ

         SUMSQ is DOUBLE PRECISION
         On entry, the value  sumsq  in the equation above.
         On exit, SUMSQ is overwritten with the value  ssq .

 Definition:
 ===========

       SUBROUTINE ZLATRS( UPLO, TRANS, DIAG, NORMIN, N, A, LDA, X, SCALE,
                          CNORM, INFO )

       .. Scalar Arguments ..
       CHARACTER          DIAG, NORMIN, TRANS, UPLO
       INTEGER            INFO, LDA, N
       DOUBLE PRECISION   SCALE
       ..
       .. Array Arguments ..
       DOUBLE PRECISION   CNORM( * )
       COMPLEX*16         A( LDA, * ), X( * )
       ..

 Purpose:
 =============

 ZLATRS solves one of the triangular systems

    A * x = s*b,  A**T * x = s*b,  or  A**H * x = s*b,

 with scaling to prevent overflow.  Here A is an upper or lower
 triangular matrix, A**T denotes the transpose of A, A**H denotes the
 conjugate transpose of A, x and b are n-element vectors, and s is a
 scaling factor, usually less than or equal to 1, chosen so that the
 components of x will be less than the overflow threshold.  If the
 unscaled problem will not cause overflow, the Level 2 BLAS routine
 ZTRSV is called. If the matrix A is singular (A(j,j) = 0 for some j),
 then s is set to 0 and a non-trivial solution to A*x = 0 is returned.

 Arguments:
 ==========

  [in] UPLO

          UPLO is CHARACTER*1
          Specifies whether the matrix A is upper or lower triangular.
```

```
          = 'U':  Upper triangular
          = 'L':  Lower triangular

  [in] TRANS

          TRANS is CHARACTER*1
          Specifies the operation applied to A.
          = 'N':  Solve A * x = s*b     (No transpose)
          = 'T':  Solve A**T * x = s*b  (Transpose)
          = 'C':  Solve A**H * x = s*b  (Conjugate transpose)

  [in] DIAG

          DIAG is CHARACTER*1
          Specifies whether or not the matrix A is unit triangular.
          = 'N':  Non-unit triangular
          = 'U':  Unit triangular

  [in] NORMIN

          NORMIN is CHARACTER*1
          Specifies whether CNORM has been set or not.
          = 'Y':  CNORM contains the column norms on entry
          = 'N':  CNORM is not set on entry.  On exit, the norms will
                  be computed and stored in CNORM.

  [in] N

          N is INTEGER
          The order of the matrix A.  N >= 0.

  [in] A

          A is COMPLEX*16 array, dimension (LDA,N)
          The triangular matrix A.  If UPLO = 'U', the leading n by n
          upper triangular part of the array A contains the upper
          triangular matrix, and the strictly lower triangular part of
          A is not referenced.  If UPLO = 'L', the leading n by n lower
          triangular part of the array A contains the lower triangular
          matrix, and the strictly upper triangular part of A is not
          referenced.  If DIAG = 'U', the diagonal elements of A are
          also not referenced and are assumed to be 1.

  [in] LDA

          LDA is INTEGER
          The leading dimension of the array A.  LDA >= max (1,N).

  [in,out] X
```

```
          X is COMPLEX*16 array, dimension (N)
          On entry, the right hand side b of the triangular system.
          On exit, X is overwritten by the solution vector x.

  [out] SCALE

          SCALE is DOUBLE PRECISION
          The scaling factor s for the triangular system
             A * x = s*b,  A**T * x = s*b,  or  A**H * x = s*b.
          If SCALE = 0, the matrix A is singular or badly scaled, and
          the vector x is an exact or approximate solution to A*x = 0.

  [in,out] CNORM

          CNORM is or output) DOUBLE PRECISION array, dimension (N)

          If NORMIN = 'Y', CNORM is an input argument and CNORM(j)
          contains the norm of the off-diagonal part of the j-th column
          of A.  If TRANS = 'N', CNORM(j) must be greater than or equal
          to the infinity-norm, and if TRANS = 'T' or 'C', CNORM(j)
          must be greater than or equal to the 1-norm.

          If NORMIN = 'N', CNORM is an output argument and CNORM(j)
          returns the 1-norm of the offdiagonal part of the j-th column
          of A.

  [out] INFO

          INFO is INTEGER
          = 0:  successful exit
          < 0:  if INFO = -k, the k-th argument had an illegal value

Further Details:
=====================

  A rough bound on x is computed; if that is less than overflow, ZTRSV
  is called, otherwise, specific code is used which checks for possible
  overflow or divide-by-zero at every operation.

  A columnwise scheme is used for solving A*x = b.  The basic algorithm
```

```
if A is lower triangular is

     x[1:n] := b[1:n]
     for j = 1, ..., n
          x(j) := x(j) / A(j,j)
          x[j+1:n] := x[j+1:n] - x(j) * A[j+1:n,j]
     end

Define bounds on the components of x after j iterations of the loop:
   M(j) = bound on x[1:j]
   G(j) = bound on x[j+1:n]
Initially, let M(0) = 0 and G(0) = max{x(i), i=1,...,n}.

Then for iteration j+1 we have
   M(j+1) <= G(j) / | A(j+1,j+1) |
   G(j+1) <= G(j) + M(j+1) * | A[j+2:n,j+1] |
          <= G(j) ( 1 + CNORM(j+1) / | A(j+1,j+1) | )

where CNORM(j+1) is greater than or equal to the infinity-norm of
column j+1 of A, not counting the diagonal.  Hence

   G(j) <= G(0) product ( 1 + CNORM(i) / | A(i,i) | )
                1<=i<=j
and

   |x(j)| <= ( G(0) / |A(j,j)| ) product ( 1 + CNORM(i) / |A(i,i)| )
                                  1<=i< j

Since |x(j)| <= M(j), we use the Level 2 BLAS routine ZTRSV if the
reciprocal of the largest M(j), j=1,..,n, is larger than
max(underflow, 1/overflow).

The bound on x(j) is also used to determine when a step in the
columnwise method can be performed without fear of overflow.  If
the computed bound is greater than a large constant, x is scaled to
prevent overflow, but if the bound overflows, x is set to 0, x(j) to
1, and scale to 0, and a non-trivial solution to A*x = 0 is found.

Similarly, a row-wise scheme is used to solve A**T *x = b  or
A**H *x = b.  The basic algorithm for A upper triangular is

     for j = 1, ..., n
          x(j) := ( b(j) - A[1:j-1,j]' * x[1:j-1] ) / A(j,j)
     end

We simultaneously compute two bounds
     G(j) = bound on ( b(i) - A[1:i-1,i]' * x[1:i-1] ), 1<=i<=j
     M(j) = bound on x(i), 1<=i<=j

The initial values are G(0) = 0, M(0) = max{b(i), i=1,..,n}, and we
```

```
  add the constraint G(j) >= G(j-1) and M(j) >= M(j-1) for j >= 1.
  Then the bound on x(j) is

       M(j) <= M(j-1) * ( 1 + CNORM(j) ) / | A(j,j) |

            <= M(0) * product ( ( 1 + CNORM(i) ) / |A(i,i)| )
                      1<=i<=j

  and we can safely call ZTRSV if 1/M(n) and 1/G(n) are both greater
  than max(underflow, 1/overflow).
```

 Definition:
 ===========

       SUBROUTINE ZROT( N, CX, INCX, CY, INCY, C, S )

       .. Scalar Arguments ..
       INTEGER            INCX, INCY, N
       DOUBLE PRECISION   C
       COMPLEX*16         S
       ..
       .. Array Arguments ..
       COMPLEX*16         CX( * ), CY( * )
       ..

 Purpose:
 =============

 ZROT   applies a plane rotation, where the cos (C) is real and the
 sin (S) is complex, and the vectors CX and CY are complex.

 Arguments:
 ==========

  [in] N

          N is INTEGER
          The number of elements in the vectors CX and CY.

  [in,out] CX

          CX is COMPLEX*16 array, dimension (N)
          On input, the vector X.
          On output, CX is overwritten with C*X + S*Y.
```

```
  [in] INCX

          INCX is INTEGER
          The increment between successive values of CY.  INCX <> 0.

  [in,out] CY

          CY is COMPLEX*16 array, dimension (N)
          On input, the vector Y.
          On output, CY is overwritten with -CONJG(S)*X + C*Y.

  [in] INCY

          INCY is INTEGER
          The increment between successive values of CY.  INCX <> 0.

  [in] C

          C is DOUBLE PRECISION

  [in] S

          S is COMPLEX*16
          C and S define a rotation
             [  C          S  ]
             [ -conjg(S)   C  ]
          where C*C + S*CONJG(S) = 1.0.

      SUBROUTINE ZTREVC( SIDE, HOWMNY, SELECT, N, T, LDT, VL, LDVL, VR,
                         LDVR, MM, M, WORK, RWORK, INFO )

      .. Scalar Arguments ..
      CHARACTER          HOWMNY, SIDE
      INTEGER            INFO, LDT, LDVL, LDVR, M, MM, N
      ..
      .. Array Arguments ..
      LOGICAL            SELECT( * )
      DOUBLE PRECISION   RWORK( * )
      COMPLEX*16         T( LDT, * ), VL( LDVL, * ), VR( LDVR, * ),
     $                   WORK( * )
      ..

Purpose:
=============

ZTREVC computes some or all of the right and/or left eigenvectors of
a complex upper triangular matrix T.
Matrices of this type are produced by the Schur factorization of
a complex general matrix:  A = Q*T*Q**H, as computed by ZHSEQR.

The right eigenvector x and the left eigenvector y of T corresponding
to an eigenvalue w are defined by:

             T*x = w*x,     (y**H)*T = w*(y**H)

where y**H denotes the conjugate transpose of the vector y.
The eigenvalues are not input to this routine, but are read directly
from the diagonal of T.

This routine returns the matrices X and/or Y of right and left
eigenvectors of T, or the products Q*X and/or Q*Y, where Q is an
input matrix.  If Q is the unitary factor that reduces a matrix A to
Schur form T, then Q*X and Q*Y are the matrices of right and left
eigenvectors of A.

Arguments:
==========

 [in] SIDE

         SIDE is CHARACTER*1
         = 'R':  compute right eigenvectors only;
         = 'L':  compute left eigenvectors only;
         = 'B':  compute both right and left eigenvectors.
```

```
[in] HOWMNY

        HOWMNY is CHARACTER*1
        = 'A':  compute all right and/or left eigenvectors;
        = 'B':  compute all right and/or left eigenvectors,
                backtransformed using the matrices supplied in
                VR and/or VL;
        = 'S':  compute selected right and/or left eigenvectors,
                as indicated by the logical array SELECT.

[in] SELECT

        SELECT is LOGICAL array, dimension (N)
        If HOWMNY = 'S', SELECT specifies the eigenvectors to be
        computed.
        The eigenvector corresponding to the j-th eigenvalue is
        computed if SELECT(j) = .TRUE..
        Not referenced if HOWMNY = 'A' or 'B'.

[in] N

        N is INTEGER
        The order of the matrix T. N >= 0.

[in,out] T

        T is COMPLEX*16 array, dimension (LDT,N)
        The upper triangular matrix T.  T is modified, but restored
        on exit.

[in] LDT

        LDT is INTEGER
        The leading dimension of the array T. LDT >= max(1,N).

[in,out] VL

        VL is COMPLEX*16 array, dimension (LDVL,MM)
        On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must
        contain an N-by-N matrix Q (usually the unitary matrix Q of
        Schur vectors returned by ZHSEQR).
        On exit, if SIDE = 'L' or 'B', VL contains:
        if HOWMNY = 'A', the matrix Y of left eigenvectors of T;
        if HOWMNY = 'B', the matrix Q*Y;
        if HOWMNY = 'S', the left eigenvectors of T specified by
                         SELECT, stored consecutively in the columns
                         of VL, in the same order as their
                         eigenvalues.
        Not referenced if SIDE = 'R'.
```

```
[in] LDVL

        LDVL is INTEGER
        The leading dimension of the array VL.  LDVL >= 1, and if
        SIDE = 'L' or 'B', LDVL >= N.

[in,out] VR

        VR is COMPLEX*16 array, dimension (LDVR,MM)
        On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must
        contain an N-by-N matrix Q (usually the unitary matrix Q of
        Schur vectors returned by ZHSEQR).
        On exit, if SIDE = 'R' or 'B', VR contains:
        if HOWMNY = 'A', the matrix X of right eigenvectors of T;
        if HOWMNY = 'B', the matrix Q*X;
        if HOWMNY = 'S', the right eigenvectors of T specified by
                         SELECT, stored consecutively in the columns
                         of VR, in the same order as their
                         eigenvalues.
        Not referenced if SIDE = 'L'.

[in] LDVR

        LDVR is INTEGER
        The leading dimension of the array VR.  LDVR >= 1, and if
        SIDE = 'R' or 'B'; LDVR >= N.

[in] MM

        MM is INTEGER
        The number of columns in the arrays VL and/or VR. MM >= M.

[out] M

        M is INTEGER
        The number of columns in the arrays VL and/or VR actually
        used to store the eigenvectors.  If HOWMNY = 'A' or 'B', M
        is set to N.  Each selected eigenvector occupies one
        column.

[out] WORK

        WORK is COMPLEX*16 array, dimension (2*N)

[out] RWORK

        RWORK is DOUBLE PRECISION array, dimension (N)

[out] INFO
```

```
          INFO is INTEGER
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an illegal value

 Further Details:
 ====================

  The algorithm used in this program is basically backward (forward)
  substitution, with scaling to make the the code robust against
  possible overflow.

  Each eigenvector is normalized so that the element of largest
  magnitude has magnitude 1; here the magnitude of a complex number
  (x,y) is taken to be |x| + |y|.

 Online html documentation available at
           http://www.netlib.org/lapack/explore-html/

 Definition:
 ===========

       SUBROUTINE ZTREXC( COMPQ, N, T, LDT, Q, LDQ, IFST, ILST, INFO )

       .. Scalar Arguments ..
       CHARACTER          COMPQ
       INTEGER            IFST, ILST, INFO, LDQ, LDT, N
       ..
       .. Array Arguments ..
       COMPLEX*16         Q( LDQ, * ), T( LDT, * )
       ..

 Purpose:
 =============

 ZTREXC reorders the Schur factorization of a complex matrix
 A = Q*T*Q**H, so that the diagonal element of T with row index IFST
 is moved to row ILST.

 The Schur form T is reordered by a unitary similarity transformation
 Z**H*T*Z, and optionally the matrix Q of Schur vectors is updated by
 postmultplying it with Z.

 Arguments:
 ==========

  [in] COMPQ

         COMPQ is CHARACTER*1
         = 'V':  update the matrix Q of Schur vectors;
         = 'N':  do not update Q.

  [in] N

         N is INTEGER
         The order of the matrix T. N >= 0.

  [in,out] T

         T is COMPLEX*16 array, dimension (LDT,N)
         On entry, the upper triangular matrix T.
         On exit, the reordered upper triangular matrix.
```

```
 [in] LDT

        LDT is INTEGER
        The leading dimension of the array T. LDT >= max(1,N).

 [in,out] Q

        Q is COMPLEX*16 array, dimension (LDQ,N)
        On entry, if COMPQ = 'V', the matrix Q of Schur vectors.
        On exit, if COMPQ = 'V', Q has been postmultiplied by the
        unitary transformation matrix Z which reorders T.
        If COMPQ = 'N', Q is not referenced.

 [in] LDQ

        LDQ is INTEGER
        The leading dimension of the array Q.  LDQ >= max(1,N).

 [in] IFST

        IFST is INTEGER

 [in] ILST

        ILST is INTEGER

        Specify the reordering of the diagonal elements of T:
        The element with row index IFST is moved to row ILST by a
        sequence of transpositions between adjacent elements.
        1 <= IFST <= N; 1 <= ILST <= N.

 [out] INFO

        INFO is INTEGER
        = 0:  successful exit
        < 0:  if INFO = -i, the i-th argument had an illegal value

       SUBROUTINE ZUNG2R( M, N, K, A, LDA, TAU, WORK, INFO )

       .. Scalar Arguments ..
       INTEGER            INFO, K, LDA, M, N
       ..
       .. Array Arguments ..
       COMPLEX*16         A( LDA, * ), TAU( * ), WORK( * )
       ..

 Purpose:
 =============

 ZUNG2R generates an m by n complex matrix Q with orthonormal columns,
 which is defined as the first n columns of a product of k elementary
 reflectors of order m

       Q  =  H(1) H(2) . . . H(k)

 as returned by ZGEQRF.

 Arguments:
 ==========

  [in] M

          M is INTEGER
          The number of rows of the matrix Q. M >= 0.

  [in] N

          N is INTEGER
          The number of columns of the matrix Q. M >= N >= 0.

  [in] K
```

```
          K is INTEGER
          The number of elementary reflectors whose product defines the
          matrix Q. N >= K >= 0.

  [in,out] A

          A is COMPLEX*16 array, dimension (LDA,N)
          On entry, the i-th column must contain the vector which
          defines the elementary reflector H(i), for i = 1,2,...,k, as
          returned by ZGEQRF in the first k columns of its array
          argument A.
          On exit, the m by n matrix Q.

  [in] LDA

          LDA is INTEGER
          The first dimension of the array A. LDA >= max(1,M).

  [in] TAU

          TAU is COMPLEX*16 array, dimension (K)
          TAU(i) must contain the scalar factor of the elementary
          reflector H(i), as returned by ZGEQRF.

  [out] WORK

          WORK is COMPLEX*16 array, dimension (N)

  [out] INFO

          INFO is INTEGER
          = 0: successful exit
          < 0: if INFO = -i, the i-th argument has an illegal value

 Online html documentation available at
           http://www.netlib.org/lapack/explore-html/

 Definition:
 ===========

       SUBROUTINE ZUNGHR( N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO )

       .. Scalar Arguments ..
       INTEGER            IHI, ILO, INFO, LDA, LWORK, N
       ..
       .. Array Arguments ..
       COMPLEX*16         A( LDA, * ), TAU( * ), WORK( * )
       ..

 Purpose:
 =============

 ZUNGHR generates a complex unitary matrix Q which is defined as the
 product of IHI-ILO elementary reflectors of order N, as returned by
 ZGEHRD:

 Q = H(ilo) H(ilo+1) . . . H(ihi-1).

 Arguments:
 ==========

  [in] N

          N is INTEGER
          The order of the matrix Q. N >= 0.

  [in] ILO

          ILO is INTEGER

  [in] IHI

          IHI is INTEGER

          ILO and IHI must have the same values as in the previous call
          of ZGEHRD. Q is equal to the unit matrix except in the
          submatrix Q(ilo+1:ihi,ilo+1:ihi).
          1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.
```

```
 [in,out] A

         A is COMPLEX*16 array, dimension (LDA,N)
         On entry, the vectors which define the elementary reflectors,
         as returned by ZGEHRD.
         On exit, the N-by-N unitary matrix Q.

 [in] LDA

         LDA is INTEGER
         The leading dimension of the array A. LDA >= max(1,N).

 [in] TAU

         TAU is COMPLEX*16 array, dimension (N-1)
         TAU(i) must contain the scalar factor of the elementary
         reflector H(i), as returned by ZGEHRD.

 [out] WORK

         WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
         On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 [in] LWORK

         LWORK is INTEGER
         The dimension of the array WORK. LWORK >= IHI-ILO.
         For optimum performance LWORK >= (IHI-ILO)*NB, where NB is
         the optimal blocksize.

         If LWORK = -1, then a workspace query is assumed; the routine
         only calculates the optimal size of the WORK array, returns
         this value as the first entry of the WORK array, and no error
         message related to LWORK is issued by XERBLA.

 [out] INFO

         INFO is INTEGER
         = 0:  successful exit
         < 0:  if INFO = -i, the i-th argument had an illegal value

 Online html documentation available at
            http://www.netlib.org/lapack/explore-html/

 Definition:
 ===========
```

```
      SUBROUTINE ZUNGQR( M, N, K, A, LDA, TAU, WORK, LWORK, INFO )

      .. Scalar Arguments ..
      INTEGER            INFO, K, LDA, LWORK, M, N
      ..
      .. Array Arguments ..
      COMPLEX*16         A( LDA, * ), TAU( * ), WORK( * )
      ..

Purpose:
=============

ZUNGQR generates an M-by-N complex matrix Q with orthonormal columns,
which is defined as the first N columns of a product of K elementary
reflectors of order M

      Q  =  H(1) H(2) . . . H(k)

as returned by ZGEQRF.

Arguments:
==========

 [in] M

         M is INTEGER
         The number of rows of the matrix Q. M >= 0.

 [in] N

         N is INTEGER
         The number of columns of the matrix Q. M >= N >= 0.

 [in] K

         K is INTEGER
         The number of elementary reflectors whose product defines the
         matrix Q. N >= K >= 0.

 [in,out] A

         A is COMPLEX*16 array, dimension (LDA,N)
         On entry, the i-th column must contain the vector which
         defines the elementary reflector H(i), for i = 1,2,...,k, as
         returned by ZGEQRF in the first k columns of its array
         argument A.
         On exit, the M-by-N matrix Q.

 [in] LDA
```

```
          LDA is INTEGER
          The first dimension of the array A. LDA >= max(1,M).

  [in] TAU

          TAU is COMPLEX*16 array, dimension (K)
          TAU(i) must contain the scalar factor of the elementary
          reflector H(i), as returned by ZGEQRF.

  [out] WORK

          WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
          On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

  [in] LWORK

          LWORK is INTEGER
          The dimension of the array WORK. LWORK >= max(1,N).
          For optimum performance LWORK >= N*NB, where NB is the
          optimal blocksize.

          If LWORK = -1, then a workspace query is assumed; the routine
          only calculates the optimal size of the WORK array, returns
          this value as the first entry of the WORK array, and no error
          message related to LWORK is issued by XERBLA.

  [out] INFO

          INFO is INTEGER
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument has an illegal value

Definition:
===========

      SUBROUTINE ZUNM2R( SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC,
                         WORK, INFO )

      .. Scalar Arguments ..
      CHARACTER          SIDE, TRANS
      INTEGER            INFO, K, LDA, LDC, M, N
      ..
      .. Array Arguments ..
      COMPLEX*16         A( LDA, * ), C( LDC, * ), TAU( * ), WORK( * )
      ..

Purpose:
=============

ZUNM2R overwrites the general complex m-by-n matrix C with

      Q * C  if SIDE = 'L' and TRANS = 'N', or

      Q**H* C  if SIDE = 'L' and TRANS = 'C', or

      C * Q  if SIDE = 'R' and TRANS = 'N', or

      C * Q**H if SIDE = 'R' and TRANS = 'C',

where Q is a complex unitary matrix defined as the product of k
elementary reflectors

      Q = H(1) H(2) . . . H(k)

as returned by ZGEQRF. Q is of order m if SIDE = 'L' and of order n
if SIDE = 'R'.

Arguments:
==========

 [in] SIDE

         SIDE is CHARACTER*1
         = 'L': apply Q or Q**H from the Left
         = 'R': apply Q or Q**H from the Right

 [in] TRANS
```

```
          TRANS is CHARACTER*1
          = 'N': apply Q  (No transpose)
          = 'C': apply Q**H (Conjugate transpose)

  [in] M

          M is INTEGER
          The number of rows of the matrix C. M >= 0.

  [in] N

          N is INTEGER
          The number of columns of the matrix C. N >= 0.

  [in] K

          K is INTEGER
          The number of elementary reflectors whose product defines
          the matrix Q.
          If SIDE = 'L', M >= K >= 0;
          if SIDE = 'R', N >= K >= 0.

  [in] A

          A is COMPLEX*16 array, dimension (LDA,K)
          The i-th column must contain the vector which defines the
          elementary reflector H(i), for i = 1,2,...,k, as returned by
          ZGEQRF in the first k columns of its array argument A.
          A is modified by the routine but restored on exit.

  [in] LDA

          LDA is INTEGER
          The leading dimension of the array A.
          If SIDE = 'L', LDA >= max(1,M);
          if SIDE = 'R', LDA >= max(1,N).

  [in] TAU

          TAU is COMPLEX*16 array, dimension (K)
          TAU(i) must contain the scalar factor of the elementary
          reflector H(i), as returned by ZGEQRF.

  [in,out] C

          C is COMPLEX*16 array, dimension (LDC,N)
          On entry, the m-by-n matrix C.
          On exit, C is overwritten by Q*C or Q**H*C or C*Q**H or C*Q.

  [in] LDC
```

```
          LDC is INTEGER
          The leading dimension of the array C. LDC >= max(1,M).

  [out] WORK

          WORK is COMPLEX*16 array, dimension
                                 (N) if SIDE = 'L',
                                 (M) if SIDE = 'R'

  [out] INFO

          INFO is INTEGER
          = 0: successful exit
          < 0: if INFO = -i, the i-th argument had an illegal value

      ..

Purpose:
=============

ZUNMHR overwrites the general complex M-by-N matrix C with

                SIDE = 'L'     SIDE = 'R'
TRANS = 'N':      Q * C          C * Q
TRANS = 'C':      Q**H * C       C * Q**H

where Q is a complex unitary matrix of order nq, with nq = m if
SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of
IHI-ILO elementary reflectors, as returned by ZGEHRD:

Q = H(ilo) H(ilo+1) . . . H(ihi-1).

Arguments:
==========

 [in] SIDE

         SIDE is CHARACTER*1
         = 'L': apply Q or Q**H from the Left;
         = 'R': apply Q or Q**H from the Right.

 [in] TRANS

         TRANS is CHARACTER*1
         = 'N': apply Q  (No transpose)
         = 'C': apply Q**H (Conjugate transpose)

 [in] M

         M is INTEGER
         The number of rows of the matrix C. M >= 0.
```

```
[in] N

        N is INTEGER
        The number of columns of the matrix C. N >= 0.

[in] ILO

        ILO is INTEGER

[in] IHI

        IHI is INTEGER

        ILO and IHI must have the same values as in the previous call
        of ZGEHRD. Q is equal to the unit matrix except in the
        submatrix Q(ilo+1:ihi,ilo+1:ihi).
        If SIDE = 'L', then 1 <= ILO <= IHI <= M, if M > 0, and
        ILO = 1 and IHI = 0, if M = 0;
        if SIDE = 'R', then 1 <= ILO <= IHI <= N, if N > 0, and
        ILO = 1 and IHI = 0, if N = 0.

[in] A

        A is COMPLEX*16 array, dimension
                              (LDA,M) if SIDE = 'L'
                              (LDA,N) if SIDE = 'R'
        The vectors which define the elementary reflectors, as
        returned by ZGEHRD.

[in] LDA

        LDA is INTEGER
        The leading dimension of the array A.
        LDA >= max(1,M) if SIDE = 'L'; LDA >= max(1,N) if SIDE = 'R'.

[in] TAU

        TAU is COMPLEX*16 array, dimension
                              (M-1) if SIDE = 'L'
                              (N-1) if SIDE = 'R'
        TAU(i) must contain the scalar factor of the elementary
        reflector H(i), as returned by ZGEHRD.

[in,out] C

        C is COMPLEX*16 array, dimension (LDC,N)
        On entry, the M-by-N matrix C.
        On exit, C is overwritten by Q*C or Q**H*C or C*Q**H or C*Q.
```

```
  [in] LDC

          LDC is INTEGER
          The leading dimension of the array C. LDC >= max(1,M).

  [out] WORK

          WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
          On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

  [in] LWORK

          LWORK is INTEGER
          The dimension of the array WORK.
          If SIDE = 'L', LWORK >= max(1,N);
          if SIDE = 'R', LWORK >= max(1,M).
          For optimum performance LWORK >= N*NB if SIDE = 'L', and
          LWORK >= M*NB if SIDE = 'R', where NB is the optimal
          blocksize.

          If LWORK = -1, then a workspace query is assumed; the routine
          only calculates the optimal size of the WORK array, returns
          this value as the first entry of the WORK array, and no error
          message related to LWORK is issued by XERBLA.

  [out] INFO

          INFO is INTEGER
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an illegal value

           http://www.netlib.org/lapack/explore-html/

 Definition:
 ===========

       SUBROUTINE ZUNMQR( SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC,
                          WORK, LWORK, INFO )

       .. Scalar Arguments ..
       CHARACTER          SIDE, TRANS
       INTEGER            INFO, K, LDA, LDC, LWORK, M, N
       ..
       .. Array Arguments ..
       COMPLEX*16         A( LDA, * ), C( LDC, * ), TAU( * ), WORK( * )
       ..

 Purpose:
 =============

 ZUNMQR overwrites the general complex M-by-N matrix C with

                 SIDE = 'L'     SIDE = 'R'
 TRANS = 'N':      Q * C          C * Q
```

```
TRANS = 'C':      Q**H * C       C * Q**H

where Q is a complex unitary matrix defined as the product of k
elementary reflectors

      Q = H(1) H(2) . . . H(k)

as returned by ZGEQRF. Q is of order M if SIDE = 'L' and of order N
if SIDE = 'R'.

Arguments:
==========

 [in] SIDE

        SIDE is CHARACTER*1
        = 'L': apply Q or Q**H from the Left;
        = 'R': apply Q or Q**H from the Right.

 [in] TRANS

        TRANS is CHARACTER*1
        = 'N':  No transpose, apply Q;
        = 'C':  Conjugate transpose, apply Q**H.

 [in] M

        M is INTEGER
        The number of rows of the matrix C. M >= 0.

 [in] N

        N is INTEGER
        The number of columns of the matrix C. N >= 0.

 [in] K

        K is INTEGER
        The number of elementary reflectors whose product defines
        the matrix Q.
        If SIDE = 'L', M >= K >= 0;
        if SIDE = 'R', N >= K >= 0.

 [in] A

        A is COMPLEX*16 array, dimension (LDA,K)
        The i-th column must contain the vector which defines the
        elementary reflector H(i), for i = 1,2,...,k, as returned by
        ZGEQRF in the first k columns of its array argument A.
        A is modified by the routine but restored on exit.
```

```
[in] LDA

        LDA is INTEGER
        The leading dimension of the array A.
        If SIDE = 'L', LDA >= max(1,M);
        if SIDE = 'R', LDA >= max(1,N).

[in] TAU

        TAU is COMPLEX*16 array, dimension (K)
        TAU(i) must contain the scalar factor of the elementary
        reflector H(i), as returned by ZGEQRF.

[in,out] C

        C is COMPLEX*16 array, dimension (LDC,N)
        On entry, the M-by-N matrix C.
        On exit, C is overwritten by Q*C or Q**H*C or C*Q**H or C*Q.

[in] LDC

        LDC is INTEGER
        The leading dimension of the array C. LDC >= max(1,M).

[out] WORK

        WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
        On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

[in] LWORK

        LWORK is INTEGER
        The dimension of the array WORK.
        If SIDE = 'L', LWORK >= max(1,N);
        if SIDE = 'R', LWORK >= max(1,M).
        For optimum performance LWORK >= N*NB if SIDE = 'L', and
        LWORK >= M*NB if SIDE = 'R', where NB is the optimal
        blocksize.

        If LWORK = -1, then a workspace query is assumed; the routine
        only calculates the optimal size of the WORK array, returns
        this value as the first entry of the WORK array, and no error
        message related to LWORK is issued by XERBLA.

[out] INFO

        INFO is INTEGER
        = 0:  successful exit
        < 0:  if INFO = -i, the i-th argument had an illegal value

;;; $Log$
;;; Revision 1.11  2006/12/01 04:29:29  rtoy
;;; Create packages for BLAS and LAPACK routines.
;;;
;;; blas.system:
;;; o Converted files are in the BLAS package.
;;; o Add blas-package defsystem to load the package definition.
;;;
;;; lapack.system:
;;; o Converted files are in the LAPACK package.
;;; o Add lapack-package defsystem to load the package definition.
;;;
;;; lapack/lapack-tests.lisp:
;;; o Tests are in the LAPACK package
;;;
;;; Revision 1.10  2006/11/28 15:49:01  rtoy
;;; Print out short title for each test.
;;;
;;; Revision 1.9  2006/11/27 22:22:23  rtoy
;;; Add expected results.
;;;
;;; Revision 1.8  2006/11/27 20:04:33  rtoy
;;; Add DGESVD and update files and tests appropriately.
;;;
;;; Revision 1.7  2006/11/27 15:23:29  rtoy
;;; Add function to run all the tests.
;;;
;;; Revision 1.6  2006/11/26 23:26:47  rtoy
;;; packages/lapack.system:
;;; o Add DGESDD and dependencies
;;; o Add DDISNA to compute condition number of singular vectors
;;;
;;; packages/lapack/.cvsignore:
;;; o Ignore new generated Lisp files.
;;;
;;; packages/lapack/lapack-tests.lisp:
;;; o Add test for DGESDD
;;;
;;; Revision 1.5  2006/11/26 14:26:42  rtoy
;;; Add expected results for DGESV.
;;;
;;; Revision 1.4  2006/11/26 14:24:46  rtoy
;;; packages/lapack.system:
```

```
;;; o DGESV and dependencies
;;;
;;; packages/.cvsignore:
;;; o Ignore generated dgesv.lisp and dependencies
;;;
;;; packages/lapack/lapack-tests.lisp:
;;; o Test routine for DGESV
;;;
;;; Revision 1.3  2006/11/26 05:31:16  rtoy
;;; packages/lapack.system:
;;; o Add DGEEVX and dependencies
;;;
;;; packages/lapack/lapack-tests.lisp:
;;; o Add test for DGEEVX
;;; o Add comments
;;;
;;; packages/lapack/dgeevx.f:
;;; packages/lapack/dlacon.f:
;;; packages/lapack/dlaexc.f:
;;; packages/lapack/dlaqtr.f:
;;; packages/lapack/dlasy2.f:
;;; packages/lapack/dtrexc.f:
;;; packages/lapack/dtrsna.f:
;;; o New files for DGEEVX and dependencies.
;;;
;;; Revision 1.2  2006/11/26 04:53:22  rtoy
;;; Add comments
;;;
;;; Revision 1.1  2006/11/26 04:51:05  rtoy
;;; packages/lapack.system:
;;; o Add defsystem for LAPACK tests
;;;
;;; packages/lapack/lapack-tests.lisp:
;;; o Add simple tests for LAPACK.  (Currently only DGEEV).
;;;
```
